A

abdomen

The region of the body between the chest and the pelvis. The abdominal cavity is bounded by the ribs and diaphragm above, and by the pelvis below, with the spine and abdominal muscles forming the back, side, and front walls. The abdominal cavity contains the liver, stomach, intestines, spleen, pancreas, and kidneys. In the lower abdomen, enclosed by the pelvis, are the bladder, rectum, and, in women, the uterus and ovaries.

STRUCTURE

The spine, pelvis, and ribs provide attachments for the layers of muscle that make up the abdominal walls. There is a layer of fat between these muscles and the skin. The inner surface of the abdominal muscles is covered by a thin membrane, the peritoneum,

which also covers the organs, such as the pancreas and kidneys, that are fixed to the back wall. Folds of peritoneum also cover the mobile organs, such as the stomach and intestines.

abdomen, acute

The medical term for persistent, severe abdominal pain, of sudden onset, that is usually associated with spasm of the abdominal muscles, vomiting, and fever.

CAUSES

The most common cause of an acute abdomen is *peritonitis* (inflammation of the membrane that lines the abdomen); underlying causes include *appendicitis*, abdominal injury, or perforation of an internal organ as a result of disorders such as *diverticular disease* (the presence of small, protruding pouches in the intestinal wall) or *peptic ulcer*.

SYMPOTMS

Acute abdomen commonly begins as a vague pain in the centre of the abdomen that gradually localizes to a particular region of the body, depending on the condition. For example, pain is felt on the right side of the body in appendicitis.

DIAGNOSIS AND TREATMENT

An acute abdomen requires urgent medical investigation usually comprising detailed questioning about the condi-

tion, a physical examination, laboratory tests, and imaging procedures such as *ultrasound scanning*. The investigation may also involve a *laparoscopy* (internal examination using a rigid or flexible viewing tube) or a *laparotomy* (surgical exploration of the abdomen). Treatment depends on the underlying cause.

abdominal

Relating to the *abdomen*.

abdominal hysterectomy

The surgical removal of the uterus (womb) through an incision in the abdomen (see *hysterectomy*).

abdominal pain

Discomfort in the abdominal cavity. Symptoms accompanying abdominal pain may include belching, nausea, vomiting, rumbling and gurgling noises, and flatulence (wind).

CAUSES

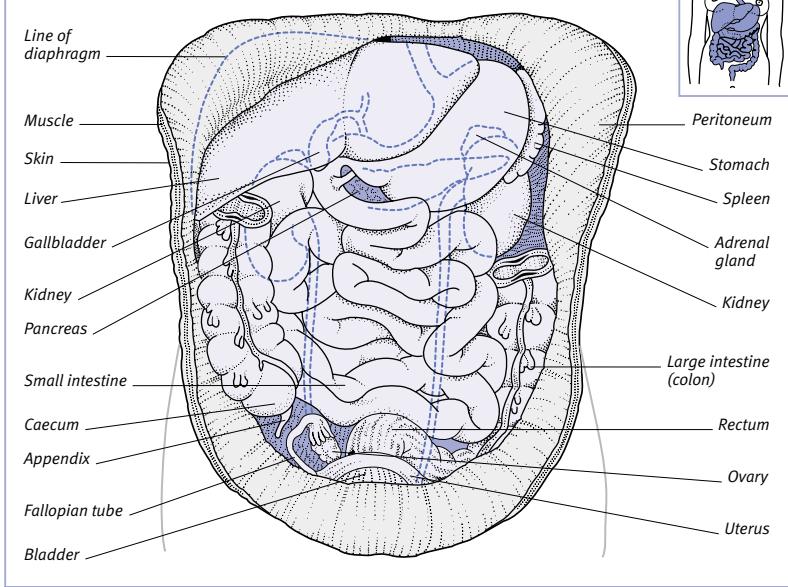

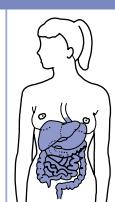

Mild abdominal pain is common and is often due to excessive alcohol intake, eating unwisely, or an attack of *diarrhoea*. Pain in the lower abdomen is common during menstruation but may occasionally be due to a gynaecological disorder such as *endometriosis* (in which fragments of uterine lining are present in abnormal sites within the abdomen). *Cystitis* (inflammation of the bladder) is another common cause of pain or discomfort in the lower abdomen. Bladder distension due to urinary obstruction may also cause abdominal pain.

Abdominal colic is the term used for pain that occurs every few minutes as one of the internal organs goes into muscular spasm. Colic is an attempt by the body to overcome an obstruction such as a stone or an area of inflammation. The attacks of colic may become more severe and may be associated with vomiting (see *abdomen, acute*).

A *peptic ulcer*, which is associated with an increase in the amount of acid formed in the stomach, often produces recurrent gnawing pain. Other possible causes of abdominal pain are infection, such as *pyelonephritis* (infection of the kidneys) and *pelvic inflammatory disease* (infection of the internal female reproductive organs), and *ischaemia* (a lack of blood supply), as occurs when a *volvulus* (twisting of the intestine) obstructs blood vessels. Tumours affecting an abdominal organ can cause pain. Abdominal pain may also have a psychological cause, such as anxiety.

LOCATION OF THE ABDOMEN

The *abdomen* is bounded by the lower ribs at the top and the pelvis below. The illustration shows the position of the abdominal organs in an adult woman.

TREATMENT

For mild abdominal pain, self-treatment measures, such as a wrapped hot-water bottle or a milky drink, are often effective. Pain due to peptic ulcer can be temporarily relieved by consuming food or by taking *antacid drugs*.

Abdominal pain that is not relieved by vomiting, persists for more than six hours, or is associated with sweating or fainting requires urgent medical attention. Urgent attention is also necessary if pain is accompanied by persistent vomiting, vomiting of blood, or passing of bloodstained or black faeces. Abdominal pain that is accompanied by unexplained weight loss or changes in bowel habits should always be investigated by a doctor.

INVESTIGATION AND DIAGNOSIS

The doctor makes a diagnosis of abdominal pain based on a physical examination and a detailed description of the patient's symptoms. Investigation of severe abdominal pain may also include *blood tests*, imaging tests such as *ultrasound scanning*, and *endoscopy*

(examination of a body cavity using a flexible viewing tube) in the form of *laparoscopy* (viewing the abdominal cavity), *gastroscopy* (viewing the stomach and duodenum), or *colonoscopy* (viewing the large intestine).

abdominal swelling

Enlargement of the abdomen, which may be due to a variety of causes. Abdominal swelling is a natural result of *obesity* and enlargement of the uterus during pregnancy.

Some causes of abdominal swelling are harmless. Wind in the stomach or intestine may cause uncomfortable, bloating distension. Distension as a result of temporary water retention may occur in some women just before *menses*. Other causes may be more serious. For instance, *ascites* (fluid accumulation in the abdominal cavity) may be a symptom of cancer or disease of the heart, kidneys, or liver; swelling may also be due to intestinal obstruction (see *intestine, obstruction of*) or an *ovarian cyst*.

INVESTIGATION

Diagnosis of the underlying cause may involve X-rays (see *abdominal X-ray*), *ultrasound scanning*, *laparotomy* (surgical exploration of the abdomen) or *laparoscopy* (examination of the inside of the abdomen using a rigid or flexible viewing tube). In ascites, some of the fluid in the abdomen may be drained for detailed examination.

abdominal thrust

A first-aid treatment for choking in which a sharp upward pressure is applied to the upper abdomen, just below the rib cage, to dislodge a foreign body that is obstructing the airway. The technique is also known as the Heimlich manoeuvre.

abdominal X-ray

An *X-ray* examination of the abdominal contents. An abdominal X-ray is often one of the first steps in the investigation of acute abdominal disease.

X-rays do not reveal the internal structure of organs, but they do show their outlines. X-rays can therefore show whether any organ is enlarged and can detect swallowed foreign bodies in the digestive tract. X-rays also show accumulations of fluid and gas: distended loops of bowel containing collections of fluid often indicate the presence of an obstruction (see *intestine, obstruction of*); gas outside the intestine indicates *intestinal perforation*.

Calcium, which is opaque to X-rays, is present in most kidney stones (see *calculus, urinary tract*) and in some *gallstones* and aortic *aneurysms*; these can sometimes be detected on an abdominal X-ray.

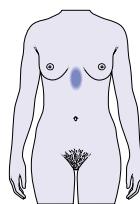

Abdominal X-rays may need to be followed by procedures that provide more information, such as *ultrasound scanning*, *barium X-ray examinations* (use of a contrast medium to detect disorders of the gastrointestinal tract), *laparoscopy* (internal examination of the abdomen using a viewing instrument), *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures).

abducent nerve

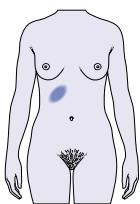

The sixth *cranial nerve*. The abducent nerve supplies the lateral rectus muscle of each eye, which is responsible for moving the eyeball outwards. The abducent nerve originates in the pons (part of the *brainstem*) and passes along the

DIAGNOSING ABDOMINAL PAIN

The doctor conducts a physical examination and listens to the patient's description of the pain. More investigations, such as blood tests, X-rays, or imaging tests (including ultrasound scanning), may be carried out. If the diagnosis is still in doubt, endoscopic inspection of the stomach and duodenum (*gastroscopy*), large intestine (*colonoscopy*), or abdominal cavity (*laparoscopy*) may be performed.

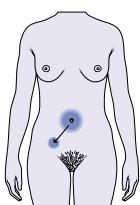

Oesophageal reflux
A burning pain in the chest that is accompanied by regurgitation of stomach acid and is often worse after meals or when lying down at night.

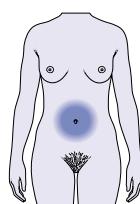

Gallbladder pain
A cramp-like or steady pain under the right ribs that is often accompanied by vomiting and fever.

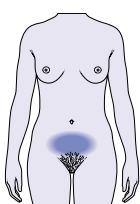

Duodenal ulcer pain
This pain often occurs in the same small area and may be temporarily relieved by eating or taking antacids.

Appendicitis pain
This pain starts around the navel before finally settling in the lower right side of the abdomen.

Wind
Excess wind in the digestive system affects a large area of the abdomen and can cause an uncomfortable, distended feeling.

Pelvic organ inflammation
A constant diffuse pain, usually accompanied by vaginal discharge or fever, that extends over the lower abdomen.

base of the skull, entering the back of the eye socket through a gap between the skull bones.

The abducent nerve may be damaged in fractures of the base of the skull, or by disorders, such as tumours, that distort the brain. Such damage may give rise to *double vision* or a *squint*.

abduction

Movement of a limb away from the central line of the body, or of a digit away from the axis of a limb. Muscles that carry out this movement are called abductors. (See also *adduction*.)

abductor

Any one of the muscles that carry out the movement of *abduction*.

aberrant

A term meaning abnormal; in medical usage the word is often applied to a blood vessel or nerve that deviates from its normal route.

abetalipoproteinaemia

A rare, inherited *genetic disorder* of *lipoprotein* (a protein that combines with fats or other lipids) metabolism. It is inherited in an autosomal recessive manner and is characterized by *malabsorption* of fats, *acanthocytosis* (distorted red blood cells), *retinopathy* (disease of the retina), *ataxia* (incoordination and clumsiness), slurred speech, muscle weakness, curvature of the spine, *neuropathy* (peripheral nerve disease), fatty stools, diarrhoea, and *failure to thrive* in infancy.

Treatment with high doses of fat soluble vitamins (*vitamin A*, *vitamin D*, *vitamin E*, and *vitamin K*) may slow the progression of certain abetalipoproteinaemia-related problems such as retinal degeneration.

ablation

The removal or destruction of diseased tissue by excision (cutting away), *cryosurgery* (freezing), *radiotherapy*, *diathermy* (burning), or *laser treatment*.

ablepharia

A *birth defect* in which the eyelids fail to develop normally, leaving the eyeball completely covered over.

abnormality

A physical deformity or malformation, behavioural or mental problem, or variation from normal in the structure or function of a body cell, tissue, or organ.

ABO blood groups

See *blood groups*.

abort

A term meaning to terminate a pregnancy, either spontaneously (see *miscarriage*) or through medical intervention (see *abortion, induced*).

abortifacient

An agent that causes *abortion*. In medical practice, abortion is induced using *prostaglandin drugs*, often given in the form of vaginal pessaries. These cause the softening and widening of the cervix (neck of the uterus) and muscular contractions of the uterus.

abortion

In medical usage, a term denoting either spontaneous abortion (see *miscarriage*) or medically induced termination (see *abortion, induced*) of pregnancy. (See also *complete abortion*; *habitual abortion*; *incomplete abortion*; *septic abortion*.)

abortion, induced

Medically induced termination of pregnancy. In the UK abortion can legally be performed up to the 24th week of pregnancy. Legally, abortion may be performed if continuation of the pregnancy would constitute a greater risk to the woman's life than the termination, if the mental or physical health of the woman or her existing children is at risk, or if there is a substantial risk of serious handicap to the baby.

MEDICAL REASONS FOR ABORTION

A doctor may recommend an abortion if the woman suffers from a life-threatening condition, such as severe heart disease, chronic kidney disease, or cancer, especially of the breast or cervix.

If a serious fetal abnormality is discovered, for example severe developmental defects (such as *anencephaly*) or chromosomal abnormalities (such as *Down's syndrome*), the parents may be offered the option of a termination. Abortion may also be recommended if the mother contracts *rubella* (German measles) during early pregnancy.

HOW IT IS DONE

Early abortion Up to the ninth week of pregnancy termination may be induced by treatment with a combination of two drugs, *mifepristone* and a *prostaglandin drug*. These end the pregnancy by inducing the uterus to contract and expel the embryo and the placenta; the process usually takes at least 48 hours.

If this drug treatment is unsuccessful, a surgical termination will be required. Until the 12th week, pregnancy may be terminated by vacuum suction curettage performed under either a general or a local anaesthetic (see *anaesthesia, general*; *anaesthesia, local*). The cervix is dilated with curved metal rods and a thin plastic tube is inserted into the uterus. The tube is connected to an apparatus that sucks out the fetal and placental tissues.

Recovery is generally fast, although strenuous activity should be avoided for several days. There is usually some bleeding, and occasionally mild cramps, for up to a week. Menstrual periods typically return four to six weeks after the termination. Sexual intercourse can be resumed after two to three weeks.

Late abortion Between the 12th and 15th weeks of pregnancy, either the suction procedure used in early abortion or the evacuation procedure may be recommended. In the evacuation procedure, which is routinely performed after the 15th week, the uterus is forced to contract so that the fetus is expelled, as in natural labour. Contractions are induced by oral administration of a dose of *mifepristone*, followed 36 to 48 hours later by the introduction, high into the vagina, of a *prostaglandin hormone pessary*. The *prostaglandin* medication may need to be repeated for the contractions to be maintained.

It usually takes from 12 to 24 hours for the fetus to be expelled using the evacuation procedure, during which time the woman is given *analgesic drugs* (painkillers). She usually remains in hospital for up to 48 hours after completion of the termination in order to be monitored for complications.

COMPLICATIONS

If termination is performed by a qualified gynaecologist in a well-equipped clinic or hospital, complications are rare. Infection, resulting in a condition called *septic abortion*, or serious bleeding occasionally occur. Repeated terminations may increase the risk of miscarriage occurring in subsequent pregnancies; but a single termination is unlikely to affect future fertility. (See also *complete abortion*; *habitual abortion*; *incomplete abortion*.)

abrasion

Also called a graze, a *wound* on the surface of the skin that is caused by scraping or rubbing.

abrasion, dental

The wearing away of tooth enamel, which is often accompanied by the erosion of dentine (the layer beneath the enamel) and cementum (the bonelike tissue that covers the tooth root). Dental abrasion is usually a result of brushing the teeth too vigorously.

Abraded areas are often sensitive to hot, cold, or sweet food and drink; a desensitizing toothpaste and/or protection with a bonding agent (see *bonding, dental*) or filling (see *filling, dental*) may be necessary.

abrasive

A substance that is used in dentistry for polishing and cleaning the teeth. (See also *dentifrice*.)

abreaction

In *psychoanalysis*, the process of becoming consciously aware of painful feelings and memories that have previously been repressed (buried). The emotional discharge of such experiences is believed to have therapeutic benefits. The concept of abreaction originates in Freudian theory, in which the process ideally occurs as a result of *catharsis* (the open expression of emotions that are associated with forgotten memories).

abruption

The medical term for the separation of one structure from another. (See also *placental abruption*.)

abruptio placenta

The medical term for the premature separation of the placenta from the wall of the uterus (see *placental abruption*) during pregnancy.

abscess

A collection of *pus* caused by infection by microorganisms, usually bacteria. Pus is formed from destroyed tissue cells, from leukocytes (a type of white blood cell) that have been carried to the area to fight infection, and from dead and live microorganisms. A lining, known as a pyogenic membrane, often forms around the abscess.

TYPES

An abscess may develop in any organ, and in the soft tissues beneath the skin, sometimes as a collar-stud abscess, a small cavity that connects to a larger cavity in deeper tissues. Common sites of abscesses include the armpit, breast

(see *breast abscess*), groin, and gums (see *abscess, dental*). Rarer sites include the liver (see *liver abscess*) and brain (see *brain abscess*).

CAUSES AND INCIDENCE

Common bacteria, such as staphylococci, are the usual cause of abscesses, although fungal infections are another cause. Amoebae (single-celled microorganisms) are an important cause of liver abscesses (see *amoebiasis*). Infectious organisms reach internal organs via the bloodstream or penetrate to tissues under the skin through an infected wound or bite.

People with impaired immunity, such as those who are taking *immunosuppressant drugs* and those with *HIV* infection or *AIDS*, are especially susceptible to abscesses.

escape; a tube may be left in place to allow continuous drainage (see *drain, surgical*). Some abscesses burst and drain spontaneously.

OUTLOOK

Many abscesses subside following drainage alone; others subside after a combination of drainage and drug treatment. Occasionally the presence of an abscess within a vital organ damages enough surrounding tissue to cause permanent loss of normal function, or even death. (See also *appendix abscess*; *Bartholin's abscess*; *bone abscess*; *caseous abscess*; *cold abscess*; *hot abscess*; *metastatic abscess*; *pelvic abscess*; *periodontal abscess*; *peritonillar abscess*; *sterile abscess*; *subphrenic abscess*; *tubercular abscess*.)

abscess, dental

Also called a periapical abscess, a pus-filled sac in the tissue around the end of the root of a tooth, usually caused by bacterial infection.

CAUSE

A periapical abscess may occur when bacteria invade the pulp (the tissues in the central cavity of a tooth), causing the pulp to die. This commonly happens as a result of dental caries (see *caries, dental*), as the tooth's enamel and dentine are destroyed allowing bacteria to reach the pulp. Bacteria can also gain access to the pulp when a tooth is injured. The infection in the pulp then spreads into the surrounding tissue to form an abscess.

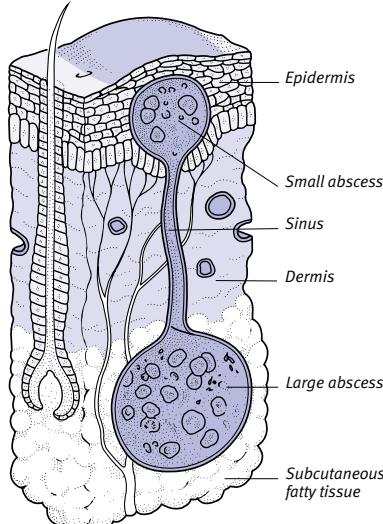

An abscess that occurs when bacteria accumulate in pockets that form between the teeth and gums is called a periodontal abscess. This type of abscess indicates chronic *periodontal disease*, in which the periodontal membrane (attachment of tooth to bone) is damaged and, in severe cases, the supporting bone eroded.

SYMPTOMS

An abscess may cause pain, depending on where it occurs. Most larger abscesses cause fever (sometimes with chills), sweating, and malaise. Abscesses may produce a sensation of intense pressure and those close to the skin may cause redness and swelling.

TREATMENT

Antibiotic drugs are usually prescribed to treat bacterial infections, *antifungal drugs* are used to treat fungal infections, and amoebicides are used for amoebiasis. Most abscesses need to be drained by making a cut in the lining of the abscess cavity to allow the pus to

Cross section of a collar-stud abscess

A small cavity in the epidermis, just beneath the skin's surface, connects, via a sinus (channel), to a larger cavity in deeper, subcutaneous tissue.

SYMPOTMS

An abscess may cause pain, depending on where it occurs. Most larger abscesses cause fever (sometimes with chills), sweating, and malaise. Abscesses may produce a sensation of intense pressure and those close to the skin may cause redness and swelling.

TREATMENT

Antibiotic drugs are usually prescribed to treat bacterial infections, *antifungal drugs* are used to treat fungal infections, and amoebicides are used for amoebiasis. Most abscesses need to be drained by making a cut in the lining of the abscess cavity to allow the pus to

TREATMENT

A periapical abscess may be drained by drilling through the crown of the tooth into the pulp cavity in order to allow the pus to escape, followed by *root-canal treatment* (filling of the pulp cavity with dental cement). In some cases, extraction of the tooth (see *extraction, dental*) is necessary. *Antibiotic drugs* are prescribed if the infection has spread. A periodontal abscess can usually be treated by careful scraping away of the infected material by the dentist.

absence

In medical usage, a temporary loss or impairment of consciousness that occurs in some forms of *epilepsy*, typically generalized absence (petit mal) seizures in childhood.

absorption

The process by which fluids or other substances are taken up by body tissues. The term absorption is commonly applied to the uptake of nutrients (from digested food) into the blood and lymph from the digestive tract.

The major site of absorption is the small intestine, which is lined with millions of microscopic fingerlike projections known as villi (see *villus*). The villi greatly increase the surface area of the intestine, thereby increasing the rate of absorption.

abuse

Maltreatment of a person or misuse of a substance. (See also *child abuse*; *drug abuse*; *heroin abuse*; *sexual abuse*; *solvent abuse*; *substance abuse*.)

acamprostate

A drug used in the treatment of *alcohol dependence*.

acanthoma

A noncancerous tumour composed of cells of the outer layer of skin. There are various types of acanthoma. They are most likely to occur on the face, where they develop in hair follicles, or on the legs. (See also *keratoacanthoma*.)

acanthosis nigricans

A rare, untreatable condition in which thickened dark patches of skin appear in the groin, armpits, neck, and other skin folds. Acanthosis nigricans may occur in young people as a genetic disorder or as the result of an endocrine disorder such as *Cushing's syndrome*. The condition

also occurs in people with carcinomas (cancerous tumours) of the lung and other organs.

Pseudoacanthosis nigricans is a much more common condition that is usually seen in dark-complexioned people who are overweight. In this form, the skin in fold areas is both thicker and darker than the surrounding skin, and excessive sweating usually occurs in affected areas. Pseudoacanthosis nigricans may improve with weight loss.

acarbose

A drug that is used in the treatment of type 2 *diabetes mellitus*. Acarbose acts on enzymes in the intestines, inhibiting the digestion of starch and therefore slowing the rise in *blood glucose* levels after a carbohydrate meal.

accessory nerve

The 11th *cranial nerve*. Unlike the other cranial nerves, most of the accessory nerve originates from the spinal cord.

The small part of the nerve that originates from the brain supplies many muscles of the palate, pharynx (throat), and larynx (voice-box). Damage to this part of the nerve may lead to *dysphonia* (difficulty in speaking) and *dysphagia* (difficulty in swallowing).

The spinal part of the accessory nerve supplies large muscles in the neck and back, most notably the sternomastoid (which runs from the breastbone to the

side of the skull) and trapezius (the large, triangular muscle of the upper back, shoulder, and neck). Damage to the spinal fibres of the nerve paralyses these muscles.

accidental death

Death that occurs as a direct result of an accident. A high proportion of deaths in young adults, particularly among males, are accidental. Many of these deaths are as a result of road traffic accidents, drowning, or drug overdose; and alcohol is a significant contributory factor.

Falls in the home, and burning or asphyxiation as a result of fires, are common causes of accidental death in elderly people. Important causes of accidental death in infants are choking on food or smothering by bedclothes or other materials such as plastic bags. Fatal accidents at work have become less common with the introduction of effective safety measures.

acclimatization

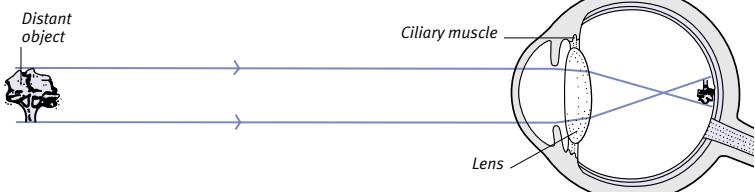

Physical or psychological adjustment to a different climate, environment, or situation. (See also *heat disorders*; *mountain sickness*.)

accommodation

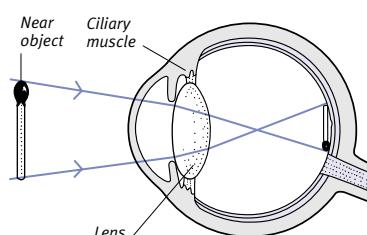

Adjustment, especially the process by which the eye adjusts itself to focus on near objects. At rest, the eye is focused

THE MECHANISM OF ACCOMMODATION

In a normal, healthy eye, light reflected from a near object is brought into focus on the retina by a process called accommodation. Focusing is achieved by an automatic change in lens shape.

Focusing on a distant object
The lens focused on a distant object is thin, flat, and completely relaxed.

Focusing on a near object
To bring a near object into sharp focus, the ciliary muscles contract and the lens becomes more convex in shape.

for distant vision, when its lens is thin and flat. To focus on a nearer object, the ciliary muscle of the eye contracts, which reduces the pull on the outer rim of the lens, allowing it to become thicker and more convex.

With age, the lens loses its elasticity. This makes accommodation increasingly difficult and results in a form of longsightedness called *presbyopia*.

accouchement

The French word for the *delivery* of an infant from the uterus (womb). (See also *childbirth*.)

accretion

A manner of growth involving the accumulation of additional material of the same type as that already present. The term accretion is used in dentistry to refer to the collection of foreign material, such as plaque (see *plaque, dental*), on the surface of a tooth or in a dental cavity.

acebutolol

A *beta-blocker drug* used to treat *hypertension* (high blood pressure), *angina pectoris* (chest pain caused by impaired blood supply to the heart muscle), and certain types of *arrhythmia* (abnormal heart rhythm) in which the heart beats too rapidly.

ACE inhibitor drugs

COMMON DRUGS

- Captopril • Cilazapril • Enalapril • Fosinopril
- Lisinopril • Moexipril • Perindopril
- Quinapril • Ramipril • Trandolapril

A group of drugs that are used to treat *heart failure* (reduced pumping efficiency of the heart), *hypertension* (high blood pressure), and kidney problems associated with *diabetes mellitus*. ACE (*angiotensin-converting enzyme*) inhibitors are often prescribed with other drugs such as *diuretic drugs* or *beta-blocker drugs*.

HOW THEY WORK

ACE inhibitors block the action of an *enzyme* that is responsible for converting *angiotensin* (a protein present in the blood) from inactive angiotensin I to angiotensin II. Angiotensin II encourages blood vessels to constrict; its absence permits them to dilate, thus reducing blood pressure. In diabetic nephropathy, ACE inhibitors slow the progress of the disorder and reduce the loss of *albumin* in the urine.

SIDE EFFECTS

Possible side effects include nausea, loss of taste, headache, dizziness, and a dry cough. The first dose may dramatically reduce blood pressure.

acellular

A term meaning "without cells" that is generally used to describe pertussis (whooping cough) *vaccines* that contain only certain parts, rather than the whole, of the pertussis bacteria cell.

acetabulum

A cuplike hollow in the pelvis into which the head of the femur (thigh bone) fits to form the *hip joint*.

acetaminophen

An *analgesic drug* that is more commonly known as *paracetamol*.

acetazolamide

A drug that is used in the treatment of *glaucoma* (raised pressure in the eyeball) and, occasionally, to prevent or treat symptoms of *mountain sickness* (headache, weakness, and other symptoms occurring at high altitudes).

Possible side effects of acetazolamide include lethargy, nausea, diarrhoea, and reduced libido.

acetic acid

The colourless, pungent, organic acid that gives vinegar its sour taste. In medicine, acetic acid is an ingredient of antiseptic gels that are used to treat certain vaginal infections.

acetone

A chemical produced naturally when the body enters a state known as *ketosis*, in which fats are broken down to produce energy. This can occur as the result of metabolic changes caused by *diabetes mellitus* or, sometimes, as the result of extreme dieting.

Pharmaceutical preparations containing acetone are used as antiseptics and solvents. Acetone is also used in cosmetics such as nail varnish remover. (See also *solvent abuse*.)

acetylcholine

A type of *neurotransmitter* (a chemical that transmits messages between nerve cells or between nerve and muscle cells). Acetylcholine is the neurotransmitter found at all nerve-muscle junctions and at many other sites in the nervous system. The actions of acetyl-

choline are called cholinergic actions, and these can be blocked by *anticholinergic drugs*.

acetylcholinesterase inhibitors

COMMON DRUGS

- Donepezil • Rivastigmine

A group of drugs that are used in the treatment of mild to moderate *dementia* caused by *Alzheimer's disease*, in which there is a deficiency of the neurotransmitter *acetylcholine* in the brain.

HOW THEY WORK

Acetylcholinesterase inhibitors work by blocking the action of acetylcholinesterase, the enzyme in the brain responsible for the breakdown of acetylcholine. This raises acetylcholine levels, and, in up to half of all patients, the drugs slow the rate of progression of dementia. However, they have no effect on dementia due to other causes, such as stroke or head injury.

SIDE EFFECTS

Common side effects include nausea, dizziness, and headache. Rarely, difficulty in passing urine may occur.

acetylcysteine

A drug that is used in the treatment of *paracetamol* overdose and also as a *mucolytic* drug to loosen sputum in *chronic bronchitis*.

To be effective as an antidote to paracetamol poisoning, acetylcysteine must be given by injection within a few hours of the overdose having been taken. The drug works by reducing the amount of toxic substances produced during the breakdown of paracetamol, thereby reducing the risk of liver damage. When taken orally, acetylcysteine makes the mucus in sputum less sticky and therefore easier to cough up.

When acetylcysteine is taken in large doses, vomiting, rash, or breathing difficulties may occur as rare side effects.

achalasia

A rare condition, of unknown cause, in which the muscles at the lower end of the *oesophagus* and the sphincter (valve) between the oesophagus and the stomach fail to relax to allow food into the stomach after swallowing. As a result, the lowest part of the oesophagus is narrowed and becomes blocked with food, while the part above widens.

SYMPTOMS AND SIGNS

Symptoms include difficulty and pain in swallowing, and pain in the lower chest

and upper abdomen. A foul taste in the mouth and bad breath may arise due to the regurgitation of food. The ability to swallow gradually deteriorates until the swallowing of liquids is also impeded.

DIAGNOSIS AND TREATMENT

A barium swallow (a type of *barium X-ray examination*) and *gastroscopy* (in which a narrow viewing tube is passed down the oesophagus) may be performed in order to investigate achalasia.

Drug treatment for achalasia is rarely successful. It is possible to widen the oesophagus for prolonged periods by *oesophageal dilatation* (passing a cylindrical rod or a *balloon catheter* down the oesophagus). Surgery to cut some of the muscles at the stomach entrance may be necessary to widen the passage-way for food.

ache

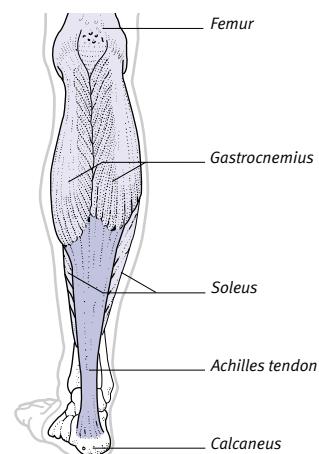

A continuous, fixed, and often dull pain that is distinct from twinges. (See also *bone pain; earache; headache; stomach-ache; toothache*.)

Achilles tendon

The tendon that raises the heel. The Achilles tendon is formed from the calf muscles (the gastrocnemius, soleus, and plantaris muscles) and is attached to the *calcaneus* (the heel-bone). The Achilles tendon is named after Achilles, the legendary Greek hero who was vulnerable only in his heel.

LOCATION OF THE ACHILLES TENDON

The tendon runs from the base of the calf to the calcaneus.

Minor injuries to the Achilles tendon are common. They are usually provoked by too much exercise, faulty running technique, or the wearing of unsuitable footwear. All of these injuries can result in inflammation of the tendon (*tendinitis*) and tearing of the tendon fibres. In most cases, these conditions clear up with rest and physiotherapy.

Violent stretching of the Achilles tendon can cause it to rupture, creating a snapping sensation in the injured area, and pain, swelling, and impaired movement of the affected part. In such cases, surgical repair may be needed, but immobilization of the ankle in a plaster cast may be sufficient.

achlorhydria

Absence of stomach acid secretions. This may be due to chronic atrophic *gastritis* or to an absence or malfunction of acid-producing parietal cells in the stomach lining.

Achlorhydria may not produce symptoms and is not in itself a cause for concern. However, it is sometimes associated with *stomach cancer* and is also a feature of pernicious anaemia, a blood disorder caused by defective absorption of vitamin B_{12} from the stomach (see *anaemia; megaloblastic*).

achondroplasia

A rare genetic disorder of bone growth that leads to *short stature*. Individuals affected with achondroplasia have short limbs, a well-developed trunk, and a head of normal size, except for a protruding forehead.

The condition is caused by a defect of a dominant gene (see *genetic disorders*) but often arises as a new *mutation*, rather than being inherited from a parent. The long bones of the arms and legs are affected mainly. The cartilage that links each bone to its epiphysis (the growing area at its tip) is converted to bone too early, preventing further limb growth.

Achondroplasia is usually obvious at birth or during the first year of life and no treatment is available to alter the outlook. Intelligence and sexual development are not affected, and lifespan is close to normal.

aciclovir

An *antiviral drug* that can be taken orally in tablet or liquid form, applied to the skin as a cream, taken as eye-drops, or given intravenously for viral infections

including *herpes simplex* (cold sores), *herpes zoster* (shingles), and varicella zoster (chickenpox) in adults.

Aciclovir can be used as a life-saving treatment for *encephalitis* (inflammation of the brain). When it is used to treat *cold sores* or recurrent genital herpes, for which an ointment is available over the counter, aciclovir does not provide a cure but does, however, reduce the severity of the attacks.

Side effects of aciclovir are uncommon, but they can include nausea, vomiting, and fatigue. Local reactions commonly occur after topical use.

acid

A substance that is defined as a donor of hydrogen ions (hydrogen atoms with positive electrical charges). Acid molecules, when mixed with or dissolved in water, split up to release their constituent ions; all acids release hydrogen as the positive ion (positive ions are known as cations; and negative ions are called anions).

Examples of acids within the body include hydrochloric acid (a corrosive mineral acid that is produced by the stomach lining), and many organic acids, such as lactic acid, carbonic acid, ascorbic acid (vitamin C), and pyruvic acid. (See also *acid-base balance; alkali*.)

acid-base balance

A combination of mechanisms that ensures that the body's fluids are neither too *acid* nor too alkaline (*alkalis* are also called bases). The body functions normally only when its fluids are close to chemical neutrality.

Metabolic processes cause fluctuations in the acidity and alkalinity of the blood and other body fluids. The body has three mechanisms for maintaining of normal acid-base balance: buffers, breathing, and the activities of the kidneys. Buffers are substances in the blood that neutralize acid or alkaline wastes. Rapid breathing increases the rate at which carbon dioxide is eliminated from the blood, resulting in the blood becoming less acidic; slow breathing has the opposite effect; the kidneys help to maintain a constant acidity level in the blood by regulating the amounts of acid or alkaline wastes in the urine.

Disturbances of the body's acid-base balance result in either *acidosis* (excessive blood acidity) or *alkalosis* (excessive blood alkalinity).

acid-fast

A characteristic of particular bacteria (especially those responsible for tuberculosis) that are resistant to the acids used to dye specimens for microscopic examination (see *staining*).

acidosis

A disturbance of the body's *acid-base balance* in which there is an accumulation of acid or loss of *alkali* (base). There are two types of acidosis: metabolic and respiratory.

CAUSES

In metabolic acidosis, an increased amount of acid is produced by metabolic processes. One form of metabolic acidosis is ketoacidosis, which occurs in uncontrolled *diabetes mellitus* and starvation. Metabolic acidosis may also be caused by loss of bicarbonate (an alkali) as a result of severe diarrhoea. In *kidney failure*, there is insufficient excretion of acid in the urine.

Respiratory acidosis occurs when breathing fails to remove enough carbon dioxide from the lungs. This causes increased acidity of the blood because the excess carbon dioxide remains in the bloodstream, where it dissolves to form carbonic acid. Impaired breathing leading to respiratory acidosis may be caused by chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*), bronchial asthma, or *airway obstruction*.

acid reflux

The regurgitation of acidic fluid from the stomach into the *oesophagus* (the tube that connects the throat to the stomach). Acid reflux is the result of inefficiency of the muscular valve at the lower end of the oesophagus.

Also known as gastro-oesophageal reflux disease (GORD), acid reflux may inflame the oesophagus, resulting in *heartburn* (a burning pain in the chest) due to *oesophagitis* (inflammation of the oesophagus).

Mild acid reflux is common but is not serious. It may occur during pregnancy and often affects overweight people. Repeated episodes of discomfort may indicate a *hiatus hernia* (in which part of the stomach protrudes into the chest).

acne

A chronic skin disorder in which there is inflammation of the *sebaceous glands* at the base of hair follicles in the skin.

TYPES

The most common type of acne is sometimes known as *acne vulgaris*, which almost always develops during puberty. Chemical acne is caused by exposure of the skin to certain chemicals and oils. This results in the development of acne in areas where the chemical has come into contact with the skin, such as on the thighs. Certain prescribed drugs, such as *corticosteroid drugs*, can also cause acne.

Acne

The spots on this boy's face are typical of acne; the darker marks are healed spots, which fade gradually. Severe acne may leave pits in the skin.

CAUSE

Acne spots are caused by the obstruction of hair follicles by excess sebum (the oily substance secreted by the sebaceous glands). Bacteria multiply in the follicle, causing inflammation. Hormonal changes at puberty, including increased levels of *androgen hormones* (male sex hormones) in both males and females, stimulate the production of sebum. There may also be a genetic predisposition to acne.

SYMPOTMS

Acne develops in areas in which there is a high concentration of sebaceous glands, mainly the face, centre of the chest, upper back, shoulders, and around the neck. Milia (whiteheads), comedones (blackheads), nodules (firm swellings under the skin), and cysts (larger, fluid-filled swellings) are the most common types of spot. Some, particularly cystic spots, leave scars.

TREATMENT AND OUTLOOK

There is no instant cure for acne, although washing the affected areas at least twice a day with a mild soap may

help to keep it under control. Over-the-counter topical drug treatments such as benzoyl peroxide or azelaic acid are often effective. Prescribed topical *antibiotic drugs* or retinoic acid (a derivative of *vitamin A*) are used to treat moderate acne. Alternative treatment is with oral antibiotics, often *tetracycline drugs*. In very severe cases, *isotretinoin* may be given under hospital supervision. In all cases, exposure to ultraviolet light (either natural or artificial) may also be beneficial. However, it is important not to burn the skin.

Acne improves slowly over time, and it often clears up by the end of the teenage years.

acoustic nerve

The part of the *vestibulocochlear nerve* (the eighth cranial nerve) concerned with hearing. The acoustic nerve is also called the auditory or cochlear nerve.

acoustic neuroma

A rare, noncancerous tumour arising from supporting cells that surround the *vestibulocochlear nerve*, usually within the internal auditory meatus (the canal in the skull through which the nerve passes from the inner ear to the brain).

CAUSE AND INCIDENCE

Acoustic neuromas most commonly occur in people between the ages of 40 and 60 and are slightly more common in women than in men.

Usually, the cause of an acoustic neuroma is unknown. However, tumours that affect the nerves on both sides of the head simultaneously may be part of a widespread *neurofibromatosis* (a disease characterized by changes in the nervous system, skin, and bones).

SYMPTOMS

An acoustic neuroma can cause *deafness*, *tinnitus* (noises in the ear), loss of balance, and pain in the face and the affected ear. As the tumour enlarges, it may lead to additional complications, such as *ataxia* (loss of coordination) due to the compression of the brainstem and cerebellum.

DIAGNOSIS AND TREATMENT

Diagnosis is made by *hearing tests* followed by *X-rays* or by *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures).

Surgery may be necessary to remove an acoustic neuroma, but treatment with *radiotherapy* to shrink it may also be effective.

acquired

A term relating to a condition that occurs after birth rather than being attributable to heredity. Acquired contrasts with *congenital*, which means present from birth.

acquired immunity

A form of *immunity* that develops after birth through exposure to microorganisms or through *immunization*.

acrocyanosis

A circulatory disorder in which the hands and feet turn blue, may become cold, and sweat excessively. Acrocyanosis is caused by spasm of the small blood vessels and is often aggravated by cold weather.

Acrocyanosis is related to *Raynaud's disease*, in which the skin of the fingers and toes may be damaged by reduced blood flow.

acrodermatitis

Inflammation of the skin, principally on the hands or feet. *Acrodermatitis enteropathica* is a chronic (long-term), inherited variety of the condition.

acrodermatitis enteropathica

A rare, inherited disorder in which areas of the skin (most commonly of the fingers, toes, scalp, and the areas around the anus and mouth) are reddened, ulcerated, and covered with *pustules* (pus-filled spots).

Acrodermatitis enteropathica is inherited in an autosomal recessive manner (see *genetic disorders*) and is due to the inability to absorb sufficient zinc from food. Zinc supplements usually bring about a rapid improvement.

acromegaly

A rare disease that is characterized by abnormal enlargement of the skull, the jaw, the hands and feet, and also of the internal organs.

CAUSE

Acromegaly is caused by excessive secretion of *growth hormone* from the anterior *pituitary gland* at the base of the brain and is the result of a noncancerous *pituitary tumour*.

If such a tumour develops before puberty, the result is *gigantism* (in which growth is accelerated) instead of acromegaly. More commonly, however, the tumour develops after growth in the long bones of the limbs has stopped. This leads to acromegaly, although it

may take several years for the symptoms and signs of the condition to appear.

SYMPOTMS AND SIGNS

Symptoms and signs of acromegaly include enlargement of the hands, feet, ears, and nose; a jutting lower jaw; and a long face. There may also be deepening or huskiness of the voice. Symptoms common to any brain tumour, such as headache and visual disturbances, are also possible.

DIAGNOSIS AND TREATMENT

Acromegaly is diagnosed by the measurement of blood levels of growth hormone before and after a quantity of glucose has been administered. Glucose usually suppresses the secretion of growth hormone; if the glucose has no effect on the blood level of the hormone, uncontrolled secretion of growth hormone by the pituitary gland can be confirmed. *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures) may be carried out to reveal a tumour or overgrowth of the pituitary gland.

A tumour of the pituitary gland may be removed surgically or treated by *radiotherapy*. The drug *octreotide* prevents growth hormone production and may be used to control symptoms by a person awaiting surgery or until the effects of radiotherapy are felt. *Bromocriptine* sometimes causes the tumour to become smaller.

**Appearance of acromegaly**

Enlargement of the hands is a typical feature of acromegaly. The condition is apparent when the acromegalic hand, on the left, is compared to a normal hand.

acromioclavicular joint

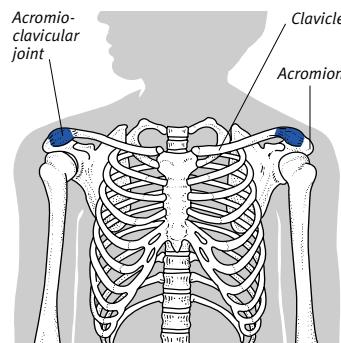

The joint that lies between the outer end of the *clavicle* (collarbone) and the *acromion* (the bony prominence at the top of the shoulderblade).

INJURIES TO THE JOINT

Injuries to the acromioclavicular joint are rare. They are usually caused by a fall on to the shoulder and may result

LOCATION OF THE ACROMIOCLAVICULAR JOINT

The joint lies at the junction of the outer end of the clavicle and the acromion.

in *subluxation* (incomplete dislocation with the bones still in contact) or, rarely, to *dislocation* (complete displacement of the bones so that they are no longer in contact).

In subluxation, the synovium (joint lining) and the ligaments around it are stretched and bruised, the joint is swollen, and the bones feel slightly out of alignment. In dislocation, the ligaments are torn, the swelling is greater, and the bone deformity is more pronounced. In both cases, the joint is painful and tender, and movement of the shoulder is restricted.

TREATMENT

Treatment for subluxation is by resting the arm and shoulder in a sling. If the pain and tenderness persist, injection of a *corticosteroid drug* and a local anaesthetic (see *anaesthesia, local*) into the joint may help.

Dislocation of the acromioclavicular joint requires strapping around the clavicle and elbow, for about three weeks, to pull the outer end of the clavicle back into position. Surgical correction may occasionally be required.

acromion

The bony prominence at the top of the *scapula* (shoulderblade) that articulates with the end of the *clavicle* (collarbone) to form the *acromioclavicular joint*.

acroparaesthesia

A medical term for tingling sensations that occur in the fingers or toes (see *pins-and-needles*).

ACTH

The common abbreviation for adrenocorticotrophic hormone (also called corticotrophin). ACTH is produced by the anterior part of the *pituitary gland* (at the base of the brain) and stimulates the adrenal cortex (the outer layer of the *adrenal glands*, situated on the top of the kidneys) to release various *corticosteroid hormones*. ACTH is also necessary for the growth and maintenance of the cells of the adrenal cortex.

ACTIONS

The most important function of ACTH is to stimulate the adrenal cortex to increase its production of *hydrocortisone* (cortisol). ACTH also causes the adrenal cortex to release *aldosterone* and *androgen hormones*.

The production of ACTH is controlled by a feedback mechanism that involves both the *hypothalamus* (an area in the centre of the brain) and the level of hydrocortisone in the blood. When ACTH levels are high, the production of hydrocortisone increases, which in turn suppresses the release of ACTH from the pituitary gland. If ACTH levels are low, hydrocortisone production falls and the hypothalamus releases factors that stimulate the pituitary gland to increase production of ACTH.

ACTH levels increase in response to stress, emotion, injury, burns, infection, surgery, and decreased blood pressure. Cancerous tumours, particularly those of the lung, can sometimes produce a chemical that is similar to ACTH and which causes symptoms.

DISORDERS OF ACTH PRODUCTION

A tumour of the pituitary gland can cause excessive production of ACTH, which, in turn, leads to overproduction of hydrocortisone by the adrenal cortex, resulting in *Cushing's syndrome* (a hormonal disorder). Insufficient ACTH production results in decreased production of hydrocortisone, causing *hypotension* (low blood pressure).

MEDICAL USES

Synthetic ACTH was once given in the treatment of *arthritis* or to treat *allergy*, but it is now rarely used.

actin

A protein component of *muscle* fibres that, together with myosin (another protein), provides the mechanism for muscles to contract. The microscopic filaments of actin and myosin slide in between each other to make the muscle fibres shorter.

acting out

Impulsive actions that may reflect an individual's unconscious wishes. The term is most often used by psychotherapists to describe behaviour during analysis when the patient "acts out", rather than reports, his or her fantasies, wishes, or beliefs. Acting out can also occur as a reaction to frustrations encountered in everyday life, often taking the form of antisocial, aggressive behaviour that may be directed against oneself or others.

actinic

Relating to changes caused by the ultraviolet rays in sunlight, as in actinic *dermatitis* (inflammation of the skin) and actinic *keratosis* (roughness and thickening of the skin). Both are caused by overexposure to solar radiation.

actinomycosis

An infection caused by *ACTINOMYCES ISRAELII* or related actinomycete bacteria. These bacteria resemble fungi and cause diseases of the mouth, jaw, chest, and pelvis.

TYPES AND CAUSES

The most common form of actinomycosis affects the jaw area. A painful swelling appears and pus and characteristic yellow granules discharge through small openings that develop in the skin. Poor oral hygiene may contribute to this form of the infection.

Another form of actinomycosis affects the pelvis in women, causing lower abdominal pain and bleeding between menstrual periods. This form was associated mainly with a type of *IUD*, no longer in use, that did not contain copper. Rarely, forms of the disorder affect the appendix or lung.

Actinomycosis is usually treated successfully with *antibiotic drugs*.

acuity, visual

See *visual acuity*.

acupressure

A derivative of *acupuncture* in which pressure is applied instead of needles.

acupuncture

A branch of *Chinese medicine* in which needles are inserted into a patient's skin as therapy for various disorders, to relieve pain or to induce *anaesthesia*.

Traditional Chinese medicine maintains that the chi (life-force) flows through the body along channels

known as meridians. A blockage in one or more of these meridians is thought to cause ill health. Acupuncturists aim to restore health by inserting needles at appropriate sites, known as acupuncture points, along the affected meridians.

HOW IT WORKS AND WHY IT IS DONE

Research suggests that acupuncture provokes the release within the central nervous system of *endorphins* (substances resembling morphine), which act as natural analgesics (painkillers).

The disorder that is being treated and degree of anaesthesia required determine the needle temperature, place of insertion, whether the needles are stimulated by rotation or electric current, and the length of time the needles remain in position.

Acupuncture may be used as an anaesthetic for surgical procedures as well as to provide pain relief following operations and for chronic conditions. Acupuncture is also claimed to help in the treatment of addiction, depression, and anxiety.

SIDE EFFECTS

After treatment with acupuncture, some people experience temporarily exacerbated symptoms. Other people may feel lightheaded, drowsy, or exhilarated for a short while.

It is important that acupuncture is performed by a fully qualified acupuncturist because the use of inadequately sterilized needles could result in the transmission of a variety of infections, including *hepatitis B* and *HIV*.

acute

A term often used to describe a disorder or symptom that develops suddenly. Acute conditions may or may not be severe, and they are usually of short duration. (See also *chronic*.)

acute heart failure

See *heart failure, acute*.

acyanotic

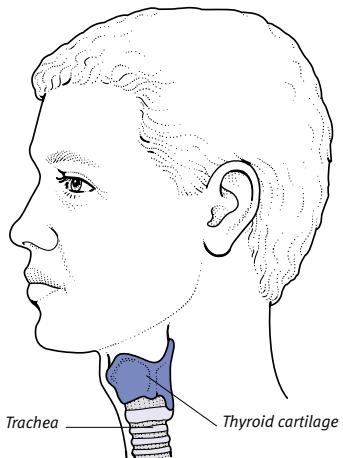

A diagnostic term meaning without *cyanosis*, a bluish coloration of the skin that is seen when blood *oxygen* levels are abnormally low. The term is commonly used in relation to the classification of congenital (present from birth) heart disease (see *heart disease, congenital*).

Adam's apple

The projection at the front of the neck, just beneath the skin, that is formed by a prominence on the thyroid

LOCATION OF THE ADAM'S APPLE

This projection at the front of the neck, beneath the skin, is formed by a prominence on the thyroid cartilage.

cartilage, which is part of the *larynx* (voice-box). The Adam's apple enlarges in males at puberty.

ADD

The abbreviation for attention deficit disorder, more commonly known as *attention deficit hyperactivity disorder*.

addiction

Dependence on, and craving for, a particular drug, such as alcohol, diazepam (a tranquillizer), or heroin. Reducing or stopping intake of the drug may lead to characteristic physiological and/or psychological symptoms (see *withdrawal syndrome*), such as tremor or anxiety. The term addiction may also be used in relation to compulsive behaviour, such as gambling. (See also *alcohol dependence; drug dependence*.)

Addison's disease

A rare chronic disorder in which there is deficiency of the corticosteroid hormones *hydrocortisone* and *aldosterone*, which are normally produced by the adrenal cortex (the outer parts of the *adrenal glands*, which are situated on the top of the kidneys). In addition, excessive amounts of the hormone *ACTH* are secreted by the pituitary gland (at the base of the brain) in an attempt to increase output of the corticosteroid hormones. The secretion and activity of

another hormone, melanocyte stimulating hormone (MSH), also increase, which leads to increased synthesis of *melanin* pigment in the skin.

CAUSES

Addison's disease can be caused by any disease that destroys the adrenal cortices. The most common cause is an *autoimmune disorder* in which the immune system produces antibodies that attack the adrenal glands.

SYMPOTMS

Symptoms of the disease generally develop gradually over months or years and include tiredness, weakness, abdominal pain, and weight loss. Excess MSH may cause darkening of the skin in the creases of the palms, pressure areas of the body, and the mouth.

Acute episodes, called Addisonian crises, brought on by infection, injury, or other stresses, can also occur. The symptoms of these are mainly due to aldosterone deficiency and include extreme muscle weakness, dehydration, *hypotension* (low blood pressure), confusion, and coma. *Hypoglycaemia* (low blood glucose) also occurs due to a deficiency of hydrocortisone.

DIAGNOSIS AND TREATMENT

Diagnosis of Addison's disease is generally made if the patient fails to respond to an injection of ACTH, which normally stimulates hydrocortisone secretion.

Lifelong *corticosteroid drug* treatment is needed to replace the deficient hormones. Treatment of Addisonian crises involves rapid infusion of saline and glucose and supplementary doses of corticosteroid hormones.

additives

See *food additives*.

adduction

Movement of a limb towards the central line of the body, or of a digit towards the axis of a limb. Muscles that carry out this movement are often called adductors. (See also *abduction*.)

adductor

Any one of the muscles that carry out the movement of *adduction*.

adenitis

Inflammation of *lymph nodes*. Cervical adenitis (swelling and tenderness of the lymph nodes in the neck) occurs in certain bacterial infections, especially *tonsillitis*, and the viral infection glandular fever (see *mononucleosis, infectious*).

Mesenteric lymphadenitis is inflammation of the lymph nodes inside the abdomen and is usually caused by a viral infection.

In many cases of adenitis, treatment is not necessary. When it occurs as the result of a bacterial infection, treatment of the infection with *antibiotic drugs* will generally also result in an improvement in the condition of the lymph nodes.

adenocarcinoma

The technical name for a *cancer* of a gland or glandular tissue, or for a cancer in which the cells form glandlike structures. An adenocarcinoma arises from epithelium (the layer of cells that lines organs).

Cancers of the colon (the main part of the large intestine), breast, pancreas, and kidney are usually adenocarcinomas, as are some cancers of the cervix, oesophagus, salivary glands, and various other organs. (See also *intestine, cancer of; kidney cancer; pancreas, cancer of*.)

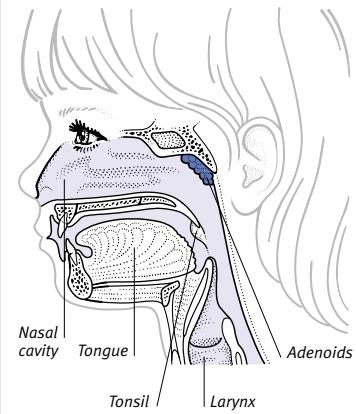

adenoidectomy

Surgical removal of the *adenoids*. An adenoidectomy is usually performed on a child with abnormally large adenoids that are causing recurrent infections of the middle ear or air sinuses. The operation may be performed together with *tonsillectomy*.

There are few after-effects, and the patient can generally begin to eat normally the following day.

LOCATION OF THE ADENOIDS

These swellings of glandular tissue are found at the back of the nasal passage above the tonsils. Enlarged adenoids are sometimes implicated in *sleep apnoea*.

adenoids

A mass of glandular tissue at the back of the nasal passage above the tonsils. The adenoids are made up of *lymph nodes*, which form part of the body's defences against upper respiratory tract infections. They tend to enlarge during early childhood, a time when such infections are common.

DISORDERS

In most children, the adenoids shrink after the age of about five years, and disappear altogether by puberty. In some children, however, they enlarge, obstructing the passage from the nose to the throat and causing snoring, breathing through the mouth, and a characteristically nasal voice. The eustachian tubes, which connect the middle ear to the throat, may also become blocked, resulting in recurrent middle ear infections and deafness.

Obstruction to the flow of secretions behind the nose can result in *rhinitis* (inflammation of the nose), which may spread to the middle ear (see *otitis media*) and to the air sinuses behind the nose (see *sinusitis*).

TREATMENT

Infections usually become less frequent as the child grows. If they do not, adenoidectomy (surgical removal of the adenoids) may be recommended.

adenoma

A noncancerous tumour or cyst that resembles glandular tissue and arises from the epithelium (the layer of cells that lines organs).

Adenomas of *endocrine glands* (such as the pituitary gland, thyroid gland, adrenal glands, and pancreas) can result in excessive hormone production, leading to disease. For example, an adenoma of the pituitary gland can result in *acromegaly* or *Cushing's syndrome*.

adenomatosis

An abnormal condition of glands in which they are affected either by *hyperplasia* (overgrowth) or by numerous *adenomas* (noncancerous tumours).

Adenomatosis may simultaneously affect two or more different *endocrine glands*, such as the adrenal glands, pituitary gland, and pancreas.

adenosine diphosphate

See *ADP*.

adenosine triphosphate

See *ATP*.

ADH

The abbreviation for antidiuretic hormone (also called vasopressin), which is released from the posterior part of the *pituitary gland* and acts on the kidneys to increase their reabsorption of water into the blood.

ACTIONS

Water is continually being taken into the body in food and drink and is also produced by the chemical reactions in cells. Conversely, water is also continually being lost in urine, sweat, faeces, and in the breath as water vapour. ADH reduces the amount of water lost in the urine and helps to maintain the body's overall water balance.

ADH production is controlled by the *hypothalamus* (an area in the centre of the brain), which detects changes in blood concentration and volume. If the blood concentration increases (in other words, the blood contains less water), the hypothalamus stimulates the pituitary gland to release more ADH. If the blood is too dilute, less ADH is produced; as a result, more water is lost from the body in the urine.

DISORDERS OF ADH PRODUCTION

Various factors can affect ADH production and thus disturb the body's water balance. For example, alcohol reduces ADH production by direct action on the brain, resulting in a temporary increase in the production of urine. Urine production is also increased in the disorder *diabetes insipidus*, in which there is either insufficient production of ADH by the pituitary gland or, more rarely, failure of the kidneys to respond to the ADH produced.

The reverse effect, water retention, may result from temporarily increased ADH production after a major operation. Water retention may also be caused by the secretion of ADH by some tumours, especially of the lung.

MEDICAL USES

Synthetic ADH is used in the treatment of a variety of conditions, such as *diabetes insipidus*. Side effects of the drug may include abdominal cramps, nausea, headache, drowsiness, and confusion.

ADHD

The abbreviation for *attention deficit hyperactivity disorder*.

adhesion

The joining of normally unconnected parts of the body by bands of fibrous tissue. Adhesions are sometimes con-

genital (present from birth), but they most often develop as a result of scarring after inflammation.

Adhesions are most common in the abdomen, where they often form after *peritonitis* (inflammation of the abdominal lining) or surgery. Sometimes, loops of intestine are bound together by adhesions, causing intestinal obstruction (see *intestine, obstruction of*). In such cases, surgery is usually required to cut the bands of tissue.

adipose tissue

A layer of fat cells lying just beneath the surface of the skin and around various internal organs.

Adipose tissue is made up of fat stored within adipocytes (fat cells). Fat is deposited as a result of excess food intake, thus acting as an energy store; excessive amounts of fat stored within the adipose tissue is a feature of *obesity*. The tissue insulates against loss of body heat and helps to absorb shock in areas subject to sudden or frequent pressure, such as the buttocks, palms of the hands or soles of the feet. Another function of adipose tissue is to cushion organs such as the heart, kidneys, and eyeballs.

After puberty, the distribution of superficial adipose tissue differs in males and females. In men, superficial adipose tissue tends to accumulate around the shoulders, waist, and abdomen; in women, it occurs more commonly on the breasts, hips, and thighs. Adipose tissue tends to make up a larger proportion of the total body weight of women than of men. In obesity, central distribution of body fat around the waist is associated with a greater risk of *cardiovascular disease* and *diabetes*. This may be because fat in this area tends to result in raised blood lipid levels. (See also *brown fat*.)

adjvant

A substance that enhances the action of another substance in the body. The term is used to describe an ingredient added to a *vaccine* to increase the production of antibodies by the immune system, thus enhancing the vaccine's effect. (See also *adjuvant therapy*.)

adjvant therapy

Treatment for *cancer*, usually with anticancer drugs, that is given once all the evidence of the original tumour has been removed. The aim of adjvant

therapy is to destroy any microscopic deposits of malignant cells that may exist, which reduces the risk of recurrence of the cancer and increases survival times.

Adlerian theory

The psychoanalytical ideas set forth by the Austrian psychiatrist Alfred Adler (1870–1937). Also known as individual psychology, Adler's theories were based on the idea that everyone is born with natural feelings of inferiority. Life is seen as a constant struggle to overcome these feelings; and failure to do so leads to neurosis. (See also *psychoanalytic theory*.)

adnexa

An anatomical term meaning the structures that are adjacent to an organ. Most commonly, the word adnexa is used to refer to the various appendages of the *uterus*: the ovaries, fallopian tubes, and ligaments.

adolescence

The period between childhood and adulthood, which broadly corresponds to the teenage years. Adolescence is a complex stage of psychological development. It commences at and overlaps with, but is not the same as, *puberty*.

Common patterns of adolescent behaviour include moodiness, a general lack of interest, and fluctuating academic performance. Adolescents often worry about their changing body shape and physical appearance. They may lack self-confidence, feel nervous and shy and be unsure of their personal identity.

Adolescents experiment with their appearance, with views and opinions, with allegiances to peer groups, and with political movements or other role models. Gender identity and sexuality may be questioned. Adolescents may also experiment with drugs and alcohol; those who do so to relieve anxiety or depression are more likely to become dependent than those who experiment due to peer-group pressure. Sexual activity is common during adolescence and may result in unwanted pregnancies and *sexually transmitted infections*.

Some adolescents are assertive and strive for independence. Rebellion against parents is common but conflicts with the emotional and financial support that adolescents still require. Aggression and delinquency usually constitute a transient phase. However, a teenager who remains too dependent

may not develop sufficiently to make his or her own decisions or to form new relationships outside the family.

Most behavioural problems resolve themselves over time. Maintaining open lines of communication between parents and children is important in easing this process. The most valuable support parents can offer is to encourage self-confidence and responsibility and thus prepare their children for adult life. Parents should also ensure that their children are informed about issues such as *contraception* and safer sex.

ADP

The abbreviation for adenosine diphosphate, the chemical that takes up energy released during biochemical reactions to form ATP (adenosine triphosphate), the body's main energy-carrying chemical. When ATP releases its energy ADP is reformed. (See also *metabolism*.)

adrenal failure

Insufficient production of hormones by the adrenal cortex (the outer part of the *adrenal glands*, situated on the top of the kidneys). Adrenal failure can be acute (of sudden onset) or chronic (of gradual onset). The condition may be caused by a disorder of the adrenal glands, in which case it is called *Addison's disease*, or by reduced stimulation of the adrenal cortex by ACTH, a hormone produced by the *pituitary gland*. (See also *adrenal glands* disorders box, overleaf.)

adrenal glands

A pair of small, triangular *endocrine glands* (glands that secrete hormones directly into the bloodstream) that are located on the top of the kidneys. Each adrenal gland has two distinct parts: the outer adrenal cortex and the smaller, inner adrenal medulla.

ADRENAL CORTEX

The adrenal cortex secretes *aldosterone*, which, by inhibiting the amount of sodium excreted in the urine, helps to maintain blood volume and blood pressure. The cortex also secretes *hydrocortisone* and corticosterone, as well as small amounts of *androgen hormones*. Hydrocortisone controls the body's use of fats, proteins, and carbohydrates and is also important in helping the body to cope with stress. Hydrocortisone and corticosterone also suppress inflammatory reactions and some activities of the immune system.

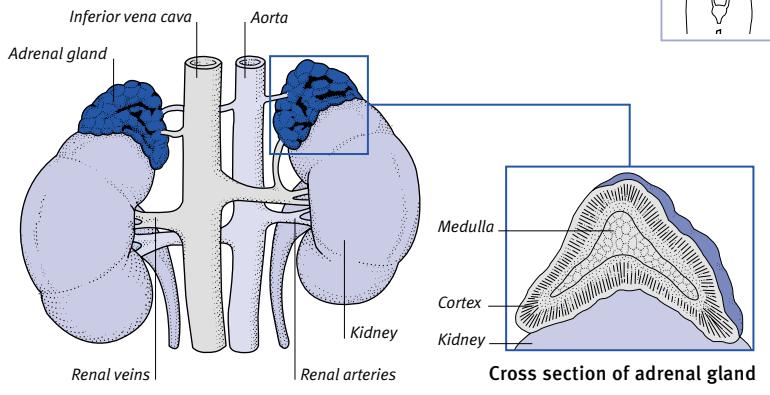

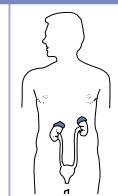

Hormone production by the adrenal cortex is governed by other hormones, such as *ACTH*, that are produced in the *hypothalamus*, in the centre of the brain, and the *pituitary gland* beneath it (see *feedback mechanism* box).

ADRENAL MEDULLA

The adrenal medulla is part of the sympathetic division of the *autonomic nervous system*, which is the body's first line of defence against physical and emotional stress. The medulla secretes the hormones *adrenaline* (epinephrine) and *noradrenaline* (norepinephrine) in

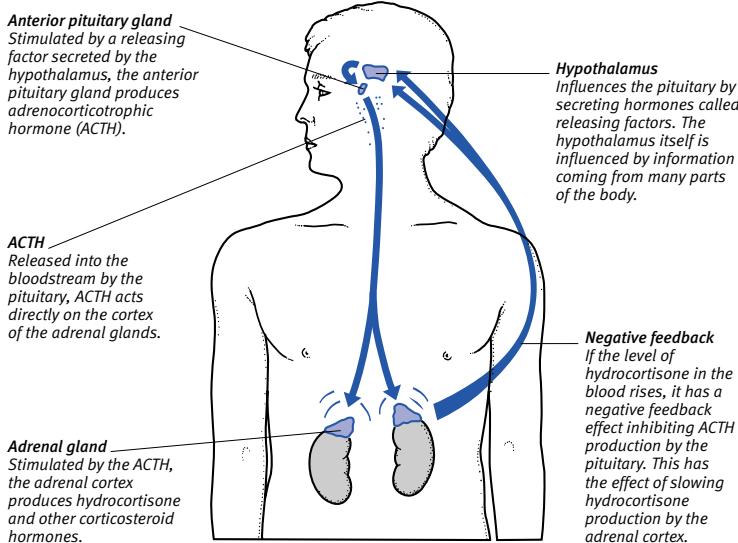

ANATOMY OF THE ADRENAL GLANDS

Also sometimes called the suprarenal glands, the adrenal glands are situated on top of the kidneys. Each gland is divided into two regions: the adrenal cortex (which secretes hormones that affect the metabolism) and the adrenal medulla (which is part of the sympathetic nervous system).

FEEDBACK MECHANISM

The rate at which many glands produce hormones is influenced by other hormones, especially those secreted by the pituitary gland and the hypothalamus. If the amount of hormone produced is increased, negative feedback mechanisms act on the hypothalamus and pituitary so that they produce less of their stimulating hormones, thus reducing the target gland's activity. If the amount of hormone produced is decreased, the feedback weakens, causing increased production of stimulating hormones.

response to stimulation by sympathetic nerves. These nerves are most active during times of stress.

The release of these hormones into the circulation produces effects similar to sympathetic nerve stimulation. The heart rate and force of contraction of the heart muscle increase so that more blood is pumped around the body and the airways are widened to ease breathing. The hormones constrict blood vessels in the intestines, kidneys, and liver, and widen blood vessels supplying the skeletal muscles. Consequently, more blood is supplied to the active muscles and less to the internal organs.

adrenal hyperplasia, congenital

A rare *genetic disorder*, present from birth, in which an *enzyme* (a protein that acts as a catalyst) defect blocks the production of corticosteroid hormones (*hydrocortisone* and *aldosterone*) from the adrenal glands.

SYMPOTMS

The enzyme block results in production of excessive amounts of *androgens* (male sex hormones), which can cause abnormal genital development in an

affected fetus. In females, these androgens cause enlargement of the clitoris and some fusion of the outer lips of the vulva, resulting in genital ambiguity (see *sex determination*). Some affected males have an enlarged penis, which may either be evident at birth or may develop later.

Other effects of the enzyme defect include *hypotension* (low blood pressure), *hypoglycaemia* (low blood sugar levels), weight loss, and dehydration. *Hyperplasia* (enlargement) of the adrenal gland occurs due to excessive secretion of the hormone *ACTH*, which is a result of insufficient production of hydrocortisone. Excessive skin pigmentation may occur in skin creases and around the nipples.

In severe cases, congenital adrenal hyperplasia is apparent soon after birth. In milder cases, symptoms appear later, sometimes producing premature puberty in boys and delayed menstruation, *hirsutism* (excessive hairiness), and potential infertility in girls.

DIAGNOSIS AND TREATMENT

A diagnosis is confirmed by measuring corticosteroid hormones in the blood

and urine. *Ultrasound scanning* may be carried out to verify that there is no tumour of the adrenal glands.

Treatment of congenital adrenal hyperplasia is with hormone replacement. If the treatment is started early, normal sexual development and fertility generally follow.

adrenaline

Also called epinephrine, a hormone released by the adrenal glands in response to signals from the sympathetic nervous system, part of the *autonomic nervous system*. These signals are triggered by stress, exercise, or emotions such as fear.

Adrenaline increases the speed and force of the heartbeat. It widens the airways to improve breathing and narrows blood vessels in the skin and intestine so that an increased flow of blood reaches the muscles.

Synthetic adrenaline is sometimes given by injection as emergency treatment of *anaphylactic shock* (a severe allergic reaction) and *cardiac arrest* (a halt in the heart's pumping action). Eye-drops containing dipivefrine (a drug that passes quickly into the tissues and converts to adrenaline), may be used to treat acute (closed-angle) *glaucoma*. Regular use can cause a burning pain and, occasionally, blurred vision or pigment deposits on the eye surface. (See also *noradrenaline*.)

adrenal tumours

Rare cancerous or noncancerous tumours in the *adrenal glands*, usually causing excess secretion of hormones.

Tumours of the adrenal cortex may secrete *aldosterone*, causing primary *aldosteronism* (also called Conn's syndrome), or *hydrocortisone*, causing *Cushing's syndrome*.

Tumours of the adrenal medulla may cause excessive secretion of *adrenaline* (epinephrine) and *noradrenaline* (norepinephrine). Two types of tumour affect the medulla: *phaeochromocytoma* and *neuroblastoma*, which affects children. These tumours may cause intermittent *hypertension* (high blood pressure) and sweating attacks.

Surgical removal of a tumour or an adrenal gland usually cures noncancerous tumours. Cancerous tumours may require additional treatment with *radiotherapy* and/or *chemotherapy*. (See also *adrenal glands disorders box*.)

adrenocorticotrophic hormone

See *ACTH*.

DISORDERS OF THE ADRENAL GLANDS

Adrenal gland disorders are a range of uncommon but sometimes serious conditions that result from deficient or excessive production of hormones by one or both of the adrenal glands.

Congenital defects

A genetic defect causes congenital *adrenal hyperplasia*, in which the adrenal cortex is unable to make sufficient hydrocortisone and *aldosterone*. As a side effect of the reduced hydrocortisone production, the glands are stimulated into producing excess androgens (male sex hormones); this can cause masculinization of female babies.

Autoimmune disorders

Deficient production of hormones by the adrenal cortex is called *adrenal failure*; if the deficiency is due to disease of the adrenal glands themselves, it is called *Addison's disease*. The most common cause of Addison's disease is an autoimmune process (in which the body's immune system attacks its own tissues). Addison's disease can take a chronic course characterized by weakness, weight loss, and skin darkening, or an acute form (Addisonian crisis or acute adrenal failure), in which the patient may become confused and comatose.

Infection

Destruction of the adrenal glands by *tuberculosis* was once a major cause of Addison's disease but is now

uncommon. The onset of an infection or other acute illness in someone with Addison's disease can precipitate acute adrenal failure.

Impaired blood supply

Loss or obstruction of the blood supply to the adrenal glands, sometimes as a result of arterial disease, is another possible cause of Addison's disease or acute adrenal failure.

Tumours

Cancerous or noncancerous growths in the adrenal glands are rare but generally lead to excess secretion of hormones. A tumour of the adrenal cortex can secrete aldosterone, causing primary *aldosteronism* (also called Conn's syndrome), a condition that is characterized by thirst and high blood pressure. A tumour can also secrete hydrocortisone, causing *Cushing's syndrome*, which has various features including muscle-wasting and obesity of the trunk. Androgens may also be produced in excess, causing masculinization in females.

Two types of tumour affect the adrenal medulla, *phaeochromocytoma* and *neuroblastoma*, which affects children. These tumours may cause excess secretion of adrenaline (epinephrine) and noradrenaline (norepinephrine).

Other disorders

In many cases, disturbed activity of the adrenals is caused, not by disease of the glands themselves, but by an increase or decrease in the blood level of hormones that influence the activity of the glands.

Hydrocortisone production by the adrenal cortex is controlled by the secretion of ACTH (adrenocorticotrophic hormone) by the pituitary gland.

A tumour or other pituitary gland disorder, or tumours in the lung, breast, and elsewhere, can cause excess ACTH secretion, leading to excess production of hydrocortisone by the adrenals and, hence, to Cushing's syndrome. Pituitary disease is a cause of Cushing's syndrome.

INVESTIGATION

Blood and/or urine tests can detect the high levels of adrenal hormones that occur with adrenal tumours. They can also detect the high levels of natural corticosteroids that occur in Cushing's syndrome, and the low levels that occur in congenital adrenal hyperplasia. Blood tests are used to measure salt and potassium levels if Addison's disease is suspected; further blood tests may be carried out to measure corticosteroid hormone levels. Diagnosis of Addison's disease can be confirmed by the response to an injection of ACTH, which, under normal circumstances, will stimulate the adrenal glands. MRI or CT scanning can detect abnormalities of the adrenal glands and can confirm the presence of an adrenal tumour. They can also distinguish between raised hormone levels due to an adrenal tumour, or those due to a pituitary tumour. Ultrasound scanning can rule out an adrenal tumour as the cause of congenital adrenal hyperplasia.

adrenogenital syndrome

See *adrenal hyperplasia, congenital*.

advanced life support

Treatment of *cardiac arrest* (a halt in the heart's pumping action) by medical or paramedical professionals when *basic life support*, (which may be performed by a first-aider) has failed to restore a normal heartbeat and spontaneous breathing. Advanced life support involves the use of drugs and medical equipment.

An *ECG* monitor is used to record the electrical activity of the heart muscle. *Ventilation* delivers oxygen by way of an *endotracheal tube* inserted, via the mouth, into the trachea (windpipe). A *cannula* (a thin plastic tube inserted into

a vein) allows administration of drugs such as *adrenaline* (epinephrine). In the event of *ventricular fibrillation* (rapid uncoordinated contractions of the heart), *defibrillation* (a brief electric shock to the heart using two paddles placed on the chest) may be used.

adverse reaction

See *side effect*.

Aedes

A genus of disease-transmitting mosquitoes. Many species of *Aedes* are responsible for spreading important viral infections; *AEDES AEGYPTI* is the main vector of *dengue* and *yellow fever*. (See also *mosquito bites*.)

aerobic

A term that refers to anything that requires oxygen to live, function, and grow. Humans and many other forms of life are dependent on oxygen for "burning" foods in order to produce energy (see *metabolism*). Because of this dependence, they are described as *obligate aerobes*.

In contrast, many bacteria have fundamentally different metabolisms and thrive without oxygen (some are even killed by exposure to oxygen); such microorganisms are described as *anaerobic*. There are also certain bacteria and yeasts, known as *facultative aerobes*, that flourish in oxygen but can also live without it. (See also *aerobics*.)

aerobics

Exercises, such as swimming, jogging, and cycling, that allow muscles to work at a steady rate with a constant, adequate supply of oxygen-carrying blood that allows them to be sustained for long periods. Oxygen is needed to release energy from the body's stores. To fuel aerobic exercise, the muscles use fatty acid, burning it completely to produce energy, carbon dioxide, and water.

Anaerobic exercise relies on a different series of biochemical reactions to obtain energy from the muscles' stores of fat and sugar. The waste products of anaerobic exercise are acidic and, as they accumulate in muscles, cause muscle fatigue; high-intensity exercises, which are anaerobic, can be performed only for relatively short periods.

BENEFITS OF AEROBIC EXERCISE

When performed regularly, aerobic exercise improves stamina and endurance. It encourages the growth of capillaries (small blood vessels), thereby improving blood supply to the cells. It improves the body cells' capacity to use oxygen and increases the amount of oxygen that the body can use in a given time.

As the body becomes fitter, the condition of the heart also improves: the heart rate becomes slower, both at rest and during exercise; the heart muscle becomes thicker and stronger; and the amount of blood pumped with each beat (the stroke volume) increases. The overall result is that the heart needs to do less work to achieve the same level of efficiency in pumping blood around the body. (See also *exercise*; *fitness*.)

aerodontalgia

Sudden pain in a tooth brought on by a change in surrounding air pressure. Flying at high altitudes in lowered atmospheric pressure can cause a pocket of air in the dental pulp to expand and irritate the nerve in the root. Aerodontalgia is more likely with improperly fitted fillings or poorly filled root canals.

aerophagy

Excessive swallowing of air, which may occur during rapid eating or drinking or may be caused by anxiety. After *laryngectomy* (surgical removal of the larynx), voluntary aerophagy is used to produce oesophageal speech.

aerosol

A suspension of minute liquid or solid particles in the air, producing a fine

mist. Some drugs are prescribed in this form for use in an *inhaler* or in a *vaporizer*. (See also *solvent abuse*.)

aetiology

The cause of, or the study of the various factors involved in causing, a disease.

For some cases of a particular disorder, a specific aetiology can be identified. For example, laboratory studies may show that an attack of diarrhoea is the result of a particular type of virus or bacterium. Other disorders have a multifactorial aetiology: the causative factors of degenerative arthritis, for example, include genetic susceptibility, repeated joint injuries, and excess weight. On the other hand, many disorders, such as schizophrenia, are of unknown aetiology.

afebrile

A medical term meaning without *fever*. (See also *febrile*.)

affect

A term used to describe a person's mood. The two extremes of affect are elation and depression. A person who experiences extreme moods or changes in moods may have an *affective disorder*. Shallow or reduced affect (in which responses to events seem flat) may be a sign of *schizophrenia* or of an organic *brain syndrome*.

affective disorders

Mental illnesses that are characterized predominantly by marked changes in *affect* (mood). Mood may vary over a period of time between *mania* (extreme elation) and severe *depression*. (See also *manic-depressive illness*.)

afferent

A term meaning carrying towards. Afferent is used mainly to describe blood vessels that supply organs, or nerves that carry impulses from peripheral sense *receptors* to the brain and spinal cord.

affinity

A term used to describe the attraction between chemicals that causes them to bind together, as, for example, between an antigen and an antibody (see *immune response*). In microbiology, affinity describes the physical similarity between organisms (viruses, for example). In psychology, the term refers to attraction between two people.

aflatoxin

A poisonous substance produced by *ASPERGILLUS FLAVUS* moulds, which contaminate stored foods, especially peanuts, grains, and cassava. Aflatoxin is believed to be one of the factors responsible for the high incidence of *liver cancer* in tropical Africa.

afterbirth

The common name for the tissues that are expelled from the uterus following the delivery of a baby (see *childbirth*). The afterbirth consists of the *placenta* and the membranes that surrounded the fetus.

aftercare

The medical care of a patient following treatment, particularly after *surgery*.

afterpains

Contractions of the uterus that continue after *childbirth*. Afterpains are normal, indicating that the uterus is shrinking as it should, and are experienced by many women, especially during breast-feeding. Afterpains usually disappear a few days after the birth, but *analgesic drugs* (painkillers) may be needed.

agammaglobulinaemia

A type of *immunodeficiency disorder* in which there is an almost complete absence of *B-lymphocytes* and *immuno-globulins* in the blood.

agar

An extract of certain seaweeds that has similar properties to gelatine. Agar can be taken for constipation to soften and give bulk to faeces, and to relieve indigestion and heartburn. It is also used as a gelling agent in media for growing bacterial *cultures*.

age

A person's age is usually measured chronologically but can also be measured in terms of physical, mental, or developmental maturity. Age may be of medical significance in diagnosis and in determining treatment.

PHYSICAL AGE

The age of a fetus is known as gestational age, which can be calculated from the date of the mother's last menstrual period. Alternatively, it can be assessed by *ultrasound scanning*, which is more accurate. The estimation of gestational age is important in neonatal paediatrics for identification of babies

who are too small and who may subsequently have problems as a result of their low birthweight.

In children, bone age (the degree of bone maturity as seen on an *X-ray*) can be a useful measure of physical development because all healthy individuals reach the same adult level of skeletal maturity and each bone passes through the same sequence of growth. Assessment of bone age is useful in the investigation of delayed *puberty* or *short stature* in children. A prediction of the final adult height can be made if the chronological age, bone age, and current height are known.

Dental age, which is another measure of physical maturity, can be assessed by the number of teeth that have erupted (see *eruption of teeth*) or by the amount of dental calcification (see *calcification, dental*), as seen on an *X-ray*, compared with standard values.

In adults, physical age is difficult to assess other than by physical appearance. It can be estimated after death by the state of certain organs, particularly by the amount of atheroma (fatty deposits) lining the arteries.

MENTAL AND DEVELOPMENTAL AGE

Mental age can be assessed by the comparison of scores achieved in *intelligence tests* with standard scores for different chronological ages. A young child's age can be expressed in terms of his or her level of developmental skills, manual dexterity, social skills, and language when compared to those of other children. Patterns of development in these fields have been described for children up to the age of five. (See also *child development*.)

agenesis

The complete absence, at birth, of an organ or a component of the body. Agenesis is caused by developmental failure in the embryo.

agent

Any substance or force capable of bringing about a biological, chemical, or physical change. (See also *reagent*.)

Agent Orange

A herbicide and defoliant of which the major constituent (50 per cent by volume) is the phenoxy acid herbicide 2,4,5 T. The highly toxic contaminant TCDD, commonly known as dioxin, may be added to this substance during manufacture (see *defoliant poisoning*).

age spots

Blemishes that appear on the skin with increasing age. The most common type are brown or yellow slightly raised spots called *seborrhoeic keratoses*, which can occur at any site. Also com-

mon in elderly people are freckles, solar keratoses (small scaly patches, often appearing on the backs of the hands, that are a result of overexposure to the sun), and *De Morgan's spots*, which are red, pinpoint blemishes on the trunk.

THE PRACTICAL EFFECTS OF AGING

In the body, aging is associated with loss of elasticity in the skin, blood vessels, and tendons. There is also progressive decline in the functioning of organs such as the lungs, kidneys, and liver. Mechanical wear and tear causes cumulative damage to certain organ systems. Brain cells, specialized kidney units, and many other body structures are never replaced after they have reached maturity.

Hip joint in a young person
The X-ray shows the rounded head of the thigh-bone (femur) separated by cartilage from the surrounding hip socket.

Hip joint in an elderly person
This X-ray of an osteoarthritic hip shows almost complete degeneration and disappearance of the cartilage in the joint.

EFFECTS OF AGING

Organ or tissue	Natural effects	Accelerated by
Skin	Loss of elastic tissue causes skin to sag and wrinkle. Weakened blood capillaries cause skin to bruise more easily.	Exposure to sun; smoking.
Brain and nervous system	Loss of nerve cells leads to reduction in ability to memorize or to learn new skills. Reaction time of nerves increases, making responses slower.	Excessive consumption of alcohol and other drugs; repeated head trauma (for example from boxing).
Senses	Some loss of acuity in all senses, mainly due to loss of nerve cells.	Loud noise (hearing); smoking (smell/taste).
Lungs	Loss of elasticity with age, so that breathing is less efficient.	Air pollution; smoking; lack of exercise.
Heart	Becomes less efficient at pumping, causing reduced tolerance to exercise.	Excessive use of alcohol and cigarettes; a fatty diet.
Circulation	Arteries harden, causing poor blood circulation and higher blood pressure.	Lack of exercise; smoking; poor diet.
Joints	Pressure on intervertebral discs causes height loss; wear on hip and knee joints reduces mobility.	Athletic injuries; being overweight.
Muscles	Loss of muscle bulk and strength	Lack of exercise; starvation.
Liver	Becomes less efficient in processing toxic substances in the blood	Damage from alcohol consumption and virus infections

Treatment is usually unnecessary for any of these age spots, apart from solar keratoses, which may eventually progress to skin cancer. Freezing the keratoses with liquid nitrogen or applying a cream containing a *cytotoxic drug* is the usual treatment. They may also be removed surgically under a local anaesthetic (see *anaesthesia, local*).

ageusia

The lack of, or an impairment of, the sense of taste (see *taste, loss of*).

agglutination

See *clumping*.

aggregation, platelet

The clumping together of platelets (small, sticky blood particles). Aggregation takes place when a blood vessel is damaged. It is the first stage of *blood clotting*, helping to plug injured vessels.

Inappropriate aggregation can have adverse effects; if it occurs in an artery, for example, *thrombosis* (a blood clot forming in an undamaged blood vessel) may result. Many drugs, including *aspirin* and *clopidogrel*, help to reduce platelet aggregation.

aggression

A general term for a wide variety of acts of hostility. A number of factors, including human evolutionary survival strategies, are thought to be involved.

CAUSES

Androgen hormones (male sex hormones) seem to promote aggression, whereas *oestrogen hormones* (the female sex hormones) may suppress it. Age is another factor; aggression is more common in teenagers and young adults, and some people believe that it can result from frustration or lack of affection as a child. Sometimes a brain tumour or head injury may lead to aggression.

Psychiatric conditions associated with aggressive outbursts are *schizophrenia*, *antisocial personality disorder*, *mania*, and abuse of alcohol or amphetamine drugs. *Temporal lobe epilepsy*, *hypoglycaemia*, and *confusion* due to physical illnesses are other, less common, medical causes.

aging

Aging is the physical and mental changes that occur with the passing of time and is associated with degenerative changes in various organs and tissues, such as loss of elasticity in the skin and a progressive decline in organ function.

Wear and tear causes cumulative damage to the joints, and the muscles lose bulk and strength. Wound healing and resistance to infection also decline. Gradual loss of nerve cells can lead to reduced sensory acuity and difficulties with learning and memory. However, *dementia* occurs in only a minority of elderly people.

Heredity is an important determinant of life expectancy, but physical degeneration may be accelerated by factors such as smoking, excessive alcohol intake, poor diet, and insufficient exercise. With advances in medical science, life expectancy in the developed world has risen dramatically over the last century.

agitation

Restlessness and the inability to keep still, usually as a result of anxiety or tension. People who are agitated engage in aimless, repetitive behaviour, such as pacing up and down or wringing their hands, and they often start tasks and fail to complete them.

Persistent agitation is seen in *anxiety disorders*, especially if there is an underlying physical cause such as alcohol withdrawal. *Depression* may also be accompanied by agitation.

agnathia

A developmental defect in the fetus in which the lower jaw is only partially formed or may be entirely absent. (See also *birth defects*.)

agnosia

The inability to recognize objects, despite adequate sensory information about them reaching the brain via the eyes or ears or through touch. In order for an object to be recognized, the sensory information it provides must be interpreted, which involves the recall of memorized information about similar objects. Agnosia is caused by damage to areas of the brain involved in interpretative and recall functions. The most common causes of this kind of damage are *stroke* or *head injury*.

TYPES

Agnosia is usually associated with just one of the senses of vision, hearing, or touch and is described as visual, auditory, or tactile respectively. For example, an object may be completely recognizable by hearing and touch, but it cannot be recognized by sight, despite the sense of vision being perfectly normal (an example of visual agnosia).

Some people, after suffering a stroke that damages the right cerebral hemisphere, seem unaware of any disability in the affected left limbs. This is called *anosognosia* or *sensory inattention*.

OUTLOOK

There is no specific treatment for agnosia, but some of the lost interpretative ability may eventually return.

agonist

A term that means to have a stimulating effect. In pharmacology, an agonist drug, which is sometimes known as an activator, is a drug that binds to a specific area on the surface of a cell (*a receptor*) and triggers or increases a particular activity in that cell.

agoraphobia

Fear of going into open spaces or public places. Agoraphobia may sometimes overlap with *claustrophobia* (a fear of enclosed spaces). Agoraphobic individuals who do venture out may have a *panic attack*, further restricting their activities, and may eventually be house-bound. Treatment with *behaviour therapy* is often successful; *antidepressant drugs* may also help.

agranulocytosis

A potentially life-threatening disorder, in which there is a severe acute lack of neutrophils (white blood cells that seek and destroy infective microorganisms). This deficiency seriously weakens the body's defences against infection.

In agranulocytosis, the bone marrow fails to produce adequate neutrophils. This may be an adverse effect of a drug such as *carbimazole* (used to treat thyroid diseases) or an effect of some drug treatments for cancer (see *chemotherapy*). Fever and mouth ulcers commonly occur.

Treatment is with *antibiotic drugs*, which should be started immediately to prevent the development of severe, and potentially fatal, infections.

agraphia

Loss of or impaired ability to write, despite normal functioning of the hand and arm muscles. Agraphia can result from damage to the parts of the *cerebrum* (the main mass of the brain) concerned with writing.

CAUSES

The ability to write depends on a complex sequence of mental processes, including the selection of words and

recall from memory of these words are spelled, formulation and execution of the required hand movements, and visual checking that written words match their representation in the brain. These processes may take place in a number of connected regions of the brain. Agraphia may be caused by damage to any of these regions (most commonly as a result of a *head injury*, a *stroke*, or a *brain tumour*) and can therefore be of different types and degrees of severity.

Agraphia is often accompanied by *alexia* (loss of reading ability) or may be part of an expressive *aphasia* (a general disturbance in expression of language).

OUTLOOK

There is no specific treatment for agraphia, but some of the lost writing skills may return in time.

ague

An outdated term for the fever in *malaria* and similar diseases, in which the sufferer alternately feels excessively hot and shivering cold.

AIDS

The abbreviation for acquired immune deficiency syndrome, a deficiency of the *immune system* due to infection with the human immunodeficiency virus (see *HIV*). The interval between infection and the development of AIDS is highly variable. Without treatment, around half of those individuals infected will develop AIDS within eight to nine years. In about one in ten cases, however, progression to AIDS is very slow, taking up to 20 years or longer. Illness and death from AIDS is a growing health problem worldwide, and there is, as yet, no cure or vaccine.

METHODS OF TRANSMISSION

HIV is transmitted in body fluids such as semen, blood, vaginal secretions, and breast milk. Major methods of transmission are sexual contact (vaginal, anal, or oral), blood to blood (via transfusions, or needle-sharing in drug users), and mother-to-fetus. HIV has also been transmitted through blood products given to treat *haemophilia*, kidney transplants, and artificial insemination by donated semen; but improved screening has greatly reduced these risks. HIV is not spread by everyday contact, such as hugging or sharing crockery.

EFFECTS OF THE VIRUS

The virus enters the bloodstream and infects cells with a particular receptor, called the CD4 receptor, on their sur-

face. These cells include a type of white blood cell called a CD4 lymphocyte (a T lymphocyte with a CD4 receptor), that is responsible for fighting infection, and cells in other tissues such as the brain. The virus reproduces within the infected cells, which then die, releasing more virus particles into the blood. If the infection is left untreated, the number of CD4 lymphocytes falls, resulting in greater susceptibility to certain infections and some types of cancer.

SYMPTOMS AND SIGNS

Some people experience a short-lived illness similar to infectious *mononucleosis* when they are first infected with HIV. Many individuals have no obvious symptoms. After the initial illness, many people remain well. Some may suffer from enlarged lymph nodes, muscle pain, and excessive sweating. Severe bacterial infections, such as pneumonia, are common. Later, vague complaints, such as weight loss, fevers, sweats, or unexplained diarrhoea (described as AIDS-related complex) may herald the development of AIDS.

Other features of infection with HIV include skin disorders and a variety of viral, fungal and bacterial infections. HIV may also affect the brain, causing neurological disorders such as *dementia*.

Certain conditions, known as AIDS-defining illnesses, mark the development of full-blown AIDS. These include cancers (lymphoma of the brain, *Kaposi's sarcoma*, and cancer of the *cervix*) and various infections (*pneumocystis pneumonia*, *cytomegalovirus* infection, *toxoplasmosis*, diarrhoea as a result of *CRYPTOSPORIDIUM* or *ISOSPORA*, candidiasis, disseminated *strongyloidiasis*, and *cryptococcosis*), many of which are described as *opportunistic infections*.

DIAGNOSIS

Confirmation of HIV infection involves testing a blood sample for the presence of antibodies to HIV (see *HIV test*), which may not develop for three months after initial infection. The condition is monitored using blood tests that measure the number of CD4 lymphocytes in the blood or by measuring viral load (the amount of virus detectable in the blood). Diagnosis of full-blown AIDS is based on a positive HIV test along with the presence of an AIDS-defining illness.

TREATMENT AND OUTLOOK

Treatment of HIV infection with a combination of *antiviral drugs* can slow the progress of the disease, and may prevent

the development of full-blown AIDS. The main types of antiviral drug used are *protease inhibitors*, such as indinavir, and *reverse transcriptase inhibitors* such as *zidovudine*. Several drugs are usually used together to prevent resistance from developing. AIDS-defining illnesses are treated as they develop.

Since the introduction of antiviral drug combination therapies, deaths from AIDS in the developed world have been reduced dramatically. HIV infection remains life-threatening, however, and the most effective strategy for defeating it is prevention of infection.

PREVENTION OF INFECTION

The risk of infection can be reduced by practising *safer sex*, and by intravenous drug users not sharing needles. There is a small risk to health workers handling infected needles or blood products, but this can be minimized by the adoption of safe practices in the workplace.

AIDS-related complex

A combination of symptoms including weight loss, fever, neurological problems, and recurrent infections in an individual who has been infected with *HIV* (the virus that causes *AIDS*) but has not yet developed AIDS. Many people with AIDS-related complex will eventually develop the features of AIDS.

air

The colourless, odourless mixture of gases that forms the Earth's atmosphere. Air consists of 78 per cent *nitrogen*, 21 per cent *oxygen*, small quantities of *carbon dioxide* and other gases, and some water vapour.

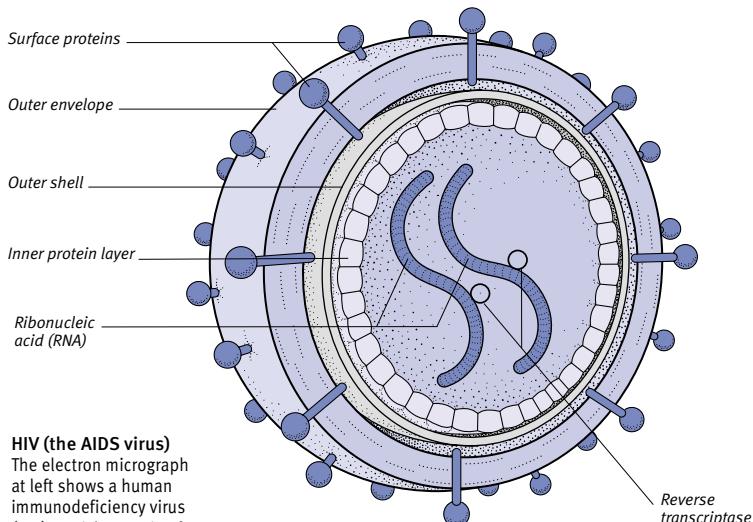

The balance of atmospheric gases is maintained largely by the mutual needs of plants and animals. Plants use carbon dioxide and release oxygen in a process called photosynthesis; animals use oxygen during respiration, and produce carbon dioxide as a waste product; However, the level of carbon dioxide in the atmosphere is gradually increasing as a result of large-scale deforestation and the burning of fossil fuels, which may lead to significant global warming, also known as the greenhouse effect. (See also *pollution*.)

air conditioning

A system that controls the temperature, humidity, and purity, of the air in a building. Contaminated air-conditioning systems may cause *legionnaires' disease* (a type of pneumonia) and

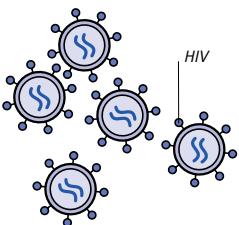

CAUSES AND PREVENTION OF AIDS

AIDS is caused by the human immunodeficiency virus (HIV) (right), which consists of some nucleic acid (genetic material) inside two protective shells and an outer envelope. Full-blown AIDS develops in only some people infected with HIV.

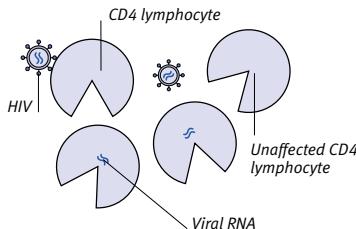

HIV (the AIDS virus)
The electron micrograph at left shows a human immunodeficiency virus (HIV) particle erupting from an infected human lymphocyte (cell of the immune system).

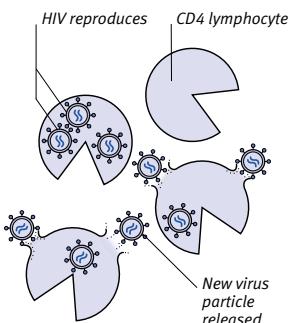

HOW HIV AFFECTS THE IMMUNE SYSTEM

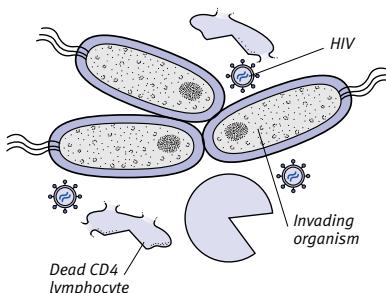

1 HIV enters the bloodstream and infects cells that have CD4 receptors on their surface, particularly CD4-lymphocytes, which are responsible for fighting infection.

2 The virus attaches to and enters the CD4-lymphocytes. It then loses its protective shell, releasing its RNA and reverse transcriptase (an enzyme).

3 Reverse transcriptase enables the viral RNA to use the host CD4-lymphocyte's genetic material to reproduce itself. The new virus particles are released into the blood, killing the infected CD4-lymphocyte.

4 When disease organisms invade, immune responses may fail, due to a shortage of CD4-lymphocytes. The disease organism may then overwhelm the immune system and lead to the features of AIDS.

RECOMMENDATIONS FOR PREVENTING THE SPREAD OF AIDS

- Do not have sexual intercourse with many partners, and especially not with people known to have HIV, without using a condom.
- Do not use intravenous (IV) drugs. If you use IV drugs, do not share needles or syringes.
- Do not have sex with people who use IV drugs.
- People with AIDS or who have had positive HIV antibody test results may pass the disease on to others and should not donate blood, plasma, body organs, other tissues, or sperm. They should not exchange body fluids during sexual activity.
- There is a risk of infecting (or being infected by) others through sexual intercourse, sharing needles, and, possibly, exposure of others to saliva through oral-genital contact or "wet" kissing. Condoms substantially reduce the risk of infection.
- Toothbrushes, razors, or other implements that could become contaminated with blood should not be shared.

humidifier fever (a lung disease causing coughing and breathing difficulties). Air conditioning is also thought to be a factor in some cases of *sick building syndrome*, which produces headache, irritability, and loss of energy.

air embolism

The blockage of a small artery by an air bubble carried in the blood. Air embolism is rare. In most cases, it is caused by air entering the circulation through a vein, either as a result of injury or following surgery. Air embolism can also occur during scuba-diving or air-travel accidents, in which lung tissue ruptures, releasing air into the bloodstream.

air pollution

See *pollution*.

air swallowing

See *aerophagy*.

air travel

See *aviation medicine; barotrauma*.

airway

A collective term for the passages through which air enters and leaves the lungs (see *respiratory system*). The airway is made up of the nasal passages, the oral cavity, the upper part of the pharynx (throat), the larynx (voicebox), the trachea (windpipe), the bronchi (the main air passages to the lungs), and the bronchioles (the smaller air passages in the lungs that branch off from the bronchi).

The term airway is also applied to a tube that is inserted into the mouth of an unconscious person to prevent the tongue from obstructing breathing. Preservation of the airway can also be achieved by inserting an *endotracheal tube* into the trachea, either through the mouth or nose or via an incision in the neck, as in a *tracheostomy* operation. (See also *respiratory system*.)

airway obstruction

Narrowing or blockage of the respiratory passages. The obstruction may be due to a foreign body, such as a piece of food, that becomes lodged in part of the upper airway and may result in *choking*. Certain diseases and disorders, such as *diphtheria* and *lung cancer*, can cause obstruction. Additionally, spasm of the muscular walls of the airway, as occurs in *bronchospasm* (a feature of

asthma and *bronchitis*), results in *breathing difficulty*. (See also *rescue breathing; lung disorders box*.)

akathisia

The inability to sit still, which occasionally occurs as a side effect of an *antipsychotic drug* or, less commonly, as a complication of *Parkinson's disease*.

akinesia

Complete or almost complete loss of movement. Akinesia may result from damage to part of the brain due, for example, to a *stroke* or *Parkinson's disease*.

albinism

A rare, inherited disorder that is characterized by a lack of the pigment *melanin*, which gives colour to the skin, hair, and eyes.

Oculocutaneous albinism (the most common type of albinism) is transmitted as an autosomal recessive trait (see *genetic disorders*). The genetic defect results in deficiency of a specific *enzyme* (a protein that acts as a catalyst); this deficiency interferes with the production of melanin in the affected tissues.

In oculocutaneous albinism, the hair, skin, and eyes are all affected. The skin cannot tan and ages prematurely. In addition, *skin cancers* may develop on areas of skin exposed to the sun. Less often, only the eyes are affected. Visual problems affecting people with albinism include *photophobia* (an intolerance to bright light), *nystagmus* (abnormal flickering movements), *myopia* (short-sightedness), and *squint*.

Glasses are usually needed from an early age, and tinted glasses help to reduce photophobia. If the skin is affected, it should be carefully protected from the sun.

albumin

The most abundant protein in the *blood* plasma. Albumin is made in the liver from *amino acids* that have been absorbed from digested protein.

Albumin helps to retain substances (such as calcium, some hormones, and certain drugs) in the circulation by binding to them to prevent them from being filtered out by the kidneys and excreted in the urine. Albumin also regulates the movement of water between tissues and the bloodstream by *osmosis* (the movement of water to an area with a higher concentration of salts or proteins). (See also *albuminuria*.)

Appearance of albinism

Albinism is characterized by the lack of melanin pigment in the skin, hair, and eyes.

Albinism in an African boy

The condition occurs only rarely, but it is found in people of all ethnic groups.

albuminuria

The presence of the protein *albumin* in the urine; a type of *proteinuria*. Normally, the glomeruli (the filtering units of the kidneys) do not allow albumin to pass into the urine. Albuminuria therefore usually indicates that there is damage to the kidneys' filtering mechanisms. Such damage may be due to a kidney disorder, such as *glomerulonephritis* or *nephrotic syndrome*, or it may be a sign that the kidneys have been affected by *hypertension*. In *diabetes mellitus*, the presence of even small amounts of albumin in the urine (a condition known as *microalbuminuria*) is an early indicator of kidney damage. Albuminuria can be detected by a simple urine test.

alcohol

A colourless liquid produced from the fermentation of carbohydrates by yeast. Also known as ethanol or ethyl alcohol, alcohol is the active constituent of alcoholic drinks such as beer, wine, and spirits. In medicine, alcohol is used as

an antiseptic and a solvent. *Methanol*, also known as methyl alcohol, is a related, highly toxic, substance.

MENTAL EFFECTS

Alcohol is a drug and produces a wide range of mental and physical effects. The effect of alcohol on the *central nervous system* (the brain and spinal cord) is as a depressant, decreasing its activity and thereby reducing anxiety, tension, and inhibitions. In moderate amounts, alcohol produces a feeling of relaxation, confidence, and sociability. However, alcohol slows reactions, and the more that is drunk, the greater the impairment of concentration and judgment. Excessive consumption of alcohol results in poisoning or acute *alcohol intoxication*, with effects ranging from euphoria to unconsciousness.

PHYSICAL EFFECTS

Short-term physical effects include peripheral *vasodilation* (widening of small blood vessels), causing flushing and increased flow of gastric juices, which stimulates the appetite. Alcohol increases sexual confidence, but high levels can cause *impotence*. Alcohol also acts as a diuretic, increasing urine output.

In the long term, regular excessive consumption of alcohol can cause *gastritis* (inflammation and ulceration of the stomach lining) and can lead to *alcohol-related disorders*. Heavy drinking in the long term may also lead to *alcohol dependence*. However, individuals who drink regular, small amounts of alcohol, (1–2 units (see *alcohol, unit of*) per day) seem to have lower rates of *coronary artery disease* and *stroke* than those who abstain totally.

The consumption of alcohol during pregnancy may result in *fetal alcohol syndrome*, *miscarriage*, or a disruption in normal fetal development.

alcohol dependence

An illness characterized by habitual, compulsive, long-term, heavy alcohol consumption and the development of withdrawal symptoms when drinking is stopped suddenly.

CAUSES

Causative factors that interact in the development of alcohol dependence include: personality, environment, and the addictive nature of alcohol. People of an inadequate, insecure, or immature personality are at greater risk. Environmental factors are important, especially the ready availability, affordability, and widespread social acceptance of alco-

hol. Genetic factors may play a part in causing alcohol dependence in some cases, but it is now widely believed that anyone, irrespective of personality, environment, or genetic background, is capable of becoming dependent. Stress is often a major factor in precipitating heavy drinking.

DEVELOPMENT OF DEPENDENCE

Alcohol dependence usually develops in four main stages that occur over a number of years and merge imperceptibly. In the first phase, tolerance (being able to drink more alcohol before experiencing its effects) develops in the heavy social drinker. In the second phase, the drinker experiences memory lapses relating to events during the drinking episodes. In the third phase, there is loss of control over alcohol consumption. The final phase is characterized by prolonged binges of intoxication, and mental or physical complications.

SYMPOTMS AND EFFECTS

Behavioural symptoms of alcohol dependence are varied, and they can include grandiose, aggressive, or furtive behaviour; personality changes (such as irritability, jealousy, or uncontrolled anger); neglect of food intake and personal appearance; and lengthy periods of intoxication.

Physical symptoms of the condition may include nausea, vomiting, or shaking in the morning; abdominal pain; cramps; numbness or tingling; weakness in the legs and hands; enlarged blood vessels in the face; irregular pulse; unsteadiness; confusion; memory lapses; and incontinence. Sudden withdrawal from alcohol may lead to *delirium tremens* (severe shakes, hallucinations, and convulsions).

Alcohol-dependent persons are more susceptible than others to a variety of physical and mental disorders (see *alcohol-related disorders*).

TREATMENT

Many problem drinkers require medical help in overcoming their physical withdrawal symptoms (detoxification) when they stop drinking alcohol, followed by long-term treatment. There are different methods of treatment, which may be combined.

Psychological treatments for alcohol dependence involve *psychotherapy* and are commonly carried out as *group therapy*. Social treatments may offer practical help, such as with problems at work, and tend to involve family members in the process. Physical treatment includes the use of *disulfiram*, a drug that sensitizes the drinker to alcohol so that he or she experiences unpleasant side effects when drinking, or acamprosate, which helps to reduce craving.

Alcoholics Anonymous and other self-help organizations can provide support and advice.

Alcoholics Anonymous

A worldwide, independent, self-help organization that is operated locally by people working on a voluntary basis to overcome *alcohol dependence*. Regular group meetings are held in which members are encouraged to help one another to stay sober by sharing their experiences openly and by offering support and advice.

alcohol intoxication

The condition that results from consuming an excessive amount of *alcohol*, often over a relatively short period.

ALCOHOL AND PREGNANCY

The damage to a fetus by alcohol intake during pregnancy has been recognized only recently. Intake of more than two units (see *alcohol, unit of*) per day increases the risk of *fetal alcohol syndrome* (consisting of facial abnormalities such as *cleft lip and palate*, heart defects, abnormal limb development, and lower-than-average intelligence). The risk of miscarriage is also increased. Binge drinking can have the same effect, even if the mother drinks little otherwise. Because a proportion of the alcohol reaches the baby, there is a risk that even small amounts can disrupt normal development (causing, for example, low birth weight).

Fetal alcohol syndrome

An affected baby is abnormally small, with small eyes and a small jaw. He or she may also suffer from heart defects or a cleft lip and palate, may suckle poorly, sleep badly, and be irritable.

ALCOHOL AND THE BODY

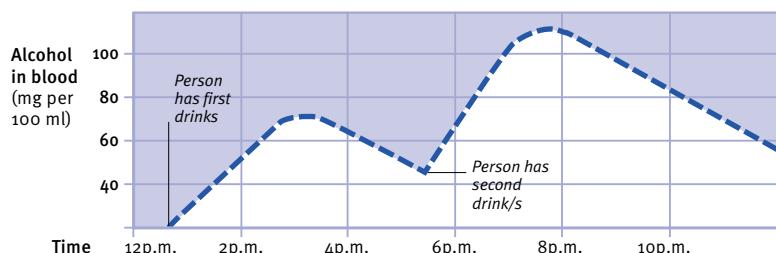

Alcohol is a drug and, even in small amounts, its effects on the body are noticeable. Problems arise when people fail to take into account the effects of alcohol on tasks requiring coordination (such as driving) when they become intoxicated or when they become dependent on the drug. Alcohol dependence can cause early death and is a major factor in crime, marital breakdown, child abuse, accidents, and absenteeism.

Prolonged heavy drinking that stops just short of dependence still may cause a wide variety of diseases, such as cardiomyopathy and cirrhosis of the liver.

The table below highlights the effects of alcohol on the occasional social drinker. These effects occur with higher concentrations as alcohol tolerance increases.

EFFECTS OF INCREASING BLOOD ALCOHOL LEVELS

Concentration (milligrams per 100 millilitres)	Observable effects
30-50	Flushed face, euphoria, talkativeness, increased social confidence
50-150	Disturbed thinking and coordination, irritability, reduced self-control, irresponsible talk and behaviour
150-250	Marked confusion, unsteady gait, slurred speech, unpredictable shows of emotion and aggression
250-400	Extreme confusion and disorientation, difficulty remaining upright, drowsiness, delayed or incoherent reaction to questions progressing to coma (a state of deep unconsciousness from which the person cannot be aroused)
400-500	Risk of death due to arrest of breathing (although habitual drinkers may survive even such high levels) and choking on vomit

Cumulative effects of alcohol

The body takes some time to eliminate even small amounts of alcohol. If a person has two drinks at lunchtime, and then has one or two early in the evening, the cumulative blood alcohol level could be over the legal limit for driving, even after several hours.

Alcohol levels in different drinks

A unit is the measure used to define the amount of alcohol in an alcoholic drink. One unit constitutes 10 ml of pure alcohol. The number of units per drink is calculated by the volume of the drink and the percentage of alcohol by volume. The drinks shown here each contain approximately one unit of pure alcohol.

LONG TERM EFFECTS ON THE BODY

Persistent heavy drinking eventually damages body tissues; the main effects are shown below.

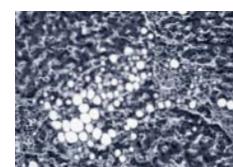

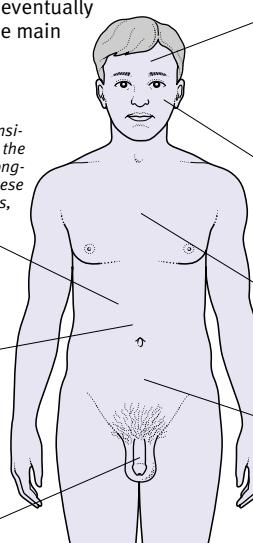

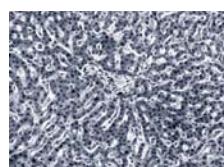

Liver

The liver is the main organ responsible for metabolizing alcohol from the blood; it manifests many of the long-term effects of heavy drinking. These effects include fatty liver, hepatitis, cirrhosis, and liver cancer.

Digestive system

Irritation from large amounts of alcohol can cause gastritis and pancreatitis.

Reproductive system
Alcohol increases sexual confidence, but in the long term can cause shrinkage of testes and breast development in men.

Brain and nervous system
Alcohol depresses the central nervous system. Prolonged alcohol abuse permanently impairs brain function and damages peripheral nerves.

Skin
Alcohol causes facial flushing, which becomes constant in heavy drinkers.

Heart and circulation
Prolonged heavy drinking can cause heart failure, hypertension, and stroke.

Urinary system
Alcohol acts as a diuretic, increasing urine output.

Cirrhosis of the liver
This condition is commonly caused by heavy drinking. When compared to a normal liver (far left), the cirrhotic liver clearly shows the formation of bands of scar tissue, which impair its function.

EFFECTS

The effects of high intake alcohol depend on many factors, including mental and physical state, body size, social situation, and acquired tolerance; but the important factor is the blood alcohol level. Mild intoxication promotes relaxation and increases social confidence.

However, alcohol causes acute poisoning if it is consumed in sufficiently large amounts. It depresses the activity of the *central nervous system*, (the brain and spinal cord), leading to loss of normal mental and physical control. In extreme cases, consumption of a large amount of alcohol over a short period of time may lead to loss of consciousness and even death.

TREATMENT

In most cases, recovery from alcohol intoxication occurs naturally as the alcohol is gradually broken down in the liver. Medical attention is required if the intoxication has resulted in *coma*.

For a description of the effects of long-term heavy drinking, see *alcohol dependence* and *alcohol-related disorders*.

alcoholism

See *alcohol dependence*.

alcohol-related disorders

A wide variety of physical and mental disorders associated with heavy, prolonged consumption of alcohol.

High alcohol consumption increases the risk of cancer of the mouth, tongue, pharynx (throat), larynx (voice-box), and oesophagus (gullet), especially if combined with smoking. Incidence of liver diseases, such as *liver cancer*, alcoholic *hepatitis* and *cirrhosis*, is higher in alcohol-dependent persons. High consumption of alcohol increases the risk of *cardiomyopathy* (disease of heart muscle), *hypertension* (high blood pressure), and *stroke*. Alcohol irritates the digestive tract and may cause *gastritis*. Heavy drinking during pregnancy increases the risk of miscarriage and *fetal alcohol syndrome*. Problem drinkers are more likely to suffer from *anxiety* and *depression* and to develop *dementia*.

Many problem drinkers have a poor diet and are prone to diseases caused by nutritional deficiency, particularly of thiamine (see *vitamin B complex*). Severe thiamine deficiency (see *beriberi*) disturbs nerve function, causing cramps, numbness, and weakness in the legs and hands. Its effects on the brain can cause confusion, disturbances of speech and

gait, and eventual coma (see *Wernicke-Korsakoff syndrome*). Severe deficiency can also cause *heart failure* (reduced pumping efficiency of the heart).

A prolonged high level of alcohol in the blood and tissues can disturb the body chemistry, resulting in *hypoglycaemia* (low blood glucose levels) and *hyperlipidaemia* (high blood fat levels). These may damage the heart, liver, blood vessels, and brain; irreversible damage may cause premature death.

aldosterone

A hormone secreted by the adrenal cortex (the outer part of the *adrenal glands*). Aldosterone plays an important role in the control of blood pressure and regulation of sodium and potassium concentrations in the blood and tissues.

Aldosterone acts on the kidneys to decrease the amount of sodium lost in the urine; the sodium is reabsorbed into the blood from urine before it leaves the kidneys and is replaced in the urine by potassium. The sodium draws water back into the blood with it, thereby increasing the blood volume and raising the blood pressure.

Aldosterone production is stimulated mainly by the action of *angiotensin II*, a chemical produced by a series of reactions involving the enzymes *renin* and *angiotensin-converting enzyme*. Production of aldosterone is also stimulated by the action of *ACTH*, which is produced by the pituitary gland.

alcohol, unit of

A measure that is commonly used to define the amount of *alcohol* that is present in a single alcoholic drink. A unit is defined as 10 millilitres of pure alcohol. The number of units in one drink is calculated by multiplying the alcohol content of that drink with its volume, then dividing by 1000. As a rough guide, half a pint (or a bottle) of beer, lager, or cider has one unit; a single measure (25 ml) of spirits has one unit; and a small glass of wine has one unit.

Various countries have official guidelines on the maximum number of units that can be consumed per day without endangering health. In the UK, the Department of Health has defined safe limits for men as three to four units per day (or less) and for women as two to three units per day (or less). In addition, one or two alcohol-free days per week are usually recommended.

aldosteronism

A disorder that results from excessive production of the hormone *aldosterone* from one or both of the *adrenal glands*. Aldosteronism caused by an *adrenal tumour* is known as Conn's syndrome. Aldosteronism may also be due to disorders, such as *heart failure* (reduced pumping efficiency of the heart) or liver damage, that reduce blood flow through the kidneys. This reduction in the flow of blood flow leads to over-production of *renin* and *angiotensin*, which, in turn, leads to excessive aldosterone production.

SYMPTOMS AND SIGNS

Symptoms of the condition are directly related to the actions of aldosterone. Excess sodium is retained in the body, leading to a rise in blood pressure, and excess potassium is lost in the urine. Low levels of potassium cause tiredness and muscle weakness and impair kidney function, leading to thirst and over-production of urine.

TREATMENT

Treatment in all cases of aldosteronism includes restriction of salt in the diet and use of the diuretic drug *spironolactone*. This drug blocks the action of aldosterone on the kidneys, leading to increased loss of sodium from the body, lowered blood pressure, and reduced potassium loss. If the cause of aldosteronism is an adrenal tumour, this may be surgically removed.

alendronate sodium

See *alendronic acid*.

alendronic acid

A *bisphosphonate drug* that is used in the treatment of *osteoporosis* and *Paget's disease* of bone. The most common side effect of alendronic acid is inflammation of the oesophagus, which causes heartburn or difficulty in swallowing. Other side effects can include headache, abdominal pain and distension, and diarrhoea or constipation.

Alexander technique

A therapy that aims to improve health by teaching people to stand and move more efficiently.

Developed in the 1920s by F. Mathias Alexander, the technique is based on the belief that bad patterns of body movement interfere with the proper functioning of the body and therefore contribute to the development of disease. By releasing unnecessary muscle

ALCOHOL-RELATED DISORDERS

Cancer

High alcohol consumption increases the risk of breast cancer in women and cancers of the mouth, tongue, pharynx (back of the throat), larynx (voicebox), and oesophagus, probably due to irritant action. In each of these cancers,

alcohol intake, along with smoking, produces a much higher total risk of cancer than the sum of their separate risks. The risk of *liver cancer*, along with most types of liver disease, is also higher among problem drinkers.

Liver damage and disease

Liver diseases caused by a high alcohol consumption include fatty liver, alcoholic *hepatitis*, cirrhosis, and liver cancer. They develop in sequence over a period of years. It is thought that a breakdown product of alcohol (acetaldehyde) has a toxic effect on liver cells and is the main cause of these diseases,

although nutritional deficiency may also play some part. The risk of alcoholic hepatitis and cirrhosis developing increases in proportion to the amount of alcohol consumed and the number of years of high consumption; liver cancer develops in about one in five sufferers of cirrhosis.

Nervous system disorders

Thiamine (vitamin B₁) deficiency, also known as *beriberi* (which disturbs nerve functioning), may develop in problem drinkers. The effect of severe deficiency on the brain produces Wernicke's encephalopathy, with symptoms such as confusion, disturbances of speech and gait, and eventual coma. Korsakoff's psychosis may also occur (see

Wernicke–Korsakoff syndrome). The effect on the peripheral nervous system (nerve pathways outside the brain and spinal cord) produces polyneuropathy, with symptoms such as pain, cramps, numbness, tingling, and weakness in the legs and hand. Excess consumption of alcohol can also cause *dementia*.

Psychiatric illness

Problem drinkers are more likely than others to suffer from anxiety and depression (frequently related financial, work, or family problems) and from paranoia. They are also more likely to

develop dementia (irreversible mental deterioration). The incidence of suicide attempts and actual suicide is also higher among problem drinkers.

Heart and circulatory disorders

Severe deficiency of thiamine in problem drinkers can result in heart failure (reduced pumping efficiency), which is usually combined with oedema (the collection of fluid in tissues). A high consumption of alcohol also

increases the risk of hypertension (high blood pressure), cerebral haemorrhage, and *cardiomyopathy*. One type of stroke is also associated with excessive consumption of alcohol.

Genito-urinary system disorders

High consumption of alcohol can lead to fertility problems in women and to impotence in men. Heavy drinking during pregnancy

carries the risk of spontaneous abortion and of the baby being born with *fetal alcohol syndrome*.

Other medical disorders

Other physical diseases and disorders that are associated with high intake of alcohol include *gastritis* and acute and chronic *pancreatitis*, (all of which are probably

linked to an irritant action of alcohol), *osteoporosis* (thinning of the bones), and damage to the skeletal muscles and those of the genito-urinary tract.

tensions, the Alexander technique aims to eliminate or reduce the severity of many disorders, including back pain, asthma, and stammering.

alexia

Word blindness; the inability to recognize and name written words. Alexia results from damage to part of the cerebrum (the main mass of the brain) by, for example, a *stroke*. The condition severely disrupts the reading ability of an individual who was previously literate. (See also *dyslexia*.)

culture, or a peer group. Alienation is common in adolescents, and it also occurs in individuals who are isolated by cultural or language differences. In some people, alienation may be an early symptom of *schizophrenia* or a *personality disorder*.

alignment, dental

The movement of teeth by the use of either fixed or removable *orthodontic appliances* (braces) to correct *malocclusion* (an incorrect bite).

alimemazine

An *antihistamine drug* that is used mainly to relieve the itching that occurs in allergic conditions such as *urticaria* and atopic *eczema*. Alimemazine frequently causes drowsiness.

alimentary tract

Also known as the alimentary canal, the tubelike structure that extends from the mouth to the anus (see *digestive system*).

alkali

Also called a base, an alkali is chemically defined as a donor of hydroxyl ions (each of which comprises an atom of hydrogen linked to an atom of oxygen and has an overall negative electrical charge). *Antacid drugs*, such as sodium bicarbonate (bicarbonate of soda), are examples of alkalis. Some alkalis, such as sodium hydroxide (caustic soda), are corrosive and cause burns. (See also *acid*; *acid–base balance*.)

alkaloids

A group of nitrogen-containing substances that are obtained from plants. *Morphine*, *codeine*, *nicotine*, and strychnine (see *strychnine poisoning*) are examples of alkaloids.

alkalosis

A disturbance of the body's *acid–base balance* in which there is an accumulation of alkali (base) or a loss of acid. There are two types of alkalosis: metabolic and respiratory.

In metabolic alkalosis, the increase in alkalinity may be caused by taking too much of an *antacid drug* or by losing a large amount of stomach acid as a result of severe vomiting.

In respiratory alkalosis, there is a reduction in the blood level of carbonic acid (derived from carbon dioxide). This reduction is a consequence of *hyperventilation* (overbreathing), which

alfacalcidol

A synthetic form of *vitamin D*.

alginates

Substances used in certain types of *antacid drugs*. Alginates float on top of the stomach contents, forming a raft, which reduces *acid reflux* and protects the oesophagus.

alienation

Feeling like a stranger, even when among familiar people or places, and being unable to identify with family, a

may occur during a panic attack or at high altitudes due to lack of oxygen. (See also *acidosis*.)

Alka-Seltzer

A brand-named analgesic and antacid containing *aspirin*, *sodium bicarbonate*, and citric acid. Alka-Seltzer is used to treat headaches and stomach upset.

alkylating agents

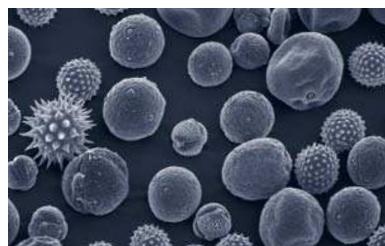

A class of *anticancer drugs*.

allele

One of two or more different forms of a *gene* that occupies a specific position on a *chromosome*. (See also *inheritance*.)

allergen

A normally harmless substance that causes an allergic reaction (see *allergy*) in people who have become sensitized to it. Allergens can include foods (for example, nuts, eggs, and shellfish); inhaled substances (such as pollen, house dust, and fur); and some drugs.

Electron micrograph of various pollen grains

Pollen is a common example of an allergen. The airborne pollen grains from plants (such as grasses and trees) can trigger an allergic reaction, the most common of which is allergic rhinitis (hay fever).

allergic alveolitis, extrinsic

See *extrinsic allergic alveolitis*.

allergic rhinitis

See *rhinitis, allergic*.

allergy

Various conditions caused by inappropriate or exaggerated reactions of the *immune system* to a wide variety of substances known as *allergens*. Many common illnesses, such as *asthma* and hay fever (see *rhinitis, allergic*), are caused by allergic reactions to substances that, in the majority of people, cause no symptoms.

Allergic reactions occur only on second or subsequent exposure to the allergen, after first contact has sensitized the body. It is unclear why only certain

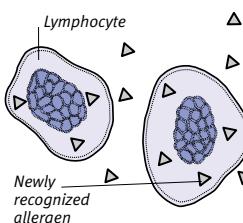

ALLERGY AND THE BODY

An allergy is an inappropriate immune system response (causing symptoms) to substances that, in most people, cause no response. The response is mainly to harmless substances that come in contact with the respiratory airways, skin, or eye surface. Common *allergens* are pollen, spores, house-dust mites, and animal *dander*. Certain

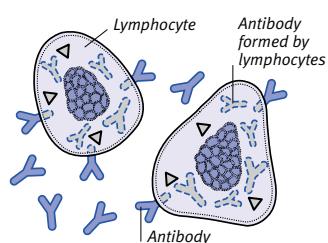

drugs, and some foods, most commonly dairy products, seafood, strawberries, and cereals, can also cause allergies. In diagnosing an allergy, the individual's medical history is important. The doctor needs to know if the symptoms vary according to the time of the day or the season, and if there are pets or other likely sources of allergens in the home.

THE ORIGIN OF AN ALLERGY

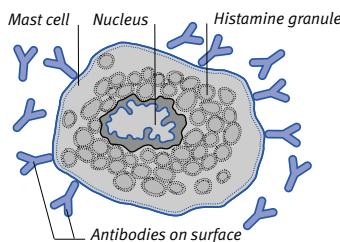

The immune system is sensitized once it has been exposed to an allergen (steps 1 to 3). Symptoms occur when the allergen is met again (step 4).

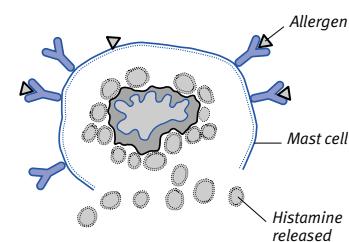

1 An allergen enters the body and is recognized by lymphocytes (blood cells that form part of the body's immune system).

2 A few days to weeks later, the lymphocytes produce antibodies that are specific to the allergens.

3 The antibodies attach to cells in the tissues called mast cells, which contain granules of histamine.

4 Binding of allergens to antibodies on the surface of mast cells leads to the release of histamine and to the symptoms of allergy.

DIAGNOSING SKIN ALLERGY

One type of skin allergy, also known as *allergic contact dermatitis*, develops slowly. Tests are performed to identify specific reactions to allergens. Small amounts of various substances are applied to the skin to see whether or not a reaction occurs.

1 Tiny samples of allergens are placed on small discs and stuck to the skin with inert tape. The discs are removed after two days.

2 A reddened area of skin where a disc had been in contact denotes a positive reaction. Some reactions may take longer to appear.

people develop allergies, but about one person in eight seems to have an inherited predisposition to them (see *atopy*).

TYPES AND CAUSES

The function of the immune system is to recognize *antigens* (foreign proteins) on the surfaces of microorganisms and to form *antibodies* (also called immunoglobulins) and sensitized *lymphocytes* (white blood cells). When the immune system next encounters these antigens, the antibodies and sensitized lymphocytes interact with them, leading to the destruction of the microorganisms.

A similar immune response occurs in allergies, except that the immune system forms antibodies or sensitized lymphocytes against harmless substances because these allergens are misidentified as potentially harmful antigens.

The inappropriate or exaggerated reactions that are seen in allergies are known as *hypersensitivity* reactions and can have any of four different mechanisms (which are termed Types I to IV hypersensitivity reactions).

TYPE I HYPERSENSITIVITY REACTIONS

Most well known allergies are caused by Type I (also known as anaphylactic or immediate) hypersensitivity, in which allergens cause immediate symptoms by provoking the immune system into producing specific antibodies, belonging to a type called immunoglobulin E (IgE), which coat cells (known as mast cells or basophils) that are present in the skin and the lining of the stomach, lungs, and upper respiratory airways. When the allergen is encountered for the second time, it binds to the IgE antibodies and causes the granules in mast cells to release various chemicals, which are responsible for the symptoms of the allergy.

Among the chemicals released is *histamine*, which causes widening of blood vessels, leakage of fluid into tissues, and contraction of muscles, especially in the airways of the lung. Symptoms can include itching, swelling, sneezing, and wheezing. Particular conditions associated with Type I reactions include asthma, hay fever, *urticaria* (nettle rash), *angioedema*, *anaphylactic shock* (a severe, generalized allergic reaction), possibly atopic *eczema*, and some food allergies.

TYPES II TO IV HYPERSENSITIVITY REACTIONS

Because Types II to IV hypersensitivity reactions have different mechanisms to Type I reactions, they are less often implicated in allergies. However, contact allergic dermatitis, in which the skin

reacts to prolonged contact with substances such as nickel, is the result of a Type IV hypersensitivity reaction.

TREATMENT

Whenever possible, the most effective treatment for allergy of any kind is avoidance of the relevant allergen.

Drug treatment for allergic reactions includes the use of *antihistamine drugs*, which relieve the symptoms. Some antihistamines have a sedative effect, which is useful, for example, in treating itching at night due to eczema; many do not cause drowsiness, making them more suitable for daytime use.

Drugs such as *sodium cromoglicate* and *corticosteroids* can be used regularly to prevent symptoms from developing.

Hyposensitization can be valuable for a minority of people who suffer allergic reactions to specific allergens such as bee stings. Treatment involves gradually increasing doses of the allergen to promote formation of antibodies that will block future reactions. Hyposensitization must be carried out under close supervision because a severe allergic reaction can result. (See also *delayed allergy*.)

allograft

Sometimes referred to as a homograft, tissue or an organ transplanted from one person to another. (See also *grafting*.)

allopathy

The practice of conventional medicine. (See also *homeopathy*.)

allopurinol

A drug used in the long-term prevention of *gout* attacks. Allopurinol works by decreasing production of *uric acid* in the body, thereby preventing the formation of uric acid crystals in the joints.

Possible adverse effects of allopurinol include itching, rashes, and nausea. The drug cannot relieve the pain of an acute gout attack and may even precipitate one at the start of treatment. Such attacks can be prevented by taking a combination of allopurinol and a *nonsteroidal anti-inflammatory drug* (NSAID) or *colchicine*.

almond oil

An oil prepared from the seeds of the bitter almond tree (*PRUNUS AMYGDALUS*). Almond oil is a common ingredient of *emollient* skin preparations.

almotriptan

A *serotonin agonist* drug that is used in the treatment of acute migraine attacks.

aloe

The juice of leaves from various plants of the *ALOE* genus. Aloe may be added to compound benzoin tincture, an aromatic *inhala-*tion for relieving *sinusitis* and *nasal congestion*.

alopecia

Loss or absence of *hair*, which may occur at any hair-bearing site on the body but which is usually noticeable only on the scalp.

TYPES

Male-pattern baldness, the most common form of alopecia, is hereditary and most commonly affects men. Normal hair is lost, initially from the temples and crown, and is replaced by fine, downy hair; the affected area gradually widens. Other hereditary forms of alopecia are rare and may be due to absence of hair roots or abnormalities of the hair shaft.

Stages in male pattern baldness

In this common form of alopecia, the man first loses hair from the temples and the crown, then the bald area gradually widens.

In generalized alopecia, the hair falls out in large amounts. Such hair loss occurs when all the hairs simultaneously enter the resting phase; they then fall out about three months later. Causes include surgery, prolonged illness, or childbirth. In such cases, the hair will regrow without treatment. Many *anti-cancer drugs* cause temporary alopecia. The hair usually regrows when the treatment is completed.

Localized alopecia may be the result of permanent skin damage (for example, following burns or *radiotherapy*) or of trauma to the hair roots by styling or, rarely, *trichotillomania* (a disorder in which sufferers pull out their hair). The most common type of localized hair loss is *alopecia areata*, an *autoimmune disorder* (in which the immune system attacks the body's own tissues). There is no specific treatment for *alopecia areata*, but the hair usually regrows within a few months. *Alopecia universalis* is a rare, permanent form of *alopecia areata* that causes loss of all hair on the scalp and body, including the eyelashes and

eyebrows. Skin diseases such as scalp ringworm (see *tinea*), *lichen planus*, *lupus erythematosus*, and *skin tumours* may also cause localized hair loss.

TREATMENT

Treatments for male-pattern baldness include *hair transplants* or drug treatments with *minoxidil* or *finasteride*. Generalized alopecia often resolves without treatment. Treatment of localized alopecia depends on the cause.

alpha₁-antitrypsin deficiency

A rare *genetic disorder* in which a person is missing the enzyme alpha₁-antitrypsin, which protects the body from damage by other enzymes. The disease mainly affects tissues in the lungs, resulting in *emphysema*, and the liver, causing *cirrhosis*. The effects of alpha₁-antitrypsin deficiency may not become apparent until after the age of 30. There is no cure, but symptoms can be relieved by drug treatment. In severe cases, a *liver transplant* may be a possibility.

alpha-blocker drugs

COMMON DRUGS

- Alfuzosin • Doxazosin • Indoramin • Prazosin
- Tamsulosin • Terazosin

A group of drugs used to treat *hypertension* (high blood pressure) and urinary symptoms resulting from an enlarged prostate gland (see *prostate, enlarged*).

Alpha-blocker drugs interfere with the nerve signals that govern the contraction of blood vessels. This causes the vessels to widen (vasodilation), thereby reducing the blood pressure. In the treatment of an enlarged prostate gland, alpha-blockers relax the ring of muscles at the bladder outlet, which improves the outflow of urine.

Side effects may include dizziness and fatigue (caused by a drop in blood pressure on standing up), drowsiness, headache, nausea, and a dry mouth.

alpha-fetoprotein

A protein that is produced in the liver and gastrointestinal tract of the fetus and by some abnormal tissues in adults.

ALPHA-FETOPROTEIN IN PREGNANCY

Alpha-fetoprotein (AFP) is excreted in the fetal urine into the amniotic fluid; the fluid is swallowed by the fetus, which introduces AFP into the fetal digestive system. Most of the AFP is broken down in the fetal intestine, but some of it passes into the mother's circulation. AFP can be measured in the

maternal blood from the latter part of the first trimester of pregnancy, and its concentration rises between the 15th and 20th weeks.

Raised levels of AFP are associated with fetal *neural tube defects*, such as *spina bifida* or *anencephaly*, and certain kidney abnormalities. High levels of AFP also occur in multiple pregnancies (see *pregnancy, multiple*) and threatened or actual *miscarriage*.

AFP levels may be unusually low if the fetus has *Down's syndrome*. For this reason, measurement of blood AFP is included in blood tests that are used to screen pregnant women for increased risk of Down's syndrome.

ALPHA-FETOPROTEIN IN ADULTS

AFP levels are commonly raised in adults with hepatoma (see *liver cancer*), cancerous *teratoma* of the testes or ovaries, or cancer of the pancreas, stomach, or lung. For this reason, AFP is known as a "tumour marker".

AFP levels can be used to monitor results of treatment of such cancers; increasing levels after chemotherapy or surgery may indicate recurrence. However, AFP levels are also raised in some noncancerous conditions such as viral and alcoholic *hepatitis* and *cirrhosis*.

alprazolam

A *benzodiazepine drug* that is used in the treatment of *anxiety*, *panic attacks*, and *phobias*.

alprostadil

A *prostaglandin drug* used to minimize the effects of congenital (present from birth) heart defects in newborn babies prior to corrective surgery; it is usually administered in hospital. Alprostadil is also used as treatment for impotence. To produce an erection, it is self-administered, either by injection into the penis or as a gel introduced into the *urethra*.

alternative medicine

Also called *complementary medicine*, any medical system based on a theory of disease or method of treatment other than orthodox Western medicine.

altitude sickness

See *mountain sickness*.

aluminium

A light, metallic element that is found in bauxite and various other minerals. Aluminium compounds are used in *antacid drugs* and in *antiperspirants*.

Most of the aluminium taken into the body is excreted. Excessive amounts are toxic and are stored in the lungs, brain, liver, and thyroid gland, where they may result in organ damage.

Certain industrial processes give off fumes containing aluminium into the air. Inhalation of these fumes can cause *fibrosis* of lung tissue. Drugs that contain aluminium interfere with the absorption and excretion of a number of other drugs and should not, therefore, be taken simultaneously.

alveolectomy

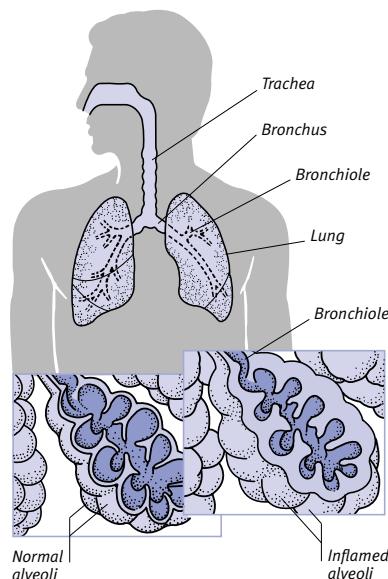

See *alveoplasty*.

alveolitis

Inflammation and thickening of the walls of the alveoli (the tiny air sacs in the lungs). Alveolitis reduces the elasticity of the lungs during breathing and reduces the efficiency of the transfer of gas between the lungs and the surrounding blood vessels.

CAUSES

Alveolitis is commonly caused by an allergic reaction to inhaled dust of animal or plant origin, as in *farmer's lung* (caused by spores from mouldy hay), *bagassosis* (caused by spores from mouldy sugar-cane residue), and pigeon fancier's lung (caused by particles from bird droppings). This type of alveolitis is known as extrinsic allergic alveolitis.

Effects of alveolitis

The alveoli become inflamed and their walls thicken, causing the lungs to become less elastic and less able to transfer oxygen.

Fibrosing alveolitis is an *autoimmune disorder* (in which the immune system attacks the body's own tissues). In some cases, it occurs with other autoimmune disorders, such as *rheumatoid arthritis* or *systemic lupus erythematosus*.

Radiation alveolitis is caused by irradiation of the lungs and may occur as a rare complication of *radiotherapy* for lung or breast cancer.

SYMPOTMS AND DIAGNOSIS

Alveolitis usually causes a dry cough and breathing difficulty on exertion.

A *chest X-ray* of a person suffering from alveolitis usually shows mottled shadowing across the lungs. *Blood tests* may be performed to look for specific antibodies (proteins manufactured by the immune system; see *antibody*) to an allergen. They may also be performed to look for evidence of an autoimmune disorder (in which the immune system attacks the body's own tissues). *Pulmonary function tests* show reduced lung capacity without obstruction to air flow through the bronchi (air passages to the lungs). A lung *biopsy* (removal of a sample of tissue for microscopic analysis) may be the only way to make a conclusive diagnosis of alveolitis.

TREATMENT AND OUTLOOK

For most types of alveolitis, a short course of *corticosteroid drugs* relieves symptoms, but for fibrosing alveolitis the drugs may need to be taken indefinitely. If the cause of allergic alveolitis is recognized and avoided before lung damage occurs, the effects are not permanent. In fibrosing alveolitis, the damage progresses despite treatment, causing increasing breathing difficulty and, sometimes, *respiratory failure*.

alveoplasty

Dental surgery that is carried out to remove protuberances and to smooth out other uneven areas from tooth-bearing bone in the jaw. Alveoplasty is performed either under a general anaesthetic (see *anaesthesia, dental*) or, more usually, under local anaesthetic. The procedure is usually carried out to facilitate the fitting of dentures on people whose alveolar ridge, underlying the gums, would not otherwise be smooth and even enough for dentures to be fitted easily or worn comfortably.

An incision is made in the gum, which is then peeled back to expose the uneven bone. The bone is then either reshaped with large forceps or filed down to the required shape. Finally, the

gum is drawn back over the bone and stitched together. Some bruising and swelling of the mouth may occur, but the gum usually heals within two weeks.

alveolus, dental

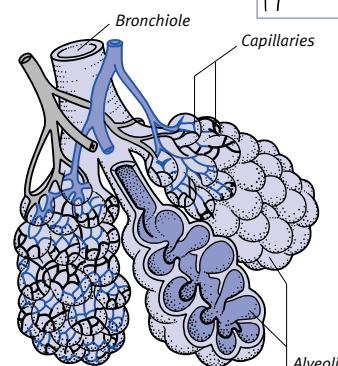

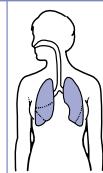

The bony cavity or socket supporting each tooth in the jaw.

alveolus, pulmonary

One of millions of tiny, balloonlike sacs at the end of a bronchiole (one of the many small air passages in the lungs) where gases are exchanged during *respiration*. In each lung, there are approximately 300 million alveoli that are arranged in groups resembling bunches of grapes.

ANATOMY OF THE ALVEOLI

These tiny sacs contain capillaries in their thin walls that allow oxygen to be absorbed into the blood.

factors also result in the abnormal deposition of a protein in the brain called beta amyloid. Other chemical abnormalities include deficiency of the *neurotransmitter acetylcholine*.

SYMPTOMS AND SIGNS

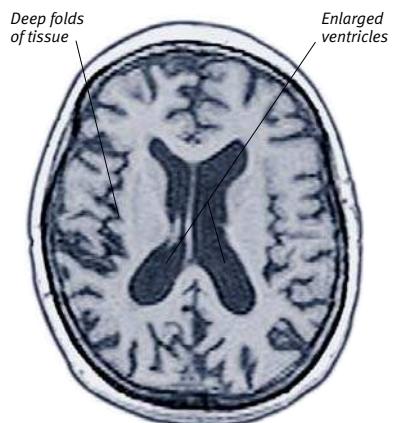

The features of Alzheimer's disease vary, but there are three broad stages. At first, the affected individual becomes increasingly forgetful; and problems with memory may cause *anxiety* and *depression*. Some deterioration in memory is a feature of normal *aging*, and this alone is not evidence of dementia.

In the second stage of the disease, loss of memory, particularly for recent events, gradually becomes more severe, and there may be disorientation as to time or place. The person's concentration and numerical ability decline, and there is noticeable *dysphasia* (inability to find the right word). Anxiety increases, mood changes are unpredictable, and personality changes may occur. If the patient is left unsupervised, he or she may repeatedly wander off.

Finally, confusion becomes profound. There may be symptoms of *psychosis*, such as *hallucinations* and *delusions*. Signs of nervous system disease, such as abnormal *reflexes* (involuntary actions) and faecal or urinary *incontinence*, begin to develop.

DIAGNOSIS

Alzheimer's disease is usually diagnosed from the symptoms, but tests including blood tests and *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images) of the brain may be needed to exclude other causes of dementia.

MRI of the brain in Alzheimer's disease

The volume of the brain substance has shrunk markedly, resulting in deep folding of the tissue and enlargement of the fluid-filled brain ventricles.

TREATMENT

The most important aspect of treatment for Alzheimer's disease is the provision of suitable nursing and social care for sufferers and support for their relatives. *Tranquillizer drugs* can often improve difficult behaviour and to help with sleep. Treatment with *acetylcholinesterase inhibitors*, such as rivastigmine and donepezil, may slow the progress of the disease for a time, but will not improve mental ability. Side effects such as nausea and dizziness may occur.

amalgam, dental

A material, consisting of an alloy of mercury with other metals, that is used as fillings for teeth. Amalgam is soft enough to be easily workable by the dentist but sets rapidly into a hard, strong solid (see *filling, dental*).

amantadine

An *antiviral drug* that is used in the prevention and treatment of *influenza A*. Amantadine is also used to help relieve symptoms of *Parkinson's disease*.

amaurosis fugax

Brief loss of vision, lasting for seconds or minutes, usually affecting one eye only and caused by the temporary blockage of a small blood vessel in the eye by an *embolus* (a particle of solid matter such as cholesterol or clotted blood). These emboli are carried in the bloodstream from diseased arteries in the neck or, rarely, the heart. Sufferers typically experience a loss or dimming of vision, in one eye only, rather like a shade being pulled down or up.

Attacks may be infrequent, or they may occur many times a day, which indicates an increased risk of *stroke* and requires medical investigation.

ambidexterity

The ability to perform manual skills, such as writing or using cutlery, equally well with either hand because there is no definite *handedness* (preference for the use of one hand in particular). Ambidexterity is an uncommon and often familial trait.

amblyopia

A permanent defect of visual acuity in which there is usually no structural abnormality in the eye. In many cases, there is a disturbance of the visual pathway between the *retina* and the brain. The term amblyopia is also some-

times applied to toxic or nutritional causes of decreased visual acuity, as in tobacco-alcohol amblyopia.

If normal vision is to develop during infancy and childhood, it is essential that clear, corresponding visual images are formed on both retinas so that compatible nerve impulses pass from the eyes to the brain. If no images are received, normal vision cannot develop. If the images from each eye differ markedly, one will be suppressed to avoid double vision.

CAUSES

The most common cause of amblyopia is *squint* (a deviation of one eye relative to the other) in young children. Failure to form normal retinal images may also result from congenital (present from birth) *cataract* (opacity of the lens of the eye), and severe, or unequal, focusing errors, such as when one eye is normal and there is an uncorrected large degree of *astigmatism* in the other. Toxic and nutritional amblyopia may be the result of damage to the retina and/or the optic nerve.

TREATMENT AND OUTLOOK

The usual treatment for amblyopia due to squint is patching (covering up the good eye to force the deviating eye to function properly). Surgery to place the deviating eye in the correct position may be necessary. Glasses may be needed to correct severe focusing errors. Cataracts may be removed surgically. After the age of eight, amblyopia cannot usually be remedied.

ambulance

A vehicle for transporting sick, injured, or disabled people, usually to hospital, that is staffed by trained personnel who can provide emergency treatment during the journey.

ambulatory ECG

In ambulatory *ECG* (electrocardiography), a wearable device called a *Holter monitor* is used to record the electrical activity of the heart by means of electrodes attached to the chest. The monitor is usually worn for at least 24 hours and detects intermittent *arrhythmias* (abnormal heart rates and rhythms). It is also used to assess the programming of a cardiac pacemaker. The wearer presses a button on the monitor to mark the recording whenever symptoms occur. The recording can be analysed later to determine whether the periods of arrhythmia coincide with the symp-

toms. In some cases, the patient can send the recording over the telephone by means of *telecardiography* (transmission of an impulse to a site that is remote from the patient).

amelioration

In medical usage, improvement in the medical condition of a patient.

amelogenesis imperfecta

An inherited condition of the teeth in which the enamel is either abnormally thin or is deficient in calcium. The teeth of affected individuals may be pitted and discoloured (see *discoloured teeth*) and more susceptible to dental *caries* (tooth decay) and wear.

amenorrhoea

The absence of menstrual periods. Primary amenorrhoea is defined as failure to start menstruating by the age of 16. Secondary amenorrhoea is the temporary or permanent cessation of periods in a woman who has menstruated regularly in the past.

PRIMARY AMENORRHOEA

The main cause of primary amenorrhoea is the delayed onset of *puberty*. The delay may not indicate a disorder but, rarely, may result from a disorder of the *endocrine system*, such as a *pituitary tumour*, *hypothyroidism* (underactivity of the thyroid gland), an *adrenal tumour*, or *adrenal hyperplasia*. Another rare cause of delayed puberty is *Turner's syndrome*, in which one female sex chromosome is missing. In some cases, menstruation fails to take place because the vagina or uterus has been absent from birth. It may also fail to occur because there is no perforation in the hymen (the membrane across the opening of the vagina) to allow blood to escape.

SECONDARY AMENORRHOEA

The most common cause of temporary secondary amenorrhoea is *pregnancy*. Secondary amenorrhoea may also be caused by hormonal changes that occur as a result of stress, *depression*, *anorexia nervosa*, certain drugs, or a pituitary or thyroid disorder. Another possible cause is a disorder of the ovary, such as *polycystic ovary* (see *ovary, polycystic*) or an ovarian tumour. Amenorrhoea occurs permanently after the *menopause* or following a *hysterectomy* (a surgical operation to remove the uterus).

INVESTIGATION AND TREATMENT

Investigation of amenorrhoea usually involves a physical examination and

blood tests to measure hormone levels. **CT scanning** or **MRI** (techniques that produce three-dimensional or cross-sectional images) of the skull may be carried out to exclude the possibility of a pituitary tumour and **ultrasound scanning** of the abdomen and pelvis to exclude a tumour of the adrenal glands or ovaries. In some cases, **laparoscopy** (examination of the inside of the abdomen using a rigid or flexible viewing tube) may be required to inspect the ovaries.

Treatment of amenorrhoea, if found to be necessary, is of the underlying cause. (See also *dietary amenorrhoea*.)

amfebutamone

A drug used, along with self-help measures, as an aid to stopping smoking. Side effects include a dry mouth and gastrointestinal disturbances.

amfetamine

An alternative spelling for amphetamine (see *amphetamine drugs*). (See also *controlled drugs*.)

amiloride

A potassium-sparing **diuretic drug**, amiloride is used in combination with loop or thiazide diuretics in the treatment of **hypertension** (high blood pressure) and the oedema (fluid retention) that results from **heart failure** (reduced pumping efficiency of the heart) or liver **cirrhosis**.

amino acids

A group of chemical compounds that form the basic structural units of all **proteins**. Each amino acid molecule consists of amino and carboxyl groups of atoms that are linked to a variable chain or ring of carbon atoms.

Individual amino acid molecules are linked together by chemical bonds (called **peptide** bonds) to form short chains of molecules called **polypeptides**. Hundreds of polypeptides are, in turn, linked together (also by peptide bonds) to form a protein molecule. What differentiates one protein from another is the sequence of the amino acids.

There are 20 different amino acids that make up all the proteins in the body. Of these, 12 can be made by the body; they are known as nonessential amino acids because they do not need to be obtained from the diet. The other eight, the essential amino acids, cannot be made by the body and must be obtained in the diet.

The 20 amino acids that make up proteins also occur free within cells and in body fluids. In addition, there are more than 200 other amino acids that are not found in proteins but play an important role in chemical reactions within cells.

aminoglutethimide

An **anticancer drug** used to treat certain types of breast cancer, prostate cancer, and some endocrine gland tumours.

aminoglycoside drugs

Aminoglycosides, a type of **antibiotic drug**, are given by injection and, because their use can damage the inner ear or kidneys, are generally reserved for the treatment of serious infections. Important examples of these drugs are **gentamicin** and **streptomycin**, which are also used topically for eye and ear infections.

aminophylline

A **bronchodilator drug** that is used to treat chronic **bronchitis**, **asthma**, and, occasionally, **heart failure** (reduced pumping efficiency of the heart).

Aminophylline relieves breathing difficulty by widening the bronchi (the main air passages to the lungs). It also dilates (widens) blood vessels, thereby improving blood flow from the heart, and increases the production of urine.

Possible side effects of aminophylline include nausea, vomiting, headache, dizziness, and palpitations.

amiodarone

An **antiarrhythmic drug** used in the treatment of various types of **arrhythmia** (irregular heart rate or rhythm). Long-term use of amiodarone may result in inflammation of the liver, thyroid problems, and damage to the eyes and lungs. For this reason, amiodarone is usually given only when other drugs have failed to be effective.

amitriptyline

A tricyclic **antidepressant drug** with a sedative effect. Amitriptyline is useful in the treatment of **depression** accompanied by **anxiety** or **insomnia**. Possible adverse effects include blurred vision, dizziness, and drowsiness.

amlodipine

A **calcium channel blocker** drug that is used to prevent **angina** and to treat **hypertension** (high blood pressure). Possible side effects of amlodipine include headaches and dizziness.

ammonia

A colourless, pungent gas that dissolves in water to form ammonium hydroxide, an alkaline solution (see *alkali*). Ammonia consists of one nitrogen atom linked to three hydrogen atoms. Ammonia is produced in the body and helps to maintain the *acid-base balance*.

In severe liver damage, the capacity of the liver to convert ammonia to **urea** is diminished. This leads to a high concentration of ammonia in the blood, which is thought to be a major cause of the impaired consciousness that occurs in *liver failure*.

amnesia

Loss of the ability to memorize information and/or recall information stored in **memory**. Amnesic conditions affect mainly long-term memory (where information is retained indefinitely) rather than short-term memory (where it is only retained for seconds or minutes).

Many people with amnesia have a memory gap that extends back for some time before the onset of the disorder. This condition, known as *retrograde amnesia*, is principally a deficit of recall. In the majority of cases, the memory gap gradually shrinks over time.

Some people with amnesia are unable to store new information in the period following the onset of the illness. The resultant gap in memory, known as *anterograde amnesia*, extends from the moment of onset of the amnesia to the time when the long-term memory resumes (if at all). This memory gap is usually permanent.

CAUSES

Amnesia is the result of damage to, or disease of, regions in the brain that are concerned with memory function. Possible causes of such damage are **head injury**, degenerative disorders such as **Alzheimer's disease** and other forms of **dementia**; infections such as **encephalitis**; thiamine deficiency in problem drinkers, which leads to **Wernicke-Korsakoff syndrome**; **brain tumours**; **strokes**; and **subarachnoid haemorrhage**. Amnesia can also occur in some forms of psychiatric illness (in which there is no apparent physical damage to the brain). Some deterioration of memory is a common feature of *aging*.

amniocentesis

A diagnostic procedure in which a small amount of **amniotic fluid** is withdrawn, using a syringe guided by **ultrasound**

scanning, from the *amniotic sac* (the membrane that surrounds the *fetus* in the *uterus*).

WHY IT IS DONE

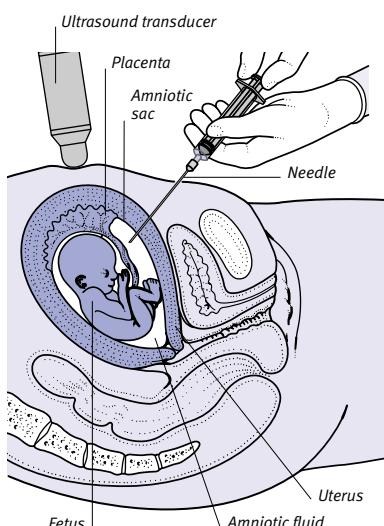

The amniotic fluid contains fetal cells, which can be subjected to *chromosome analysis* in order to identify or exclude chromosomal defects, such as *Down's syndrome*, or genetic analysis to look for *genetic disorders* such as *haemophilia*, *cystic fibrosis*, and *Tay-Sachs disease*. The amniotic fluid also contains chemicals; and analysis of the fluid can help to diagnose or exclude developmental abnormalities such as *spina bifida*. The severity of *rhesus incompatibility* and the maturity of the fetal lungs can also be checked by amniocentesis.

HOW IT IS DONE

Amniocentesis is usually performed in the 14th to 18th week of pregnancy. It may be performed earlier, but this is technically more difficult at this early stage. The skin of the abdomen is cleaned and a needle is inserted into the amniotic sac; (in all cases, ultrasound scanning is used to avoid contact with the fetus and placenta). An attached *syringe* removes some fluid for analysis.

COMPLICATIONS

Amniocentesis slightly increases the risk of *miscarriage* or early rupture of the membranes, and the procedure is therefore recommended only when the fetus is thought to be at increased risk of an abnormality. (See also *antenatal care*, *chorionic villus sampling*.)

Procedure for amniocentesis

A needle, guided by ultrasound, is introduced through the uterine wall into the amniotic sac; a sample of amniotic fluid is then withdrawn.

amnion

One of the membranes that surrounds the *fetus* in the *uterus*. The outside of the amnion is covered by another membrane called the *chorion*.

amniotic fluid

The clear, watery fluid (popularly called the "waters") that surrounds the *fetus* in the *uterus* and is contained within the *amniotic sac* (a thin, membranous bag). Amniotic fluid cushions the fetus against pressure from the mother's internal organs, allowing movement.

Amniotic fluid is produced by cells that line the amniotic sac and is constantly circulated. The fetus swallows the fluid, which is absorbed into the fetal bloodstream and then excreted by the kidneys as urine. The fluid is 99 per cent water. The remainder consists of dilute concentrations of the substances found in *blood plasma*, along with cells and *lipids* (fats) from the fetus.

Amniotic fluid appears during the first week following conception, and it gradually increases in volume until the tenth week, when it increases very rapidly. After approximately 35 weeks' gestation, the volume of fluid slowly starts to decline.

In a small number of pregnancies, *polyhydramnios* (the formation of excessive amounts of amniotic fluid) occurs; less frequently, *oligohydramnios* (the formation of insufficient fluid) occurs.

amniotic sac

The membranous bag that surrounds the *fetus* and is filled with *amniotic fluid* as pregnancy advances. The sac is made up of two membranes, the inner *amnion* and the outer *chorion*.

amniotomy

Artificial rupture of the amniotic membranes. Amniotomy, which is popularly known as "breaking of the waters", is performed for *induction of labour*.

amoeba

A type of protozoan (see *protozoa*). An amoeba is a microscopic single-celled organism with an irregular, changeable shape. Amoebae live in moist environments such as fresh water and soil. Some types are parasites of humans, causing diseases such as *amoebiasis*.

amoebiasis

An infection caused by the amoeba *ENTAMOEBA HISTOLYTICA*, a tiny single-

celled parasite that lives in the human large intestine. *Amoebiasis* is spread through eating food or drinking water contaminated by human excreta containing cysts of the amoeba.

Once the cysts are swallowed, the cyst walls break down, and the amoebae hatch out to parasitize the large intestine. In the intestine, the amoebae multiply and develop protective capsules, forming new cysts. These cysts are passed out of the body in the faeces and can survive for long periods before the next person acquires them.

SYMPTOMS

Some individuals carry the *ENTAMOEBA HISTOLYTICA* parasite in their intestines and excrete cysts without having symptoms. However, some strains of the amoebae invade and ulcerate the intestinal wall, causing diarrhoea and abdominal pain, which may develop into full-blown *dysentery*.

The amoebae may spread through the bloodstream to the liver or, rarely, to the brain or lung, where they cause abscesses. Symptoms of an amoebic liver abscess include weight loss, chills, fever, and painful liver enlargement. Liver abscesses may also sometimes occur in the absence of symptoms.

PREVENTION AND TREATMENT

Travellers to countries where sanitary standards are low can reduce their risk of acquiring amoebiasis by drinking only bottled or thoroughly boiled water and by not eating uncooked vegetables or unpeeled fruit.

Treatment of all forms of amoebiasis is with drugs such as *metronidazole* or *diloxanide*. These drugs kill the parasite within a few weeks, leading to complete recovery.

amoebic dysentery

See *amoebiasis*.

amoebicides

A group of drugs that are used to treat *amoebiasis*. Examples of amoebicides are *diloxanide* and *metronidazole*. The drugs work by killing amoebae (see *amoeba*) in the intestine and in other body tissues.

amoxapine

A tricyclic *antidepressant drug*. Possible adverse effects of amoxapine include a dry mouth, blurred vision, dizziness, drowsiness, abnormal muscular movements, menstrual irregularities, and enlargement of the breasts.

amoxicillin

A *penicillin* drug commonly used to treat a variety of infections, including *cystitis*, *bronchitis*, and ear and skin infections. Allergy to it causes a blotchy rash and, rarely, fever, swollen mouth and tongue, itching, and breathing difficulty.

Amoxil

A brand name for the antibiotic drug *amoxicillin*.

amoxyccillin

See *amoxicillin*.

amphetamine drugs

COMMON DRUGS

- Dexamfetamine

A group of *stimulant drugs* used mainly in the treatment of *narcolepsy* (a rare disorder that is characterized by excessive sleepiness).

HOW THEY WORK

Amphetamine drugs stimulate secretion of *neurotransmitters* (chemicals released by nerve endings), such as *noradrenaline* (norepinephrine), which increase nerve activity in the brain and make a person wakeful and alert.

SIDE EFFECTS

In high doses, amphetamines can cause tremor, sweating, anxiety, and sleeping problems. Delusions, hallucinations, high blood pressure, and seizures may also occur. Prolonged use may produce *tolerance* and *drug dependence*.

ABUSE

Amphetamines are often abused for their stimulant effect and, for this reason, they are *controlled drugs*.

amphotericin

An antifungal drug used to treat *candidiasis* of the mouth or intestine. The drug is taken as tablets but is also given by intravenous infusion to treat life-threatening systemic (generalized) fungal infections such as *cryptococcosis* and *histoplasmosis*.

Side effects, which include vomiting, fever, headache, and, rarely, seizures, may occur with intravenous infusion.

ampicillin

A *penicillin* drug commonly used to treat *cystitis*, *bronchitis*, and ear infections. Diarrhoea is a common adverse effect. Some people are allergic to ampicillin and suffer from rash, fever, swelling of the mouth and tongue, itching, and breathing difficulty.

ampoule

A small glass or plastic vessel that can be hermetically sealed to hold liquid substances, in a sterile condition, for *injection*. Each ampoule usually contains a single dose of a drug.

ampulla

An enlarged, flask-shaped area at the end of a tubular structure or canal. There are several ampullae in the body, including those at the end of each fallopian tube, on each of the three semicircular canals of the inner ear, and at the opening of the bile duct leading into the intestine.

amputation

The surgical removal of part or all of a limb. Amputation may be needed if the blood supply to the limb has been permanently lost. It may also be necessary in some instances of cancer. The operation is now quite rarely performed.

WHY IT IS DONE

Amputation is necessary if *peripheral vascular disease*, as a result of *atherosclerosis* or *diabetes mellitus*, has destroyed the blood supply to a limb. If the blood supply cannot be restored, amputation is carried out to prevent the development of *gangrene* (tissue death).

Amputation may also occasionally be performed to prevent the spread of a *bone cancer* or malignant melanoma (see *melanoma*, *malignant*), a type of skin cancer. If a limb has been irreparably damaged in an accident, a decision may also be taken to amputate.

HOW IT IS DONE

During the operation, skin and muscle are cut below the level at which the bone is to be severed to create flaps that will later provide a fleshy stump. The blood vessels are tied off, the bone is sawn through, the area is washed with saline (salt solution), and the flaps of skin and muscle are stitched over the sawn end of bone to form a smooth and rounded stump.

If a prosthesis (see *limb, artificial*) is to be fitted, the surgeon tries to ensure that nerves are severed well above the stump in order to reduce the risk of pressure pain. In an amputation at the ankle (Syme's amputation), the tough skin of the heel pad is retained to cover the stump, reducing the need for a prosthetic foot.

RECOVERY AND OUTLOOK

The stump is usually swollen for about six weeks after the operation. For some

time after amputation, there may also be an unpleasant sensation that the limb is still present. This phenomenon is known as "phantom limb". A prosthesis will usually be fitted, if necessary, once the stump has healed and the swelling has gone down.

amputation, congenital

The separation of a body part (usually a limb, finger, or toe) from the rest of the body, as a result of the blood supply to the part being blocked, in the uterus, by a band of *amnion* (fetal membrane). At birth, the affected part may be either completely separated, or it may show the marks of the "amniotic band". (See also *limb defects*.)

amputation, traumatic

Loss of a finger, toe, or limb through injury. (See also *microsurgery*.)

amylase

An *enzyme* that is found in *saliva* and pancreatic secretions (see *pancreas*). Amylase helps the body to digest dietary starch, breaking it down into smaller components, such as the sugars *glucose* and *maltose*.

Amsler chart

A diagnostic tool used by ophthalmologists to detect changes in the retina, particularly those changes that indicate *macular degeneration*. A typical Amsler chart consists of a grid of black lines on a white background. In an individual with retinal changes, the lines may appear distorted.

amyl nitrite

A *nitrate drug* that was once prescribed to relieve *angina pectoris* (chest pain as a result of impaired blood supply to the heart muscle). Because it frequently causes adverse effects, the drug has now been superseded by other drugs such as *glyceryl trinitrate* and *isosorbide*. Amyl nitrite is sometimes abused for its effect of intensifying pleasure during orgasm.

amyloidosis

An uncommon disease in which a substance called amyloid, composed of fibrous protein, accumulates in tissues and organs, including the liver, kidneys, tongue, spleen, and heart.

CAUSES

Amyloidosis may occur for no known reason, in which case it is known as primary amyloidosis; more commonly,

it is a complication of some other disease, and in such cases it is called secondary. Conditions that may lead to amyloidosis include *multiple myeloma* (a cancer of bone marrow), *rheumatoid arthritis*, *family Mediterranean fever*, *tuberculosis*, and other longstanding infections such as chronic *osteomyelitis* (bone infection). Amyloid is also deposited in the brain in *Alzheimer's disease*. Small deposits of amyloid are a normal feature of *aging*.

SYMPOTMS AND SIGNS

The symptoms of amyloidosis vary, depending on the organs affected and the duration of the condition. Affected organs typically become enlarged. An accumulation of amyloid in the heart may result in *arrhythmias* (disturbances of the heart rate or rhythm) and *heart failure* (reduced pumping efficiency of the heart). If the stomach and intestines are affected, symptoms such as diarrhoea may develop, and the lining of these organs may become ulcerated. Primary amyloidosis is often characterized by deposits of amyloid in the skin, which appear as slightly raised, waxy spots. Deposits of amyloid in the kidneys may cause *kidney failure*, which can be fatal.

TREATMENT

There is no treatment for the removal of amyloid deposits. However, it is possible to halt the progression of secondary amyloidosis by treatment of the underlying disorder.

amyotrophic lateral sclerosis

See *motor neuron disease*.

amyotrophy

Shrinkage or wasting away of a muscle, caused by a reduction in the size of its fibres, leading to weakness. Amyotrophy is usually the result of poor nutrition, reduced use of the muscle (as occurs when a limb is immobilized for a long period), or disruption of the blood or nerve supply to the muscle (as can occur in *poliomyelitis* or *diabetes mellitus*). (See also *atrophy*.)

anabolic steroids

See *steroids, anabolic*.

anabolism

The manufacture of complex molecules such as *fats* and *proteins* from simpler molecules by metabolic (chemical and physical) processes in living cells. (See also *catabolism; metabolism*.)

anaemia

A condition in which the concentration of the oxygen-carrying pigment *haemoglobin* in the blood is below normal. Haemoglobin molecules are carried inside red *blood cells* and transport oxygen from the lungs to the tissues. Normally, stable haemoglobin concentrations in the blood are maintained by a balance between red-cell production in the bone marrow and red-cell destruction in the spleen. Anaemia may result if this balance is upset.

TYPES AND CAUSES

Anaemia is not a disease in itself but a feature of many different disorders. There are various types, which can be

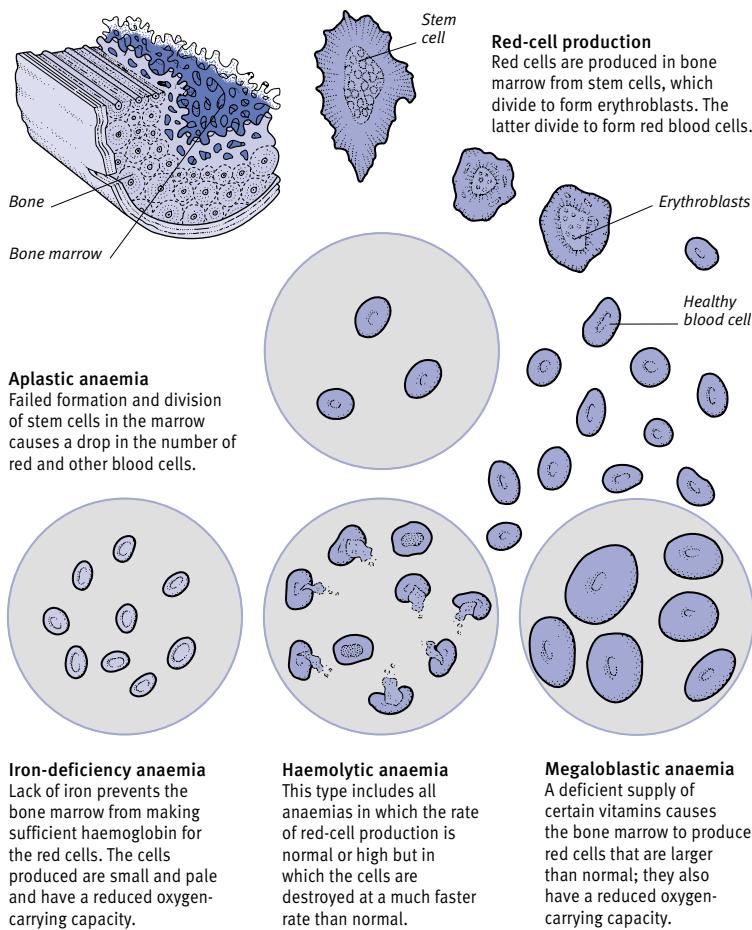

classified into those due to decreased or defective red blood cell production by bone marrow (see *anaemia, aplastic*; *anaemia, megaloblastic*; *anaemia, iron-deficiency*) and those due to decreased survival of the red cells in the blood (see *anaemia, haemolytic*). The illustrated box shows the main types of anaemia.

SYMPTOMS

The symptoms common to all forms of anaemia result from the reduced oxygen-carrying capacity of the blood, and the severity of symptoms depends on how low the haemoglobin concentration has become. Slightly reduced levels can cause tiredness, and lethargy. Severely reduced levels can cause breathing

TYPES AND CAUSES OF ANAEMIA

Anaemia results either from reduced or defective production or an excessively high rate of destruction of oxygen-carrying red blood cells. Four of the main types are shown below, but anaemia can have many other causes (such as various forms of leukaemia).

difficulty on exercise, dizziness as a result of reduced oxygen reaching the brain, *angina pectoris* (chest pain due to impaired oxygen supply to the heart muscle), and palpitations as the heart works harder to compensate. General symptoms include pallor, particularly of the skin creases, the lining of the mouth, and the inside of the eyelids.

Other features may occur with particular forms of anaemia. For example, some degree of *jaundice* occurs in most types of haemolytic anaemia because the high rate of destruction of red blood cells leads to an increased level of the yellow pigment bilirubin (produced by the breakdown of the haemoglobin in red cells) in the blood.

DIAGNOSIS

Anaemia is diagnosed from the patient's symptoms and by blood tests (see *blood count*). A *bone marrow biopsy* (removal of a small sample of bone marrow for analysis) may be required to determine whether or not red blood cell production is defective.

anaemia, aplastic

A rare but serious type of *anaemia* (a reduced level of the oxygen-carrying pigment *haemoglobin* in the blood). In aplastic anaemia, the red cells, white cells, and platelets in the blood are all reduced in number. The condition is caused by a failure of the *bone marrow* to produce stem cells, the initial form of all blood cells.

CAUSES

Treatment of cancer with *radiotherapy* or *anticancer drugs* can temporarily interfere with the cell-producing ability of bone marrow, as can certain viral infections and other drugs. Long-term exposure to insecticides or benzene fumes may cause more persistent aplastic anaemia; and another recognized cause is a moderate to high dose of nuclear radiation. An *autoimmune disorder* (in which the immune system attacks the body's own tissues) is responsible in some cases. Aplastic anaemia sometimes develops for no known reason.

SYMPOTMS

A low level of red blood cells may cause symptoms, such as fatigue and breathlessness, that are common to all types of anaemia. Deficiency of white cells increases susceptibility to infection, resulting in frequent or severe infections; platelet deficiency may lead to a tendency to bruise easily, bleeding gums, and nosebleeds.

DIAGNOSIS AND TREATMENT

Aplastic anaemia is usually suspected from the results of a blood test, particularly a *blood count*, and is confirmed by a *bone marrow biopsy* (the removal of a small sample of bone marrow for microscopic analysis).

Blood and platelet transfusions can control symptoms. Immunosuppression (therapy to suppress the immune system) is used to treat aplastic anaemia due to an autoimmune process. Severe persistent aplastic anaemia may be fatal without a *bone marrow transplant*.

anaemia, deficiency

Forms of *anaemia* (a reduced level of the oxygen-carrying pigment *haemoglobin* in the blood) caused by lack of one or more substance that are essential for normal haemoglobin synthesis and maintenance. Deficiency anaemia may arise by various means, such as by *malabsorption* or insufficient dietary intake of a particular nutrient. *Iron-deficiency anaemia* and *megaloblastic anaemia* are examples of deficiency anaemias.

anaemia, haemolytic

A form of *anaemia* (a reduced level of the oxygen-carrying pigment *haemoglobin* in the blood) caused by premature destruction of red blood cells in the bloodstream (see *haemolysis*). The bone marrow has the capacity to increase its red cell production approximately six-fold over normal rates. Haemolytic anaemia will result only if the shortening of the lifespan of red blood cells is sufficiently severe to overcome the reserve capacity of the bone marrow.

TYPES AND CAUSES

Haemolytic anaemias can be classified in two ways: if the cause of the haemolysis is an abnormality of the red cells themselves, the condition is usually inherited; if the cause of the haemolysis is outside the cells, the condition is usually acquired later in life.

When haemolysis is due to a defect within the red cells, the underlying problem may be abnormal rigidity of the cell membrane (the thin layer of tissue surrounding each cell). This causes the cells to become trapped, at an early stage of their life-span, in the small blood vessels of the spleen, where they are destroyed by macrophages (cells that ingest foreign particles). Abnormal rigidity may result from an inherited defect of the cell membrane (as in hereditary *spherocytosis*), a defect of the

haemoglobin in the cell (as in *sickle-cell anaemia*), or a defect of one of the cell's enzymes. An inherited deficiency of the glucose-6-phosphate dehydrogenase enzyme (see *G6PD deficiency*) may result in episodes of haemolytic anaemia since the red cells are prone to damage by infectious illness or certain drugs or foods. One variety of G6PD deficiency is most common in Mediterranean countries (see *favism*).

Haemolytic anaemias due to defects outside the red cells fall into three main groups. First are disorders in which red cells are destroyed by buffeting (by artificial surfaces such as replacement heart valves, abnormal blood-vessel linings, or a blood clot in a vessel, for example). In the second group, the red cells are destroyed by the *immune system*. Immune haemolytic anaemias may occur if foreign blood cells enter the bloodstream, as occurs in an incompatible blood transfusion, or they may be due to an *autoimmune disorder* (in which the immune system attacks the body's own tissues). In *haemolytic disease of the newborn*, the baby's red cells are destroyed by antibodies, produced by the mother, crossing the placenta. Thirdly, the red cells may be destroyed by microorganisms in the blood; the most common cause is *malaria*.

SYMPTOMS

People with haemolytic anaemia may have symptoms common to all types of anaemia, such as fatigue and breathlessness, or symptoms that are specifically due to haemolysis, such as *jaundice* (caused by an excessive concentration in the blood of bile pigments formed from the destruction of red blood cells).

DIAGNOSIS AND TREATMENT

Diagnosis is confirmed by microscopic examination of the blood (see *blood film*). Treatment depends on the cause. Some inherited anaemias can be controlled by removing the spleen (see *splenectomy*). Others, such as G6PD deficiency and favism, can be prevented by avoiding the drugs or foods that precipitate haemolysis. Anaemias due to immune processes can often be controlled by *immunosuppressant drugs*. Transfusions of red cells are sometimes needed for emergency treatment of life-threatening anaemia.

anaemia, iron-deficiency

The most common form of *anaemia* (a reduced level of the oxygen-carrying pigment *haemoglobin* in the blood).

Iron-deficiency anaemia is caused by a deficiency of iron, an essential constituent of haemoglobin.

CAUSES

The commonest cause of iron-deficiency anaemia is iron loss due to heavy or persistent bleeding; the most common cause in women of childbearing age is particularly heavy periods (see *menorrhagia*). Pregnancy stops menstrual losses, but the baby is an even greater drain on maternal iron stores. Other causes include blood loss from the digestive tract due to disorders such as erosive *gastritis*, *peptic ulcer*, *stomach cancer*, *inflammatory bowel disease*, *haemorrhoids*, and bowel tumours (see *colon, cancer of*). Prolonged use of aspirin and other *nonsteroidal anti-inflammatory drugs* (NSAIDs) can cause gastrointestinal bleeding. In some countries, *hookworm infestation* of the digestive tract is an important cause of anaemia. Rarely, bleeding may also occur as a result of disorders of the urinary tract (such as *kidney tumours* or *bladder tumours*).

Iron deficiency may also be caused or worsened by lack of iron in, or its poor absorption from, the diet. Malabsorption of iron may have various causes, including the removal of part or all of the stomach (see *gastrectomy*) or *coeliac disease* (a disorder that impairs digestion).

SYMPTOMS

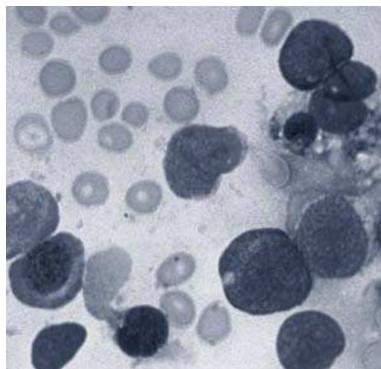

The symptoms of iron-deficiency anaemia are those of the underlying cause, along with a sore mouth or tongue; and those that are common to all forms of anaemia, such as fatigue, headaches, and breathlessness.

DIAGNOSIS AND TREATMENT

Diagnosis is made from a *blood count* that reveals the red blood cells to be microcytic (abnormally small). Measurement of the iron levels in the blood confirms the diagnosis but further investigation will be needed to establish the underlying cause. Treatment is given for the underlying cause, along with a course of iron tablets or, very rarely, iron injections in order to build up the depleted iron stores.

anaemia, megaloblastic

A major type of *anaemia* (a reduced level of the oxygen-carrying pigment haemoglobin in the blood). Megaloblastic anaemia is caused by deficiency of vitamin B_{12} or another vitamin, folic acid. Either of these deficiencies seriously interferes with the production of red blood cells in the bone marrow. An

Bone marrow in megaloblastic anaemia

In this microscopic view, some of the large cells are abnormal red-cell precursors (megaloblasts).

excess of cells known as megaloblasts (abnormal immature red cells) appears in the marrow. Megaloblasts give rise to enlarged and deformed red blood cells known as macrocytes.

CAUSES

Vitamin B_{12} deficiency Vitamin B_{12} is found only in foods of animal origin, such as meat and dairy products. It is absorbed from the small intestine by first combining with intrinsic factor, a chemical produced by the stomach lining. The most common cause of vitamin B_{12} deficiency is *pernicious anaemia* in which the stomach lining fails to produce intrinsic factor, usually as a result of an *autoimmune disorder* (in which the immune system attacks the body's own tissues). Total gastrectomy (removal of the stomach) also prevents the production of intrinsic factor, and removal of part of the small intestine prevents B_{12} absorption, as does the intestinal disorder *Crohn's disease*. In a minority of cases, vitamin B_{12} deficiency is due to a vegan diet (which excludes all foods of animal origin).

Folic acid deficiency Folic acid is found mainly in green vegetables and liver. The usual cause of deficiency is a poor diet. It can also be caused by anything that interferes with absorption of folic acid from the small intestine (*Crohn's disease* or *coeliac disease*, for example). Folic acid is required by rapidly dividing cells, as in the fetus. Women are advised to take folic acid supplements before conception and in early pregnancy, although this is to reduce the risk of the fetus having a *neural tube defect* rather than to prevent anaemia.

SYMPTOMS

Many people with mild megaloblastic anaemia have no symptoms. Others may

experience tiredness, a sore mouth and tongue, weight loss, and mild *jaundice*. If B_{12} deficiency continues for a long time, additional symptoms as a result of nerve damage, including numbness and tingling in the feet, may develop.

DIAGNOSIS AND TREATMENT

Megaloblastic anaemia is diagnosed by *blood tests* and confirmed if a *bone marrow biopsy* (removal of a small sample of marrow for microscopic analysis) reveals the presence of large numbers of megaloblasts.

Megaloblastic anaemia caused by poor diet can be remedied with a short course of vitamin B_{12} injections or folic acid tablets and the introduction of a normal diet. A lifelong course of vitamin B_{12} injections or folic acid tablets is required if the underlying cause of malabsorption is incurable.

anaemia, pernicious

See *pernicious anaemia*.

anaemia, sickle cell

See *sickle cell anaemia*.

anaerobic

Capable of living, functioning, and growing without oxygen. Many bacteria are anaerobes and thrive in the intestinal canal or in tissue that has a poor supply of oxygenated blood.

Some human body cells are capable of limited anaerobic activity. When muscular exertion is so strenuous that oxygen is used faster than the blood circulation can supply it (during sprinting, for example), the muscle cells can temporarily work anaerobically. When this happens, lactic acid is produced as a waste product (instead of the carbon dioxide that is produced from *aerobic* activity). This acid buildup can cause muscle fatigue and pain, thereby limiting the time for which anaerobic activity can be carried out. Compensation for this anaerobic activity requires oxygen to convert the lactic acid to glucose or to carbon dioxide, which explains the need to continue to breathe rapidly following vigorous exertion. The deficit of oxygen that builds up in the muscles during exercise is known as the oxygen debt.

anaesthesia

The absence of all sensation; insensibility. The term most commonly refers to anaesthesia that is induced artificially for medical purposes.

Two types of anaesthesia may be used: local (see *anaesthesia, local*) and general (see *anaesthesia, general*). A patient given a local anaesthetic remains conscious, and sensation is abolished in only a specific part of the body. A patient under general anaesthesia is rendered unconscious and maintained in this state with a combination of drugs that are either injected into a vein or inhaled.

Damage to nerve tissues by injury or disease can produce anaesthesia in a localized area.

anaesthesia, dental

Loss of sensation induced in a patient to prevent pain during dental treatment. Topical anaesthetics (usually using the drug lidocaine (lignocaine) as a cream or spray) are often used on the surface of the gums before injection of a local anaesthetic (see *anaesthesia, local*).

For minor procedures, a local anaesthetic is injected either into the gum at the site being treated or around the nerve a short distance away (a procedure known as a peripheral *nerve block*). For more complicated procedures, such as periodontal (gum) surgery and multiple tooth extractions, general anaesthesia (see *anaesthesia, general*) is carried out.

anaesthesia, epidural

See *epidural anaesthesia*.

anaesthesia, general

Loss of sensation and consciousness that is induced to prevent the perception of pain throughout the body during surgery. General anaesthesia is also used to abolish muscle tone and cardiovascular reflexes in the patient.

The state of general anaesthesia is produced and maintained by an anaesthetist, who gives combinations of drugs by injection, inhalation, or both. The anaesthetist is also responsible for the pre-anaesthetic assessment and medication of patients, their safety during surgery, and their recovery during the post-anaesthetic period.

HOW IT IS DONE

General anaesthesia is usually induced by intravenous injection of a *barbiturate drug*, usually via a *cannula* (a blunted tube), which is left in place in case further drugs need to be given. Anaesthesia is maintained by the inhalation of anaesthetic gases such as *enflurane* or halothane, which may be introduced into the lungs via a face mask or an *endotracheal tube* (a flexible

tube passed into the *trachea* through the nose or mouth). During the anaesthetic, blood pressure, pulse, oxygen saturation (see *oximeter*), and other vital signs are monitored continuously. The principal stages in administering, maintaining, and reversing general anaesthesia are shown in the illustrated box.

POSSIBLE COMPLICATIONS

General anaesthetics have become much safer and serious complications are now rare. However, the presence of severe pre-existing diseases, such as lung or heart disorders, increase the risks of the procedure. Minor after-effects, such as nausea and vomiting, are usually controlled effectively with *antiemetic drugs*.

anaesthesia, local

Loss of sensation induced in a limited region of the body to prevent pain during diagnostic or treatment procedures, examinations, and surgery. Local anaesthesia is produced by administration of drugs that temporarily interrupt the action of pain-carrying nerve fibres.

HOW IT IS DONE

Local anaesthetics may be applied topically, before injections or blood tests, as sprays, skin creams, and ointments. These

are often used for children. The throat, larynx (voice-box), and respiratory passages can be sprayed with an anaesthetic before *bronchoscopy* (examination of the bronchi, the main airways of the lungs, using a rigid or flexible viewing tube) and the urethra can be numbed with a gel before *cystoscopy* (examination of the urethra and bladder using a rigid or flexible viewing tube).

For minor surgical procedures, such as stitching of small wounds, local anaesthesia is usually produced by direct injection into the area to be treated. To anaesthetize a large area, or when a local injection would not penetrate deeply enough into body tissues, a *nerve block* (in which the local anaesthetic is injected around nerves at a point remote from the area to be treated) may be used. Nerve impulses can also be blocked where they branch off from the spinal cord, as in *epidural anaesthesia*, which is used in childbirth or caudal block, and *spinal anaesthesia*, which is used for surgery on the lower limbs and abdomen.

POSSIBLE COMPLICATIONS

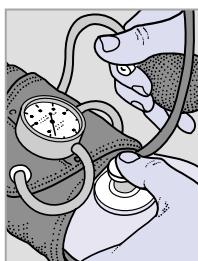

Serious reactions are uncommon, but repeated use of topical preparations may cause local allergic rashes.

LOCAL ANAESTHETICS

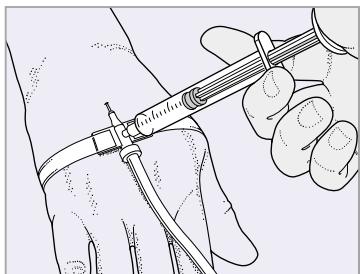

Drug	Common uses	How taken
tetracaine (amethocaine)	Prior to taking a blood sample or inserting a cannula	Gel
benzocaine	To treat painful conditions of the mouth and throat, painful anal conditions (e.g. haemorrhoids), skin wounds	Lozenges, suppositories, spray, cream, ointment
bupivacaine	As nerve block (e.g. epidural anaesthesia and caudal block)	Injection
cocaine	For surgery on the nose, throat and larynx	Spray, liquid
lidocaine (lignocaine)	For relief of pain during dental treatment; for spinal anaesthesia, nerve blocks (e.g. epidural anaesthesia), eye surgery, and before taking blood samples in children; for urethra prior to catheterization and larynx prior to laryngoscopy	Injection, gel, spray, cream, ointment, liquid, eye-drops, suppositories
prilocaine	As nerve block (e.g. epidural anaesthesia and caudal block)	Injection

TECHNIQUES FOR GENERAL ANAESTHESIA

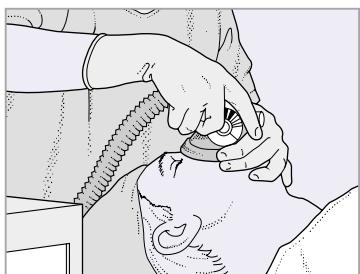

The main phases in the administration of a general anaesthetic are induction (bringing about unconsciousness), maintenance (of unconsciousness), and emergence (returning the patient to consciousness). Some of the main stages are shown below. Often, to allow surgical manipulation, a muscle relaxant must be given in addition to anaesthetic gases or injections. Because the relaxant temporarily paralyses the breathing muscles, the patient's lungs must be ventilated artificially. Modern general anaesthetics have few side effects, and recovery is usually prompt.

1 Before the operation, the anaesthetist talks to and examines the patient to assess his or her fitness for anaesthesia and surgery. He or she also answers any questions the patient may have.

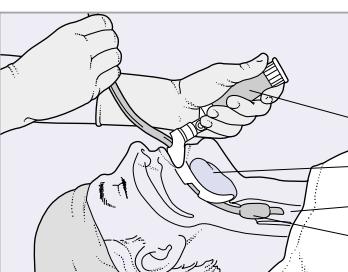

2 The induction agent is usually given via a cannula inserted into a vein. The cannula is left in position so that other drugs can be given rapidly if needed.

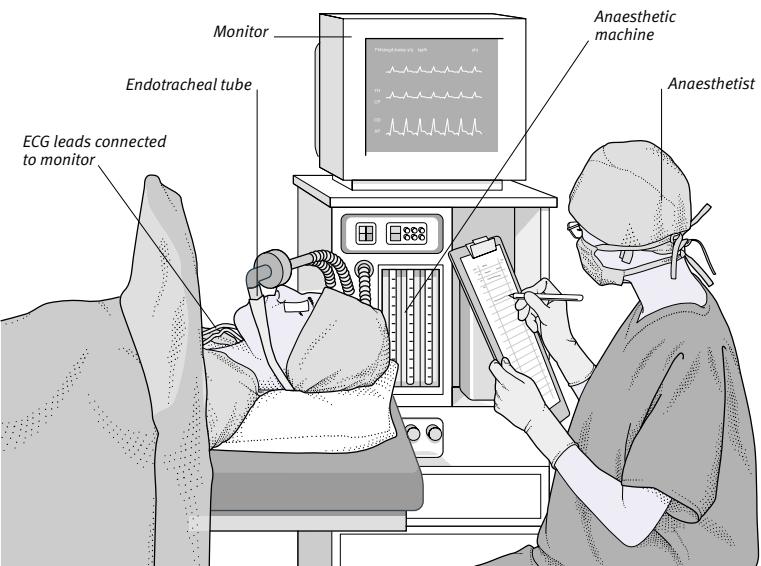

3 Sometimes, anaesthesia is induced or maintained with gases delivered by mask. If no muscle relaxant is used, the patient may be able to continue breathing naturally.

DRUGS USED IN GENERAL ANAESTHESIA

Type	Action	Examples
Drugs given as premedication	Relax patient, relieve anxiety; some reduce saliva and mucus formation	Atropine, diazepam, hyoscine, lorazepam, temazepam
Induction agents	Induce unconsciousness	Etomidate, ketamine, propofol, thiopental sodium
Anaesthetic gases and volatile agents	Induce and/or maintain unconsciousness	Enflurane, halothane, isoflurane, nitrous oxide
Analgesics	Abolish pain	Fentanyl, ketoprofen, morphine
Muscle relaxants	Relax (paralyse) muscles	Pancuronium, vecuronium
Reversal agents	Reverse muscle relaxation	Neostigmine

4 In other cases, an endotracheal tube is inserted for delivery of the anaesthetic gases. If a muscle relaxant is used, artificial ventilation is necessary.

5 During surgery, the patient is kept at a level of anaesthesia deep enough for him or her to be unaware of the operation. The composition of the gas mixture, and the patient's heart rate, breathing, blood pressure, temperature, blood oxygenation, and exhaled carbon dioxide are monitored. After surgery, anaesthesia is stopped, and reversal agents are given if necessary.

anaesthesia, spinal

See *spinal anaesthesia*.

anaesthetics

A term for the group of drugs that produce *anaesthesia* and for the medical discipline that is concerned with their administration.

An anaesthetist is a specialist who administers anaesthetics. Before a patient goes to the operating theatre, the anaesthetist assesses the condition of the patient's heart, lungs, and circulation. He or she decides the type and amount of drugs needed to induce and maintain anaesthesia, determines the patient's position on the operating table, watches for problems, and decides on the action to be taken if an emergency develops. The anaesthetist is also responsible for monitoring the progress of the waking patient, and watching for and treating any post-anaesthetic complications.

anal dilatation

A procedure in which the anus is stretched. Anal dilatation is used to treat conditions in which the anus becomes too tight, such as *anal stenosis* and *anal fissure*. It is also used to treat *haemorrhoids*. Anal dilatation is usually performed under general anaesthesia (see *anaesthesia, general*).

Reflex anal dilatation, in which the anus dilates in response to local contact, may occur in certain anal disorders or after repeated anal penetration.

anal discharge

The loss of mucus, pus, or blood from the anus. *Haemorrhoids*, *anal fissures* (tears), and *proctitis* (inflammation of the rectum) can all cause anal discharge.

analeptic drugs

Drugs that stimulate breathing. Replaced by *ventilation*, analeptic drugs are now seldom used.

anal fissure

A common disorder of the anus that is caused by an elongated ulcer or tear that extends upwards into the anal canal from the anal sphincter (the ring of muscle that surrounds the anal orifice). An anal fissure may be caused by the passage of hard, dry faeces.

There is usually pain during defaecation, and the muscles of the anus may go into spasm. There may also be a small amount of bright red blood on faeces or toilet paper.

The tear often heals naturally over a few days, although spasm of the anal muscles may delay healing. Treatment of recurrent or persistent fissures is usually by *anal dilatation* (a procedure to enlarge the anus) and a high-fibre diet, including whole-grain products, fruit and vegetables, and plenty of fluids, to help soften the faeces. Surgery to remove the fissure is occasionally necessary.

anal fistula

An abnormal channel connecting the inside of the anal canal with the skin surrounding the anus.

An anal fistula may be an indication of *Crohn's disease*, *colitis*, or cancer of the colon or rectum (see *colon, cancer of; rectum, cancer of*). In most cases, it is the result of an *abscess* that develops for unknown reasons in the anal wall. The abscess discharges pus into the anus and out on to the surrounding skin.

An anal fistula is treated surgically by opening the abnormal channel and removing the lining. The operation is performed under a general anaesthetic (see *anaesthesia, general*). The wound is then left to heal naturally.

analgesia

The loss of or reduction in pain sensation. Analgesia differs from *anaesthesia* (loss of all sensation) in that sensitivity to touch is still preserved. Analgesia can be induced by the use of *analgesic drugs*.

analgesic drugs**COMMON DRUGS**

- OPIOIDS** • Co-codamol • Co-codaprin • Codeine
- Co-dydramol • Co-proxamol • Diamorphine
- Dipipanone • Fentanyl • Meptazinol
- Methadone • Morphine • Pentazocine
- Pethidine • Phenazocine • Tramadol
- NSAIDS** • Aspirin • Celecoxib • Diclofenac
- Diflunisal • Etodolac • Fenbufen
- Fenoprofen • Flurbiprofen • Ibuprofen
- Indomethacin • Ketoprofen • Ketorolac
- Mefenamic acid • Naproxen • Piroxicam
- Rofecoxib

OTHER NONOPIOIDS • Nefopam • Paracetamol

Drugs used to relieve pain. The two main types are nonopioid and *opioid* analgesics. Nonopioid analgesics are useful for treating mild to moderate pain. They include *paracetamol* for headache; or toothache and nonsteroidal anti-inflammatory drugs (NSAIDs) such as *aspirin* and *ibuprofen*, which can help to relieve mild pain and stiffness in arthritic conditions. Combinations of a

weak opioid (such as *codeine*) with a nonopioid analgesic (such as aspirin) relieve more severe pain. Potent opioids such as *morphine* can produce *tolerance* and *drug dependence* and are used only when other preparations are ineffective.

HOW THEY WORK

When body tissues are damaged, they produce *prostaglandins* (chemicals that trigger the transmission of pain signals to the brain). Except for paracetamol, nonopioid analgesics work by preventing the production of prostaglandin; paracetamol works by blocking the pain impulses within the brain itself, preventing the perception of pain. Opioid analgesics act in a similar way to *endorphins* (pain-relieving substances formed by the body) by blocking pain impulses at specific sites in the brain and spinal cord.

SIDE EFFECTS

Side effects are uncommon with paracetamol; aspirin and most NSAIDs may irritate the stomach lining and cause nausea, abdominal pain, and, rarely, a *peptic ulcer*. Nausea, drowsiness, constipation, and breathing difficulties may occur with opioid analgesics. The euphoric effect produced by some opioid analgesics have led to their abuse.

WARNING

Over-the-counter (nonopioid) analgesic drugs should not be taken for longer than 48 hours, after which time medical advice should be sought. If pain persists, becomes more severe, recurs, or differs from pain previously experienced, a doctor should be consulted. For precautions on specific drugs, see the individual drug entries.

anal phase

A term used in *psychoanalytic theory* to refer to a stage of a person's psychosexual development. The anal phase begins at around 18 months of age and lasts for up to two years. (See also *genital phase*; *oral phase*.)

anal stenosis

Tightness of the anus, sometimes known as anal stricture. Anal stenosis prevents normal passage of faeces, causing constipation and pain during defaecation.

Anal stenosis may be present from birth or may be caused by a number of conditions in which scarring has occurred, such as *anal fissure*, *colitis*, or cancer of the anus. The condition sometimes occurs after surgery on the anus (for example, to treat *haemorrhoids*).

Anal stenosis is treated by *anal dilatation* (a procedure that expands or enlarges the anus).

anal stricture

See *anal stenosis*.

anal tag

A type of *skin tag*.

analysis, chemical

Determination of the identity of a substance or of the individual chemical constituents of a mixture. Analysis may be qualitative (as in determining whether or not a particular substance is present), or it may be quantitative (that is, measuring the amount or concentration of one or more constituents). (See also *assay*.)

analysis, psychological

See *psychoanalysis*.

anaphylactic shock

A rare, life-threatening allergic reaction. Anaphylactic shock is a Type I hypersensitivity reaction (see *allergy*) that occurs in people with extreme sensitivity to a particular substance (an allergen), most commonly insect venom or certain foods or drugs.

When the allergen enters the bloodstream, massive amounts of *histamine* and other chemicals are released, causing sudden, severe lowering of blood pressure and constriction of the airways. Other symptoms of anaphylactic shock may include abdominal pain, diarrhoea, swelling of the tongue and throat, and an itchy rash.

Anaphylactic shock requires emergency medical treatment. An injection of *adrenaline* (epinephrine) may be life-saving. If the person's breathing or heartbeat has stopped, *cardiopulmonary resuscitation* should be performed, and

antihistamine drugs and *corticosteroid drugs* may also be given. (See also *hyposensitization*.)

anastomosis

A natural or artificial communication between two blood vessels or between tubular cavities that may or may not normally be joined.

Natural anastomoses usually occur when small *arteries* are attached directly to *veins* without passing through capillaries. Anastomoses occur in the skin where they are used to help control temperature regulation.

A surgical anastomosis is used to create a bypass around a blockage in an artery or in the intestine. They are also used to rejoin cut ends of the bowel or blood vessels. (See also *bypass surgery*.)

anastrozole

An *anticancer drug* that is used to treat advanced *breast cancer* in postmenopausal women.

anatomical snuffbox

A depression on the back of the wrist that is formed between the tendons of the thumb when the thumb is stretched outwards. The anatomical snuffbox is of significance because tenderness in this area is a feature of a fracture of the *scaphoid* bone.

anatomy

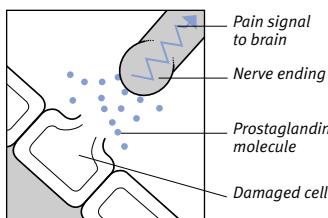

The structure of the body of any living thing, and its scientific study. Human anatomy, together with *physiology* (the study of the functioning of the body), dates back to ancient Egyptian times and forms the foundation of all medical science. The dissection of human corpses has provided the primary source of information for anatomists.

Anatomy as a scientific study today is subdivided into many branches. These include comparative anatomy (the study of the differences between human and animal bodies), surgical anatomy (the practical knowledge required by surgeons), *embryology* (the study of structural changes that occur during the development of the embryo and fetus), systematic anatomy (the study of the structure of particular body systems), and *cytology* and *histology* (the microscopic study of cells and tissues respectively).

Every anatomical structure is scientifically named in Latin, but today anatomists prefer to use simpler terms,

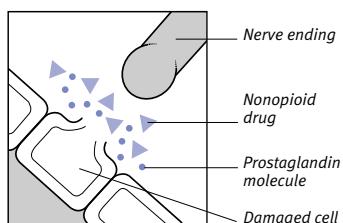

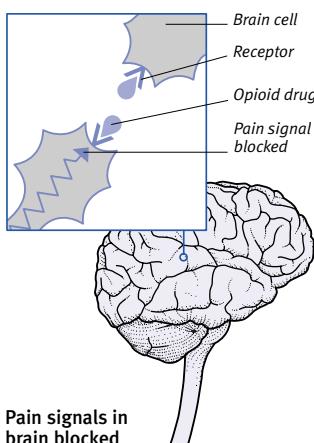

HOW ANALGESICS WORK

When tissue is damaged (for example, by injury, inflammation, or infection) the body produces prostaglandins. These substances combine with receptors (specific sites on the surface of cells in the brain and spinal cord). As a result, a signal is passed along a series of nerve cells to the brain, where the signal is interpreted as pain by brain cells. Analgesics (except for paracetamol) work either by preventing the production of prostaglandins at the site of damage or by blocking pain impulses in the brain and spinal cord. Paracetamol works by blocking prostaglandin production in the brain, which prevents pain impulses from being transmitted in the brain.

Action of opioids

When tissue damage occurs, the body produces prostaglandins, chemicals that trigger the transmission of pain signals (above). Normally, the pain signal is transmitted between brain cells, but opioid drugs (below) combine with opiate receptors to prevent the signals from being transmitted.

Action of NSAIDs

Non-opioid drugs block the production of prostaglandins (chemicals released in response to tissue damage). This action prevents stimulation of the nerve endings, so that no pain signal passes on to the brain. As a result, these drugs provide pain relief.

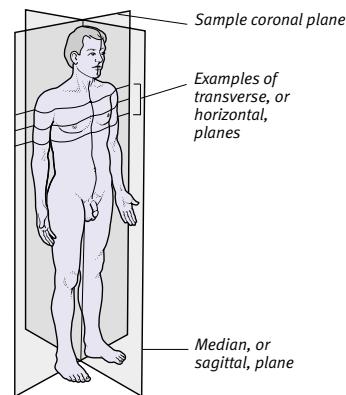

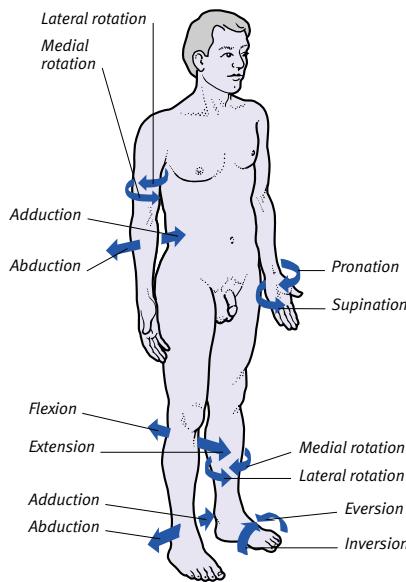

DESCRIPTIVE TERMS IN ANATOMY

The relative positions and movements of body parts are conventionally described with reference to the “anatomical position” (that is, an upright posture with the eyes and palms facing forwards). In this position, the parts of the body can be described in relation to various geometrical planes.

In radiology, body imaging pictures (such as CT scans and MRI) are often taken in a series of transverse planes through part of the body.

Joint movements

Extension is straightening, and flexion is bending; abduction is moving away from, adduction is moving towards, the midline of the body. Other movements are forms of rotation around an axis.

**Planes through the body**

The median plane divides the body into right and left halves. Coronal planes are vertical planes at right angles to the median plane; the coronal plane most often referred to divides the body into front and back halves. Transverse planes are horizontal slices through the body.

where they exist, as alternatives. For example, the main blood vessel in the femur (thigh) is usually referred to as the femoral artery rather than the arteria femoralis. For further information on the descriptive terms used in anatomy, see the illustrated box.

ancylostomiasis

Infestation of the small intestine by the *ANCYLOSTOMA* hookworm species. (See also *hookworm infestation*.)

androblastoma

See *arrhenoblastoma*.

androgen drugs

Natural or synthetic *androgen hormones* (male sex hormones) that are used as drugs, of which one of the most important is *testosterone*. Androgen drugs are used in the treatment of male *hypogonadism* (underactivity of the testes) to stimulate the development of male sexual characteristics.

Androgen drugs are occasionally used to treat certain types of *breast cancer*. They have also been widely used by athletes and bodybuilders wishing to increase their muscle bulk and strength, which can be dangerous to health (see *steroids, anabolic*).

Possible side effects include fluid retention, weight gain, increased blood cholesterol, and, rarely, liver damage.

When taken by women, the drugs can lead to the development of male characteristics, such as facial hair.

androgen hormones

A group of hormones (the male sex hormones) that stimulate *virilization* (the development of male secondary sexual characteristics such as growth of facial hair, deepening of the voice, and increased muscle bulk).

FORMATION

Androgens are produced by specialized cells in the *testes* in males and the adrenal glands in both sexes. The ovaries secrete very small quantities of androgens until the menopause. The most active androgen is *testosterone* (produced in the testes). Androgen production by the testes is controlled by certain pituitary hormones called *gonadotrophins*. Adrenal androgens are controlled by *ACTH*, another pituitary hormone.

EFFECTS

Androgens stimulate the appearance, at *puberty*, of male secondary sexual characteristics such as deepening of the voice and the growth of facial hair. They have an anabolic effect (they raise the rate of protein synthesis and lower the rate at which it is broken down), which increases muscle bulk and accelerates growth. At the end of puberty, androgens cause the long bones to stop growing. They also stimulate the secre-

tion of sebum, which, if excessive, causes *acne*. In early adult life, androgens promote male-pattern baldness.

DEFICIENCY

Androgen deficiency may occur if the testes are diseased or the pituitary gland fails to secrete gonadotrophins. Typical effects include high-pitched voice, decreased body and facial hair, underdeveloped genitalia, reduced sexual drive, and poor muscle development.

EXCESS

Overproduction of androgens may be the result of adrenal disorders such as *adrenal tumours*, congenital adrenal hyperplasia (see *adrenal hyperplasia, congenital*), testicular tumours (see *testis, cancer of*), or, rarely, androgen-secreting ovarian tumours (see *ovary, cancer of*).

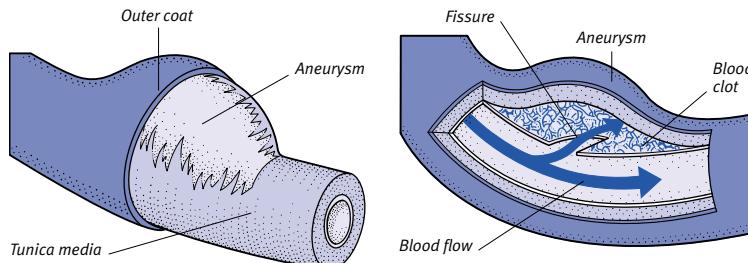

In men, excess androgens accentuate male physical characteristics; in boys, they cause premature sexual development. In women, excess androgens cause virilization, features of which include increased body hair, deepening of the voice, enlarged *clitoris*, and *amenorrhoea* (the absence of menstruation).

anencephaly

Absence of the brain and cranial vault (top of the skull) at birth. Most infants with anencephaly are stillborn or survive for only a few hours. Anencephaly is detectable early in pregnancy by measurement of the maternal *alpha-fetoprotein*,

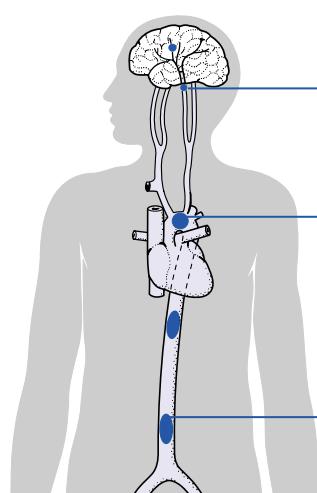

TYPES OF ANEURYSM

An aneurysm forms when pressure from the blood flow causes a weakened artery wall to distend or forces blood through a fissure. Aneurysms can form anywhere in the body, although the most common sites are the aorta and the arteries supplying the brain.

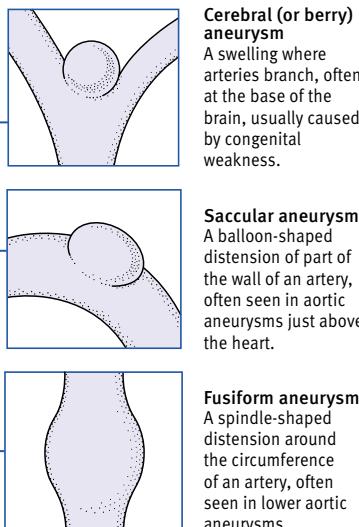

Common aneurysm

This type forms when the tunica media, the artery's middle wall, is weakened; the strong force of the blood flow distends the wall of the artery.

Dissecting aneurysm

In this type, blood is forced through a fissure in the internal wall of the artery. The internal lining is stripped away, forming a false channel.

by *ultrasound scanning*, by *amniocentesis*, or by *fetoscopy*; if anencephaly is detected, termination of the pregnancy may be considered (see *abortion, induced*).

Anencephaly is caused by a failure in the development of the neural tube, which is the nerve tissue in the embryo that normally develops into the spinal cord and brain (see *neural tube defects*).

aneurysm

Abnormal dilation (ballooning) of an *artery* caused by the pressure of blood flowing through a weakened area. The weakening may be due to disease, injury, or a congenital (present from birth) defect of the arterial wall.

Aneurysms most commonly affect the *aorta* and arteries supplying the brain.

TYPES AND CAUSES

The most common cause of an aneurysm is *atherosclerosis*, a condition in which fatty deposits weaken the artery wall. The aorta is the usual site of atherosclerotic aneurysms.

Less commonly, aneurysms may be due to a congenital (present from birth) weakness of the artery walls. Most cerebral aneurysms, known as *berry aneurysms* because of their appearance, are congenital. *Marfan syndrome*, an inherited disorder in which the wall of the aorta is defective, is often associated with aneurysms just above the heart. The

arterial wall can also be weakened by inflammation, as occurs in *polyarteritis nodosa*. A dissecting aneurysm is one in which the inner layer of the artery wall ruptures, allowing blood to track along the length of the artery and block any branching arteries. Ventricular aneurysms are aneurysms that sometimes develop in the heart wall due to weakening of an area of heart muscle as a result of a heart attack (see *myocardial infarction*).

Some of the common types, sites, and shapes of aneurysm are shown in the illustrated box.

SYMPTOMS AND SIGNS

Most aneurysms are symptomless and remain undetected. However, if the aneurysm expands rapidly and causes pain, or is very large, the symptoms are due to pressure on nearby structures. Aneurysms may eventually rupture, cause fatal blood loss, or, in the case of a cerebral aneurysm, loss of consciousness (see *subarachnoid haemorrhage*). A *dissecting aneurysm* usually causes severe pain, and there is a high risk of the vessel rupturing. Ventricular aneurysms seldom rupture, but they interfere with the pumping action of the heart.

DIAGNOSIS AND TREATMENT

Aneurysms of the aorta may be detected by *ultrasound scanning*, and cerebral aneurysms by *CT scanning* or *MRI*. *Angiography* can provide more detailed information on all types of aneurysm. A ruptured or enlarged aneurysm requires immediate *arterial reconstructive surgery*. (See also *microaneurysm*.)

angina

A strangling or constrictive pain. The term angina has become synonymous with the heart disorder *angina pectoris*. Other types of angina include abdominal angina (abdominal pain after eating caused by poor blood supply to the intestines) and Vincent's angina, which is pain caused by inflammation of the mouth (see *Vincent's disease*).

angina pectoris

Pain in the chest that is the result of insufficient oxygen being carried to the heart muscle in the blood. The pain of angina pectoris usually occurs when the heart is working harder and requires more oxygen, such as during exercise or at times of stress.

CAUSES

Inadequate blood supply to the heart is usually due to *coronary artery disease*, in which the coronary arteries are

narrowed by *atherosclerosis* (fat deposits on the artery walls). Other causes include coronary artery spasm, in which the blood vessels narrow suddenly for a short time, *aortic stenosis*, in which the heart's aortic valve is narrowed, and *arrhythmias* (abnormal heart rhythms).

The pain of angina pectoris is brought on by exertion and is relieved by rest. If the pain continues, it may be due to a heart attack (see *myocardial infarction*). Rarer causes of the pain include severe *anaemia*, which reduces the blood's oxygen-carrying efficiency, and *polycythaemia*, which thickens the blood and causes its flow through the heart muscle to slow down.

SYMPTOMS

The chest pain of angina varies from mild to severe and is often described as a sensation of pressure on the chest. The pain usually starts in the centre of the chest but can spread to the throat, upper jaw, back, and arms (usually the left), or between the shoulderblades. If it develops during sleep or without provocation, it is called unstable angina.

Other possible symptoms of angina pectoris include nausea, sweating, dizziness, and breathing difficulty.

DIAGNOSIS AND TREATMENT

Diagnostic tests usually include an *ECG* (measurement of the electrical activity of the heart), which may register normal between attacks, and a *cardiac stress test* (an ECG undertaken while the patient is exercising enough to cause chest pain). Blood tests and coronary *angiography* (*X-ray* examination of the blood vessels) may also be performed to look for an underlying cause.

To help to control the symptoms of angina pectoris, it is important for the person to stop smoking and to lose weight if necessary. Attacks may be prevented and treated by *nitrate drugs*, which increase blood flow through the heart muscle. *Beta-blocker drugs*, *calcium channel blockers*, *lipid-lowering drugs*, and *antiplatelet drugs* may also be prescribed.

Drug treatment can control the symptoms for many years but cannot cure the disorder. If attacks become more severe or more frequent, despite treatment, *coronary artery bypass surgery* or *angioplasty* may be necessary.

angina, Prinzmetal's

A type of unstable angina pectoris (see *angina, unstable*) in which the attacks of chest pain occur while the body is at rest and are not brought on by exertion.

angina, unstable

A type of *angina pectoris* (chest pain due to impaired blood supply to the heart muscle) that occurs during sleep or without provocation (such as exertion).

angioedema

A type of reaction caused by *allergy*. Angioedema is similar to *urticaria* (hives) and is characterized by large, well-defined swellings, of sudden onset, in the skin, larynx (voice-box), and other areas. If they are left untreated, the swellings may last a number of days.

CAUSES

The most common cause of angioedema is a sudden allergic reaction to a food. Less commonly, the condition may be due to a drug allergy (such as to *penicillin*), a reaction to an insect bite or sting, or it may occur as a result of infection, emotional stress, or exposure to animals, moulds, pollens, or cold conditions. There is also a hereditary form of angioedema.

SYMPTOMS

Angioedema may cause sudden difficulty in breathing, swallowing, and speaking, accompanied by swelling of the lips, face, and neck, depending on the area of the body affected.

Angioedema that affects the throat and the larynx is potentially life-threatening because the swelling can block the airway, causing asphyxia (suffocation).

TREATMENT

Severe cases are treated with injections of *adrenaline* (epinephrine) and may require intubation (a breathing tube inserted via the mouth into the windpipe) or *tracheostomy* (surgical creation

of a hole in the windpipe) to prevent suffocation. *Corticosteroid drugs* may also be given. In less severe cases, *antihistamine drugs* may relieve symptoms.

angiogenesis

The growth of new blood vessels. Angiogenesis is the process that enables tumours to grow: cancerous cells produce chemicals (called *growth factors*) that stimulate new blood vessels to form near the tumour, supplying it with nutrients and oxygen.

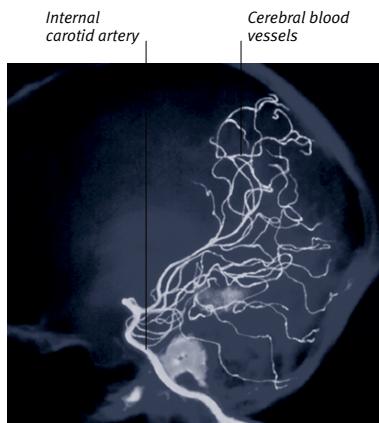

angiography

An imaging procedure that enables blood vessels to be seen clearly on X-ray film following the injection of a *contrast medium* (a substance that is opaque to X-rays). Digital subtraction angiography uses computer techniques to process images and remove unwanted background information. Magnetic resonance angiography (MRA) can produce images of blood vessels without the use of a contrast medium.

WHY IT IS DONE

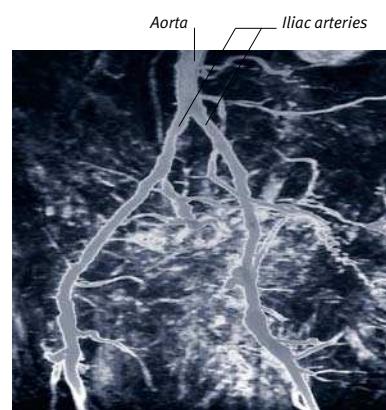

Angiography is used to detect conditions that alter the appearance of blood vessels, such as an *aneurysm* (ballooning of an artery) and narrowing or blockage of blood vessels by *atherosclerosis* (fatty deposits lining artery walls), a *thrombus* (abnormal clot), or an *embolus* (fragment of a clot that is carried in the blood). Angiography is also used to detect changes in the pattern of blood vessels that supply organs injured or affected by a tumour.

Carotid angiography (angiography of the arteries in the neck) may be used to

Angiogram of brain

Contrast medium is passed through a catheter into the arteries at the back of the brain, and a series of X-rays is taken.

Magnetic resonance angiogram of groin

This MRA provides a clear image of the arteries of the groin area without the need for X-rays or the injection of radio-opaque dye.

investigate *transient ischaemic attacks* (symptoms of *stroke* lasting for less than 24 hours). Cerebral angiography can be used to detect an aneurysm in the brain or to pinpoint the position of a brain tumour. Coronary angiography, often combined with cardiac *catheterization*, can identify sites of narrowing or blockage in *coronary artery disease*.

During angiography, some types of treatment, such as balloon angioplasty (see *angioplasty, balloon*) and *embolization*, that sometimes eliminate a previous need for surgery may be carried out. (See also *aortography*.)

angioma

A noncancerous tumour made up of blood vessels (see *haemangioma*) or lymph vessels (see *lymphangioma*).

angioplasty, balloon

A technique for widening a narrowed or blocked section of blood vessel by the introduction of a balloon-tipped catheter (flexible tube) into the constricted area of the vessel.

The balloon is inflated to widen the narrowed area, deflated, then removed. Balloon angioplasty is used to increase or restore blood flow in a significantly narrowed artery in *peripheral vascular disease* and *coronary artery disease*.

Coronary balloon angioplasty is usually successful in the short term, but narrowing of the affected vessel may recur, requiring repeat treatment. Angioplasty of peripheral vessels is most successful in treating the iliac and femoral arteries in the legs. Results have improved further with the introduction

of stents (metal mesh structures), which are inserted into an artery following balloon dilation to help keep the blood vessel open.

angiotensin

The name of two related proteins involved in regulating blood pressure. The first, angiotensin I, is inactive and is formed when renin, which is produced by the kidneys, acts on the substance angiotensinogen. Angiotensin I is then converted to the second, active, form, angiotensin II, by angiotensin-converting enzyme.

Angiotensin II causes narrowing of the small blood vessels in tissues, resulting in increased blood pressure. It also stimulates release (from the adrenal cortex, the outer part of each *adrenal gland*) of the hormone *aldosterone*, which also increases blood pressure.

Certain kidney disorders can increase the production of angiotensin II, resulting in *hypertension* (high blood pressure). Hypertension can be treated with *ACE inhibitor drugs*, which reduce the formation of angiotensin II, or with angiotensin II antagonists.

angiotensin-converting enzyme

A substance that converts angiotensin I to its active form, angiotensin II. Drugs that reduce the action of angiotensin-converting enzyme are known as *ACE inhibitor drugs* and are used in the treatment of *hypertension* (high blood pressure) and *heart failure* (reduced pumping efficiency of the heart).

angiotensin-II antagonists

COMMON DRUGS

- Candesartan • Irbesartan • Losartan
- Valsartan

A group of drugs used in the treatment of *hypertension* (high blood pressure). Angiotensin-II antagonists have a similar action to *ACE inhibitor drugs* (in that they block the action of *angiotensin II*) but do not cause the persistent dry cough that is a common side effect of treatment with ACE inhibitors.

angular stomatitis

See *stomatitis*.

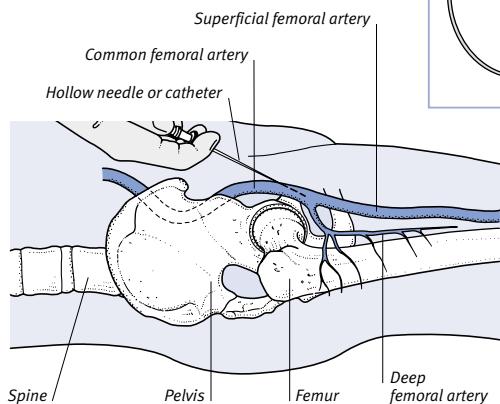

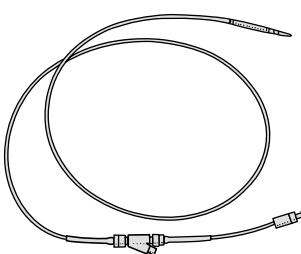

anhedonia

Total loss of the feeling of pleasure from activities that would normally give pleasure. Anhedonia is often one of the common symptoms of *depression*.

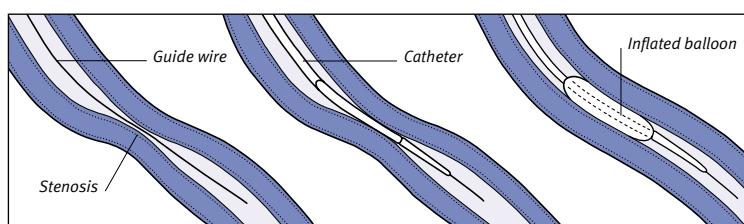

PROCEDURE FOR BALLOON ANGIOPLASTY

A blockage or narrowing of a blood vessel may be treated by introducing a balloon catheter into the area and then inflating the balloon to stretch the constricted part. The balloon is then deflated and the catheter withdrawn. The procedure is carried out using a local anaesthetic.

BALLOON CATHETER

How it is done
A hollow needle is inserted into the femoral artery (left). A guide wire is pushed through the needle into the artery, then along it (using X-ray imaging) towards the blood vessel or heart valve to be treated. Then the steps shown below are carried out.

1 The thin guide wire is manoeuvred through the arteries (using X-ray control) until it is just past the stenosis (narrowing) to be treated.

2 A balloon-tipped catheter (top right) is then threaded over the guide wire and pushed along it until it reaches the narrowed area.

3 A sausage-shaped balloon at the end of the catheter is inflated and deflated a few times, to widen the narrowed part, and then withdrawn.

anhidrosis

Complete absence of sweating. (See also *hypohidrosis*.)

animal experimentation

The use of live animals in research and safety testing to provide information about animal biology or, by inference, human physiology or behaviour. Animal research has contributed to the development of surgical techniques, such as transplant surgery and drugs, such as vaccines. Due to ethical concerns, however, alternative practices, such as cell cultures, are now used whenever possible.

animals, diseases from

See *zoonosis*.

anion

An *ion* of negative charge, such as a chloride ion. (See also *electrolyte*.)

anisometropia

Unequal focusing power in the two eyes, usually due to a difference in size and/or shape of the eyes, that causes visual discomfort. For example, one eye may be normal and the other affected by *myopia* (shortsightedness), *hypermetropia* (longsightedness), or *astigmatism* (uneven curvature of the cornea). Glasses or contact lenses correct the problem in most cases.

ankle joint

The hinge joint between the foot and the leg. The talus (uppermost bone in the foot) fits between the two bony

protuberances formed by the lower ends of the tibia (shinbone) and the fibula (outer bone of the lower leg). Strong ligaments on either side of the ankle joint give it support. The ankle joint allows for up-and-down movement of the foot.

DISORDERS

An ankle *sprain* is one of the most common injuries. It is usually caused by twisting of the foot over on to its outside edge, which causes overstretching and bruising of the ligaments. Severe sprains can result in tearing of the ligaments, which may need to be repaired surgically.

Violent twisting of the ankle can result in a combined fracture and dislocation, known as *Pott's fracture*, in which the fibula breaks above the ankle and either the tibia breaks or the ligaments tear, resulting in dislocation of the ankle.

ankylosing spondylitis

An uncommon inflammatory disease affecting joints between the vertebrae of the spine and the sacroiliac joints (the joints between the spine and the pelvis). Ankylosing spondylitis may also affect other large joints, such as those in the hips.

CAUSES AND INCIDENCE

The cause of ankylosing spondylitis is usually unknown, but in some cases the disease may be associated with *colitis* (inflammation of the colon) or *psoriasis* (a skin disease). Ankylosing spondylitis may run in families; and about 90 per cent of people with the condition have the genetically determined *histocompatibility antigen* (HLA-B27).

SYMPTOMS

Ankylosing spondylitis usually starts with pain and stiffness in the hips and lower back that are worse after resting and are especially noticeable in the early morning. Other, less common, symptoms include chest pain, painful heels due to additional bone formation, and redness and pain in the eyes due to *iritis* (inflammation of the iris). In time, inflammation in the spine can lead to *ankylosis* (permanent stiffness and limited movement) and *kyphosis* (curvature of the spine).

DIAGNOSIS AND TREATMENT

Ankylosing spondylitis can be diagnosed by *X-rays* and *blood tests*. There is no cure, but treatment with a programme of exercise and physiotherapy and *anti-inflammatory drugs* can reduce the pain

and limitation of movement. In some cases, DMARDs (see *disease-modifying antirheumatic drugs*) are also prescribed. To prevent curvature of the spine, patients are taught breathing exercises and exercises to improve posture.

ankylosis

Complete loss of movement in a joint that results from fusion of the bony surfaces. Ankylosis may be caused by degeneration as a result of inflammation, infection, or injury. The condition can also be produced surgically by an operation to fuse a diseased joint to correct deformity or to alleviate persistent pain (see *arthrodesis*). (See also *ankylosing spondylitis*.)

annular

A term meaning shaped like a ring. Annular is a description applied to certain body structures, such as ligaments, and, in dermatology, to the appearance of skin rashes, such as ringworm. The term may also be applied to a cancer that encircles an organ.

anodontia

Failure of some or all of the teeth to develop. Anodontia, which can be partial or total, may be due to the absence of tooth buds at birth, or it may be the result of damage to developing tooth buds by infection or other widespread disease. Both primary and permanent teeth may be affected. Partial anodontia is far more common than total.

If only a few teeth are missing, a dental *bridge* (false teeth that are attached to natural teeth on either side of the gap) can be fitted. If all the teeth are missing, a *denture* is required. Recently, however, dental implants (see *implant, dental*) have become the treatment of choice in selected cases (in which the individual has the correct anatomy and bone density).

anomaly

A deviation from what is accepted as normal, especially a birth defect such as a limb malformation.

Anopheles

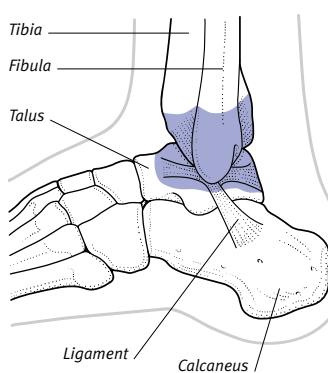

A genus of disease-transmitting mosquitoes, many species of which are carriers of *malaria*. (See also *mosquito bites*.)

anorexia

The medical term for loss of appetite (see *appetite, loss of*).

LOCATION OF THE ANKLE JOINT

The hinge joint is formed where the top of the talus fits in between the lower ends of the tibia and fibula.

FEATURES OF ANOREXIA NERVOSA

- Weight loss
- Overactivity and obsessive exercising
- Tiredness and weakness
- Lanugo (babylight) hair on body, thinning of hair on head
- Extreme choosiness over food
- Binge eating
- Induced vomiting
- Use of laxatives to promote weight loss

anorexia nervosa

An eating disorder that is characterized by severe weight loss and altered self-image that leads sufferers to believe that they are fat even when they are, in fact, dangerously underweight.

CAUSES AND INCIDENCE

The causes of anorexia are unclear, but the condition may be linked to a lack of self-worth that leads to excessive concern over physical appearance. Sufferers may feel that they can have some control over their lives by controlling their eating. Normal dieting may develop into starvation.

Anorexia nervosa most commonly affects teenage girls and young women, but the incidence in young men is rising.

SYMPTOMS AND SIGNS

In the early stages, sufferers may be overactive and may exercise excessively. They are obsessed with food, and often make complicated meals for others, but are reluctant to eat socially and avoid eating the meals themselves. As their weight loss continues, they become tired and weak, the skin becomes dry, lanugo hair (fine, downy hair) grows on the body, and normal hair becomes thinner. Starvation leads to *amenorrhoea* (the absence of menstrual periods) in many women.

Some sufferers of anorexia nervosa have food binges and then make themselves vomit, or take *laxative drugs* or *diuretic drugs*, to promote weight loss (see *bulimia*). Chemical imbalances as a result of starvation, with or without vomiting, can cause potentially fatal cardiac *arrhythmias*.

TREATMENT AND OUTLOOK

Hospital treatment is often necessary and is usually based on a closely controlled feeding programme combined with *psychotherapy* or *family therapy*. For some people, *antidepressant drugs* may be helpful. Many sufferers relapse after treatment, and long-term psychotherapy is required.

anorgasmia

Inability to achieve orgasm (see *orgasm, lack of*).

anosmia

Loss of the sense of *smell*.

anovulatory menstruation

The occurrence of a menstrual cycle during which there is no *ovulation* (release of an egg from the ovary). Anovulatory menstruation is often the result of reduced production of the hormone *oestrogen* and occurs most commonly at the beginning and the end of reproductive life, in which case it is normal. However, anovulatory menstruation may also be a sign of a hormonal abnormality. (See also *fertility; menstruation*.)

anoxia

The total absence of oxygen within a body tissue such as the brain or a muscle. Anoxia causes disruption of cell *metabolism* (chemical activity) and results in cell death unless it is corrected within a few minutes.

Anoxia is rare, occurring during cardiopulmonary arrest or asphyxiation. It will cause permanent organ damage or even death if not corrected. *Hypoxia* (the reduction of oxygen supply to a tissue) is a more common problem.

Antabuse

A brand name for *disulfiram*, a drug used to treat *alcohol dependence*. Antabuse is a powerful deterrent, which, if taken with even a small amount of alcohol, produces extremely unpleasant side effects such as nausea, headache, dizziness, and *palpitations*.

antacid drugs

COMMON DRUGS

- Aluminium hydroxide ● Calcium carbonate
- Hydrotalcite ● Magnesium hydroxide
- Sodium bicarbonate

Drugs that are taken to relieve the symptoms of *indigestion, heartburn, acid reflux* (the regurgitation of stomach

acids into the oesophagus), *oesophagitis* (inflammation of the oesophagus), and *peptic ulcer*.

HOW THEY WORK

Antacids usually contain compounds of *magnesium* or *aluminium*, which neutralize stomach acid. Some also contain alginates, which protect the oesophagus by reducing *acid reflux*, or dimeticone, an antifoaming agent, which helps to relieve flatulence.

SIDE EFFECTS

Aluminium may cause constipation, and magnesium may cause diarrhoea. These effects can be avoided, however, if a preparation contains both ingredients. Antacids interfere with the absorption of many drugs and should therefore not be taken at the same time as other medications.

WARNING

Antacids should not be taken regularly except under medical supervision because they may suppress the symptoms of a more serious disorder or provoke serious complications.

antagonist

Having an opposing effect. For example, antagonist drugs counteract the effects of naturally occurring chemicals in the body. (See also *agonist*.)

antenatal care

The care of a pregnant woman and her unborn baby throughout pregnancy to ensure that both are healthy at delivery. Antenatal care involves regular visits to a doctor or midwife, who performs blood and urine tests and abdominal examinations and also monitors blood pressure and fetal growth in order to detect disease or potential problems (see the antenatal screening procedures chart, overleaf).

High-risk pregnancies, in which, for example, the woman suffers from *hypertension* (high blood pressure) or diabetes (see *diabetic pregnancy*), require more frequent antenatal visits. In some cases, the woman may be admitted to hospital for closer observation.

Ultrasound scanning is carried out to identify any abnormalities in the fetus. *Amniocentesis* or *chorionic villus sampling* may be performed if the fetus is thought to be at increased risk of a *chromosomal abnormality* or a *genetic disorder*. Electronic fetal monitoring may be carried out, in order to check the fetal heartbeat, in pregnancies that are high-risk or overdue.

ANTENATAL SCREENING PROCEDURES		
When performed	Procedure	Reason for procedure
First visit	Medical history and examination	To look for pre-existing risk factors, such as long-term illnesses.
	Urine tests	To check the urine for glucose, which may indicate diabetes developing in pregnancy and for protein, which may indicate pre-existing kidney disease.
	Blood test	To determine the woman's blood type and to check for anaemia; antibodies to rubella; hepatitis B virus; and, sometimes, after discussion, HIV infection which might be transmitted to the baby. Genetic counselling may be offered to couples with a family history of inherited disease or from ethnic groups at high risk.
	Weight and blood pressure	To provide initial measurements against which later ones are compared.
Between 11 and 20 weeks	Ultrasound scans (one or more)	To check the age of the fetus and to look for fetal abnormalities.
Follow-up visits at regular intervals from 11 weeks to delivery	Weight (not routine in women of normal weight) and examination	To assess the growth of the fetus and to see which way it is lying in the uterus.
	Urine tests	To detect diabetes or pre-eclampsia.
	Blood pressure	To detect developing pre-eclampsia.
	Blood tests (at some visits only)	To look for anaemia and, in combination with ultrasound scanning, to assess the risk of fetal abnormalities such as neural tube defects or Down's syndrome. A test to screen for diabetes mellitus in the mother may also be necessary.

The woman is also advised on general aspects of pregnancy, such as diet, exercise, and techniques to help her with childbirth. (See also *childbirth, natural*.)

antepartum haemorrhage

Bleeding from the vagina after the 28th week of pregnancy.

Antepartum haemorrhage is most commonly due to a problem with the placenta (the organ in the uterus that sustains the developing fetus), such as *placenta praevia* (in which the placenta is positioned too close to the birth canal) or *placental abruption* (detachment of part of the placenta from the wall of the uterus). Bleeding can also be caused by *cervical erosion* or other disorders of the cervix or vagina.

SYMPOMTS

The bleeding is often painless but may be accompanied by abdominal pain if the placenta becomes partly separated from the uterus.

Investigation and treatment requires hospital admission. *Ultrasound scanning* is used to diagnose problems with the placenta. In some cases, it is necessary only to keep a careful watch on the condition of the woman and her baby. If the bleeding is severe, the woman is given a *blood transfusion*; the baby may be delivered immediately by *caesarean section*.

anterior

Relating to the front of the body. In human *anatomy*, the term is synonymous with *ventral*.

anterior knee pain syndrome

See *chondromalacia patellae*.

anterior compartment syndrome

See *compartment syndrome; shin splints*.

anthelmintic drugs

COMMON DRUGS

- Albendazole • Diethylcarbamazine
- Ivermectin • Levamisole • Mebendazole
- Niclosamide • Piperazine • Praziquantel
- Tiabendazole

A group of drugs that are used to eradicate *worm infestation* of the body. Anthelmintic drugs kill or paralyse worms in the intestines, preventing them from gripping the intestinal wall, and causing them to pass out of the body in the *faeces*.

Possible side effects of anthelmintic drugs include nausea, abdominal pain, rash, headache, and dizziness.

anthracosis

An outdated term for coal workers' *pneumoconiosis*. Anthracosis is a lung disease caused by inhalation of large amounts of coal dust over many years.

anthrax

A serious bacterial infection of livestock that occasionally spreads to humans. The most common form of the infection in humans is cutaneous anthrax, which affects the skin. Another form, pulmonary anthrax, affects the lungs and is potentially fatal.

CAUSES

Anthrax is caused by *BACILLUS ANTHRACIS*. This bacterium produces spores that can remain dormant for years in soil and animal products and are capable of reactivation.

Animals become infected by grazing on contaminated land. Infection can occur in humans via a scratch or a sore if materials from infected animals are handled. Pulmonary anthrax occurs as a result of inhaling spores from infected animal fibres.

SYMPTOMS AND TREATMENT

In cutaneous anthrax, a raised, itchy area develops at the site of entry of the spores, progressing to a large blister and finally a black scab, with swelling of the surrounding tissues. Cutaneous anthrax is treatable in its early stages with *antibiotic drugs*. Without treatment, infection may spread to lymph nodes and the bloodstream and may be fatal.

Pulmonary anthrax causes severe breathing difficulty and may be fatal despite intensive treatment.

antiallergy drugs

Drugs used to treat or prevent allergic reactions (see *allergy*). There are several types of antiallergy drug, including *antihistamine drugs*, *leukotriene receptor antagonists*, *sodium cromoglicate*, and *corticosteroid drugs*.

antianxiety drugs

A group of drugs that are used to relieve the symptoms of *anxiety*. *Benzodiazepine drugs*, buspirone, and *beta-blocker drugs* are the three main types of antianxiety drug, although *antidepressant drugs* are often used. In most cases, the underlying disorder is best treated by counselling, psychotherapy, or other forms of therapy.

Benzodiazepine drugs promote mental and physical relaxation by reducing nerve activity in the brain; they can also be used to treat insomnia but their use for this purpose is avoided because they are addictive; buspirone is less addictive. Beta-blockers reduce only the physical symptoms of anxiety, such as shaking and palpitations, and are not addictive.

antiarrhythmic drugs

A group of drugs used to prevent or treat different types of *arrhythmia* (irregular heartbeat).

A number of drugs are used to prevent intermittent arrhythmias or slow the rate if an arrhythmia is persistent. These include *beta-blocker drugs*, *calcium channel blockers*, *digitalis drugs*, *amiodarone*, *disopyramide*, *flecainide*, *lidocaine* (lignocaine), mexiletine, and *procainamide*. Some antiarrhythmic drugs, such as adenosine and bretyllium, may only be used in hospital. They may be given intravenously to treat arrhythmias that are causing symptoms such as breathlessness or chest pain.

HOW THEY WORK

The heart's pumping action is governed by electrical impulses. Some antiarrhythmics alter these impulses within, or on their way to, the heart; others affect the heart muscle's response to the impulses received.

SIDE EFFECTS

Side effects of antiarrhythmic drugs are common, and they often include nausea and a rash. Some can result in tiredness or breathlessness because they reduce the pumping ability of the heart.

antibacterial drugs

A group of drugs that are used to treat infection due to *bacteria*. The term antibacterial was once used to describe only those *antibiotic drugs* that had been produced synthetically rather than naturally. The two terms are now used interchangeably.

antibiotic drugs

COMMON DRUGS

AMINOGLYCOSIDES

- Amikacin • Gentamicin
- Neomycin • Netilmicin • Streptomycin
- Tobramycin

CEPHALOSPORINS

- Cefaclor • Cefadroxil
- Cefalexin • Cefamandole • Cefazolin
- Cefixime • Cefotaxime • Cefoxitin
- Cephadroxime • Cefradine • Ceftazidime

MACROLIDES

- Azithromycin • Clarithromycin
- Erythromycin

PENICILLINS

- Amoxicillin • Ampicillin
- Azlocillin • Aztreonam • Benzylpenicillin
- Co-amoxiclav • Co-fluampicil • Flucloxacillin
- Imipenem • Phenoxymethylpenicillin

TETRACYCLINES

- Doxycycline • Oxytetracycline
- Tetracycline

OTHERS

- Chloramphenicol • Ciprofloxacin
- Colistin • Fusidic acid • Metronidazole
- Rifampicin • Spectinomycin • Teicoplanin
- Trimethoprim • Vancomycin

A group of drugs used to treat infections caused by *bacteria* and to prevent bacterial infection in individuals who are *immunocompromised*. Most of the commonly used antibiotic drugs belong to one of the following classes: *aminoglycosides*,

glycosides, *cephalosporins*, *macrolides*, *penicillins*, and *tetracyclines*. Some antibiotics are effective against only certain types of bacteria; others, which are known as broad-spectrum antibiotics, are effective against a wide range.

ANTIBIOTIC RESISTANCE

Some bacteria develop resistance to a previously effective antibiotic drug. This resistance is most likely to occur during long-term treatment. Some alternative antibiotics are available to treat bacteria that have become resistant to the more commonly prescribed drugs.

SIDE EFFECTS

Most antibiotic drugs can cause nausea, diarrhoea, or a rash. Antibiotics may disturb the normal balance of "good" bacteria in the body. This can cause problems such as *candidiasis* (thrush), in which there is excess growth of fungus. Some individuals experience a severe allergic reaction to the drugs, resulting in facial swelling, itching, or breathing difficulty.

WARNING

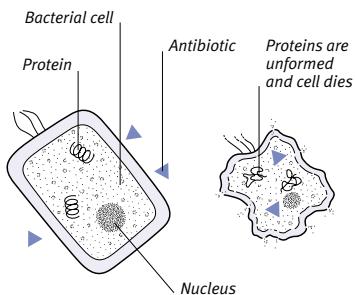

Patients should inform their doctor of any previous allergic reaction that they have had to an antibiotic drug.

antibody

A protein that is made by certain lymphocytes (white blood cells) to neutralize an *antigen* (foreign protein) in the body. Bacteria, viruses, and other microorganisms contain a number of antigens; antibodies that are formed

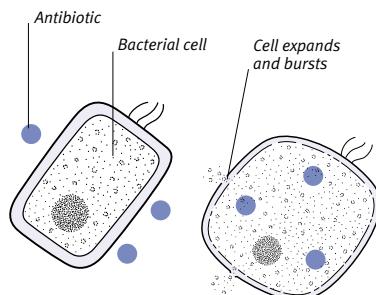

HOW ANTIBIOTICS WORK

Antibiotic drugs are either bactericidal or bacteriostatic. Bactericidal antibiotics, such as penicillins and cephalosporins, kill bacteria directly. Bacteriostatic antibiotics, such as erythromycin, halt growth and multiplication of the bacteria, allowing the immune system to cope with the infection.

Bacteriostatic antibiotics

These drugs prevent the production of proteins that the bacterial cell needs in order to grow and multiply, and the cell eventually dies.

Bactericidal antibiotics

These kill bacteria directly by causing the cell wall to disintegrate; water is taken into the cell, which expands and then bursts.

against these antigens help the body to neutralize or destroy the invading microorganisms. Antibodies may also be formed in response to *vaccines*, thereby giving immunity against certain infections. Antibodies are also known as *immunoglobulins*.

Inappropriate or excessive formation of antibodies may lead to illness, as in an *allergy*. Antibodies against antigens in organ transplants may result in rejection of the transplanted organ. In some disorders, antibodies are formed against the body's own tissues, resulting in an *autoimmune disorder*.

antibody, monoclonal

An artificially produced *antibody* that neutralizes only one specific *antigen* (foreign protein).

Monoclonal antibodies are produced in a laboratory by stimulating the growth of large numbers of antibody-producing cells that are genetically identical. In effect, this process enables antibodies to be tailor-made to react with a particular antigen.

Monoclonal antibodies are used in the study of human cells, hormones, microorganisms, and in the development of vaccines. They are also being used in the diagnosis and treatment of some forms of cancer. Genetically engineered monoclonal antibodies are designed to bind to the proteins on the surface of certain cancer cells, marking them out for destruction. The immune system can then recognize these marked cells and destroy them.

HOW ANTICHOLINERGICS WORK

Acetylcholine combines with a receptor on the cell's surface. This interaction stimulates activity in that cell (e.g. contraction of a muscle fibre or secretion of a fluid). Anticholinergic drugs block the stimulatory action of acetylcholine by combining with the

anticancer drugs

COMMON DRUGS

- **ALKYLATING AGENTS** • Chlorambucil
- Cyclophosphamide • Melphalan
- **ANTIMETABOLITES** • Cytarabine • Fluorouracil
- Mercaptopurine • Methotrexate

CYTOTOXIC ANTIBIOTICS • Doxorubicin

- Epirubicin

HORMONE TREATMENTS • Anastrozole

- Bicalutamide • Cyproterone acetate
- Flutamide • Goserelin • Letrozole
- Leuprorelin • Medroxyprogesterone
- Megestrol • Tamoxifen

CYTOKINES • Interferon alfa • Interleukin 2

TAXANES • Docetaxel • Paclitaxel

OTHERS • Carboplatin • Cisplatin • Etoposide

- Irinotecan • Rituximab

Drugs that are used to treat many forms of *cancer*. Some tumours respond to drug treatment better than others. Anticancer drugs are particularly useful in the treatment of *lymphomas*, *leukaemias*, *breast cancer*, cancer of the testis (see *testis, cancer of*), and *prostate cancer*.

HOW THEY WORK

Most anticancer drugs are cytotoxic (they kill or damage cells or prevent them from dividing). Cytotoxic drugs fall into several classes, including alkylating agents, antimetabolites, cytotoxic antibiotics, and taxanes. *Cytokines* (proteins released by cells in response to the presence of harmful organisms) such as interferon alpha bind to other cells, activating the immune response (see *immune system*).

In some cases, drug treatment is used alone, but it is often combined with surgery or *radiotherapy*. Anticancer

drugs are often given in combination to maximize their effects. Treatment with cytotoxic drugs is commonly given by injection in short courses repeated at intervals.

SIDE EFFECTS

Some cytotoxic drugs cause nausea and vomiting and may cause hair loss and increased susceptibility to infection. Others (such as tamoxifen for breast cancer) are given continuously by mouth for months or years and cause few side effects.

anticholinergic drugs

COMMON DRUGS

- **AS BRONCHODILATORS** • Ipratropium bromide
- Oxitropium

FOR IRRITABLE BOWEL SYNDROME • Atropine

- Dicyclomine • Hyoscine • Propantheline

FOR PARKINSONISM • Benztropine

- Biperiden • Orphenadrine • Procyclidine
- Trihexyphenidyl (Benzhexol)

FOR URINARY INCONTINENCE • Flavoxate

- Oxybutynin • Propiverine • Tolterodine
- Trospium

A group of drugs, also called antimuscarinics, that are used in the treatment of *irritable bowel syndrome*, urinary incontinence (see *incontinence, urinary*), COPD (see *pulmonary disease, chronic obstructive*), *Parkinson's disease*, and *bradycardia* (an abnormally slow heartbeat). Anticholinergic drugs are used to dilate the pupil before eye examination or surgery. They may also be used as *premedication* before general anaesthesia (see *anaesthesia, general*) and to treat *motion sickness*.

HOW THEY WORK

Anticholinergics block the effects of *acetylcholine*, a chemical released from nerve endings in the parasympathetic *autonomic nervous system*. Acetylcholine triggers activity in a number of cells. For example, it stimulates muscle contraction, slows the heartbeat, and increases secretions in the mouth and lungs.

SIDE EFFECTS

Possible side effects of anticholinergics may include dry mouth, blurred vision, urinary retention, and confusion.

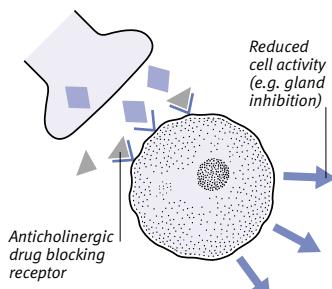

anticoagulant drugs

COMMON DRUGS

- Certoparin • Dalteparin • Danaparoid
- Enoxaparin • Heparin • Nicoumalone
- Tinzaparin • Warfarin

A group of drugs used to treat and prevent abnormal *blood clotting*, to treat *thrombosis*, and to prevent and treat

acetylcholine receptors. This action produces, for example, muscle relaxation (e.g. in the bladder, intestine, and bronchi) and dries up secretions in the mouth and lungs. Anticholinergic drugs are used to treat COPD and other conditions.

stroke and *transient ischaemic attack* (symptoms of stroke lasting less than 24 hours). Anticoagulant drugs are also given long-term to prevent abnormal blood clotting after major surgery (especially heart-valve replacement) or during haemodialysis (see *dialysis*).

The most common anticoagulants are *heparin* and the newer heparin-derived drugs, such as tinzaparin, all of which have to be given by injection, and *warfarin*, which is taken orally. Heparin is usually given initially and is then withdrawn when warfarin therapy has become effective.

HOW THEY WORK

Anticoagulant drugs reduce the activity of certain enzymes, known as blood clotting factors, that are needed for the blood to clot. Anticoagulants do not dissolve clots that have already formed, which can be treated with *thrombolytic drugs*, however they may help to stabilize an existing clot so that it does not break away causing an *embolism* (blockage of an artery by a blood clot).

SIDE EFFECTS

Excessive doses of warfarin or its use with other drugs, such as aspirin and alcohol, may increase the risk of unwanted bleeding. Regular monitoring with *blood-clotting tests* is required.

WARNING

A doctor should always be consulted before any other drug is taken during anticoagulant treatment.

anticonvulsant drugs

COMMON DRUGS

- Carbamazepine • Clobazam • Clomethiazole
- Clonazepam • Diazepam • Ethosuximide
- Gabapentin • Lamotrigine • Lorazepam
- Phenobarbital • Phenytoin • Piracetam
- Primidone • Sodium valproate • Tiagabine
- Topiramate • Vigabatrin

A group of drugs used to treat or prevent seizures. Anticonvulsant drugs are used mainly in the treatment of *epilepsy*, but they are also prescribed to prevent seizures following serious *head injury* or some types of brain surgery. They may be needed to control seizures in children with a high fever (see *convulsions, febrile*). Different drugs are effective at treating different types of seizure.

HOW THEY WORK

Seizures are caused by an abnormally high level of electrical activity in the brain. Anticonvulsant drugs have an inhibitory effect that suppresses this excessive electrical activity, thereby pre-

venting its spread throughout areas of the brain. If seizures continue following treatment with an anticonvulsant, two drugs may be used in combination.

SIDE EFFECTS

Anticonvulsants may produce various side effects, including impaired memory, reduced concentration, poor coordination, and fatigue. If the side effects are troublesome, an alternative anticonvulsant can be tried. The dose of an anticonvulsant drug may need to be monitored using *blood tests*.

WARNING

The dosage of anticonvulsants should not be reduced or the treatment stopped without a doctor being consulted first. The doctor will supervise a gradual reduction in dosage. Stopping the drugs abruptly could cause withdrawal symptoms and a recurrence of the original problem.

antidepressant drugs

COMMON DRUGS

SELECTIVE SEROTONIN REUPTAKE INHIBITORS (SSRIS)

- Citalopram • Fluoxetine
- Fluvoxamine • Paroxetine • Sertraline

TRICYCLICS (TCAs)

- Amitriptyline • Amoxapine
- Clomipramine • Dosulepin • Doxepin
- Imipramine • Lofepramine • Nortriptyline
- Trimipramine

MONOAMINE OXIDASE INHIBITORS (MAOIs)

- Isocarboxazid • Moclobemide • Phenelzine
- OTHERS • Fluoxetine • Maprotiline • Mianserin
- Mirtazapine • Reboxetine • Trazodone
- Venlafaxine

Drugs used in the treatment of *depression*. Most of the commonly used antidepressant drugs belong to one of the following groups: *tricyclic antidepressants* (TCAs), *selective serotonin reuptake inhibitors* (SSRIs), and *monoamine oxidase inhibitors* (MAOIs).

HOW THEY WORK

Normally, brain cells release enough *neurotransmitters* (chemical messengers) in the brain to stimulate nearby brain cells. Neurotransmitters are constantly being reabsorbed into the brain cells by another chemical, monoamine oxidase. Depression is thought to be due to a reduction in the release of neurotransmitters. TCAs increase the level of the neurotransmitters noradrenaline (norepinephrine) and serotonin by preventing their reabsorption. MAOIs work by blocking the action of monoamine oxidase, which increases neurotransmitter levels. SSRIs only prevent the reabsorption of serotonin.

Antidepressants usually relieve the symptoms of depression, but it often takes two to three weeks for any beneficial effects to be felt. Treatment usually lasts for at least six months; and the dosage is reduced gradually before being stopped altogether.

SIDE EFFECTS

TCAs may cause constipation, a dry mouth, drowsiness, blurred vision, urinary difficulty, and irregular heartbeat. SSRIs may cause nausea, indigestion, loss of appetite, or sexual difficulties but are less dangerous in overdose than other antidepressants. MAOIs may interact with foods and other drugs, although *moclobemide* is less likely to cause problems.

Antidepressants are not addictive, but abrupt withdrawal of some types can result in physical symptoms and should therefore be avoided.

WARNING

Food and drink containing tyramine (for example, cheese and red wine) and other drugs may cause a dangerous rise in blood pressure when taken during treatment with an MAOI. Always tell your doctor if you are taking an MAOI.

antidiabetic drugs

COMMON DRUGS

SULPHONYLUREA DRUGS

- Chlorpropamide
- Glibenclamide • Gliclazide • Glimepiride
- Glipizide • Gliquidone • Tolbutamide

OTHERS

- Acarbose • Glucagon • Guar gum
- Insulin • Insulin lispro • Metformin
- Repaglinide • Rosiglitazone

A group of drugs that are used to treat *diabetes mellitus*, in which a lack of *insulin*, or resistance to its actions, results in *hyperglycaemia* (high levels of glucose in the blood). A wide range of antidiabetics are used to keep the blood glucose level as close to normal as possible, thereby reducing the risk of complications such as vascular (blood vessel) disease. Antidiabetic drugs include insulin, which must be administered by injection, and oral hypoglycaemics (see *hypoglycaemics, oral*) such as *glibenclamide* and *metformin*.

HOW THEY WORK

Most antidiabetic drugs promote the uptake of glucose into the body tissues, helping to prevent an excessive rise in blood glucose levels. However, different antidiabetics work in different ways. *Acarbose* and *guar gum* reduce or slow the absorption of carbohydrate from the intestines after meals. *Repaglinide*

stimulates release of insulin from the pancreas. *Rosiglitazone* reduces resistance to the effects of insulin in the tissues and may be used together with other hypoglycaemics.

SIDE EFFECTS

Certain antidiabetics may lower the blood glucose level too much, leading to *hypoglycaemia* (low blood glucose levels). Rarely, these drugs may also cause a decreased blood cell count, a rash, or intestinal or liver disturbances.

Metformin does not cause hypoglycaemia, although treatment with this drug may result in nausea, appetite loss, abdominal distension, and diarrhoea. It should not be taken by people with liver, kidney, or heart problems.

antidiarrhoeal drugs

COMMON DRUGS

ANTISPASMODICS • Atropine • Dicycloverine

- Hyoscine

OPPIOIDS • Codeine • Diphenoxylate

- Loperamide

BULK-FORMING AGENTS AND ABSORBENTS

- Ispaghula • Kaolin • Methylcellulose

Drugs that are used to reduce or stop diarrhoea and to help regulate bowel action in people who have had a *colostomy* or *ileostomy*. In most acute (of sudden onset) cases of diarrhoea, the only treatment recommended is *oral rehydration therapy*. Antidiarrhoeal drugs are not suitable for children.

HOW THEY WORK

Antidiarrhoeal drugs include adsorbents (such as kaolin), which can absorb the toxic substances that cause diarrhoea; bulk-forming agents (such as ispaghula), which absorb water from the faeces thereby making them firmer; and antimotility drugs (including the opioid drugs, *morphine* and *codeine*, and loperamide, which is chemically similar to opioids but does not have an opioid effect), which slow movement through the intestine.

SIDE EFFECTS

Antidiarrhoeal drugs may cause constipation. In cases of diarrhoea that has resulted from an infection, antidiarrhoeals may delay recovery by slowing down the elimination of the causative microorganisms.

Bulk-forming agents may cause intestinal obstruction if taken without sufficient drinking water or if the bowel is narrowed.

Prolonged use of opioid antidiarrhoeals may lead to physical dependence

(see *drug dependence*), producing nausea, abdominal pain, and diarrhoea if the drug is stopped suddenly.

WARNING

Antidiarrhoeals should not be taken regularly except on medical advice since they may mask a serious underlying disorder.

antidiuretic hormone

See *ADH*.

antidote

A substance that neutralizes or counteracts the effects of a poison.

A chemical antidote works by combining with a poison to form an innocuous substance or by, in some way, blocking or diverting the action of the poison. A mechanical antidote prevents the absorption of poison into the blood from the stomach and intestine.

anti-D(Rh₀) immunoglobulin

An *antiserum* that contains antibodies (see *antibody*), proteins that are manufactured by the immune system against Rhesus (Rh) D factor, a substance present on the red blood cells of people with Rh-positive blood.

Anti-D(Rh₀) immunoglobulin is given to all Rh-negative women routinely at intervals during normal pregnancy and at delivery. A dose is also given after an *amniocentesis*, miscarriage, or any event in which the baby's blood may enter the mother's circulation. The injected antibodies destroy any red blood cells from the fetus that have entered the woman's bloodstream. This helps to prevent the woman from forming her own antibodies against Rh-positive blood, which might adversely affect a subsequent pregnancy. (See also *haemolytic disease of the newborn*; *Rhesus incompatibility*.)

antiemetic drugs

COMMON DRUGS

ANTICHOLINERGICS • Hyoscine hydrobromide

ANTIHISTAMINES • Cinnarizine • Cyclizine

- Dimenhydrinate • Meclozine • Promethazine

BUTYROPHENONES • Haloperidol

PHENOTHIAZINES • Chlorpromazine

- Perphenazine • Prochlorperazine

SEROTONIN ANTAGONISTS • Granisetron

- Ondansetron • Tropisetron

MOTILITY STIMULANTS • Domperidone

- Metoclopramide

OTHERS • Betahistine • Nabilone

A group of drugs used in the treatment of the *nausea* and *vomiting* that are associated with *motion sickness*, *vertigo*,

Ménière's disease, *radiotherapy*, and certain drugs. Antiemetics are not normally used in the treatment of food poisoning because the body needs to rid itself of harmful substances.

HOW THEY WORK

Antihistamines and *anticholinergic drugs* reduce vomiting associated with vertigo by suppressing the vomiting reflex (in which the stomach muscles contract to expel the stomach contents), which is triggered by nerve activity in the balance centre of the inner ear.

Motility stimulants work by increasing movement through the gastrointestinal tract. The most powerful antiemetics are used to control nausea and vomiting associated with radiotherapy or *anticancer drugs* and include *serotonin antagonists*, such as *ondansetron*, and *nabilone*. These drugs act on *neurotransmitters* in the brain.

SIDE EFFECTS

Only certain antiemetics are used to treat vomiting in early pregnancy because some can damage the developing fetus. Many antiemetics can cause drowsiness.

WARNING

Antiemetics should not be taken regularly except on medical advice since they may mask a serious underlying disorder.

antifreeze poisoning

Most antifreeze in the UK contains ethylene glycol, which is poisonous. Most cases of antifreeze poisoning, which is extremely rare, occur as a result of accidental swallowing.

SYMPTOMS

Drinking antifreeze initially produces effects similar to *alcohol intoxication*, but vomiting, stupor, seizures, and coma may follow; acute *kidney failure* may occur within 24 to 36 hours.

TREATMENT

Any person believed to have drunk antifreeze requires immediate medical attention. Until such help arrives, small amounts of alcohol (preferably a spirit such as brandy or whisky) should be given, if possible, because alcohol reduces the rate at which antifreeze is metabolized by the body.

Hospital treatment may include removing the antifreeze from the stomach using a stomach pump (see *lavage, gastric*) and giving *diuretic drugs*, alcohol, and bicarbonate, intravenously, to correct excess acidity in the body fluids. Haemodialysis (see *dialysis*) may be required to remove ethylene glycol from the blood and to treat kidney failure.

antifungal drugs

COMMON DRUGS

- Amorolfine • Amphotericin • Benzoyl peroxide • Clotrimazole • Econazole
- Fenticonazole • Fluconazole • Griseofulvin
- Itraconazole • Ketoconazole • Miconazole
- Nystatin • Sulconazole • Terbinafine
- Tioconazole

A group of drugs used to treat infections caused by *fungi*. Antifungals are commonly used to treat different types of *tinea* (including *athlete's foot* and scalp ringworm); *candidiasis* (thrush) and rare infections, such as *cryptococcosis*, that affect internal organs. Antifungals are available in various forms, including tablets, injection, creams, and pessaries.

HOW THEY WORK

Antifungal drugs work by damaging the cell walls of fungi, causing chemicals essential for normal cell function and growth to escape. The fungal cells are unable to survive without these chemicals.

SIDE EFFECTS

Topical antifungals rarely cause side effects but may occasionally increase skin irritation. Prolonged treatment, by mouth or injection, of serious fungal infections can result in side effects including liver or kidney damage.

antigen

A substance that can trigger an *immune response*, resulting in production of an *antibody* as part of the body's defence against infection and disease. Many antigens are foreign proteins such as parts of microorganisms and toxins or tissues from another person that have been used in organ transplants. Sometimes, harmless substances (such as pollen) are misidentified by the immune system as potentially harmful antigens, which results in an allergic response (see *allergy*).

antihistamine drugs

COMMON DRUGS

- NON-SEDATING** • Acrivastine • Cetirizine
- Fexofenadine • Loratadine • Mizolastine
- SEDATING** • Azatadine • Brompheniramine
- Chlorphenamine • Clemastine
- Dimenhydrinate • Diphenhydramine
- Diphenylpyraline • Doxylamine
- Promethazine • Trimeprazine • Triprolidine

A group of drugs that block the effects of *histamine*, a chemical released during allergic reactions (see *allergy*).

Antihistamines are used to treat rashes such as *urticaria* (hives) and to relieve sneezing and a runny nose in allergic

rhinitis. They are also sometimes included in *cough remedies* and *cold remedies*, and they are used as *antiemetic drugs* because they suppress the vomiting reflex. Antihistamines are usually taken by mouth but may be given by injection for *anaphylactic shock*.

HOW THEY WORK

Antihistamine drugs block the effect of histamine on tissues such as the skin, eyes, and nose. Without drug treatment, histamine dilates small *blood vessels*, resulting in *inflammation* of the surrounding tissue due to leakage of fluid from the circulation. Antihistamines also prevent histamine from irritating nerve fibres, which causes itching.

SIDE EFFECTS

Many antihistamines cause drowsiness, but newer drugs have little sedative effect. Other uncommon side effects include loss of appetite, nausea, dry mouth, blurred vision, and difficulty in passing urine.

WARNING

A person should not drive or operate potentially dangerous machinery while taking an antihistamine drug unless he or she is certain that the treatment is not causing dizziness, drowsiness, or impaired concentration.

antihypertensive drugs

COMMON DRUGS

- ACE INHIBITORS** • Captopril • Cilazapril
- Enalapril • Fosinopril • Lisinopril • Moexipril
- Perindopril • Quinapril • Ramipril
- Trandolapril

- ALPHA-BLOCKERS** • Doxazosin • Prazosin

- Terazosin

- ANGIOTENSIN-II ANTAGONISTS** • Candesartan

- Irbesartan • Losartan • Valsartan

- BETA-BLOCKERS** • Acebutolol • Atenolol

- Betaxolol • Bisoprolol • Carvedilol • Celiprolol
- Labetalol • Metoprolol • Nadolol • Pindolol
- Propranolol • Sotalol • Timolol

- CALCIUM CHANNEL BLOCKERS** • Amlodipine

- Diltiazem • Nicardipine • Nifedipine

- CENTRALLY ACTING HYPERTENSIVES** • Clonidine

- Methyldopa • Moxonidine

- DIURETICS** • Amiloride • Bendroflumethiazide

- Bumetanide • Chlorothiazide

- Chlortalidone • Cyclopenthiazide

- Ethacrynic acid • Furosemide

- Hydrochlorothiazide

- Hydroflumethiazide • Indapamide

- Metolazone • Spironolactone

- Torasemide • Triamterene • Xipamide

A group of drugs that are used in the treatment of *hypertension* (high blood pressure) to prevent complications such

as *stroke*, *heart failure* (reduced pumping efficiency of the heart), *myocardial infarction* (heart attack), and kidney damage. There are several types of antihypertensive, each one working in a different way to lower blood pressure.

HOW THEY WORK

Antihypertensive drugs work in a variety of ways to lower blood pressure. ACE inhibitors and angiotensin-II antagonists act on enzymes in the blood to dilate blood vessels; alpha-blockers block nerve signals that trigger the constriction of blood vessels; beta-blockers reduce the force of the heartbeat, thereby lowering the pressure of blood flow; diuretics increase the amount of salts and water excreted in the *urine*, thereby reducing blood volume; calcium channel blockers and ACE inhibitors control the size of blood vessels by preventing constriction of arterial wall muscles; and centrally acting hypertensives act on the mechanism in the brain that controls the size of blood vessels.

SIDE EFFECTS

Side effects depend on the type of antihypertensive used, but all types can cause dizziness if the blood pressure falls excessively.

WARNING

The dosage of antihypertensives should not be reduced or the treatment stopped without first consulting a doctor, who will supervise a gradual reduction in dosage. Abrupt cessation of the drug could cause a dangerous rise in blood pressure.

anti-inflammatory drugs

Drugs that reduce *inflammation*. The main groups of these drugs are *corticosteroid drugs* and *nonsteroidal anti-inflammatory drugs* (NSAIDs). (See also *analgesic drugs*.)

antimalarial drugs

Drugs used to treat *malaria*. One antimalarial drug, *chloroquine*, is also used to treat arthritis.

antimotility drugs

See *antidiarrhoeal drugs*.

antimuscarinic drugs

See *anticholinergic drugs*.

antobesity drugs

A group of drugs that includes *appetite suppressants* and *orlistat*, a drug that acts on the gastrointestinal tract to prevent the digestion of fats.

anti-oestrogen drugs

A group of drugs that oppose the action of the hormone *oestrogen*. The most important of these drugs is *tamoxifen*, which is used in the treatment of certain breast cancers.

antioxidant

A type of chemical that neutralizes potentially damaging oxidizing molecules known as *free radicals* (molecules that bind to and destroy body cells).

Some antioxidants occur naturally in the body; others (vitamin C, vitamin E, and beta-carotene, for example) are obtained through food intake or from dietary supplements.

antiperspirant**COMMON DRUGS**

- Aluminium chloride

A substance applied to the skin in the form of a lotion, cream, or spray in order to reduce sweating. High concentrations are sometimes used to treat *hyperhidrosis* (abnormally heavy sweating).

HOW IT WORKS

An antiperspirant reduces the production of sweat by the *sweat glands* and blocks the ducts that drain sweat on to the surface of the skin.

SIDE EFFECTS

Antiperspirants may cause skin irritation, particularly if they are used on broken skin. (See also *deodorants*.)

antiphospholipid syndrome

See *Hughes' syndrome*.

antiplatelet drugs**COMMON DRUGS**

- Abciximab • Aspirin • Dipyridamole
- Clopidogrel • Ticlopidine

Drugs that reduce the tendency of *platelets* to stick together to form blood clots (see *blood clotting*) when blood flow in the arteries is disrupted. Antiplatelet drugs reduce the risk of *thromboembolism* (in which a clot breaks off and is carried in the bloodstream to lodge elsewhere in the body), which can cause potentially fatal disorders such as a *myocardial infarction* (heart attack) or *stroke*.

Aspirin and dipyridamole are commonly used antiplatelet drugs. Others, such as ticlopidine, are used specifically to protect against the stroke or formation of blood clots in the *coronary arteries* in people who have had a stroke or heart attack or have *angina*.

antipruritic drugs**COMMON DRUGS**

- ANTIHISTAMINES • Antazoline • Diphenhydramine

- Trimeprazine

- CORTICOSTEROIDS • Hydrocortisone

- LOCAL ANAESTHETICS • Tetracaine (amethocaine)

- Benzocaine • Lignocaine

EMOLlient AND COOLING PREPARATIONS

- Aqueous cream • Calamine lotion

- Cold cream • Emulsifying ointment

- OTHERS • Colestyramine • Doxepin

Drugs that are used to relieve persistent itching (*pruritus*), including pruritus that occurs as a result of a specific condition. For example, colestyramine (a *lipid-lowering drug*) is used to relieve pruritus associated with primary *biliary cirrhosis*. Antipruritic drugs can be applied as creams and *emollients* and may contain *corticosteroid drugs*, *antihistamine drugs*, or *local anaesthetics*. Oral antihistamines may also be used to relieve itching.

HOW THEY WORK

Irritation of the skin causes the release of substances, such as histamine, that cause the blood vessels to dilate and fluid to accumulate under the skin, which results in inflammation and itching. Antipruritic drugs work either by reducing inflammation, and therefore itching, or by numbing the nerve impulses that transmit sensation to the brain.

SIDE EFFECTS

Prolonged or heavy use of any antipruritic, especially antihistamine and local anaesthetic creams, may lead to further skin irritation. Oral antihistamines may cause drowsiness. Prolonged use of potent topical corticosteroids may result in permanent skin changes, most commonly thinning of the skin.

antipsychotic drugs**COMMON DRUGS**

- PHENOTHIAZINES • Chlorpromazine

- Fluphenazine • Levomepromazine (methotrimeprazine) • Pericyazine

- Perphenazine • Pipotiazine • Thioridazine

- Trifluoperazine

- BUTYROPHENONES • Benperidol • Droperidol

- Haloperidol

- OTHERS • Amisulpride • Clozapine

- Flupentixol • Olanzapine • Pimozide

- Quetiapine • Risperidone • Zotepine

- Zuclopentixol

A group of drugs used to treat *psychoses* (mental disorders involving loss of contact with reality), particularly *schizophrenia* and *mania* (abnormal elation and overactivity) in bipolar disorder (see *manic-depressive illness*). Antipsychotic drugs may also be used to sedate people who are suffering from other mental disorders (such as *dementia*) and who are very agitated or aggressive.

HOW THEY WORK

Most antipsychotic drugs block the action of *dopamine*, a chemical that stimulates nerve activity in the brain. Antipsychotic drugs include *phenothiazine drugs*, butyrophenones such as *haloperidol*, and several new drugs including *risperidone*.

SIDE EFFECTS

Antipsychotic drugs can cause drowsiness, lethargy, *dyskinesia* (abnormal muscular movements), and *parkinsonism*. Other possible side effects include dry mouth, blurred vision, and difficulty in passing urine. However, newer drugs may have fewer side effects when used long term.

antipyretic drugs

Drugs that reduce fever. Examples of antipyretic drugs include *paracetamol*, *aspirin*, and other *non-steroidal anti-inflammatory drugs*.

antiretroviral drugs**COMMON DRUGS**

- NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS

- Didanosine • Lamivudine • Stavudine

- Zalcitabine • Zidovudine (AZT)

- PROTEASE INHIBITORS • Indinavir • Nelfinavir

- Ritonavir • Saquinavir

- NON-NUCLEOSIDE REVERSE TRANSCRIPTASE

- INHIBITORS • Efavirenz • Nevirapine

Drugs that are used to slow or halt the spread of viruses (see *retrovirus*) in individuals who have *HIV* infection and *AIDS*. There are three main types of antiretroviral drug: nucleoside reverse transcriptase inhibitors, non-nucleoside reverse transcriptase inhibitors and protease inhibitors. A combination of antiretroviral drugs from different groups is often used.

HOW THEY WORK

Antiretroviral drugs work by interfering with the action of enzymes used by the virus to produce genetic material.

SIDE EFFECTS

Antiretroviral drugs can have a range of side effects, including nausea, vomiting, diarrhoea, tiredness, and a variety of effects on blood chemistry, particularly those that involve fats. (See also *antiviral drugs*.)

antirheumatic drugs

COMMON DRUGS

- **CORTICOSTEROIDS** • Dexamethasone
- Hydrocortisone • Methylprednisolone
- Prednisolone • Triamcinolone

- **GOLD-BASED DRUGS** • Auranofin • Sodium aurothiomalate

- **IMMUNOSUPPRESSANTS** • Azathioprine

- Cyclophosphamide • Ciclosporin
- Methotrexate

- **NSAIDS** • Aspirin • Celecoxib • Diclofenac
- Etodolac • Felbinac • Ibuprofen • Ketoprofen
- Mefenamic acid • Meloxicam • Naproxen
- Piroxicam

- **OTHERS** • Chloroquine • Hydroxychloroquine
- Penicillamine • Sulfasalazine

A group of drugs that are used to treat *rheumatoid arthritis* and types of arthritis that are the result of other *autoimmune disorders* (in which the immune system attacks the body's own tissues) such as systemic *lupus erythematosus*. Antirheumatic drugs affect the disease process and may, therefore, limit joint damage, unlike NSAIDs (see *nonsteroidal anti-inflammatory drugs*), which only relieve pain and stiffness. The most commonly used antirheumatic drugs are *corticosteroid drugs*, *immunosuppressant drugs*, *chloroquine*, *penicillamine*, *gold*, and *sulfasalazine*.

HOW THEY WORK

Different types of antirheumatic drug work in different ways, by suppressing either the production or the activity of *lymphocytes* (white blood cells). All antirheumatics reduce *inflammation* caused by the autoimmune reaction and slow down the degeneration of the cartilage that lines the joints.

SIDE EFFECTS

Many antirheumatic drugs can have serious side effects, and treatment, other than with NSAIDs, is therefore given only under specialist medical supervision.

antiseptics

Chemicals that are applied to the skin in order to destroy bacteria and other microorganisms, thereby preventing sepsis (infection). Antiseptis (the use of antiseptics to prevent infection) is not the same as asepsis, which is the creation of a germ-free environment (see *aseptic technique*). Antiseptics are milder than *disinfectants*, which decontaminate inanimate objects but are too strong to be used on the body.

Antiseptic fluids are generally used for bathing wounds; antiseptic creams are applied to wounds before they are

dressed. Common antiseptics are *chlorhexidine*, *cetrimide*, *hexachlorophene*, and compounds containing *iodine*.

antiserum

A preparation containing antibodies (proteins manufactured by the immune system, see *antibody*) that combine with specific *antigens* (foreign proteins), usually components of microorganisms, leading to the deactivation or destruction of the microorganisms.

Antiserum is usually used, along with *immunization*, as an emergency treatment when an individual has been exposed to a dangerous infection, such as *rabies*, and has not previously been immunized against it. The antiserum helps to provide some immediate protection against the infective microorganisms while full immunity is developing. Such measures are not as effective in preventing disease as earlier (pre-exposure) immunization, however.

antisocial personality disorder

Impulsive, destructive behaviour that often disregards the feelings and rights of others. People who have an antisocial personality lack a sense of guilt and cannot tolerate frustration. They may have problems with relationships and are frequently in trouble with the law.

Behaviour therapy and various forms of *psychotherapy* may help to improve social integration. In general, the effects of the condition decrease with age.

antispasmodic drugs

COMMON DRUGS

- Atropine • Dicycloverine • Hyoscine
- Mebeverine

A group of drugs that relax spasm in smooth (involuntary) muscle in the wall of the intestine or bladder. Antispasmodic drugs are used in the treatment of irritable bowel syndrome and irritable bladder.

HOW THEY WORK

Some antispasmodic drugs have an anticholinergic action (that is, they work by blocking the action of *acetylcholine*, a neurotransmitter chemical released from nerve endings that stimulates muscle contraction). Others work by direct action on smooth muscle.

SIDE EFFECTS

Possible side effects of antispasmodic drugs include a dry mouth, blurred vision, and difficulty in passing urine. (See also *anticholinergic drugs*.)

antithyroid drugs

COMMON DRUGS

- Carbimazole • Iodine • Propylthiouracil

A group of drugs that are used to treat *hyperthyroidism*, in which the thyroid gland is overactive. They may be used as the sole treatment for hyperthyroidism or may be given prior to thyroid surgery.

HOW THEY WORK

Carbamazole and *propylthiouracil* work primarily by interfering with production of thyroid hormones by the thyroid gland. Radioactive iodine works by destroying part of the thyroid tissue in people with hormone-secreting thyroid nodules.

SIDE EFFECTS

Side effects of carbimazole and propylthiouracil include nausea, headaches, mild gastrointestinal disturbances, dizziness, joint pain, itching, and rash. Carbimazole can suppress white blood cell production. Iodine can cause hypersensitivity reactions resembling coryza (nasal symptoms of the common cold).

antitoxin

Any of a variety of commercially prepared substances containing *antibodies* (proteins manufactured by the *immune system*) that can combine with and neutralize the effect of a specific *toxin* that has been released into the bloodstream by particular bacteria (such as those that cause *tetanus* and *diphtheria*).

Antitoxins are usually given by injection into a muscle. Occasionally, an antitoxin may cause an allergic reaction (see *allergy*); rarely, it may cause *anaphylactic shock* (a severe allergic reaction requiring emergency treatment).

antitussive drugs

Drugs that suppress or relieve a *cough* (see *cough remedies*).

antivenom

A specific treatment for bites or stings inflicted by venomous animals such as snakes, spiders, and scorpions.

Antivenom is prepared by the inoculation of animals, such as horses, with venom from a particular poisonous animal, thereby provoking the production of *antibodies* (proteins manufactured by the *immune system*) that neutralize the poisons in the venom. A preparation of these antibodies can be produced from samples of the animal's blood.

Antivenoms are given by intravenous injection and may cause allergic reactions (see *allergy*).

antiviral drugs

COMMON DRUGS

ANTIRETROVIRALS

• Didanosine • Efavirenz

• Indinavir • Lamivudine • Nelfinavir

• Nevirapine • Ritonavir • Saquinavir

• Stavudine • Zalcitabine • Zidovudine

OTHERS

• Aciclovir • Amantadine • Cidofovir

• Famciclovir • Foscarnet • Ganciclovir

• Idoxuridine • Inosine pranobex • Interferon

• Penciclovir • Ribavirin • Valaciclovir

• Zanamivir

Drugs used in the treatment of infection by *viruses*. No drugs have been developed that can eradicate viruses completely, and at present *immunization* is the most effective way of preventing serious viral infections. However, anti-viral drugs can reduce the severity of some viral infections (most notably *herpes*, *influenza*, viral *hepatitis*, and *cytomegalovirus* infections), particularly in people who have reduced immunity. Advances have also been made in the treatment of HIV infection (see *antiretroviral drugs*).

HOW THEY WORK

Most antiviral drugs destroy viruses by disrupting the chemical processes necessary for the virus to grow and multiply within a cell. Some antivirals actually prevent viruses penetrating the cells.

SIDE EFFECTS

Side effects of antiviral drugs used in the treatment of HIV infection and AIDS may include nausea, diarrhoea, and tiredness. These drugs may also affect blood chemistry, leading to conditions such as *anaemia* (a reduced level of the oxygen-carrying pigment *haemoglobin* in the blood).

Most other antivirals rarely cause side effects. Antiviral creams may cause skin irritation and those given by mouth or injection may lead to nausea, dizziness, and rarely, in prolonged treatment, to kidney damage.

antral irrigation

Irrigation (flushing out) of the maxillary antrum, one of the nasal sinuses. More commonly known as a sinus washout, antral irrigation is used to treat persistent *sinusitis*. The procedure is performed less often nowadays since the introduction of nasal *endoscopy*, (examination of the nasal cavity using a flexible viewing tube).

anuria

Complete cessation of urine output. Anuria may be caused by a severe mal-

function of the kidneys, but a much more common cause is a complete blockage of the flow of urine as a result of enlargement of the prostate gland (see *prostate, enlarged*), a *bladder tumour*, or a bladder or kidney stone in the (see *calculus, urinary tract*). Failure of the kidneys to produce urine may be due to oxygen depletion as a result of reduced blood flow through the kidneys, as occurs in *shock*, or to severe kidney damage caused by a disease such as *glomerulonephritis*.

Anuria requires urgent investigation to establish the cause and to allow treatment (such as rehydration or removal of the blockage) to begin. Treatment of the cause may restore urine production, but any delay can result in permanent kidney damage, leading to *uraemia* (excess urea and other waste products in the blood).

anus

The end of the alimentary tract through which faeces are expelled from the body. The anus is an extension of the rectum as it passes downwards and backwards through the pelvic floor.

The orifice at the end of the anal canal is open only during defaecation; at other times it is kept closed by the muscles of the anal sphincter. These muscles are arranged in two layers: the internal sphincter, which cannot be controlled voluntarily, and the external sphincter, which can be relaxed at will for defaecation. Disorders of the anus include anal cancer (see *anus, cancer of*) and imperforate anus (see *anus, imperforate*). (See also *digestive system*.)

anus, cancer of

A rare cancer of the skin of the anus. Possible early signs of anal cancer are the development of swelling or an ulcer at the anus, accompanied by bleeding and discomfort. Treatment is by surgical removal and/or *radiotherapy*.

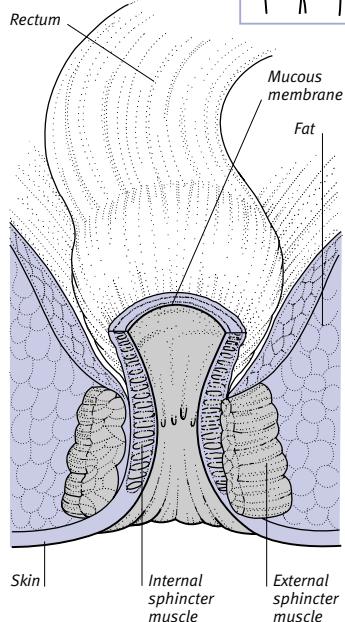

anus, imperforate

A rare congenital (present from birth) abnormality in which the anal opening is missing or covered over. The severity of the condition varies from complete absence of the anal canal to only a layer of skin covering the anal opening.

Treatment is with surgery. In severe cases, a *colostomy* may be needed initially before definitive surgery to construct an anus. Where surgery simply involves removal of a layer of skin over the anal

STRUCTURE OF THE ANUS

The anus is a canal at the end of the alimentary tract, with internal and external sphincters to open and close the orifice.

opening, *anal dilation* (a procedure to enlarge the anus) may be required for several months afterwards.

anxiety

An unpleasant emotional state that ranges from mild unease to intense fear. Anxiety is a normal response to stressful situations and prepares the mind and body to respond effectively. However, anxiety that occurs without reason may be a symptom of an *anxiety disorder* or another psychological disorder such as *depression*.

SYMPTOMS

A variety of physical symptoms are associated with anxiety. The most common include palpitations (a more forceful or faster heartbeat), chest pains, a feeling of tightness in the chest, and a tendency to overbreath (see *hyperventilation*). Muscle tension leads to headaches and back pains.

Gastrointestinal symptoms of anxiety include dry mouth (see *mouth, dry*), bloating, diarrhoea, nausea, and difficulty in swallowing. Other symptoms

DISORDERS OF THE ANUS

Most anal disorders are minor but may cause considerable discomfort and concern. Many are aggravated by constipation and may be helped by regular toilet habits, an increased intake of fluids, wholemeal products, fruits, and vegetables to soften the faeces, and the use of glycerine suppositories, if necessary.

Congenital defects

Imperforate anus is an uncommon birth defect in which the anus is sealed (see *anus, imperforate*).

In *anal stenosis*, the anus is too narrow to allow the normal passage of faeces. This is sometimes a congenital abnormality, but it can also result from scarring following surgery to treat another disorder.

Injury

Anal fissures originate from small tears in the lining of the anus, usually as a result of straining to pass hard, dry faeces.

Tumours

Cancer of the skin around the anus is rare (see *anus, cancer of*).

Other disorders

Haemorrhoids are enlarged blood vessels under the lining of the anus and may cause bleeding during defaecation, itching, and pain.

An *anal fistula* is an abnormal tunnel connecting the inside of the anal canal with the skin surrounding the anus. These fistulas usually result from an abscess in the wall of the anus.

Itching of the anus (*pruritus ani*) may be a direct result of another disorder, such as an anal fistula, haemorrhoids or *threadworm* infestation.

Anal warts (see *warts, genital*) are transmitted by sexual contact and are caused by a papillomavirus.

INVESTIGATION

Investigation of anal disorders is usually by visual inspection, sometimes involving *proctoscopy* (use of a rigid internal viewing tube) and digital examination (feeling with a finger). Sometimes a *biopsy* (small sample of tissue removed for microscopic analysis) or *swab* may be taken for bacteriological culture.

include lightheadedness, sweating, pallor, blushing, and a frequent need to urinate or defaecate.

People with anxiety may have a constant feeling that something bad is going to happen. They may fear illness or worry about the health and safety of family and friends. Fear of losing control is also common. Anxiety often leads to increasing dependence on others, irritability, a sense of fatigue, and frustration. Inability to relax may lead to difficulty in sleeping.

TREATMENT

People suffering from anxiety may be helped by *counselling* or *psychotherapy*. If there is an underlying disorder, such as depression, treatment with *antidepressant drugs* can help. Antianxiety drugs are used for short-term control of symptoms but are avoided for long-term treatment because they are addictive.

anxiety disorders

A group of mental illnesses, including several specific syndromes, in which symptoms of *anxiety* are the principal

feature. Anxiety disorders are common and mainly affect young adults.

TYPES

In *generalized anxiety disorder*, the affected individual suffers from persistent tension and apprehension that has no specific focus or cause, together with physical or psychological symptoms that disrupt normal activity. *Panic disorder* is characterized by sudden and recurrent attacks of extreme, unreasonable fear and anxiety. *Phobias* are irrational fears, such as the fear of open spaces or of spiders, that lead to avoidance of certain situations or objects. *Post-traumatic stress disorder* is a form of anxiety that develops following a stressful or traumatic event and *obsessive-compulsive disorder* is a condition in which a person's obsessions and fears lead them to carry out repetitive, ritualized acts.

TREATMENT

Counselling, *psychotherapy*, and group or individual *cognitive-behavioural therapy* are used to treat anxiety disorders. *Antidepressant drugs* are often used, and

antianxiety drugs (especially *benzodiazepine drugs*) may be used for short-term treatment but are addictive.

anxiolytics

See *antianxiety drugs*.

aorta

The main *artery* of the body, which supplies oxygenated blood to all other parts. The aorta arises from the left ventricle (the main pumping chamber of the *heart*) and arches up over the heart before descending, behind it, through the chest cavity. It terminates in the abdomen by dividing into the two common iliac arteries of the legs. The aorta is thick-walled and has a large diameter to cope with the high pressure and large volume of blood passing through it.

DISORDERS

The aorta, like other arteries, can become narrowed as a result of *atherosclerosis* (fat deposits on its walls), which may cause *hypertension* (high blood pressure). *Coarctation of the aorta* (in which the aorta is abnormally narrow at birth) and *aortitis* (inflammation of the aorta wall) are examples of aorta-specific disorders. Both aortitis and atherosclerosis may result in an aortic *aneurysm* (ballooning of the aorta wall), which may require surgery. (See also *arteries, disorders of; circulatory system*.)

aortic incompetence

Leakage of blood through the aortic valve (one of the *heart valves*), resulting in a backflow of blood from the aorta into the left ventricle (the heart's main pumping chamber).

CAUSES

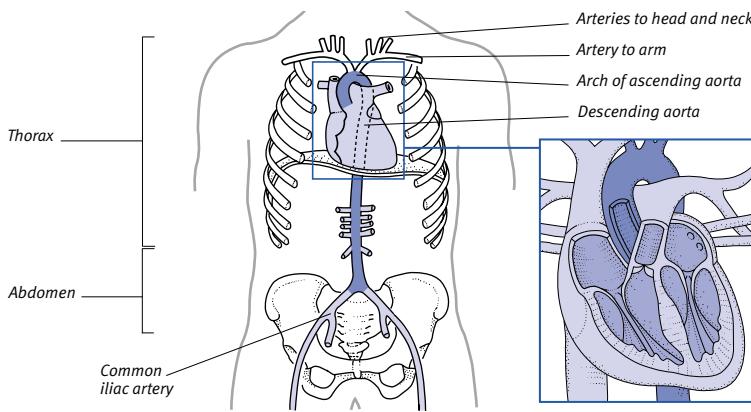

Failure of the aortic valve to close properly may be due to a *congenital* (present from birth) abnormality in which the valve has two leaflets (flaps) rather than three. The valve leaflets can be destroyed by infective *endocarditis* (inflammation of the membrane lining the heart). Long-term *hypertension* can sometimes cause the root of the aorta to stretch so that the valve does not close properly.

Aortic incompetence is also associated with *ankylosing spondylitis* (a disorder that affects the spine), and *Marfan syndrome*, a congenital disorder of connective tissues. *Rheumatic fever*, which is now rare, may damage the valve, causing a combination of *aortic stenosis* (narrowing of the aortic valve) and incompetence. In addition, aortic incompetence may occur in untreated *syphilis*.

LOCATION AND STRUCTURE OF THE AORTA

From its origin at the left ventricle, the aorta passes upwards, curves behind the heart, and runs downwards, passing through the thorax (chest) and into the abdomen, where it terminates by dividing into two common iliac arteries. The aorta is thick-walled and large in

diameter (about 2.5 cm at its origin) to cope with the high pressure and large volume of blood that passes through it. The thick walls of the aorta have an elastic quality that helps to even out the peaks and troughs of pressure that occur with each heartbeat.

SYMPTOMS AND SIGNS

Aortic incompetence may not cause symptoms; it is sometimes found during a routine medical examination when the doctor hears a murmur (abnormal heart sound) over the front of the chest wall to the left of the sternum (breastbone).

The heart compensates for the backflow of blood into the left ventricle by working harder, until the combination of hypertrophy (muscle thickening) and dilatation (ballooning) of the left ventricle wall eventually leads to *heart failure* (reduced pumping efficiency of the heart); this causes breathing difficulty and *oedema* (a buildup of fluid).

DIAGNOSIS AND TREATMENT

A *chest X-ray*, *ECG* (measurement of the electrical activity of the heart), and *echocardiography* (imaging of the heart structures by measuring the pattern of reflection of sound waves from them) may be carried out to diagnose aortic incompetence. A cardiac catheter (flexible tube inserted into the heart via blood vessels) is sometimes used to demonstrate the degree of incompetence (see *catheterization, cardiac*).

Heart failure resulting from aortic incompetence can be treated with *diuretic drugs* or other drugs to remove retained fluid from the lungs. *Heart-valve surgery* to replace the damaged valve may eventually be necessary.

aortic stenosis

Narrowing of the opening of the aortic valve (one of the *heart valves*), causing obstruction of blood flow into the circulation. Aortic stenosis makes the heart work harder and causes the muscle in the wall of the left ventricle (the main pumping chamber of the heart) to thicken. Narrowing of the valve also reduces the amount of blood flowing into the *coronary arteries* (the main arteries that supply the tissues of the heart with oxygen-rich blood).

CAUSES

The most common cause of aortic stenosis is deposition of calcium on the aortic valve. This deposition is usually associated with *atherosclerosis* (fatty deposits). Aortic stenosis may also be the result of a *congenital* (present from birth) abnormality.

SYMPTOMS AND SIGNS

Aortic stenosis may not cause any symptoms; it is sometimes found during a routine medical examination when the doctor hears a murmur (an abnormal heart sound) over the front of the chest wall to the right of the sternum (breastbone) and sometimes up into the neck. Symptoms, when they do occur, include fainting, lack of energy, chest pain on exertion as a result of *angina pectoris*, and breathing difficulties. Other features, which occur

at a late stage, include a weak pulse and *cardiomegaly*, (enlargement of the heart).

DIAGNOSIS AND TREATMENT

A *chest X-ray*, an *ECG* (measurement of the electrical activity of the heart), and *echocardiography* (imaging of the heart structures by measuring the pattern of reflection of sound waves from them) may be carried out to diagnose aortic incompetence. A cardiac catheter (flexible tube that is inserted into the heart via blood vessels) can be used to demonstrate the degree of stenosis (see *catheterization, cardiac*).

Heart-valve surgery may be needed to widen or replace the damaged valve.

aortitis

Inflammation of the *aorta* (the main artery of the body). Aortitis is a rare condition that occurs in people with *arteritis* (inflammation of the arteries) or untreated *syphilis* and in some people with *ankylosing spondylitis* (a disorder affecting the spine).

Aortitis may cause part of the aorta to widen and its walls to become thinner. This may lead to an *aneurysm* (ballooning of the artery), which may burst and cause severe, sometimes fatal, blood loss. Aortitis may also damage the ring around the aortic valve in the heart, leading to *aortic incompetence* (a condition which allows the backflow of blood into the heart), which may eventually result in *heart failure* (reduced pumping efficiency of the heart).

aortography

An imaging technique that enables the *aorta* (the main artery of the body) and its branches to be seen clearly on *X-ray* film following injection of a *contrast medium* (a substance that is opaque to X-rays) into the aorta.

HOW AND WHY IT IS DONE

The contrast medium is usually injected into the aorta through a fine catheter (a flexible plastic tube) that is inserted either into the femoral artery at the groin, the brachial artery on the inside of the elbow, or directly into the aorta within the lower abdomen.

Aortography is used if surgery is needed to treat an *aneurysm* (ballooning of the aorta).

apathy

The absence of feelings that is often associated with a lack of energy. Healthy people may be described as apathetic, but true apathy is a feature of certain

APGAR CHART			
Sign	0	1	2
Colour	Blue, pale	Body pink; extremities blue	Completely pink
Respiratory effort	Absent	Weak cry; irregular breathing	Good strong cry; regular breathing
Muscle tone	Limp	Bending of some limbs	Active motion; limbs well-flexed
Reflex irritability	No response	Grimace (on nasal stimulation)	Cry
Heart rate	Absent	Slow (below 100 beats per minute)	Over 100 beats per minute

mental illnesses, such as *schizophrenia*. An affected person fails to take interest in everyday activities and tends to be inactive and lacking in volition (drive).

aperient

A mild *laxative drug*.

apex

The tip or uppermost surface of an organ or structure, such as the lungs or the heart. The apex of a tooth is the tip of its root.

apex beat

A normal heartbeat felt through the chest wall. As the heart contracts, its tip hits the chest wall and the beat can be felt between the fifth and sixth ribs on the left side of the chest. The apex beat is displaced when the heart is enlarged.

Apgar score

A system devised by Virginia Apgar, an American anaesthetist, to assess the condition of a newborn baby and help to direct appropriate care. Five features (breathing, heart rate, colour, muscle tone, and response to stimulation) are scored one minute, and again five minutes, after birth.

aphakia

The absence of the *lens* from the eye. Aphakia may be congenital (present from birth), may result from surgery (for example, *cataract surgery*), or may be due to a penetrating injury.

Aphakia causes severe loss of focusing in the affected eye and requires correction by implanting a lens or with contact lenses or glasses.

aphasia

Complete absence of previously acquired language skills caused by a brain disorder that affects the ability to speak

and write, and/or comprehend and read. Related disabilities that may occur as a feature of aphasia are *alexia* (word blindness) and *agraphia* (writing difficulty).

CAUSES

Language function in the brain lies in the dominant cerebral hemisphere (see *cerebrum*). Two particular areas in this hemisphere, Broca's and Wernicke's areas, and the pathways connecting the two, are important in language skills. Damage to these areas, which most commonly occurs as a result of *stroke* or *head injury*, can lead to aphasia.

TYPES AND SYMPTOMS

Broca's aphasia causes difficulty in expressing language. Speech is laboured and normal rhythm is lost, but the few words uttered tend to be meaningful. Writing may also be impaired.

Wernicke's aphasia causes difficulty in language comprehension. Speech is fluent but its content is disturbed, with errors in word selection and grammar. Writing is also impaired, and spoken and/or written language may not be understood.

In *associative aphasia*, comprehension is normal, and the affected individual can write and speak. However, he or she is unable to repeat what has been heard and cannot read aloud.

Global aphasia comprises the total, or near total, inability to speak, write, or understand language.

Nominal aphasia is restricted to difficulty in naming objects or in finding words, although the sufferer may be able to choose the correct word from several offered.

In *jargon aphasia*, an affected individual cannot form grammatical sentences and utters meaningless phrases composed of jumbled words or neologism.

TREATMENT AND OUTLOOK

Some recovery from aphasia is usual following a stroke or head injury, but

the more severe the aphasia, the less the chances of recovery. *Speech therapy* is the main treatment. (See also *aphonia*; *dysarthria*; *dysphasia*; *dysphonia*; *speech*; *speech disorders*.)

apheresis

A procedure in which blood is withdrawn from a donor or patient and reinfused after one or more selected components have been separated and removed. For example, in *plasmapheresis*, *antibodies* (proteins manufactured by the *immune system*) that are causing a disease (such as *Guillain–Barré syndrome* or *Goodpasture's syndrome*) are removed; in leukapheresis, white blood cells (see *lymphocyte*) are removed either to reduce their number or to harvest them for use in a *blood transfusion*.

aphonia

Complete loss of the voice, which may result from surgery to the *larynx* (voice-box) or may be temporary, sudden in onset, and due to emotional stress. In *aphonia*, the vocal cords fail to meet as normal when an individual tries to speak, although they may come together when the person coughs.

There is no particular treatment for *aphonia*, but in the temporary form of the condition, the sufferer's voice usually returns as suddenly as it disappeared. (See also *dysphonia*.)

aphrodisiac

Any substance that is thought to stimulate erotic desire and enhance sexual performance. Aphrodisiacs are named after Aphrodite, the Greek goddess of love, beauty, and fertility.

For centuries, various substances (most notably oysters and rhinoceros horn) have been used as aphrodisiacs. In fact, no substance has a proven aphrodisiac effect.

aphthous ulcerSee *ulcer, aphthous*.**apical**

A term used to describe the position of structures that are found at the *apex* (tip) of particular organs and structures, including the lungs and heart.

apicectomy

The surgical removal of the tip of a tooth root in order physically to eliminate an infection or an infected cyst at the root tip. The procedure was once performed as part of *root-canal treatment* but is now used less often because root-canal treatment alone usually achieves the desired result.

aplasia

Absent or severely reduced growth and development of any organ or tissue. For example, in bone marrow aplasia, the rate of cell division in the bone marrow is reduced, leading to insufficient blood-cell production (see *anaemia, aplastic*). Some birth defects, such as stunted limbs (see *phocomelia*), occur as a result of incomplete tissue formation during prenatal development.

aplastic anaemiaSee *anaemia, aplastic*.**apnoea**

Cessation of breathing that can occur either temporarily (for a few seconds or up to a minute or two) or for a prolonged period.

CAUSES

Breathing is an automatic process that is controlled by the respiratory centre in the *brainstem* (a stalk of nerve tissue linking the brain to the spinal cord). The respiratory centre sends nerve impulses that regulate contraction of the diaphragm and muscles in the chest wall, thereby controlling the rate and depth of breathing. Failure of this centre to maintain normal breathing is known as *central apnoea*. The condition may occur in babies, particularly those who are premature, and can be detected by an apnoea alarm. Central apnoea can also be the result of damage to the brainstem (following a *stroke* or *head injury*, for example).

In obstructive apnoea, breathing is prevented by a blockage in the airway. The most common type is *sleep apnoea*, in which blockage of the upper airway occurs repeatedly during sleep.

Deliberate temporary apnoea occurs in *breath-holding attacks*. Another type of apnoea occurs in *Cheyne–Stokes respiration*, in which cycles of deep, rapid breathing alternate with episodes of breathing stoppage.

TREATMENT

Treatment depends on the cause; in newborn babies, apnoea resolves itself as they mature. In cases of stroke or head injury, artificial ventilation may be necessary, temporarily, until recovery occurs.

apocrine gland

A gland that discharges cellular material in addition to the fluid that it secretes. The term apocrine is usually applied to the type of *sweat glands* that appear in hairy areas of the body after puberty. (See also *eccrine gland*.)

apocrinitis

Inflammation of the *apocrine glands*, which are located in the armpit, groin, and perineum.

apolipoprotein

Any of a group of proteins that are constituents of *lipoproteins*, the carriers of fat in the bloodstream. Apolipoproteins are also involved in the growth and repair of nerve tissues.

apomorphine

A drug that is used in the treatment of *Parkinson's disease*. Nausea and vomiting are common side effects of apomorphine at the start of treatment.

aponerousis

A wide sheet of tough, fibrous tissue that acts as a tendon by attaching a muscle to a bone or a joint.

apophysis

An outgrowth of bone at the site of attachment of a tendon to bone. Inflammation may occur, as in *Osgood–Schlatter disease*.

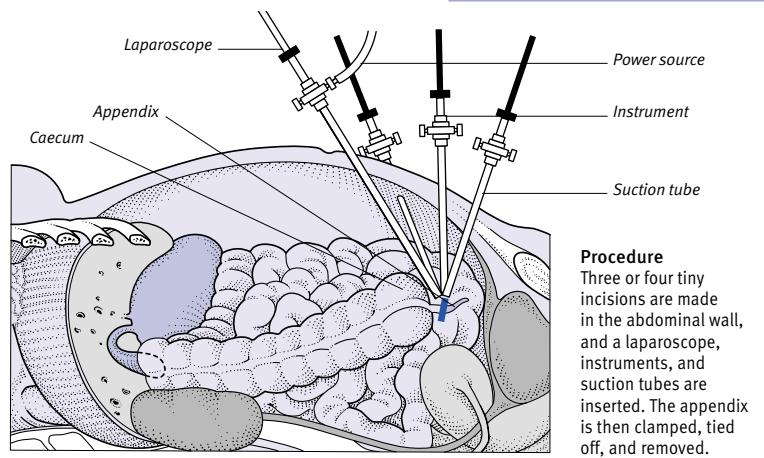

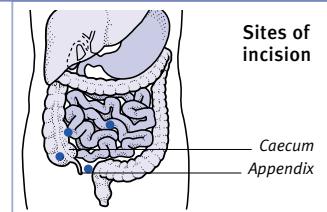

apoplexyAn outdated term for a *stroke*.**apoptosis**

The natural process of programmed cell death. Apoptosis occurs in embryonic development, when the shaping of body parts is taking place, and continues throughout life in the constant cycle of death and renewal of body cells. Failure of apoptosis is implicated in the development of cancers.

apothecaryAn outdated term for a *pharmacist*.**LAPAROSCOPIC APPENDICECTOMY**

Surgery to remove the appendix can be carried out, under general anaesthesia, either conventionally or laparoscopically.

Laparoscopic appendicectomy takes approximately an hour, which is three times as long as conventional surgery, but recovery is quicker.

appendage

An additional piece of *tissue* that is attached to a main structure. An auricular appendage is a small tag of tissue attached near the ear that may be present from birth.

appendicectomy

Surgical removal of the appendix to treat acute *appendicitis* (inflammation of the appendix).

WHY IT IS DONE

Appendicectomy is performed to prevent an inflamed appendix bursting and causing *peritonitis* (inflammation of the peritoneum, the lining of the abdominal cavity) or an abdominal abscess.

HOW IT IS DONE

The two methods of appendicectomy are conventional appendicectomy and *minimally invasive surgery*. Conventional surgery involves making a hole in the abdominal wall that is large enough for the surgeon's instruments and fingertips to be introduced. In minimally invasive surgery, three or four small holes are made in the abdominal wall; a laparoscope (viewing instrument) that incorporates a video camera is inserted into one of the openings, and instruments and suction tubes into the others. In both types of operation, the appendix is identified, clamped, tied off at its base, and removed.

If the appendix has burst, the infected area of the abdominal cavity is washed out with saline and drained via a tube inserted into one of the incisions. Antibiotic drugs may also be given to prevent peritonitis.

COMPLICATIONS AND OUTLOOK

Possible complications are infection of the incision wound, an abscess at the site from which the appendix was removed, or localized peritonitis.

In the absence of complications, normal physical activities can usually be resumed within two to three weeks.

appendicitis

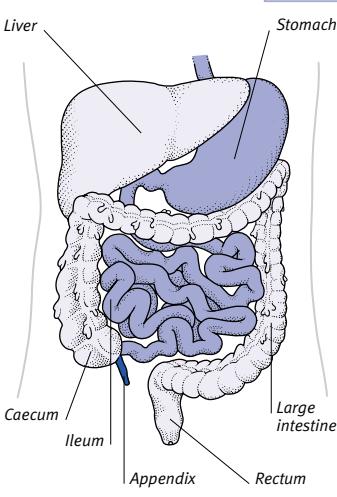

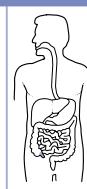

Acute inflammation of the *appendix* (a narrow, finger-shaped tube that branches off the large intestine), which is a common cause of abdominal pain and *peritonitis* (inflammation of the lining of the abdominal cavity).

CAUSE AND SYMPTOMS

The cause of appendicitis is usually not known, but the condition is sometimes caused by obstruction of the appendix by a lump of faeces. The closed end of the appendix beyond the obstruction

LOCATION OF THE APPENDIX

In the lower right-hand side of the abdomen, the appendix may lie behind the caecum, or in front of or behind the ileum.

becomes inflamed, swollen, and infected. This may lead to *gangrene* (tissue death) in the appendix wall, which may perforate (burst).

The first symptom is usually vague discomfort around the navel. Within a few hours, this develops into severe, more localized pain, which is usually most intense in the lower right-hand side of the abdomen. Symptoms may differ if the appendix is not in the most common position. For example, if the appendix impinges on the ureter, the urine may become bloodstained.

DIAGNOSIS AND TREATMENT

Diagnosis may be difficult because the symptoms of appendicitis are similar to those of many other abdominal disorders. Sometimes a *laparotomy* (surgical investigation of the abdomen) is necessary in order to confirm or exclude a diagnosis of appendicitis.

The usual treatment for appendicitis is *appendicectomy*, which is often performed endoscopically (see *minimally invasive surgery*).

COMPLICATIONS

If treatment is delayed, an inflamed appendix may burst, releasing its contents into the abdomen. At this point, the pain ceases abruptly, but the perforation leads to peritonitis. In some

cases, the omentum (fold of peritoneum that covers the intestines) envelops the inflamed appendix; this prevents the spread of infection but may result in a localized *abscess* around the appendix.

appendix

A small, narrow tube that projects out of the caecum (the first part of the colon) at the lower right-hand side of the abdomen. The appendix may lie behind or below the caecum, or in front of or behind the ileum (part of the small intestine).

The appendix has no known function, but it contains a large amount of lymphoid tissue, which provides a defence against localized infection. The position of an individual's appendix partly determines the symptoms produced by acute *appendicitis* (inflammation of the appendix).

appendix abscess

An *abscess* (a collection of pus) that may form after the rupture of an inflamed appendix (see *appendicitis*).

appetite

A desire for food; a pleasant sensation that is felt in anticipation of eating. Appetite is distinct from *hunger*, which is a disagreeable feeling caused by the need for food.

Appetite, which is regulated by two parts of the *brain* (the *hypothalamus* and cerebral cortex), is learned by enjoying a variety of foods that smell, taste, and look good. It combines with *hunger* to ensure that the right amount of a wide range of foods is eaten in order to stay healthy. (See also *appetite, loss of*.)

appetite, loss of

Loss of appetite, known medically as *anorexia*, is usually temporary and due to an emotional upset or minor illness. Persistent loss of appetite may be a symptom of a more serious underlying physical or psychological disorder and requires investigation by a doctor.

CAUSES

In adolescents and young adults, loss of appetite may be due to *anorexia nervosa* (an eating disorder) or to *drug abuse*, particularly of *amphetamine drugs*. *Depression* or *anxiety* may result in loss of appetite at any age.

Possible physical causes of appetite loss include a *stroke* (damage to part of the brain caused by an interruption to its blood supply), a *brain tumour*, or a

head injury that has damaged the *hypothalamus* or cerebral cortex (the parts of the brain that control appetite). Other physical causes include intestinal disorders, such as *gastritis* (inflammation of the stomach lining, which is common in problem drinkers), *stomach cancer*, a *gastric ulcer*, and liver disorders such as *hepatitis*. Many infectious diseases, such as *influenza*, can also lead to loss of appetite.

Between the ages of about two and four, some children go through a period of refusing food. If there are no other symptoms, this phase should be regarded as a normal part of a child's development.

For an otherwise healthy person, a period of two or three days without food is not harmful, provided that plenty of nonalcoholic fluids are drunk. A doctor should always be consulted, however, if there are other health problems (particularly *diabetes mellitus*) or if regular medication is being taken.

All cases of appetite loss that last for more than a few days should be investigated by a doctor. Appetite generally returns to normal once any underlying illness has been treated. (See also *appetite stimulants*.)

appetite stimulants

Various tonics and remedies that have been traditionally prescribed to stimulate the appetite. None are proven to be effective.

Some drugs, such as *corticosteroid drugs*, may stimulate the appetite when used to treat unrelated disorders.

appetite suppressants

A group of drugs that reduce the desire to eat. Sibutramine is the only appetite suppressant now commonly prescribed. Appetite suppressants may be used in the treatment of severe *obesity*, along with dieting and exercise, when serious attempts at dieting and exercise have previously failed to bring about sufficient weight loss.

HOW THEY WORK

Sibutramine works by inhibiting the reuptake of *noradrenaline* (norepinephrine) and *serotonin*.

SIDE EFFECTS

Common side effects of sibutramine include constipation, a dry mouth (see *mouth, dry*), insomnia, nausea, palpitations, *hypertension* (high blood pressure), headache, anxiety, sweating, and disturbance of the sense of taste.

The use of sibutramine is strictly controlled and is limited to a maximum of one year.

appliance

See *orthodontic appliances*.

apraxia

The inability to carry out purposeful movements despite normal muscle power and coordination. Apraxia is caused by damage to nerve tracts in the *cerebrum* (the main mass of the brain) that translate the idea for a movement into an actual movement. People with apraxia usually know what they want to do but are unable to recall from memory the sequence of actions necessary to achieve the movement. Damage to the cerebrum may be caused by a *head injury*, an infection, a *stroke* (damage to part of the brain caused by interruption to its blood supply), or a *brain tumour*.

TYPES

Apraxia takes various forms, and each is related to damage in different parts of the brain. Ideomotor apraxia is the inability to carry out a spoken command to make a certain movement, but to make the same movement unconsciously at other times. In sensory apraxia, a person may not be able to use an object due to loss of ability to recognize its purpose.

Agraphia (difficulty in writing) and *aphasia* (severe difficulty in expressing language) are special forms of apraxia.

OUTLOOK

Recovery from apraxia is highly variable and is dependent on the cause. Lost skills may need to be relearned.

APUD cell tumour

A growth composed of cells that produce various hormones. APUD (amine precursor uptake and decarboxylation) cells occur in different parts of the body.

Some tumours of the thyroid gland, pancreas, and lungs are APUD cell tumours, as are carcinoid tumours (tumours of the intestine or lung; see *carcinoid syndrome*) and *phaeochromocytoma* (a type of adrenal tumour).

aqueous cream

An *emollient* preparation that is commonly used to treat dry, scaly, or itchy skin in conditions such as *eczema*.

aqueous humour

A watery fluid that fills the front chamber of the *eye*, behind the *cornea* (the transparent front part of the eyeball).

arachidonic acid

One of the fatty acids in the body that are essential for growth.

arachis oil

Peanut or ground-nut oil. Arachis oil is used in *enemas* to lubricate and soften impacted faeces and to make bowel movements easier. It can also be applied to the scalp, followed by shampooing, in the treatment of *cradle cap*.

arachnodactyly

A term for long, thin, spiderlike fingers and toes. Arachnodactyly sometimes occurs spontaneously but is also characteristic of *Marfan syndrome*, an inherited connective tissue disease.

arachnoiditis

A rare condition that is characterized by chronic inflammation and thickening of the arachnoid mater, which is the middle of the three *meninges* (membranes) that cover the brain and spinal cord.

The cause of arachnoiditis is often unknown. However, the condition may develop following an episode of *meningitis* (inflammation of the meninges) or a *subarachnoid haemorrhage* (a type of brain haemorrhage). It may also be a feature of *syphilis* or *ankylosing spondylitis* (a disorder affecting the spine). Arachnoiditis may also result from injury or certain medical procedures.

Symptoms may include headache, epileptic seizures, blindness, or difficulty with movements due to increased muscle tension. There is no effective treatment for arachnoiditis.

arachnoid mater

The middle of the three layers of membrane (see *meninges*) that cover the *brain* and spinal cord.

arbovirus

Any of the many viruses transmitted by a member of the arthropod group of animals, including insects, mites, and ticks. (See also *insects and disease; mites and disease; ticks and disease*.)

ARC

An abbreviation for *AIDS-related complex*. (See also *AIDS*.)

arcus senilis

A grey-white ring near the edge of the *cornea* (the transparent front part of the eyeball) overlying the iris (the coloured part of the eye).

**Arcus senilis**

The arcus senilis is the lighter ring that overlies the edge of the iris (the coloured part of the eye).

Arcus senilis, which is caused by degeneration of fatty material in the cornea, develops gradually during adult life. The ring never spreads to the centre and does not affect eyesight. The development of the condition in early adulthood may be associated with an abnormally high level of fats in the blood (see *hyperlipidaemia*).

areola

The pigmented circular area surrounding the *nipple*. The term is also used to describe an inflamed area around a pimple (see *pustule*).

Aricept

A brand name for donepezil, an *acetylcholinesterase inhibitor* used to treat *Alzheimer's disease*.

aromatherapy

A form of *complementary medicine* that uses aromatic oils extracted from plants to treat a wide range of disorders. Practitioners claim that aromatherapy is particularly effective in treating stress-related and *psychosomatic* conditions.

The oil is applied in small quantities through massage; it may also be inhaled, incorporated into creams or lotions, or, very occasionally, taken internally. There is no conclusive scientific evidence of the benefits.

arousal

The awakening of a person from unconsciousness or semiconsciousness. The term is also used to describe any state of heightened awareness, such as that caused by sexual stimulation or fear. Arousal is regulated by the reticular formation in the *brainstem*.

arrhenoblastoma

A rare tumour of the ovary that occurs in young women. The tumour is non-cancerous, but it secretes *androgen*

hormones (male sex hormones) that cause *virilization* (development of male characteristics). Treatment of arrhenoblastoma is by surgical removal of the affected ovary.

arrhythmia, cardiac

An abnormality of the rhythm or the rate of the *heartbeat*. Arrhythmias are the result of a disturbance in the electrical impulses within the *heart* (see *Cardiac arrhythmia* box, below). Any isolated irregular beat is known as an *ectopic heartbeat*. Ectopic beats do not necessarily indicate the presence of an abnormality, however.

TYPES

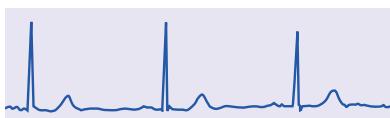

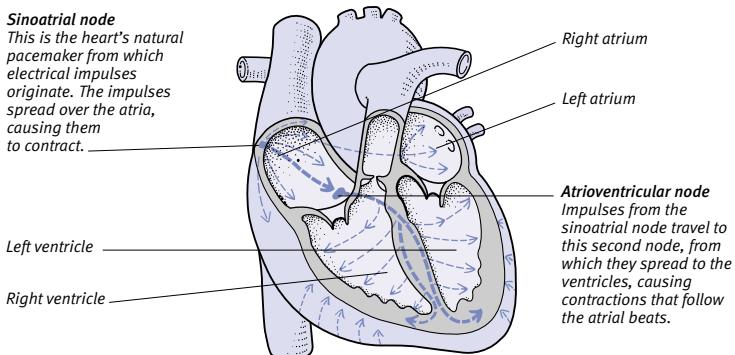

Arrhythmias can be divided into two main groups: tachycardias, in which the rate of the heartbeat is faster than normal, and bradycardias, in which the rate is slower. The rhythm may be regular, with each beat of the *atria* (upper chambers, see *atrium*) being followed by one beat of the *ventricles* (lower chambers).

Tachycardias In sinus tachycardia, the rate is raised, the rhythm is regular, and the beat originates in the sinoatrial node (see *pacemaker*). *Supraventricular tachycardia* is faster and the rhythm is regular. It may be caused by an abnormal electrical pathway that allows an impulse to circulate continuously in the heart and take over from the sinoatrial node. A rapid, irregular beat that originates in the ventricles is known as a *ventricular tachycardia*. In *atrial flutter*, the atria beat regularly and very rapidly, but not every impulse reaches the ventricles, which beat at a slower rate. Uncoordinated, fast beating of the atria is known as *atrial fibrillation* and produces totally irregular ventricular beats. *Ventricular fibrillation* is a form of *cardiac arrest* in which the heart does not pump blood because the ventricles are twitching very rapidly in a disorganized manner.

Bradycardias *Sinus bradycardia* is a slow, regular beat. In *heart block*, the conduction of electrical impulses through the

CARDIAC ARRHYTHMIA

Any disorder that interferes with the generation or transmission of impulses through the heart's electrical conducting system (below) can lead to a disturbance of cardiac rate or rhythm. These ECG recordings show two kinds of arrhythmia: sinus bradycardia and atrial fibrillation.

**Sinus bradycardia**

The heart rate is slow, but the rhythm normal, with each atrial beat (small rise) followed by a ventricular beat (spike). Sinus bradycardia is common in athletes but can also be caused by hypothyroidism.

**Atrial fibrillation**

The atria beat rapidly and irregularly. Ventricular beats (spikes) do not follow each atrial beat and are irregularly spaced. This arrhythmia is common in the elderly and in people with hyperthyroidism.

heart muscle is either partially or completely blocked, leading to a slow, irregular heartbeat. Periods of bradycardia may alternate with periods of tachycardia due to a fault in impulse generation (see *sick sinus syndrome*).

CAUSES

A common cause of arrhythmia is *coronary artery disease*, in which the coronary arteries are narrowed by *atherosclerosis* (fat deposits on the artery walls), particularly when following *myocardial infarction* (heart attack). Some tachycardias are the result of a *congenital* (present from birth) defect in the heart's conducting system.

Caffeine can cause tachycardia in some people. *Amitriptyline* and some other *antidepressant drugs* can cause serious cardiac arrhythmias if they are taken in high doses.

SYMPOTMS

An arrhythmia may be felt as palpitations, in which the individual becomes aware of an abnormally rapid heartbeat. However, in some cases, arrhythmias cause fainting and dizziness as a result of reduced blood flow to the brain, or chest pain and breathlessness if there is a reduction in blood flow to the lungs. These may be the first symptoms.

DIAGNOSIS

Arrhythmias are diagnosed by an *ECG*, which shows the pattern of electrical activity within heart muscle. If the arrhythmia is intermittent, a continuous recording may need to be made using an *ambulatory ECG*.

TREATMENT

Treatments for arrhythmias include *anti-arrhythmic drugs*, which prevent or slow tachycardias. With an arrhythmia that has developed suddenly, it may be possible to restore normal heart rhythm by using electric shock to the heart (see *defibrillation*).

Repeated attacks of tachycardia can sometimes be treated by radio frequency ablation (the removal of dead or diseased tissue) of the heart's abnormal conduction pathway. This may be carried out during cardiac catheterization (see *catheterization, cardiac*). In some cases, a pacemaker can be fitted to restore normal heartbeat by overriding the heart's abnormal rhythm.

arrowroot

A starchy substance that is obtained from the roots of the West Indian plant *MARANTA ARUNDINACEA*. Arrowroot was

traditionally used as an easily digestible invalid or baby food, being either mixed to a paste with milk or water or used as an ingredient in biscuits.

arsenic

A poisonous metallic element that occurs naturally in its pure form and various compounds. Arsenic poisoning, which is now rare, once occurred as a result of continuous industrial or pesticide exposure.

arterial reconstructive surgery

An operation to repair *arteries* that are narrowed, blocked, or weakened.

WHY IT IS DONE

Arterial reconstructive surgery is most often performed to repair arteries that have been narrowed by *atherosclerosis* (fatty deposits on artery walls). It is also used to repair *aneurysms* (ballooning of arteries) and arteries damaged as a result of injury.

HOW IT IS DONE

A narrowed or blocked section of artery, particularly a coronary artery, can be bypassed by sewing in a length of vein above and below the constricted area. Elsewhere in the body, the affected section is commonly replaced using an artificial tube or a section of vein. (See also *angioplasty, balloon; coronary artery bypass; endarterectomy*.)

arteries, disorders of

Disorders of the arteries may take the form of abnormal narrowing (which reduces blood flow and may cause tissue damage), complete obstruction (which may cause tissue death), or abnormal widening and thinning of an artery wall (which may cause rupture of the blood vessel).

TYPES

Atherosclerosis, in which fat deposits build up on the lining of artery walls, is the most common arterial disease. It can involve arteries throughout the body, including the brain (see *cerebrovascular disease*), heart (see *coronary artery disease*), and legs (see *peripheral vascular disease*). Atherosclerosis is the main type of *arteriosclerosis*, a group of disorders that cause thickening and loss of elasticity of artery walls.

Hypertension (high blood pressure) is another common cause of thickening and narrowing of arteries. Hypertension predisposes people to coronary artery disease and increases the risk of a *stroke* or *kidney failure*.

Arteritis is inflammation of artery walls that causes narrowing and sometimes blockage.

Aneurysm is ballooning of an artery wall caused by the pressure of blood flowing through a weakened area.

Thrombosis occurs when a thrombus (blood clot) forms in a blood vessel, causing obstruction of the blood flow.

An *embolism* is blockage of an artery by a fragment of blood clot or other material travelling in the circulation.

Raynaud's disease is a disorder in which there is intermittent spasm of small arteries in the hands and feet, usually precipitated by the cold.

arteriography

An alternative name for *angiography*, an X-ray technique for imaging arteries.

arteriole

A blood vessel that is a branch from an *artery* and which branches further to form *capillaries*. Arterioles have muscular walls, and their nerve supply enables them to be narrowed or widened to meet the blood-flow needs of tissues they supply.

arteriopathy

Any disorder of an artery (see *arteries, disorders of*).

arterioplasty

Surgical repair of an artery (see *arterial reconstructive surgery*).

arteriosclerosis

A group of disorders that cause thickening and loss of elasticity of artery walls. *Atherosclerosis* is the most common type of arteriosclerosis, and the two terms are often used synonymously.

Other types are medial arteriosclerosis (in which muscle and elastic fibres in larger arteries are replaced by fibrous tissue) and Monckeberg's arteriosclerosis (in which there are calcium deposits in the arterial lining).

arteriovenous fistula

An abnormal communication directly between an artery and a vein. An arteriovenous fistula may be present at birth or may result from injury. A fistula can also be created surgically for easy access to the bloodstream, as occurs in *dialysis*.

If the fistula is close to the skin surface it may cause a small, pulsating swelling. If several are present in the lungs, uptake of oxygen into the blood

may be impaired, resulting in *cyanosis* (blue skin colour) and breathing difficulty on exertion.

An isolated fistula that is causing symptoms can often be cut away and the ends of the blood vessels stitched closed. However, if there are many fistulas, surgery is not practicable.

arteritis

Inflammation of an artery wall, which causes narrowing or complete blockage of the affected artery, reduced blood flow, and, in some cases, *thrombosis* and tissue damage.

TYPES

There are several types of arteritis. *Buerger's disease* is an arteritis that affects the limbs, causing pain, numbness, and, in severe cases, *gangrene*. *Polyarteritis nodosa*, a serious *autoimmune disorder* (in which the immune system attacks the body's own tissues), can affect arteries in any part of the body, especially the heart and kidneys. *Temporal arteritis* affects arteries in the scalp

over the temples and may also affect the retinal artery in the eye. Takayasu's arteritis is thought to be an autoimmune disorder. This rare type of arteritis usually affects young women and involves the arteries that branch from the *aorta* into the neck and arms.

artery

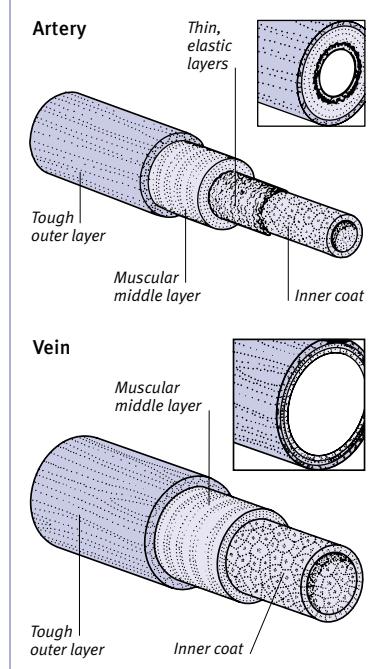

A blood vessel that carries blood away from the *heart*. Systemic arteries carry blood that has been pumped from the left ventricle (lower chamber) of the heart to all other parts of the body except the lungs. The largest systemic artery is the *aorta*, which emerges from the left ventricle; other major systemic arteries branch off from the aorta. The pulmonary arteries carry blood from the right ventricle to the lungs.

STRUCTURE

Arteries are tubes with thick, elastic, muscular walls able to withstand the high pressure of blood flow, to which they are subjected on each heartbeat. The structure of arteries helps to even out the peaks and troughs of blood pressure caused by the heartbeat, so that the blood is flowing at a relatively constant pressure by the time it reaches the smaller blood vessels (*arterioles*, which branch directly off the arteries and connect to the even smaller *capillaries*). The pulmonary arteries are thinner-walled than systemic arteries and contain blood at a lower pressure. (See also *arteries, disorders of*.)

STRUCTURE OF AN ARTERY

The walls of an artery consist of three layers: a smooth inner lining, a thick, muscular, elastic middle layer, and a tough, fibrous outer covering. Veins have thinner walls, and most of them contain valves.

Arthritis in the hands

The joints in the hands of a person suffering from rheumatoid arthritis are painful, swollen, and stiff. In severe cases, the joints become deformed.

system attacks the body's own tissues) that causes inflammation in the joints and other body tissues such as the pericardium (the membrane covering the heart), the lungs, and the eyes. The disorder has different effects in children (see *juvenile chronic arthritis*).

Ankylosing spondylitis is another persistent type of arthritis that initially affects the spine and the joints between the base of the spine and the pelvis. Other tissues, such as the eyes, may also be affected. Eventually, the disorder may cause the vertebrae (the bones of the spine) to fuse.

Reactive arthritis typically develops in susceptible people following an infection, most commonly of the genital tract or intestines.

Gout and *pseudogout* are types of arthritis in which crystals are deposited in a joint, causing swelling and pain.

Septic arthritis is a relatively rare condition that can develop when infection enters a joint either through a wound or from the bloodstream.

DIAGNOSIS

Diagnosis of particular types of arthritis is made from *blood tests* and, in some cases, microscopic examination of fluid from the affected joint. *X-rays* or *MRI* (a technique that produces cross-sectional or three-dimensional images of body structures) can indicate the type and extent of joint damage.

TREATMENT

Physiotherapy and exercises can help to minimize the effects of arthritis, and there are specific treatments for certain types (*antibiotic drugs* for septic arthritis, for example).

In severe cases, one or more of the diseased joints may require *arthroplasty*

(replacement of a joint with an artificial substitute) or *arthrodesis* (fusion of the bones in a joint).

arthrodesis

A surgical procedure in which the two bones in a diseased joint are fused to prevent the joint from moving, which relieves pain in the affected area.

HOW AND WHY IT IS DONE

Arthrodesis is performed if a joint is painful or unstable and other treatments, such as drugs or *arthroplasty* (replacement of the joint with an artificial substitute), have failed or are inappropriate.

Arthrodesis of a small joint, such as a finger joint, may be carried out under local anaesthetic (see *anaesthesia, local*). Otherwise, a general anaesthetic (see *anaesthesia, general*) is used. In most cases, cartilage (smooth, shock-absorbing tissue) is removed from the ends of the two bones, along with a surface layer of bone from each. The two ends are then joined so that they will fuse when fresh bone cells grow. The bones may need to be kept in position with plates, rods, or screws; a *bone graft* may also be carried out in some cases.

In arthrodesis of the knee or ankle joints, additional immobilization of the joint (by transfixing it with pins inserted through the skin) may be necessary to keep the area stable until healing is complete.

RECOVERY AND OUTLOOK

Complete union of the bones can take up to six months but may be much quicker. In some cases the bones fail to fuse, but fibrous tissue usually fills the gap between them and is strong enough to provide the same effect and strength as bone fusion.

Following arthrodesis, no movement can take place in the affected joint, unlike after arthroplasty. However, the advantage of arthrodesis over arthroplasty is that, once it has been performed, it requires no regular surveillance or further care; and the patient can be reasonably confident that the problem with the joint has been resolved permanently.

arthrography

A diagnostic technique in which the interior of a damaged joint is X-rayed following the injection of a radiopaque (visible on X-ray) solution. The procedure is gradually being replaced by *MRI*, *ultrasound scanning*, and *arthroscopy*.

arthrogryposis

See *contracture*.

arthropathy

A medical term for any disease or disorder that involves the *joints*. (See also *diabetic arthropathy*.)

arthroplasty

Replacement of a joint or part of a joint by metal or plastic components. A *hip replacement* is one of the most common operations of this type, as is a *knee-joint replacement*. Replacement of other joints, such as the finger (see *finger-joint replacement*), shoulder, and elbow, is also common.

arthroscopy

Inspection through an *endoscope* (a viewing tube) of the interior of a joint, usually for diagnostic purposes.

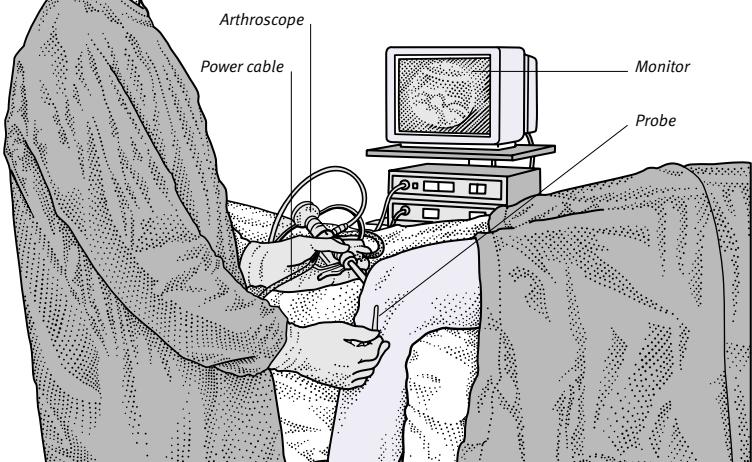

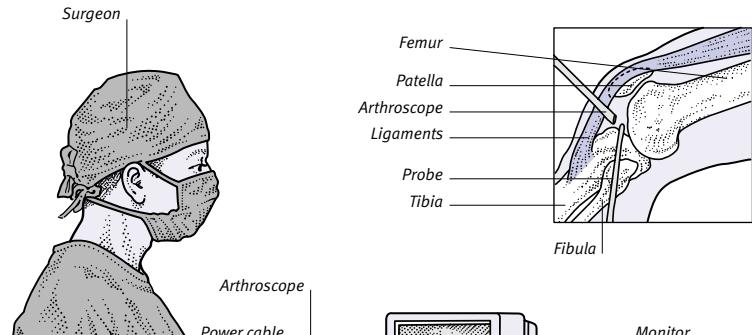

WHY IT IS DONE

Arthroscopy is most often used to diagnose disorders of the knee joint but can also be used in other joints such as the shoulder, hip, or wrist. The procedure allows the surgeon to see the surface of the bones, the ligaments, the cartilages, and the synovial membrane. Specimens can be taken for examination.

Some surgical procedures that used to involve making a large incision, such as removal of damaged cartilage, repair of ligaments, and shaving of the patella

HOW ARTHROSCOPY IS DONE

The procedure is usually performed under general anaesthesia. The joint is distended by injecting air or a saline solution, and the arthroscope and a probe are inserted into it through small skin incisions. While watching the monitor, the surgeon can repair or remove tissue, such as damaged cartilage, or drill or shave the surface of the patella (kneecap).

Arthroscope

An arthroscope is a type of rigid endoscope – a hollow stainless steel tube containing optical fibres, a lens, and a light source.

(kneecap), are now usually performed arthroscopically. Arthroscopic surgery substantially reduces the amount of recovery time required.

Arthrotec

The brand name of an *antirheumatic drug* containing *diclofenac* and *misoprostol*.

articulation

The junction point of two or more bones (see *joint*).

artificial feeding

See *feeding, artificial*.

artificial heart

See *heart, artificial*.

artificial insemination

A form of assisted conception in which semen is introduced artificially into the uterus, instead of by sexual intercourse, with the aim of inducing conception and pregnancy.

TYPES

There are two types of artificial insemination: AIH, artificial insemination with the semen of the woman's male partner; and AID, insemination with a donor's sperm. AIH is usually used for couples who are unable to have intercourse, or if the man has a low sperm count or a low volume of ejaculate. It is also used when a man's semen has been stored prior to his having treatment (such as chemotherapy) that has made him sterile. AID is available to couples if the man is infertile or a carrier of a genetic disease. It may also be used by a woman who wants children but has no male partner.

HOW IT IS DONE

Artificial insemination is carried out at centres that are specially staffed and equipped to obtain, test, and store semen, to carry out the insemination, and to give counselling before and after the procedure. Semen donors are screened for a wide variety of physical and mental disorders.

Insemination is performed by injecting a sample of semen into the woman's cervix using a small syringe. The procedure is timed to coincide with her natural ovulation (the development and release of an egg from the ovary), or it may be combined with treatment to stimulate ovulation.

artificial kidney

The common name for the machine used in *dialysis*.

artificial limb

See *prosthesis*.

artificial respiration

See *rescue breathing*.

artificial rupture of membranes

See *amniotomy*.

artificial saliva

A preparation used to relieve a persistently dry mouth, which may be a side effect of certain drugs or *radiotherapy* or may be due to *Sjögren's syndrome* (an autoimmune disorder in which the immune system attacks the body's own tissues). Artificial saliva, as a spray, gel, or pastilles, is formulated to resemble natural saliva as closely as possible.

artificial sweeteners

Synthetic substitutes for sugar that are used by people on slimming diets and by the food industry.

Saccharin and aspartame are often recommended for use in calorie-controlled diets. They are, however, of questionable value because the *appetite* compensates for the lack of calories from sugar, therefore other foods are eaten to maintain the calorie intake.

artificial tears

Preparations that are used to supplement tear production in disorders, such as *keratoconjunctivitis sicca*, that cause dry eye and to relieve irritation.

arytenoid

One of two pyramid-shaped cartilages that form part of the *larynx* (voice-box).

asbestos-related diseases

A variety of diseases that are caused by inhalation of asbestos fibres. Asbestos is a fibrous mineral formerly used as a heat- and fire-resistant insulating material. There are three main types of asbestos fibre: white, which is widely used, blue, and brown. Blue and brown are the most dangerous types of asbestos. The use of all types is now carefully controlled.

TYPES

In asbestososis, widespread fine scarring occurs in the lungs. The disease causes breathlessness and a dry cough, eventually leading to severe disability and death. Asbestosis develops mostly in industrial workers who have been heavily exposed to asbestos. The period from initial exposure to development of the disease

Electron micrograph of asbestos fibre in lung

An inhaled asbestos fibre impales and kills a macrophage (a scavenger cell that would normally engulf and destroy foreign particles in the lungs).

is usually at least 20 years. Diagnosis is by *chest X-ray*. Asbestosis increases the risk of developing *lung cancer*.

Mesothelioma is a cancerous tumour of the *pleura* (the membrane surrounding the lungs) or the *peritoneum* (the membrane lining the abdominal cavity). In the pleura, mesotheliomas cause pain and breathlessness; in the peritoneum they cause enlargement of the abdomen and intestinal obstruction. The condition cannot be treated and usually leads to death within one or two years. The average interval between initial exposure to asbestos and death is between 20 and 30 years. Mesothelioma affects people who have been exposed to blue or brown asbestos.

Diffuse pleural thickening is a condition in which the outer and inner layers of the pleura become thickened, and excess fluid may accumulate in the cavity between them. This combination restricts the ability of the lungs to expand, resulting in shortness of breath. The condition may develop even after short exposure to asbestos.

asbestosis

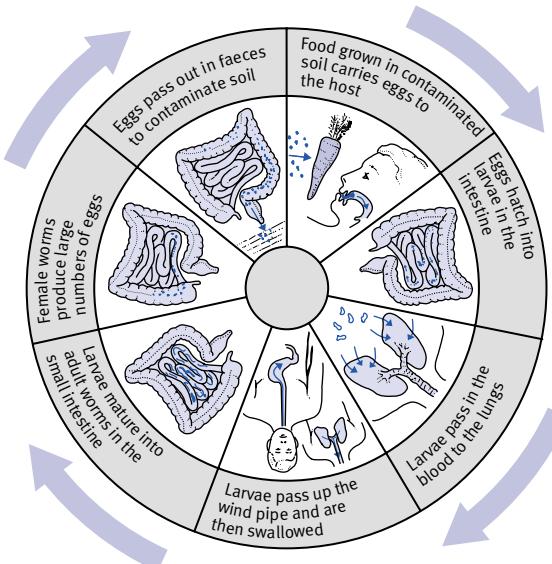

See *asbestos-related diseases*.

ascariasis

Infestation with the roundworm *ASCARIS LUMBRICOIDES*, which lives in the small intestine of its human host. Ascariasis is common worldwide, especially in the tropics. One or several worms may be present, but symptoms usually only occur with heavy infestation.

LIFE CYCLE OF THE ASCARIS WORM

The person becomes infested by swallowing the eggs, which hatch into larvae in the intestine. The larvae travel in the blood through the wall of the intestine to the lungs, up the windpipe, and are swallowed back into the small intestine. There they become adult worms.

**CAUSES**

The parasite that causes ascariasis is a pale, cylindrical, tapered roundworm, which reaches between 15 and 35 cm in length in its adult form.

Ascariasis is spread by ingestion of worm eggs, usually from food grown in soil that has been contaminated by human faeces. In some dry, windy climates, airborne eggs may be swallowed after being blown into the mouth.

SYMPOTMS

Light infestation may cause no symptoms, although mild nausea, abdominal pain, and irregular bowel movements may occur. A worm may be passed via the rectum, or it may be vomited. A large number of worms may compete with the host for food, leading to malnutrition and *anaemia*, which, in children, can retard growth.

TREATMENT

The worm infestation is treated with *anthelmintic drugs*, such as levamisole, which usually bring about complete recovery. The worms are passed out of the body via the rectum some days after the drug is taken.

ascites

Excess fluid in the peritoneal cavity, the space between the two layers of the peritoneum (the membranes that line the inside of the abdominal wall and cover the abdominal organs).

CAUSES

Ascites may occur in any condition that causes generalized *oedema* (excessive accumulation of fluid in the body tissues), such as in congestive *heart failure*, *nephrotic syndrome*, and *cirrhosis* of the liver. Ascites may occur in *cancer* if metastases (secondary growths) from a cancer elsewhere in the body develop in the peritoneum. The condition also occurs if *tuberculosis* affects the abdomen.

SYMPOTMS

Ascites causes abdominal swelling and discomfort. Additionally, it may cause breathing difficulty as a result of pressure on, and the immobilization of, the diaphragm, the sheet of muscle that separates the thorax (the chest) from the abdomen.

DIAGNOSIS

The doctor diagnoses the cause of ascites by removing and analysing a sample of ascitic fluid via a sterile needle inserted through the abdominal wall.

TREATMENT

The underlying cause is treated if possible. *Diuretic drugs*, particularly *spironolactone*, are often used to treat ascites associated with cirrhosis. If the ascites is causing discomfort or breathing difficulty, fluid can be drained from the peritoneal cavity.

ascorbic acid

The chemical name for *vitamin C*.

ASD

The abbreviation for *atrial septal defect*.

aseptic necrosis

Death of an area of bone tissue in the absence of infection. The cause of aseptic necrosis is almost always damage to the blood supply to bone, often as a result of a fracture. In some cases, the condition is associated with treatment with *corticosteroid drugs*.

Aseptic necrosis often results in chronic (long-term) pain and may cause stiffness in adjacent joints. Early treatment of fractures reduces the risk of the condition developing.

The head of the *femur* (thigh-bone) and the *scaphoid* (a bone in the wrist) are particularly likely to be affected. Aseptic necrosis may be diagnosed from *X-rays*; the affected area of bone appears denser than the surrounding bone.

aseptic technique

The creation of a germ-free environment to protect a patient from infection. Aseptic technique is used during surgery and other minor procedures, such as the insertion of a urinary catheter. It is also used during the care of people suffering from diseases in which the *immune system* is suppressed, such as *leukaemia*. Such conditions result in a weakening of the body's natural defences against infection.

All people who come in contact with the patient must scrub their hands and wear disposable gloves and masks and pre-sterilized gowns. Surgical instruments are sterilized in an *autoclave*. The patient's skin is cleaned with *antiseptic* solutions of, for example, iodine or *chlorhexidine*. In operating theatres, special ventilation systems purify the air. (See also *barrier nursing; isolation*.)

aspartame

An *artificial sweetener* used in some foods and drugs.

Asperger's syndrome

A developmental disorder that is usually first recognized in childhood because of stilted speech, difficulties with social interactions, and very specialized interests. Intelligence is normal or high.

Asperger's syndrome is one of a group of conditions known as *pervasive developmental disorders*; it is considered to be an *autism spectrum disorder* (a developmental disorder characterized by obsessive behaviour and impaired com-

munication and social skills). Special educational support may be necessary, often within mainstream education. Asperger's syndrome is a lifelong condition.

aspergillosis

An infection caused by inhalation of spores of *Aspergillus*, a fungus that grows in decaying vegetation. *Aspergillus* is harmless to healthy people but may proliferate in the lungs of people with *tuberculosis*. It can also worsen the symptoms of *asthma* and may produce serious, even fatal, infection in people with reduced immunity, such as those taking *immunosuppressant drugs*.

aspermia

See *azoospermia*.

asphyxia

The medical term for suffocation. Asphyxia may be caused by the obstruction of a large airway, usually by a foreign body (see *choking*), by insufficient oxygen in the surrounding air (as occurs when, for example, a closed plastic bag is put over the head), or by poisoning with a gas, such as carbon monoxide, that interferes with the uptake of oxygen into the blood.

The person initially breathes more rapidly and strongly to try to overcome the lack of oxygen in the blood. There is also an increase in heart rate and blood pressure.

First-aid treatment is by clearing the airway of obstruction followed by *rescue breathing*. Untreated asphyxia leads to death within a few minutes.

aspiration

The withdrawal of fluid or cells from the body by suction. The term also refers to the act of accidentally inhaling a foreign body, usually food or drink. If consciousness is impaired, for example by a head injury or excess alcohol intake, aspiration of the stomach contents is common.

Aspiration *biopsy* is the removal of cells or fluid, using a needle attached to a syringe, for examination. Aspiration biopsy is commonly used to obtain cells from a fluid-filled cavity (such as a *breast cyst*). The procedure is also used to obtain cells from the bone marrow (see *bone marrow biopsy*), or from internal organs, when a fine needle is guided to the site of the biopsy by *CT scanning* or *ultrasound scanning*. (See also *aspiration pneumonia*.)

aspiration pneumonia

A form of pneumonia that results from accidental inhalation of vomit. Aspiration pneumonia usually occurs in people whose cough reflex is not functioning, such as those who have drunk excessive amounts of alcohol, taken certain illegal drugs, or suffered a head injury.

aspirin

A nonopioid *analgesic drug* (painkiller) that may be given in tablet or suppository form to treat disorders such as headache, menstrual pain, and muscle discomfort. Aspirin has an *anti-inflammatory* action. It also reduces fever and is included in some *cold remedies*.

In small doses, aspirin reduces the stickiness of platelets (blood particles involved in clotting). This has led to its use in preventing *thrombosis* (abnormal blood clots) in people at risk of developing *stroke* or *myocardial infarction* (heart attack) and as an initial treatment of chest pain that may be due to myocardial infarction. Aspirin may also reduce the risk of *colon cancer* and slow the progress of *dementia*.

In children, aspirin can cause *Reye's syndrome*, a rare but serious brain and liver disorder. For this reason, it should not be given to children under the age of 16 years, except on the advice of a doctor. Aspirin may cause irritation of the stomach lining, resulting in indigestion or nausea. Prolonged use may cause bleeding from the stomach due to *gastric erosion* (disruption of the stomach lining) or *peptic ulcer*.

Aspro

A brand name for *aspirin*.

assay

The analysis or measurement of a substance to determine its presence or effects. A qualitative assay determines only whether or not a substance is present, whereas a quantitative assay determines the actual amount present.

Biological assays (known as bioassays) measure the response of an animal or organ to particular substances. Assays can be used, for example, to assess the effects of a drug or to measure hormone levels. (See also *immunoassay*; *radioimmunoassay*.)

assisted conception

Treatment for *infertility* involving techniques that assist the fertilization and implantation of eggs.

association area

One of a number of areas in the cortex (outer layer) of the *brain* that are concerned with higher levels of mental activity. Association areas interpret information received from sensory areas and prompt appropriate responses, such as voluntary movement.

associative aphasia

Also known as conductive aphasia, a form of *aphasia* (loss of language skills, including comprehension and/or speech production) in which comprehension is normal, and the affected individual can write and speak, but he or she is unable to repeat what has been heard and cannot read aloud. Associative aphasia is caused by damage to a localized area in the brain, often as a result of a *stroke*.

astereognosis

The inability to recognize objects by touch when they are placed in the hand, even though there is no defect of sensation in the fingers or difficulty in holding the object. Astereognosis is either left- or right-sided; tactile recognition is normal on the other side. If both sides are affected, the condition is called tactile *agnosia*.

Astereognosis and tactile agnosia are caused by damage to parts of the *cerebrum* (the main mass of the brain) that are involved in recognition by touch. The conditions may occur as a result of a *stroke* or a *head injury*.

asthenia

An outdated term for loss of strength and energy (see *weakness*).

asthenia, neurocirculatory

See *cardiac neurosis*.

asthma

A lung disease in which there is intermittent narrowing of the *bronchi* (airways), causing shortness of breath, wheezing, and a cough. The illness often starts in childhood but can develop at any age. At least one child in seven suffers from asthma, and the number affected has increased dramatically in recent years. Childhood asthma may be outgrown in about half of all cases.

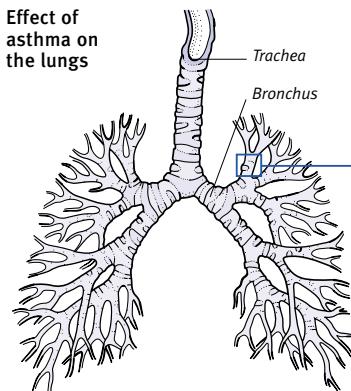

During an asthma attack, the muscle in the walls of the airways contracts, causing narrowing. The lining of the airways also becomes swollen and inflamed, producing excess mucus that can block the smaller airways.

THE CAUSE OF ASTHMA

Breathlessness and wheezing in asthma are caused by narrowing of the bronchioles (small airways in the lungs). Asthma can be triggered by a wide variety of stimuli, including exercise, infection, pollen, and dust, which would have no effect on non-asthmatic people.

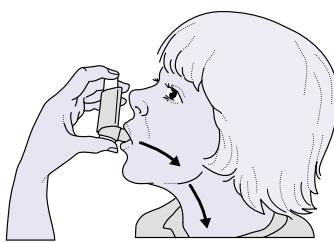

Inflammation of the linings of these bronchioles results in increased production of sputum (phlegm), which makes the obstruction worse. A dry cough often develops as the sufferer attempts to clear the airways.

Effect of asthma on the lungs

TREATMENT OF AN ASTHMA ATTACK

Attacks are treated by inhalation of a bronchodilator drug from an inhaler. For a severe attack, a nebulizer can be used to dispense the drug as fine mist through a face mask or mouthpiece. Babies, young children, or any adults who are unable to coordinate their breathing, require a spacer.

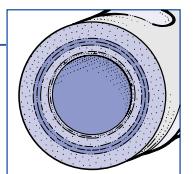

Using an inhaler

To use the inhaler correctly, exhale first then tilt the head back. Take in a slow, deep breath while releasing the drug by depressing the canister. Two puffs should increase air flow within 15 minutes.

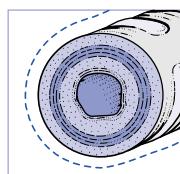

Using a spacer

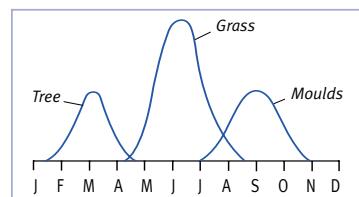

The inhaler, fitted with a spacer and face mask, is placed over the baby's nose and mouth. This allows the baby to inhale the drug while breathing normally.

Healthy bronchiole
Inhalation of the bronchodilator widens the bronchiole and improves airflow.

Obstructed bronchiole
Before treatment, the airflow is obstructed by a narrowing of the bronchiole.

Seasonal asthma

When symptoms occur only during a few months, the cause is likely to be allergy to pollen or spores.

TYPES AND CAUSES

In some people, an allergic response triggers the swelling and inflammation in the airways. This allergic type of asthma tends to occur in childhood, and it may develop in association with the allergic skin condition, *eczema* or certain other allergic conditions such as hay fever (see *rhinitis*, *allergic*). Susceptibility to these conditions frequently runs in families.

Some substances are known to trigger attacks of allergic asthma (see *allergens*). These include pollen, house-dust mites, mould, feathers, and dander (tiny scales) and saliva from furry animals such as cats and dogs. Rarely, certain foods, such as milk, eggs, nuts, and wheat, provoke an allergic asthmatic reaction. Some people with asthma are sensitive to *aspirin*, and taking it may trigger an attack.

When asthma starts in adulthood, there are usually no identifiable allergic triggers. The first attack is sometimes brought on by a respiratory tract infection, stress, or anxiety.

In some cases, a substance that is inhaled regularly in the work environment can result in the development of asthma in a previously healthy person. This is known as occupational asthma, and it is one of the few occupational lung diseases that are still increasing in incidence.

There are currently about 200 substances used in the workplace that are known to trigger symptoms of asthma, including glues, resins, latex, and some chemicals, especially isocyanate chemicals used in spray painting. However, occupational asthma can be difficult to diagnose because a person may be regularly exposed to a particular trigger

substance for weeks, months, or even years before the symptoms of asthma begin to appear.

Factors that can provoke attacks in a person with asthma include cold air, exercise, smoke, and occasionally emotional factors such as stress and anxiety. Although industrial pollution and exhaust emission from motor vehicles do not normally cause asthma, they do appear to worsen symptoms in people who already have the disorder. Pollution in the atmosphere may also trigger asthma in susceptible people.

SYMPTOMS

Asthma attacks can vary in severity from mild breathlessness to *respiratory failure*. The main symptoms are wheezing, breathlessness, dry cough, and a tightness in the chest. In a severe attack, breathing becomes increasingly difficult, resulting in a low level of oxygen

in the blood. This causes *cyanosis* (a bluish discolouration) of the face, particularly of the lips. Left untreated, such attacks can be fatal.

TREATMENT

There is no cure for asthma, but attacks can be prevented to a large extent if a particular allergen can be identified and consequently avoided.

Treatment involves inhaled *bronchodilator drugs* (sometimes known as relievers) to widen the airways, thereby relieving symptoms. When symptoms occur frequently, or are severe, inhaled *corticosteroids* are also prescribed. These drugs (also known as preventers) are used continuously to prevent attacks by reducing inflammation in the airways.

Other drug treatments include *sodium cromoglicate* and nedocromil sodium, both of which are useful in the prevention of exercise-induced asthma. The use of a *leukotriene receptor antagonist* in combination with a corticosteroid drug may enable the required dose of corticosteroid to be reduced. *Theophylline* or the inhaled *anticholinergic drug* ipratropium bromide may also be used as bronchodilators. An asthma attack that has not responded to treatment with a bronchodilator needs immediate assessment and treatment in hospital.

asthma, cardiac

Breathing difficulty in which *bronchospasm* (narrowing of the airways) and wheezing occur as a result of fluid accumulation in the lungs (*pulmonary oedema*). Cardiac asthma is usually due to reduced pumping efficiency of the left side of the heart (see *heart failure*) and is not true asthma. Treatment is with *diuretic drugs* or other drugs for heart failure.

astigmatism

A condition in which the front surface of the *cornea* does not conform to the normal "spherical" curve, even though the eye is perfectly healthy. Because the cornea is unevenly curved, it refracts (bends) the light rays that strike it to differing degrees. The *lens* is then unable to bring all the rays into focus on the light-sensitive *retina*. A minor degree of astigmatism is normal and does not require correction. More severe astigmatism causes blurring of lines at a certain angle and does require correction.

TREATMENT

Correction may be achieved by using special "cylindrical" glasses that can be

framed at a precise angle; contact lenses that can give an even spherical surface for focusing; or by undergoing *laser treatment* on the cornea.

astringents

COMMON DRUGS

- Aluminium acetate • Potassium permanganate • Silver nitrate • Zinc sulphate

Substances that cause tissue to dry and shrink by reducing its ability to absorb water. Astringents are widely used in *antiperspirants* and to promote healing of broken or inflamed skin. They are also used in some eye or ear preparations. Astringents may cause burning or stinging when applied.

astrocytoma

A type of cancerous *brain tumour*. Astrocytomas are the most common type of *glioma*, a tumour that arises from the glial (supporting) cells within the nervous system.

Astrocytomas most commonly develop in the cerebrum (the main mass of the brain) and are classified in four grades (I to IV) according to their rate of growth and malignancy. A grade I astrocytoma is a slow-growing tumour that may spread widely throughout the brain but may be present for many years before causing symptoms. The most severe and fast-growing type is called *glioblastoma multiforme* (a grade IV astrocytoma).

Symptoms are similar to those of other types of brain tumour. Diagnostic tests include *CT scanning* or *MRI*. Treatment is with surgery as well as, in some cases, *radiotherapy*.

asylum

An outdated term for an institution that provides care for the mentally ill.

asymptomatic

A medical term meaning without *symptoms* (indications of illness noticed only by the patient). For example, *hypertension* (high blood pressure) is often asymptomatic and is usually discovered during a routine blood pressure test and *diabetes mellitus* is often diagnosed from a routine blood or urine test.

Most disorders have no symptoms in their early stages. In the case of *cancer*, much effort has been made to devise screening tests for the detection of tumours at their early, asymptomatic, stage. (See also *sign*.)

asystole

A term meaning absence of the heart-beat (see *cardiac arrest*).

ataxia

Incoordination and clumsiness that may affect balance and gait (see *walking*), limb and eye movements, and/or speech.

CAUSES

Ataxia may be the result of damage to the *cerebellum* (the part of the brain concerned with coordination) or to nerve pathways in the *brainstem* (a stalk of nerve tissue linking the brain to the *spinal cord*) and/or spinal cord.

Possible causes include injury to the brain or spinal cord. In adults, ataxia may be caused by *alcohol intoxication*; a *stroke* or *brain tumour* affecting the cerebellum or brainstem; a disease of the balance organ in the ear; or *multiple sclerosis* or other types of nerve degeneration. In children, causes include acute infection, brain tumours, and the inherited condition *Friedreich's ataxia*.

SYMPTOMS

Symptoms of ataxia depend on the site of damage within the nervous system, although a lurching, unsteady gait is common to most forms. In addition, damage to certain parts of the brain may cause *nystagmus* (jerky eye movements) and slurred speech.

DIAGNOSIS AND TREATMENT

CT scanning or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures) may be used to determine the cause of ataxia. Treatment of the condition depends on the cause.

atelectasis

Collapse of part or all of a *lung* caused by obstruction of the bronchus (the main air passage through the lung) or the bronchioles (smaller air passages). When obstruction occurs, air already in the lung cannot be breathed out and is therefore absorbed into the blood, leading to the collapse of all or part of the lung. After collapsing, the lung loses its elasticity and cannot take in air; consequently, the blood passing through it can no longer absorb oxygen or dispose of carbon dioxide.

In an adult, atelectasis is not normally life-threatening because unaffected parts of the lung and/or the other lung can compensate for the loss of function in the collapsed area. However, when a newborn baby's lung collapses, the baby's life is at risk.

CAUSES

Obstruction of a bronchus or bronchiole may be caused by the accumulation of mucus. This buildup of mucus most commonly occurs in a baby at birth; in people with asthma; following an abdominal or chest operation that has made coughing difficult because of pain; in certain infections such as *pertussis* (whooping cough) in children or chronic *bronchitis* (inflammation of the bronchi) in adults.

Obstruction may also result from an accidentally inhaled foreign body, a tumour in the lung, or enlarged *lymph nodes* (which occur in *tuberculosis*, some other lung infections, or certain forms of *cancer*) exerting pressure on the airway. The collapsed lung may become infected.

SYMPOTMS

The main symptom of atelectasis is shortness of breath. There may also be a cough and chest pain, depending on the underlying cause.

DIAGNOSIS AND TREATMENT

Atelectasis can be diagnosed by *chest X-ray*, and treatment is aimed at removing the cause of the blockage. The treatment may include *physiotherapy* or *bronchoscopy*, a procedure that involves removal of the blockage using a rigid or flexible viewing tube (see *endoscope*). If the obstruction can be removed, the lung should reinflate normally.

atenolol

A *beta-blocker drug* that is commonly used to treat *hypertension* (high blood pressure), *angina pectoris* (chest pain caused by an impaired blood supply to the heart muscle), and certain types of *arrhythmia* (irregular heartbeat) in which the heart beats too rapidly.

atheroma

Fatty deposits on the inner lining of an artery that occur in *atherosclerosis* and restrict blood flow. The deposits are also known as atheromatous plaques.

atherosclerosis

The accumulation of *cholesterol* and other fatty substances (lipids) in the walls of arteries, causing the arteries to narrow. Atherosclerosis can affect arteries in any area of the body and is a major cause of *stroke*, heart attack (see *myocardial infarction*), and poor circulation in the legs.

The arteries become narrowed when fatty substances carried in the blood accumulate on the inside lining of the arteries and form yellow deposits known as atheromatous plaques. These deposits restrict the blood flow through the arteries. In addition, the muscle layer of the artery wall becomes thickened, which narrows the artery even further. Platelets (tiny blood cells that are responsible for blood clotting)

may collect in clumps on the surface of the deposits and initiate the formation of blood clots. A large clot may completely block the artery, resulting in the organ it supplies being deprived of oxygen. A complete blockage in a coronary artery can cause a sudden, often fatal, heart attack.

CAUSES

The risk of developing atherosclerosis is determined largely by the level of cholesterol in the bloodstream, which depends on dietary and genetic factors. Atherosclerosis is more common in developed countries, where most people eat a diet high in fat. Some disorders such as *diabetes mellitus* can be associated with a high cholesterol level, regardless of diet.

SYMPTOMS

Atherosclerosis usually produces no symptoms in its early stages. As the condition progresses, symptoms occur as a result of reduced, or total absence of, blood supply to the organs supplied by the affected arteries.

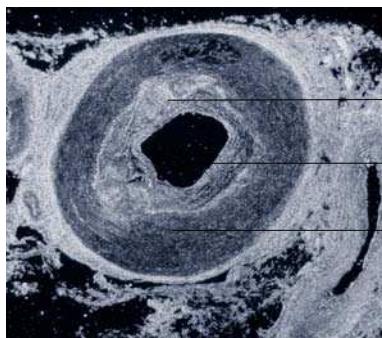

Partial blockage of the coronary arteries (which supply the heart muscle) may produce symptoms such as the chest pain of *angina pectoris*. Narrowing of the arteries supplying blood to the brain may cause *transient ischaemic attacks* (symptoms and signs of a stroke that last for less than 24 hours) and episodes of dizziness.

ARTERIAL DEGENERATION IN ATHEROSCLEROSIS

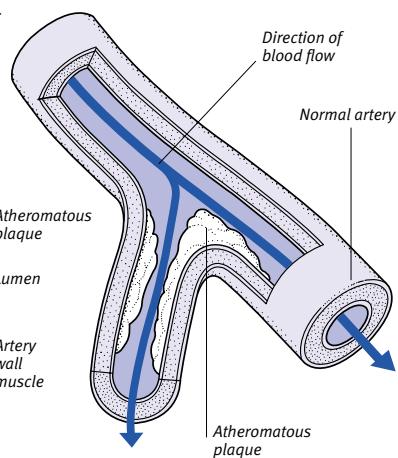

Atherosclerosis is narrowing of the arteries due to plaques of atheroma on their inner linings. The plaques are composed mainly of fats, deposited from the bloodstream, that disrupt normal blood flow through the artery. Men are affected earlier than women because premenopausal women are protected by natural oestrogen hormones.

RISK FACTORS

- Cigarette smoking
- Hypertension
- Male gender
- Obesity
- Physical inactivity
- Diabetes mellitus
- Heredity
- High cholesterol

Micrograph of artery in atherosclerosis
The artery shown here has an atheromatous (fibrous and fatty) plaque deposit on its inner wall. The lumen (channel) has been narrowed, disrupting blood flow.

**Atherosclerotic artery**

A deposit of atheromatous plaque disrupts normal blood flow through the artery at the point where it branches. This occurs because of the greater level of turbulence in this area.

Intermittent *claudication* (a cramplike pain on walking) is often the first symptom of atherosclerosis in the leg arteries. If the condition is associated with an inherited lipid disorder (see *hyperlipidaemias*), fatty deposits may develop on tendons or as visible lumps under the skin.

DIAGNOSIS AND TREATMENT

Blood flow through an artery can be investigated by *angiography* (X-rays after injection of a *radiopaque* substance) or *Doppler* ultrasound scanning.

The best treatment for atherosclerosis is to prevent it from progressing by the maintenance of a healthy lifestyle. This includes adoption of a low-fat diet, not smoking, regular exercise, and maintenance of the recommended weight for height. These measures lead to a reduced risk of developing significant atherosclerosis.

Those individuals found to have high blood cholesterol levels but who are otherwise in good health will be advised to adopt a low-fat diet. They may also be given drugs that decrease blood cholesterol levels (see *lipid-lowering drugs*). For people who have had a heart attack, research has shown that there may be a benefit in lowering blood cholesterol levels, even if the level is within the average range for healthy people.

People with atherosclerosis and those at risk may be prescribed a drug such as *aspirin* to reduce the risk of blood clots forming on the damaged artery lining.

Surgical treatment of atherosclerosis, such as coronary angioplasty (see *angioplasty, balloon*), may be recommended for those people thought to be at high risk of severe complications. If blood flow to the heart is severely obstructed, a *coronary artery bypass* may be carried out to restore blood flow.

athetosis

A disorder of the nervous system that is characterized by involuntary slow, writhing movements, most often of the face, head, neck, and limbs. These movements commonly include facial grimacing, with contortions of the mouth. There may also be difficulty in balancing and walking.

Athetosis tends to be combined with *chorea* (involuntary irregular, jerky movements). Both athetosis and chorea arise from damage to the *basal ganglia*, clusters of nerve cells in the brain that control movement.

Causes of athetosis include brain damage prior to or at birth (see *cerebral palsy*), *encephalitis* (brain infection), degenerative disorders such as *Huntington's disease*, or as a side effect of *phenothiazine drugs* or *levodopa*. If drug treatment is the cause of the condition, the abnormal movements may stop when the drug is withdrawn.

athlete's foot

A common condition in which the skin between the toes becomes itchy and sore and may crack, peel, or blister.

Athlete's foot

The typical appearance of athlete's foot is of fissuring in the cleft between the fourth and fifth toes. There is usually an annoying itch.

CAUSES

Athlete's foot is usually the result of a fungal infection known medically as *tinea pedis*, but the condition may also be caused by bacteria.

Because the fungi thrive in humid conditions, athlete's foot is more common in people with particularly sweaty feet and those who wear shoes and socks made from synthetic fibres, which do not absorb sweat.

TREATMENT

Self-treatment with topical *antifungal drugs* is usually effective and should be combined with careful washing and drying of the feet.

atlas

The topmost cervical *vertebra* in the human *spine*. The atlas is attached to and supports the skull. A pivot joint attaching the atlas to the second cervical vertebra, the *axis*, allows the atlas to rotate, thereby turning the head from side to side.

atonny

Loss of tension in a muscle, so that it is completely flaccid. Atony can occur in some nervous system disorders or after injury to nerves. For example, the arm

muscles may become atonic after injury to the *brachial plexus* (nerve roots in the neck passing into the arm).

atopic eczema

Atopic *eczema* is the most common form of eczema (an inflammatory skin condition). It usually begins in infancy but may flare up during adolescence and adulthood. The cause of atopic eczema is unknown, but people with *atopy* (a predisposition to allergic reactions) are more susceptible.

atopy

A predisposition to various allergic reactions (see *allergy*). Atopic individuals have a tendency to suffer from one or more allergic disorders, such as *asthma*, *eczema*, *urticaria* (nettle rash), and *allergic rhinitis* (hay fever).

The mechanism that underlies the predisposition is unclear, but atopy seems to run in families.

ATP

An abbreviation for the compound *adenosine triphosphate*, the principal energy-carrying chemical in the body. (See also *ADP; metabolism*.)

atresia

Congenital (present from birth) absence or severe narrowing of a body opening or tubular organ due to a failure of development in the uterus. Examples are *biliary atresia*, in which the bile ducts between the liver and duodenum are absent; *oesophageal atresia*, in which the oesophagus comes to a blind end; and *anal atresia* (see *anus, imperforate*), in which the anal canal is shut off. Most forms of atresia require surgical correction early in life.

atrial fibrillation

A type of abnormality of the heartbeat (see *arrhythmia, cardiac*) in which the atria (see *atrium*), the upper chambers of the heart, beat irregularly and very rapidly. The *ventricles* (the heart's lower chambers) also beat irregularly but at a slower rate. As a result, the pumping ability of the heart is reduced.

CAUSES

Atrial fibrillation can occur in almost any longstanding heart disease, but it is most often associated with *heart-valve disorders* or *coronary artery disease*.

SYMPTOMS AND SIGNS

Sudden onset of atrial fibrillation can cause *palpitations* (awareness of a fast

heartbeat), *angina pectoris* (chest pain as due to impaired blood supply to the heart muscle), or breathlessness. The inefficient pumping action of the heart reduces the output of blood into the circulation. Blood clots may form in the atria and may enter the bloodstream and lodge in an artery (see *embolism*).

DIAGNOSIS AND TREATMENT

Diagnosis of atrial fibrillation is confirmed by an *ECG*, which shows the electrical activity of the heart.

Digoxin or *beta-blocker drugs* may be given to control the heart rate. If the atrial fibrillation is of recent onset, it may be reversed by *defibrillation* (the application of a short electric shock to the heart). In most cases, *anticoagulant drugs* or *aspirin* are also given to reduce the risk of an embolism occurring.

atrial flutter

A type of abnormality of the heartbeat (see *arrhythmia, cardiac*) in which the atria (see *atrium*), the heart's upper chambers beat regularly but very rapidly. Symptoms and treatment of atrial flutter are the same as for *atrial fibrillation*.

atrial natriuretic peptide

A substance that is produced in special cells in the muscular wall of the atria (see *atrium*), the upper chambers of the heart. Atrial natriuretic peptide is released into the bloodstream in response to swelling of the atrial muscle due, for example, to *heart failure* or *hypertension* (high blood pressure).

Atrial natriuretic peptide increases the amount of sodium excreted in the urine. Sodium draws water out with it, which decreases the volume of the blood, thereby reducing blood pressure.

Children who have congenital (present from birth) heart disorders that result in heart disease (see *heart disease, congenital*) possess high levels of atrial natriuretic peptide. Following successful surgery to correct the heart abnormality, the levels of atrial natriuretic peptide fall.

atrial septal defect (ASD)

A congenital (present from birth) heart abnormality (see *heart disease, congenital*) in which there is a hole in the dividing wall (see *septal defect*) between the heart's two upper chambers, or atria (see *atrium*).

atrioventricular block

A type of *heart block*.

atrioventricular node

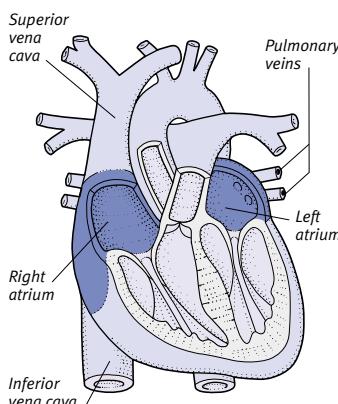

A small knot of specialized muscle cells in the right *atrium* (upper chamber) of the heart. Electrical impulses from the *sinoatrial node* (a cluster of muscle cells that act as the heart's natural pacemaker) pass through the atrioventricular node and along conducting fibres to the *ventricles* (the lower chambers of the heart), causing them to contract and pump blood around the body.

atrium

Also known as an auricle, either of the two (right and left) upper chambers of the heart. The atria open directly into the *ventricles* (the lower chambers of the heart). Deoxygenated blood from the body enters the right atrium through the *venae cavae*. Oxygenated blood from the lungs enters the left atrium through the *pulmonary veins*.

ANATOMY OF THE ATRIUM

Deoxygenated blood flows into the right atrium through the *venae cavae*; oxygenated blood flows into the left atrium via the *pulmonary veins*.

atrophy

The wasting away or shrinkage of a normally developed tissue or organ that results from a reduction in the size or number of its cells.

Atrophy is commonly caused by disuse (such as when a limb has been immobilized in a plaster cast) or inadequate cell nutrition as a result of poor blood circulation. Atrophy may also occur during prolonged illness, when the body needs to use up the protein reserves in the muscles. In some circumstances, atrophy is a normal process

(as in ovarian atrophy, for example, which occurs in women who have passed the *menopause*).

atropine

An *anticholinergic drug* that is derived from the deadly-nightshade plant (see *belladonna*). Atropine is used to dilate the pupil in eye conditions such as *iritis* (inflammation of the iris) and *corneal ulcer*. It is also used in young children, in the form of eye-drops, to dilate (widen) the *pupil* for examination.

Atropine was often given (by injection) as a *premedication* before a general anaesthetic (see *anaesthesia, general*) to reduce secretions from the lungs, but it is now rarely used for this purpose. It is used as emergency treatment for *bradycardia* (abnormally slow heartbeat) and is also sometimes prescribed for its anticholinergic effects; it is combined with an *antidiarrhoeal drug* to relieve the abdominal cramps that accompany diarrhoea.

Side effects include dry mouth, blurred vision, retention of urine, and, in the elderly, confusion. Atropine eye-drops are rarely given to adults because they cause disturbance of vision that lasts for two to three weeks and may precipitate acute *glaucoma* in susceptible people.

attachment

An affectionate bond between individuals, especially between a parent and child (see *bonding*) or between a person and an object, such as a young child and a security blanket.

The term attachment is also used to refer to the site at which a muscle or tendon is attached to a bone.

attempted suicide

See *suicide, attempted*.

attention deficit hyperactivity disorder (ADHD)

A behavioural disorder in which a child has a consistently high level of activity and/or difficulty in attending to tasks. Attention deficit hyperactivity, or hyperkinetic, disorder affects up to five per cent of children in the UK.

The disorder, which is more common in boys, should not be confused with the normal boisterous conduct of a healthy child. Children with ADHD show abnormal patterns of behaviour over a period of time. An affected child is likely to be constantly restless, unable to sit still for more than a few moments, inattentive, and impulsive.

CAUSES

The causes of ADHD are not fully understood, but the disorder often runs in families, which suggests that genetic factors may be involved. ADHD is not, as popularly believed, a result of poor parenting or abuse.

SYMPTOMS AND SIGNS

Symptoms of the condition develop in early childhood, usually between the ages of three and seven, and may include the inability to finish tasks; inability to concentrate in class; a short attention span; difficulty in following instructions; a tendency to talk excessively, frequently interrupting other people; difficulty in waiting or taking turns; inability to play alone, quietly; and physical impulsiveness.

Children with ADHD may have difficulty in forming friendships. Self-esteem is often low because an affected child is frequently scolded and criticized.

TREATMENT AND OUTLOOK

Treatment of ADHD includes behaviour modification techniques, both at home and at school. In some children, avoidance of certain foods or food additives seems to reduce symptoms. In severe cases, *stimulant drugs*, usually *methylphenidate*, may be prescribed. Paradoxically, the use of stimulant drugs in the treatment of ADHD reduces hyperactivity and improves concentration.

In general, the condition improves by adolescence but may be followed by antisocial behaviour and *drug abuse* or *substance abuse*.

attenuated

A term used to refer to microorganisms that have been treated to reduce their ability to cause disease. Attenuated organisms are used in some *vaccines*.

atypical

A term used to describe something that is not the usual type or that does not fit into the usual pattern. The atypical presentation of a disease or disorder is one in which the early symptoms and signs differ from those that normally occur, which may make diagnosis of the condition more difficult.

audiogram

A graph that is produced as a result of *audiometry* (measurement of the sense of hearing). An audiogram shows the hearing threshold (the minimum audible decibel level) for each of a range of sound frequencies.

audiology

The study of hearing, especially impaired hearing.

audiometry

Measurement of the sense of hearing. The term audiometry often refers to *hearing tests* in which a machine is used to produce sounds of a defined intensity (loudness) and frequency (pitch), and in which the hearing in each ear is measured over the full range of normally audible sounds. (See also *impedance audiometry*.)

auditory nerve

The part of the *vestibulocochlear nerve* (the eighth *cranial nerve*) concerned with hearing. The auditory nerve is also known as the acoustic nerve.

aura

A peculiar "warning" sensation that precedes or marks the onset of a *migraine* attack or a seizure in *epilepsy*.

A migraine attack may be preceded by a feeling of elation, excessive energy, or drowsiness; thirst or a craving for sweet foods may develop. A migraine may also be heralded by flashing lights before the eyes, blurred or tunnel vision, or difficulty in speaking. There may also be weakness, numbness, or tingling in one half of the body. As these symptoms subside, the migraine headache begins.

An epileptic aura may occur as a distorted perception, such as a hallucinatory smell or sound or a sensation of movement in a part of the body. One type of attack (in people who have *temporal lobe epilepsy*) is often preceded by a vague feeling of discomfort in the upper abdomen, sometimes followed by borborygmi (rumbling or gurgling bowel sounds, and by a sensation of fullness in the head).

auranofin

A *gold* preparation used as an *anti-rheumatic drug* in the treatment of *rheumatoid arthritis*. Unlike other gold preparations, which are given as intramuscular injections, auranofin can be taken by mouth.

auricle

Another name for the pinna, the external flap of the *ear*. The term is also used to describe the earlike appendages of the atria (the upper chambers of the heart, see *atrium*).

auriscope

Also called an *otoscope*, an instrument for examining the ear.

auscultation

A procedure that involves listening to sounds within the body, using a *stethoscope*, to assess the functioning of an organ or to detect disease.

AUSCULTATION OF THE HEART

To listen to the heart, the doctor places the stethoscope on the chest at four points which correspond to the location of the heart valves. With the patient either sitting up, lying in a semi-reclining position, or lying on his or her left side, the doctor listens for any abnormality in the rate and rhythm of the heartbeat and for a heart *murmur* or other abnormal *heart sound* that may indicate a heart defect.

AUSCULTATION OF THE LUNGS

When listening to the lungs, the doctor places the stethoscope on numerous areas of the chest and back. The patient breathes normally, and then takes deep breaths, so that the doctor can compare the sounds on the right and left sides. Abnormal breath sounds may indicate *pneumonia*, *bronchitis*, and *pneumothorax* (in which air enters the space between the *pleura*, the membranes lining the outside of the lungs and the inside of the chest cavity). Cracking or bubbling sounds (known as *crepitations*) are caused by fluid in the lungs; wheezing sounds result from spasm of the airways, usually as a result of *asthma*. *Pleurisy* (inflammation of the pleura) causes a scratching sound as inflamed areas of the lung rub together.

The doctor may also test for vocal resonance by asking the patient to whisper something. The sound is louder if there is pus in the lung due to a condition such as pneumonia.

AUSCULTATION OF THE BLOOD VESSELS

Blood vessels near the skin surface (usually the carotid artery in the neck, the abdominal aorta, or the renal artery) may be listened to for bruits (sounds made by turbulent or abnormally fast blood circulation). Bruits occur when blood vessels are narrowed (for example by fatty deposits in *atherosclerosis*) or widened (by an *aneurysm*, for example). They may also be present if heart valves have been narrowed or damaged (for example by *endocarditis*).

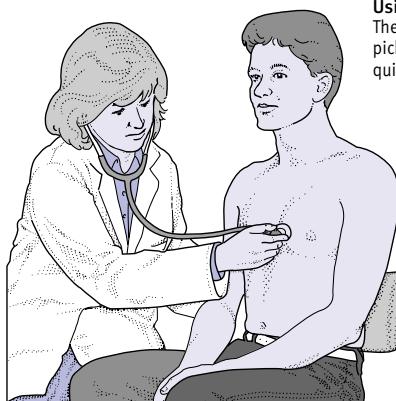

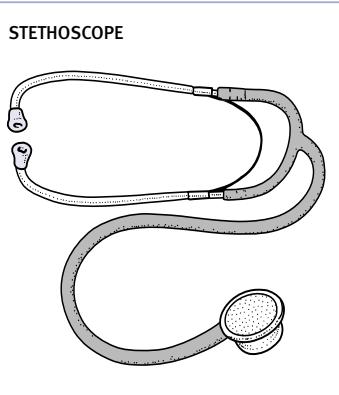

AUSCULTATION OF THE ABDOMEN

The abdomen is auscultated for borborygmi (loud rumbling, gurgling sounds

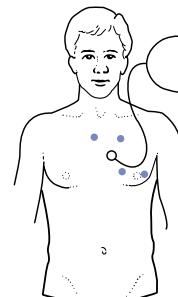

PROCEDURE FOR AUSCULTATION

A doctor's examination often includes auscultation (listening to sounds within the body using a stethoscope). Some sounds, such as movement of fluid through the stomach and intestine, opening and closing of heart valves, and flow of air through the

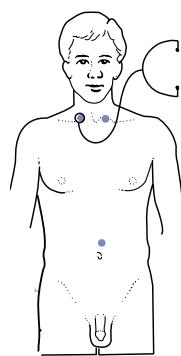

lungs and airways, are made during normal functioning of organs. The presence of abnormal sounds usually indicates disease of that tissue, however. An obstetrician listens for the baby's heartbeat as part of routine antenatal examination.

**Using a stethoscope**

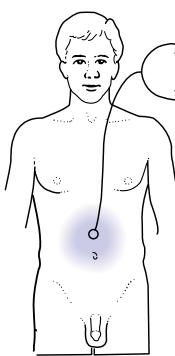

The end is held against the skin. The diaphragm picks up most noises, while the bell detects quiet, deep noises.

**The heart**

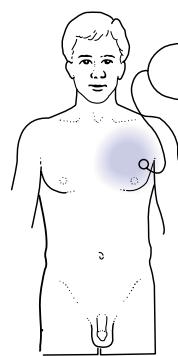

The stethoscope is usually placed at four places on the chest overlying the sites of the heart valves. The doctor listens for the presence of murmurs, clicks, and extra heart sounds that may indicate disease of a heart valve.

**Carotid artery and abdominal aorta**

The doctor may listen to the flow of blood through a blood vessel that passes just beneath the skin. The presence of bruits (sounds of turbulence) usually indicates abnormal narrowing or widening of an artery.

**The abdomen**

The doctor may listen to the abdomen for the sounds made by the movement of fluid through the intestine. A disorder of the intestine may cause these sounds to be absent, abnormal, or very loud.

**The lungs**

The doctor places the stethoscope over several different areas of the chest and back to listen to the sounds made during breathing. The presence of crackles and dry or moist wheezes indicates various types of lung disease.

that are made by the movement of air and fluid in the intestine), and also for abnormal bowel sounds that may indicate intestinal obstruction (see *intestine, obstruction of*).

autism

A rare condition in which an affected person has difficulty with social relationships, communication, and with imagination, together with repetitive patterns of behaviour. Autism is more common in boys. The condition is, by definition, evident before the age of 30 months and is usually apparent in the first year of life. The precise causes of autism are unknown.

SYMPOTMS AND SIGNS

Autistic children often seem normal for the first few months of life, before becoming increasingly unresponsive to parents or other stimuli. The child fails

to form relationships, avoids eye contact, and has a preference for playing alone. Extreme resistance to change of any kind is an important feature of the condition, which can make it very difficult to teach the autistic child new skills.

Rituals develop in play, and there is often attachment to unusual objects or obsession with one particular idea. Delay in speaking is common and most autistic children have a low IQ. Other behavioural abnormalities may include walking on tip-toe, rocking, self-injury, screaming fits, and hyperactivity.

Appearance and coordination are normal. Some autistic people have an isolated special skill, such as musical ability or an outstanding rote memory.

TREATMENT AND OUTLOOK

There is no cure for autism, which is a lifelong condition. Special schooling, support and counselling for the families,

and, sometimes, *behaviour therapy* (such as to reduce violent self-injury) can be helpful. Medication is useful only for specific problems, such as hyperactivity.

The outlook depends on the intelligence and language ability of the individual. The majority of autistic people need special care.

autism spectrum disorders

A range of developmental disorders that are characterized by obsessive behaviour and impaired communication and social skills (see *Asperger's syndrome; autism*). Autism spectrum disorders are usually diagnosed during childhood.

autoantibody

An *antibody* (a protein that is manufactured by the immune system) that reacts against the body's own cells (see *autoimmune disorders*).

autoclave

A piece of apparatus that produces steam at high pressure within a sealed chamber; the heat of the water vapour destroys microorganisms. Autoclaving is used in hospitals for the *sterilization* of surgical equipment.

autograft

Tissue that has been transplanted from one part of an individual's body to another (see *grafting*). Autografting is often used to treat severe burns.

autoimmune disorders

Any of a number of disorders caused by a reaction of the body's *immune system* against its own cells and tissues. Such disease-producing processes, known as *hypersensitivity* reactions, are similar to the reactions that occur in *allergy*, except that in autoimmune disorders the hypersensitivity response is to the body itself rather than to an external substance.

CAUSES

The immune system normally distinguishes "self" from "nonself". Some *lymphocytes* (a type of white blood cell) are capable of reacting against self, but these lymphocytes are generally suppressed. Autoimmune disorders occur when

there is interruption of the normal control process, allowing such lymphocytes to escape from suppression, or when there is alteration in a particular body tissue meaning that it is no longer recognized as self and is attacked.

Bacteria, viruses, and drugs may play a role in initiating an autoimmune disorder in someone who already has a genetic (inherited) predisposition, but in most cases the trigger is unknown.

TYPES

Autoimmune processes can have various results, such as the destruction of a particular type of cell or tissue, stimulation of an organ into excessive growth, or interference in an organ's function.

Autoimmune disorders are classified into organ-specific and non-organ-specific types. In organ-specific disorders, the autoimmune process is directed mainly against one organ. Examples include *Hashimoto's thyroiditis* (thyroid gland), pernicious *anaemia* (stomach), *Addison's disease* (adrenal glands), and type 1 *diabetes mellitus* (pancreas).

In non-organ-specific disorders, autoimmune activity is towards a tissue, such as connective tissue, that is widespread in the body. Examples of such disorders are systemic *lupus erythematosus* and *rheumatoid arthritis*.

TREATMENT

Initial treatment for any autoimmune disorder is to reduce the effects of the disease by, for example, replacing hormones, such as insulin, that are not being produced.

In cases in which the disease is having widespread effects, treatment is also directed at diminishing the activity of the immune system while maintaining the body's ability to fight disease. *Corticosteroid drugs* are most commonly used for this purpose but may be combined with other *immunosuppressant drugs*.

autologous blood transfusion

See *blood transfusion, autologous*.

automatism

A state in which behaviour is not controlled by the conscious mind. An individual carries out activities without being aware of doing so, and later he or she has no clear memory of what happened. Episodes of automatism start abruptly and are usually no more than a few minutes in duration.

Automatism is uncommon and may be a symptom of *temporal lobe epilepsy*, *dissociative disorders* (psychological ill-

nesses in which a particular mental function is lost), drug or *alcohol intoxication*, or *hypoglycaemia* (low blood sugar levels).

autonomic nervous system

Also called the involuntary nervous system, the part of the *nervous system* that controls the involuntary activities of a variety of body tissues, including blood vessels, organs, and glands. The autonomic nervous system consists of a network of nerves divided into the sympathetic and parasympathetic nervous systems.

The two systems act in conjunction and normally balance each other. However, during exercise or at times of stress, the activity of the sympathetic system predominates, while during sleep the parasympathetic system exerts greater control.

SYMPATHETIC NERVOUS SYSTEM

The sympathetic nervous system comprises two chains of nerves that pass from the spinal cord throughout the body tissues. Into these tissues, the nerve endings release the *neurotransmitters* (chemical messengers) *adrenaline* (epinephrine) and *noradrenaline* (norepinephrine). The sympathetic nervous system also stimulates the release of adrenaline from the adrenal glands.

In general, the actions of the sympathetic nervous system heighten activity in the body. This activity is known as the *fight-or-flight response*. Among the most important effects produced are the acceleration and strengthening of the heartbeat, widening of the airways, widening of the blood vessels in muscles and narrowing of those in the skin and abdominal organs (in order to increase the blood flow through the muscles), and the induction of sweating. In addition, the activity of the digestive system is decreased and the pupils are dilated.

PARASYMPATHETIC NERVOUS SYSTEM

The parasympathetic nervous system is composed of a chain of nerves that passes from the brain and another that leaves the lower spinal cord. The nerves are distributed to the same tissues that are supplied by the sympathetic nerves. The parasympathetic nerves release the neurotransmitter *acetylcholine*, which has the opposite effect to those of adrenaline and noradrenaline.

The parasympathetic system is concerned mainly with everyday functions such as digestion and excretion.

AUTOIMMUNE DISORDERS

Specific (organs or cells affected)

- Addison's disease (adrenal glands)
- Autoimmune haemolytic anaemia (red blood cells)
- Autoimmune chronic active hepatitis (liver)
- Autoimmune infertility (sperm or ovary)
- Diabetes mellitus type 1 (pancreas)
- Goodpasture's syndrome (lung and kidney)
- Graves' disease (thyroid gland)
- Hashimoto's thyroiditis (thyroid gland)
- Idiopathic thrombocytopenia purpura (platelets)
- Myasthenia gravis (muscle receptors)
- Pernicious anaemia (stomach lining)
- Vitiligo (melanocytes)

Nonspecific

- Behcet's syndrome
- Rheumatoid arthritis
- Sjögren's syndrome
- Systemic lupus erythematosus

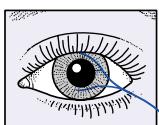

FUNCTIONS OF THE AUTONOMIC NERVOUS SYSTEM

The autonomic nervous system (also known as the involuntary nervous system) is responsible for controlling the involuntary body functions, such as sweating, digestion and heart rate.

The system affects smooth muscles, such as those of the airways and the intestine, rather than the striated muscles, which are under the body's voluntary control.

SYMPATHETIC SYSTEM

Dilates pupils

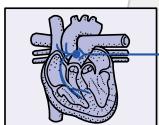

Inhibits salivation

Dilates bronchi

Accelerates heart rate

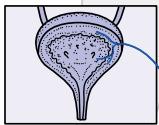

Inhibits gastric juice production

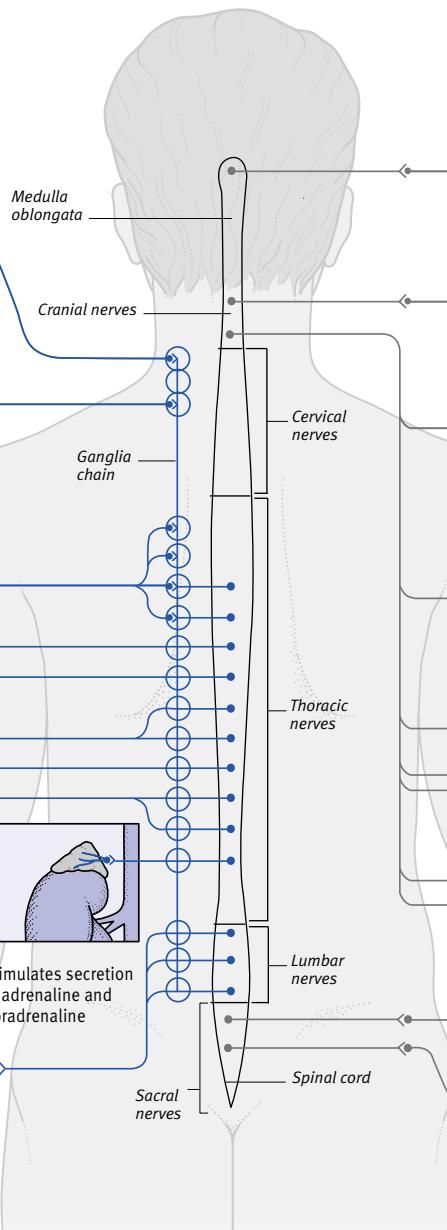

Inhibits digestive process

Relaxes bladder muscles; contracts bladder neck

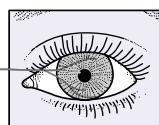

Contracts rectal sphincter

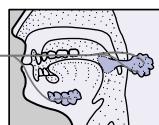

PARASYMPATHETIC SYSTEM

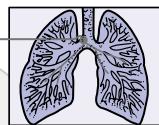

Contracts pupils

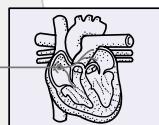

Stimulates salivation

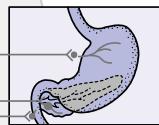

Constricts bronchi

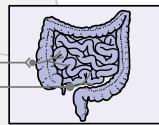

Slows heart rate

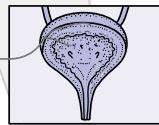

Stimulates gastric juice production

Speeds up digestive process

Contracts bladder muscles; relaxes bladder neck

Relaxes rectal sphincter

The autonomic nervous system

The autonomic nervous system is divided into two separate systems: the sympathetic nervous system and the parasympathetic nervous system. The sympathetic system is primarily concerned with preparing the body for action; it predominates at times of stress or excitement. The sympathetic system stimulates functions such as heart-rate and sweating and dilates the blood vessels to the muscles so that more blood is diverted to them. Simultaneously, it subdues the activity of the digestive system. In contrast,

the parasympathetic nervous system is concerned mainly with the body's everyday functions such as digestion and the excretion of waste products; this system dominates during sleep. The parasympathetic system slows the heart rate and stimulates the organs of the digestive tract. Most of the time, activity is balanced between the two systems, with neither dominating. Both of the systems play an important part in sexual arousal and orgasm in both men and women.

EFFECT OF DRUGS

Certain disorders can be treated by administration of drugs that affect the autonomic nervous system. *Anticholinergic drugs*, for example, block the effect of acetylcholine, which can reduce muscle spasms in the intestine. *Beta-blocker drugs* block the action of adrenaline (epinephrine) and noradrenaline (nor-epinephrine) on the heart, thus slowing the rate and force of the heartbeat.

autopsy

A postmortem examination of the body, including the internal organs, which is usually undertaken to determine the precise cause of death. An autopsy is sometimes required by law.

When the cause of death is known and there are no legal requirements for an autopsy to be carried out, hospitals and/or doctors may seek the next-of-kin's permission to perform an autopsy in order to advance knowledge of the disease that caused death, thereby helping in the care of future patients with the same condition. Relatives are free to refuse such consent.

autoregulation

Processes occurring within the body that maintain ideal conditions for normal function. Such processes include the distribution of blood between different organs, and balance of the body's salt and water content.

autosomal disorders

See *genetic disorders*.

autosome

Any *chromosome* that is not a sex chromosome. Of the 23 pairs of chromosomes in each human cell, 22 pairs are autosomes.

autosuggestion

Putting oneself into a receptive hypnotic-like state as a means of stimulating the body's ability to heal itself. The idea that symptoms could be relieved merely through attitude was put forward by the Frenchman Emile Coué at the end of the nineteenth century.

Although, autosuggestion enjoyed only brief popularity, some techniques used today are based on its premise. For example, in one method used to control anxiety symptoms, people are taught muscular relaxation techniques (see *biofeedback*) and learn to summon up calming imagery or pleasant thoughts.

avascular

A term meaning without blood vessels.

avascular necrosis

Cell death in body tissues as a result of damage to the blood vessels that supply the area.

aversion therapy

An outdated form of *behaviour therapy* in which unpleasant stimuli, such as electric shocks, are administered at the same time as an unwanted behaviour in an attempt to alter behavioural patterns. Other forms of therapy are now generally considered to be more appropriate.

aviation medicine

The medical speciality concerned with the physiological effects of air travel, such as the effects of reduced oxygen, pressure changes, and accelerative forces, as well as with the causes and treatment of medical problems that may occur during a flight.

Aviation medicine includes assessment of the fitness of the aircrew, and sometimes of passengers, to fly, the management of medical emergencies in the air, the consequences of special types of flights (such as in helicopters and spacecraft), and the investigation of aircraft accidents.

AIR TRAVEL-RELATED PROBLEMS

Increasing altitude causes a fall in air pressure and with it a fall in the pressure of oxygen. *Hypoxia* (a seriously reduced oxygen concentration in the blood and tissues) is a threat to anyone who flies at altitude. Aviator's *decompression sickness* has the same causes as the related condition that affects scuba divers but it is not normally a risk for passengers on regular flights. Rapid decompression (a sudden drop in air pressure) in civil aircraft is extremely rare, but passengers and crew are provided with oxygen masks for use in emergencies while the aircraft descends to a safe altitude.

Hypoxia or, more commonly, anxiety during flight can lead to *hyperventilation* (overbreathing), in which increased breathing results in excess loss of carbon dioxide. This loss alters the body's acidity and gives rise to symptoms such as tingling around the mouth, muscle spasms, and lightheadedness. If such symptoms develop, the treatment is to rebreathe air from a paper bag held over the nose and mouth, which reduces the loss of carbon dioxide.

The changes in altitude or cabin pressure during a flight affect the body's gas-containing cavities, principally the middle ears, the facial sinuses, the

CONDITIONS AFFECTING PASSENGER SUITABILITY FOR AIR TRAVEL

Conditions	Comments
Lung disease (such as chronic bronchitis or emphysema)	The lowered cabin pressure (and thus the oxygen level) at higher altitudes aggravates an already impaired ability to oxygenate the blood and/or tissues and may cause severe respiratory distress or collapse. Seek your doctor's advice.
Severe anaemia	Flying may be possible if you are able to walk 50 metres without breathlessness or chest pain.
Heart condition (such as angina pectoris, heart failure, or recent heart attack)	Seek your doctor's advice. You may need to wait some weeks before flying.
Recent stroke	Seek your doctor's advice. You may need to wait some weeks before flying.
Recent surgery to inner or middle ear, abdomen, chest, or brain; a recently collapsed lung or a fractured skull.	Seek your doctor's advice. You may need to wait before flying to avoid damage to your hearing mechanism from the expansion of gas trapped in the chest, abdomen, or skull.
Pregnancy	No flying after 34 to 36 weeks on most airlines.
Newborn baby	An infant should not fly until at least 48 hours old.
Psychiatric disorder	May need trained escort.
Infectious disease, terminal illness, or vomiting	May be refused entry to aircraft: Check with airline.

lungs, and the intestines. When pressure drops during ascent, the volume of gas in these cavities increases and usually escapes freely. On descent, the gas volume decreases as pressure outside the body rises. Unless preventative measures are taken, this may cause pain and, rarely, damage (see *barotrauma*).

There is increasing concern about the risk of developing deep vein thrombosis (see *thrombosis, deep vein*) during air travel. The condition may be caused by long periods of sitting in one position or compression of the tissues, both of which occur during long-haul flights.

The accelerative forces experienced by civil aircraft passengers are mild, even during take-off and landing, and no medical precautions are necessary. Military aircraft pilots, on the other hand, may experience severe accelerations and must wear special suits and use a reclined seat to prevent pooling of blood in the feet, which would cause immediate loss of consciousness.

Motion sickness usually causes fewer problems during air travel than during road or sea travel. Passengers who are prone to motion sickness may benefit from taking an anti-motion sickness preparation.

Air travel allows the rapid crossing of several time zones within a short period of time, which can affect sleep-waking cycles, causing *jet-lag*.

AVIATION MEDICINE SPECIALISTS

Most large airlines have doctors who are specially trained in aviation medicine who are responsible for the healthcare of the airline staff. The doctors also give advice on the transportation of sick passengers, the provision of training and equipment to deal with illness during flight, and the maintenance of airline hygiene.

avitaminosis

See *hypovitaminosis*.

Avloclo

A brand name for *chloroquine*, a drug that is used to prevent and treat *malaria*. Avloclo is also used in the treatment of some rheumatic disorders, such as *rheumatoid arthritis*.

avulsed tooth

A tooth that has become completely dislodged from its socket following an injury. If the tooth is kept clean and moist (ideally by being stored in milk, saliva, or contact-lens solution), is not

otherwise washed, and treatment is sought immediately, reimplantation (see *reimplantation, dental*) may be possible.

avulsion

The tearing away of a body structure from its point of attachment. Avulsion may be due to an injury, for example excessive contraction of a *tendon* may avulse a small piece of bone at its attachment point. Avulsion may also be performed as part of a surgical procedure, as in the surgical removal of *varicose veins*.

axilla

The medical name for the armpit.

axis

The second cervical *vertebra* in the human *spine*. The axis is attached by a pivot joint to the *atlas*, the topmost vertebra, which in turn is attached to the base of the skull. The pivot joint allows the head to turn to either side.

axon

The thin, elongated part of a *neuron* (nerve cell) that conducts nerve impulses. Many axons in the body are covered with a fatty *myelin* sheath.

Ayurvedism

See *Indian medicine*.

azathioprine

An *immunosuppressant drug* used to treat severe *rheumatoid arthritis* and other *autoimmune disorders* (in which the *immune system* attacks the body's own tissues). The drug is also used to prevent organ rejection after *transplant surgery*. Azathioprine may be injected or given in tablet form. Side effects include increased susceptibility to infection.

azelaic acid

A *topical* (applied to the skin) drug that is used to treat mild to moderate *acne*.

azithromycin

A macrolide *antibiotic drug* used to treat infections of the skin, chest, throat, and ears. Azithromycin is also used to treat genital infections due to chlamydia (see *chlamydial infections*).

azoospermia

The absence of sperm from semen, causing *infertility* in males. Azoospermia may be caused either by a congenital (present from birth) disorder or by one that

develops later in life. It can also occur following a *vasectomy*.

CAUSES

Congenital azoospermia may be due to a *chromosomal abnormality* such as *Klinefelter's syndrome* (the presence of an extra sex chromosome); failure of the testes to descend into the scrotum; absence of the vasa deferentia (ducts that carry sperm from the testes to the seminal vesicles, where it is stored prior to ejaculation); or *cystic fibrosis* (a genetic disease of the lungs and pancreas that may also cause defects of the vasa deferentia).

In some males, azoospermia may be the result of hormonal disorders affecting the onset of puberty. Another cause is blockage of the vasa deferentia, which may follow a *sexually transmitted infection, tuberculosis*, or surgery on the groin.

Azoospermia can also be the result of damage to the testes. This can follow *radiotherapy*, treatment with certain drugs (for example, *anticancer drugs*), prolonged exposure to heat, or the effects of occupational exposure to toxic chemicals. In some cases, production of sperm ceases permanently for no known reason.

TREATMENT AND OUTLOOK

If the cause is treatable (with hormones to bring on puberty or surgery to unblock ducts closed by infection, for example), sperm production may restart. However, in some cases the testes will have been permanently damaged.

AZT

The abbreviation for azidothymidine, the former name for *zidovudine*.

aztreonam

An *antibiotic drug* used to treat some types of *meningitis* and infections by certain types of bacteria, including *PSEUDOMONAS*.

azygous

A term meaning not paired. Azygous describes a structure such as the heart, which does not have a twin organ on the opposite side of the body. The azygous vein drains blood from the abdomen and chest and travels along the right side of the spine.

B

babesiosis

A general term covering a number of diseases that are caused by the *BABESIA* genus of *protozoa* (single-celled parasites). Babesiosis is mainly a disease of animals; it may affect sheep, cattle, horses, and other domestic animals. Babesiosis can be transmitted from animals to humans by tick bites, producing symptoms similar to those of *malaria*.

Treatment is with the antimalarial drug *quinine* and an *antibiotic drug*. (See also *ticks and disease*.)

Babinski's sign

A *reflex* movement in which the big toe bends upwards when the outer edge of the sole of the foot is scratched. In babies, Babinski's sign is a normal reflex action. In adults, Babinski's sign is an indication of damage to, or disease of, the *brain* or the *spinal cord*.

baby blues

A common name for a mild form of depression that sometimes occurs in women after childbirth. The baby blues almost always disappear without treatment but can occasionally develop into a more serious depressive illness (see *postnatal depression*).

baby teeth

Also known as milk teeth, an alternative term for the first teeth (see *primary teeth*).

bacillary dysentery

A type of *dysentery* (infection of the intestinal tract) caused by bacteria of the *SHIGELLA* genus (see *shigellosis*).

bacille Calmette-Guérin

See *BCG vaccination*.

bacilli

Rod-shaped *bacteria*. *Bacilli* (singular: *bacillus*) are responsible for causing a variety of diseases, including *infectious diseases* such as tuberculosis, tetanus, typhoid fever, pertussis (whooping cough), and diphtheria.

bacitracin

A type of *antibiotic drug* used in combination with other drugs to treat infections of the eyes and skin. Bacitracin is most commonly applied as an external skin preparation or as eye-drops.

back

The area between the shoulders and buttocks. The back is supported by the spinal column (see *spine*), which is bound together by *ligaments* (bands of tough, fibrous tissue) and supported by muscles that also help to control posture and movement.

DISORDERS

Back problems are numerous and may be the result of a variety of factors affecting the spine. They can be related to disorders of bones, muscles, ligaments, tendons, nerves, and joints in the spine, all of which can cause back pain. (See also *spine disorders box*.)

background radiation

The small amounts of natural *radiation* that emanate from such sources as rocks and the soil.

back pain

Most people suffer from back pain at some time in their lives. In many cases, no exact diagnosis is made because the pain gets better with rest and because analgesic drugs (painkillers) are used before any tests, such as X-rays, are carried out. In such cases, doctors may use the term "nonspecific back pain" to describe the condition.

CAUSES

Nonspecific back pain is one of the largest single causes of working days lost through illness in the UK. The people most likely to suffer from back pain are those whose jobs involve a lot of heavy lifting and carrying or those who spend long periods sitting in one position or bending awkwardly. Overweight people are also more prone to back pain – their backs carry a heavier load and they tend to have weaker abdominal muscles, which usually help to provide support to the back.

Nonspecific back pain is thought to be caused by a mechanical disorder affecting one or more structures in the back. This may be a ligament strain, a muscle tear, damage to a spinal facet joint, or *disc prolapse* (slipped disc).

In addition to pain from a damaged structure, spasm of surrounding muscles will cause pain and tenderness over

a wider area. This can result in temporary *scoliosis* (an abnormal sideways curvature of the spine).

Abnormalities of a facet joint and prolapse of an intervertebral disc can both cause *sciatica* (pain in the buttock and down the back of the leg into the foot). This condition is the result of pressure on a sciatic nerve root as it leaves the spinal cord. Coughing, sneezing, or straining will increase the pain. Pressure on the sciatic nerve can also cause a *pins-and-needles* sensation in that leg as well as weakness in muscles that are activated by the nerve. Rarely, pain may radiate down the femoral nerve at the front of the thigh.

Osteoarthritis in the joints of the spine can cause persistent back pain. *Ankylosing spondylitis* (an inflammatory disorder in which arthritis affects the spine) causes back pain and stiffness with loss of back mobility. *Coccydynia* (pain and tenderness at the base of the spine) may occur after a fall in which the coccyx has struck the ground, during pregnancy, or spontaneously for unknown reasons.

Fibrositis is an imprecise term that is sometimes used to describe pain and tenderness in muscles, which may affect the back. Fibrositis is often worse in cold and damp weather and is occasionally associated with feeling generally unwell. Unlike other causes of back pain, fibrositis is not accompanied by muscle spasm or restriction of back movement. It often improves when treated with *nonsteroidal anti-inflammatory drugs*.

Pyelonephritis can cause back pain as well as pain and tenderness in the loin, fever, chills, and pain when passing urine. Cancer in the spine can cause persistent back pain that disturbs sleep and is not relieved by rest.

SELF-HELP

People with back pain and sciatica are usually advised to remain as mobile as possible. Sleeping on a firm mattress and taking analgesic drugs can help to relieve pain. However, if pain persists, is very severe, or is associated with weakness in a leg or bladder control problems, immediate medical advice should be sought.

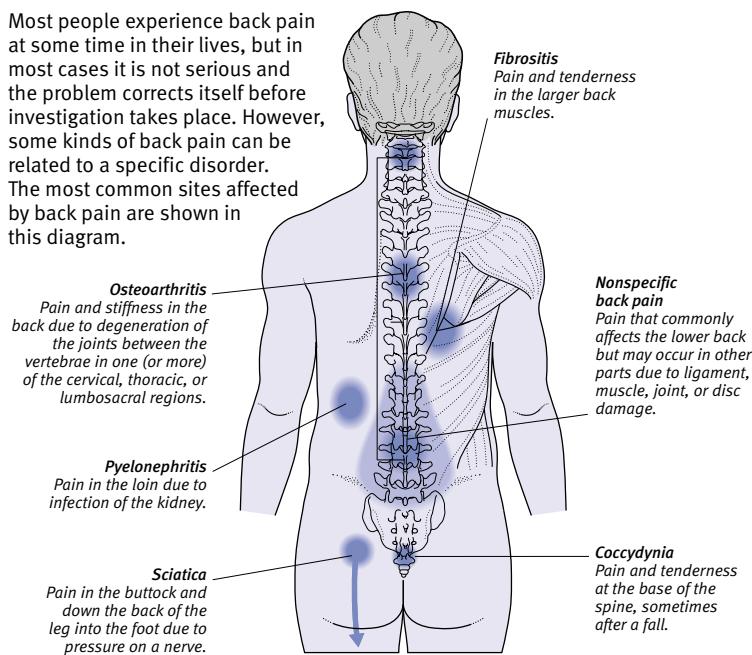

INVESTIGATION

Examination of the back may show tenderness in specific areas or loss of back mobility. Weakness or loss of sensation in the legs implies pressure on a nerve root, which needs prompt investigation.

X-rays of the spine may reveal narrowing between the intervertebral discs; osteoarthritis; *osteoporosis*; ankylosing

BACK PAIN

Most people experience back pain at some time in their lives, but in most cases it is not serious and the problem corrects itself before investigation takes place. However, some kinds of back pain can be related to a specific disorder. The most common sites affected by back pain are shown in this diagram.

spondylitis; compression fracture; stress fracture; **bone cancer**; or **spondylolisthesis** (displacement of vertebrae). X-rays will not reveal ligament, muscle, facet joint, or disc damage. To detect pressure on a nerve root (due to disc prolapse, for example), *myelography*, *CT scanning*, or *MRI* is performed.

TREATMENT

If a specific cause is found for the back pain, treatment will be for that cause. Research has shown that acute nonspecific back pain is best treated by early return to normal activity, helped by analgesic drugs. Bed rest should not be continued for more than two days. Chronic nonspecific back pain is often more difficult to treat. Treatment may include use of **aspirin** and related drugs, **nonsteroidal anti-inflammatory drugs**, **muscle-relaxant drugs**, **acupuncture**, or spinal injection. Exercise, spinal *manipulation*, or wearing a surgical *corset* may also be helpful; and spinal surgery may sometimes be necessary.

baclofen

A **muscle-relaxant drug** that blocks nerve activity in the spinal cord. Baclofen is used to relieve muscle **spasm** and stiffness caused by injury to either the brain or spinal cord, by neurological disorders

such as *multiple sclerosis*, or by a *stroke*. The drug does not cure the underlying disorder but helps to facilitate movement and allows *physiotherapy* to be more effective. The drug is taken in either tablet or liquid form.

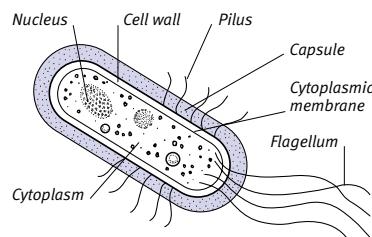

Side effects of baclofen may include drowsiness and muscle weakness. These effects can be reduced if the dose of the drug is increased gradually under medical supervision until the desired degree of relaxation is achieved.

bacteraemia

The presence of **bacteria** in the bloodstream. Bacteraemia commonly occurs for a few hours after minor surgical operations and dental treatment and may also occur in infections such as tonsillitis. The *immune system*, the body's natural defence mechanism, usually prevents the bacteria from multiplying and causing damage. However, in people with abnormal heart valves (due to conditions such as a congenital defect or scarring from rheumatic fever), the bacteria may cause *endocarditis* (inflammation of the heart lining and valves). If bacteraemia affects a person whose immune system is weakened by illness or major surgery, *septicaemia* (an infection of the blood) may develop.

bacteria

Single-celled *microorganisms* that are invisible to the naked eye. The singular form of the term is *bacterium*. Abundant in the air, soil, and water, most bacteria are harmless to humans. Some, such as those that live in the intestine, are beneficial and help to break down food for digestion.

**Magnified bacterium**

A typical bacterial cell enlarged to approximately 20,000 times its normal size.

DISEASE-CAUSING TYPES

Disease-causing bacteria are known as *pathogens* and are classified, according to shape, into three main groups: *cocci* (spherical); *bacilli* (rod-shaped); and *spirochaetes* or *spirilla* (spiral-shaped).

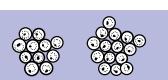

Among the wide range of diseases caused by cocci are pneumonia, tonsillitis, bacterial endocarditis (inflammation of the lining inside the heart), meningitis (inflammation of the membranes surrounding the brain and spinal cord), toxic shock syndrome, and various disorders of the skin.

Diseases that are caused by bacilli include tuberculosis, pertussis (whooping cough), typhoid fever, diphtheria, tetanus, salmonellosis, shigellosis (bacillary dysentery), legionnaires' disease, and botulism.

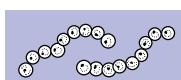

Bacteria from the third, and smallest, group, the spirochaetes, are responsible for causing syphilis, yaws, leptospirosis, and Lyme disease.

GROWTH AND MOVEMENT

The bacteria that colonize the human body thrive in warm, moist conditions.

Common types of bacteria

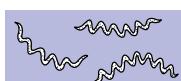

Staphylococcus
(causes boils)

Streptococcus
(causes sore throat)

Salmonella typhi
(causes typhoid fever)

Spirochaete
(causes syphilis)

Some of these bacteria are aerobic (they need oxygen to grow and multiply) and are therefore most commonly found on the skin or within the respiratory system. Others are anaerobic, thriving where there is no oxygen, deep within tissue or wounds.

Some types of bacteria are naturally static; if they move around the body at all, they do so only when carried in currents of air or fluid. However, there are also highly motile types of bacteria, such as salmonella, which move through fluids by lashing with their whiplike tails (known as flagella) and can anchor themselves to other cells with filamentous threads called pili.

REPRODUCTION

Bacteria reproduce by simple cell division, which can occur every few minutes in ideal conditions (exactly the right temperature and sufficient nourishment for all cells). Some bacteria multiply by each producing a spore (a single new bacterium). Spores, which are protected by a tough membrane, can survive high temperatures, dry conditions, and lack of nourishment.

HOW BACTERIA ENTER THE BODY

Bacteria can enter the body through the lungs if they are inhaled in infected droplets spread by coughs and sneezes. The digestive tract may become infected if contaminated food is eaten. Some bacteria cause diseases, such as sexually transmitted infections, by entering the genitourinary system.

Bacteria can also penetrate the skin in various ways: through hair follicles; by way of superficial cuts and abrasions; through burns; and via deep, penetrating wounds.

HOW BACTERIA CAUSE DISEASE

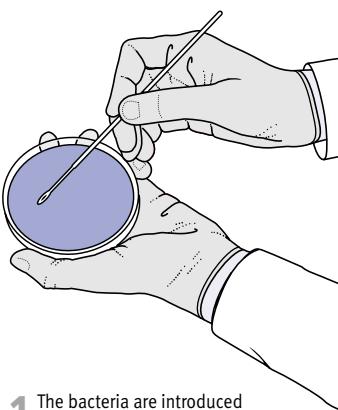

Some bacteria release poisons (toxins) that are harmful to human cells. The toxins either destroy the cell or disrupt its chemical processes. Less commonly, certain types of bacteria directly enter, and multiply within, body cells, causing tissue damage as they spread.

THE BODY'S DEFENCES

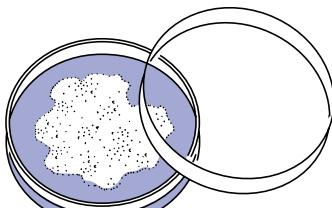

The body's first defences against disease-causing bacteria are the skin and the *mucous membranes* lining the respiratory tract, the digestive tract, and the genitourinary system. The eyes are protected by an *enzyme* in tears and the stomach secretes hydrochloric acid, which kills many of the bacteria found in food and water.

If bacteria pass through these barriers, the body's *immune system* responds by

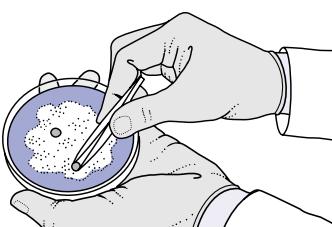

CULTURING AND TESTING BACTERIA

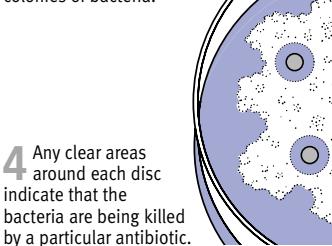

1 The bacteria are introduced on to a nutrient plate (i.e. agar or blood agar) and placed in an incubator at body temperature.

2 Any bacteria present multiply rapidly to form visible colonies that can be studied under the microscope and identified by different patterns of growth.

3 To test sensitivity to specific antibiotics, discs of different antibiotics are placed within the colonies of bacteria.

4 Any clear areas around each disc indicate that the bacteria are being killed by a particular antibiotic.

sending various types of white blood cell to seek and destroy the bacteria.

Immunity can also be generated by *immunization*. This involves injecting a weakened form of the bacterium or its poison into the body to stimulate an immune response. Immunization is now routine for a number of conditions, including *diphtheria*, *tetanus*, and some forms of *meningitis*.

TREATMENT OF BACTERIAL DISEASES

The immune response is sometimes enough to bring about recovery, and mild bacterial infections may not need any treatment. However, *antibiotic drugs* are the main form of treatment for more severe infections. Superficial infected wounds may be treated with *antiseptics*.

Some bacteria, such as *MRSA*, are now becoming resistant to treatment with antibiotics. In these circumstances, bacterial infections can be difficult or even impossible to treat and may be life-threatening. (See also *infectious disease*.)

bacterial endocarditis

See *endocarditis*.

bacterial food poisoning

See *food poisoning*.

bacterial vaginosis

An infection of the *vagina* that causes a greyish-white discharge and itching. The disorder is due to excessive growth of *bacteria* that normally live in the vagina. Bacterial vaginosis occurs most commonly in sexually active women and is treated with *antibiotic drugs*.

bactericidal

A term that is used to describe any substance that kills bacteria. (See also *antibiotic drugs*; *bacteriostatic*.)

bacteriology

The study of *bacteria*, particularly of the types that cause disease. Bacteriology includes techniques used to isolate and identify bacteria from specimens such as a throat swab or urine. Bacteria are identified by their appearance under a microscope, including their response to stains (see *Gram's stain*; *staining*), and by the use of *culture*. Testing for sensitivity to *antibiotic drugs* may be performed.

bacteriostatic

A term used to describe a substance that stops the growth or multiplication of *bacteria* but does not kill them. (See also *antibiotic drugs*; *bactericidal*.)

bacteriuria

The presence of *bacteria* in the urine. It is common for small, harmless numbers of bacteria to be found in the urine of healthy people. Bacteriuria is of significance only if more than 100,000 bacteria are present in each millilitre of urine, or if 100 white blood cells (pus cells) per millilitre of urine are present (which is an indication of the body's response to the infection).

Bacteroides

A genus of *anaerobic* (capable of living without oxygen) bacilli (rod-shaped *bacteria*) that normally inhabit the intestines. One particular type, *BACTEROIDES FRAGILIS*, is commonly found in abdominal wound infections and in the blood when the intestines are diseased.

bad breath

See *halitosis*.

bagassosis

An occupational disease affecting the lungs of workers who handle mouldy bagasse (the fibrous residue of sugarcane after juice extraction). Bagassosis is one cause of allergic *alveolitis*, a reaction of the lungs to inhaled dust containing fungal spores. Symptoms develop four to five hours after inhalation of the dust and may include shortness of breath, wheezing, fever, headache, and cough; typically, they last for about 24 hours. Repeated exposure to dust may lead to permanent lung damage. Protective measures taken by industry have made the disease rare.

Baker's cyst

A firm, fluid-filled lump behind the knee. A Baker's cyst occurs as a result of increased pressure in the knee joint due to a buildup of fluid. Such a buildup is a feature of disorders such as *rheumatoid arthritis*. The cyst is created by a backward ballooning-out of the synovial membrane covering the knee joint.

Most Baker's cysts are painless, and some disappear spontaneously, sometimes after many months. Occasionally, a cyst may rupture, causing fluid to seep down between the layers of the calf muscles. This can produce pain and swelling in the calf that may mimic a deep vein thrombosis (see *thrombosis, deep vein*).

Diagnosis of a Baker's cyst is confirmed by *ultrasound scanning*. Treatment is rarely needed, but in a few cases surgery may be performed.

balance

The ability to remain upright and move without falling over. Keeping one's balance is a complex process that relies on a constant flow of information to the brain about body position. The integration of all of this information, and continual instructions from the brain, enable the body to make the changes needed to maintain balance.

The brain receives data on body position from various sources: the eyes; the sensory organs (called proprioceptors) in the skin, muscles, and joints; and the three semicircular canals of the labyrinth of the inner ear. The part of the brain called the *cerebellum* collates this information and sends instructions to muscles to contract or relax to maintain balance.

DISORDERS

Balance can be affected by various disorders, particularly inner-ear disorders such as *labyrinthitis* (inflammation of the ear's labyrinth) and *Ménière's disease* (an abnormally high pressure of fluid in the labyrinth). Less commonly, *otitis media* (a disorder of the middle ear) may disturb balance.

Damage to nerve tracts in the spinal cord that carry information from position sensors in the joints and muscles to the brain can also impair balance. This damage to the nerves may result from spinal tumours, circulatory disorders, nerve degeneration due to deficiency of vitamin B₁₂, or, rarely, tabes dorsalis (a complication of *syphilis*). A tumour or *stroke* that affects the cerebellum in the brain may cause clumsiness of the arms and legs as well as other features of impaired muscular coordination.

balanitis

Inflammation of the foreskin and the glans (head) of the penis. Balanitis results in pain and/or itchiness, and the entire area may be red and moist. Causes of balanitis include bacterial or fungal infection, *phimosis* (tightness of the foreskin), or chemical irritation by contraceptive creams (see *contraception*) or laundry products.

Treatment is usually with *antibiotic drugs* or *antifungal drugs* (either applied to the skin as cream or taken orally) and careful washing of the penis and foreskin. If balanitis recurs frequently, or is due to phimosis, *circumcision* (surgical removal of the foreskin) may be recommended.

baldness

See *alopecia*.

ball-and-socket joint

A highly mobile *joint*, such as the shoulder or hip.

ballismus

Violent jerking and twitching of the limbs that is caused by brain damage within the area below the *thalamus* (a structure that relays sensory information). In most cases, only one side of the body is affected, in which case the condition is known as hemiballismus.

balloon angioplasty

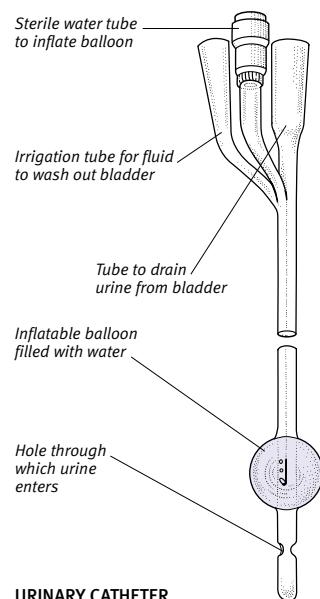

See *angioplasty, balloon*.

ballottement

A technique occasionally used during a physical examination (see *examination, physical*) to check the position of an organ, particularly in a fluid-filled area of the body. It involves flicking or tapping the area with the fingers, causing the organ to move up and down. The technique was once widely used to confirm pregnancy; when the wall of the uterus is tapped, the fetus moves away and floats back with a responding tap.

balloon catheter

A flexible tube with a balloon at its tip, which, when inflated, keeps the tube in place or applies pressure to an organ or vessel. One type of balloon catheter is

BALLOON CATHETER**URINARY CATHETER**

used to drain urine from the bladder (see *catheterization, urinary*). Balloon catheters are sometimes used to expand narrowed arteries (see *angioplasty, balloon*). They may also be used to control bleeding from widened veins in the lower part of the oesophagus (known as *oesophageal varices*) before surgery.

balm

A soothing or healing medicine applied to the skin.

balsam

An aromatic oily liquid that is obtained from various evergreen trees. Balsam is an *antiseptic* substance and was once also widely used in remedies for respiratory disorders.

bambuterol

A *bronchodilator drug* that is taken orally for the relief of *asthma*.

bandage

A strip or tube of fabric used to keep *dressings* in position, to apply pressure, to control bleeding, or to support a sprain or strain. Roller and tubular bandages are the type most widely used. Tubular gauze bandages require a special applicator and are used mainly for areas that are awkward to bandage, such as a finger. Triangular bandages are used to make *slings*. (See also *wounds*.)

banding

A procedure for treating *haemorrhoids* (piles) that are large or are causing particular discomfort. Using a special instrument, a doctor places a rubber band around the base of the haemorrhoid, which causes it to shrink and, eventually, to fall off. Banding is virtually painless and the procedure can be performed in a doctor's surgery.

barber's itch

See *sycosis barbae*.

barbiturate drugs

COMMON DRUGS

- Amobarbital • Butobarbital • Phenobarbital
- Secobarbital • Thiopental

A group of sedative drugs that work by depressing activity within the brain. Barbiturate drugs include thiopental, which is very short-acting and is used to induce anaesthesia (see *anaesthesia, general*), and phenobarbital, which is long-acting and is sometimes used as

an *anticonvulsant drug* in the treatment of epilepsy. In the past, barbiturates were widely used as *antianxiety drugs* and *sleeping drugs*, but they have been largely replaced by *benzodiazepine drugs* and other nonbarbiturates. Because barbiturates are habit-forming and are widely abused for their sedative effect, they are now classed as *controlled drugs*.

HOW THEY WORK

The sedative action of barbiturate drugs is produced by the drug molecules blocking the conduction of stimulatory chemical signals between the nerve cells of the brain and reducing the ability of the cells to respond. Barbiturates, especially phenobarbital, also reduce the sensitivity of brain cells to abnormal electrical activity.

POSSIBLE SIDE EFFECTS

The possible adverse effects of barbiturate drugs include excessive drowsiness, staggering gait, and, in some cases, excitability. An overdose of barbiturates can be fatal, particularly when taken in combination with alcohol, which dangerously increases their depressant effect on the brain (including suppression of the respiratory centre).

Barbiturates are likely to produce *drug dependence* if used for longer than a few weeks, and withdrawal effects, such as sleeplessness and twitching, may then occur when treatment is stopped.

Bardet–Biedl syndrome

A very rare *genetic disorder* characterized by *learning difficulties*, *retinopathy* (an eye defect), *obesity*, *polydactyly* (the presence of extra fingers or toes) and *hypogonadism* (underactivity of the testes or ovaries).

barium sulphate

A salt that is used in solution as a *contrast medium* in X-ray examinations of the intestinal tract (see *barium X-ray examinations*). Barium is opaque to X-rays and is used to view the outline of hollow internal organs, which would otherwise not be visible.

barium X-ray examinations

Procedures used to detect and follow the progress of some disorders of the gastrointestinal tract. Because barium (a metallic element) is opaque to X-rays, it is used to outline organs, such as the stomach, which are not normally visible on an X-ray image. Barium sulphate mixed with water is passed into the part of the tract requiring examination before X-rays are taken. In some cases,

barium X-ray examinations can be used as an alternative to *endoscopy* (internal examination using a rigid or flexible viewing tube), although endoscopy is often the preferred form of investigation.

Barium X-rays may be single- or double-contrast. Single-contrast X-rays use barium sulphate alone. The barium fills the section of the tract under examination and provides an outline image that shows up any prominent abnormalities. In double-contrast barium X-rays, the barium forms a thin film over the inner surface of the tract and the tract is subsequently filled with air so that any small surface abnormalities can be seen.

TYPES OF EXAMINATION

Various types of barium X-ray examination are used to investigate different parts of the gastrointestinal tract. A barium swallow involves drinking a solution of barium; this procedure is used to investigate the swallowing mechanism or the oesophagus. A barium meal is carried out to look at the lower oesophagus, stomach, and duodenum.

A barium follow-through examination can be used to investigate disorders of the small intestine; after barium has been swallowed, a series of X-rays are taken at intervals as the barium travels down the oesophagus to the intestine. A barium enema can be used to investigate disorders of the large intestine and the rectum; the barium is introduced into the body through a tube inserted in the rectum.

Any barium that remains in the intestine may be a cause of constipation. For this reason, it is important to ensure that a patient has a high-fibre diet and drinks plenty of water following a barium examination, until all the barium has passed through. (See also *Barium X-ray procedures* box, overleaf.)

barotrauma

Damage or pain, mainly affecting the middle *ear* and the facial *sinuses*, that is caused by changes in surrounding air pressure. Air travellers are at the greatest risk of barotrauma, but scuba divers face similar problems.

CAUSE

Aircraft cabin pressure decreases as the plane ascends and increases as it descends. As the aircraft ascends, the ears may seem to "pop" as the air in the middle ear expands and is expelled via the eustachian tubes, which connect the middle ear to the back of the throat. On descent, the higher pressure may push the eardrum inwards and cause pain.

BARIUM X-RAY PROCEDURES

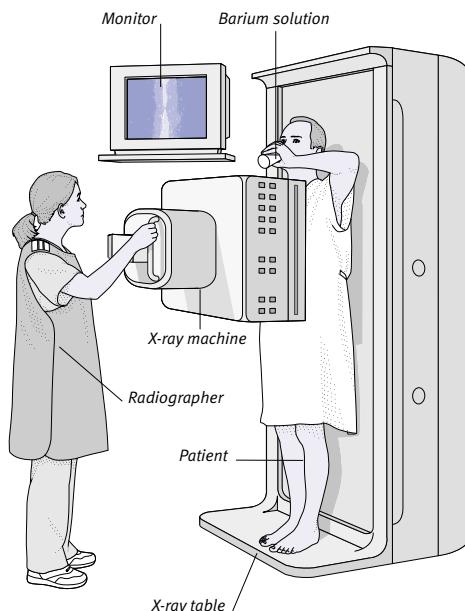

Barium X-ray examinations are used to reveal abnormalities or disorders within the upper and lower gastrointestinal tract. Barium swallows are used to investigate the oesophagus, and

barium meals are used for the examination of areas such as the stomach and duodenum. The large intestine is examined by means of a barium enema.

BARIUM SWALLOW/MEAL

Barium swallows and meals are used to investigate the upper gastrointestinal tract. No food or drink is permitted for six to nine hours beforehand. At the examination, the patient swallows a glass of barium mixed with a flavoured liquid, or is given a piece of bread or a biscuit soaked in barium if a disorder of the swallowing mechanism is being investigated.

Taking the X-ray
The radiographer takes X-ray pictures while the patient swallows. For a barium swallow, the patient stands; for a barium meal, the patient lies on the table in different positions; for a barium follow-through, the patient lies on the right side and X-rays are taken at intervals until the barium has progressed through the small intestine.

Barium swallow result
This contrast X-ray has revealed a narrowed area, known as an oesophageal stricture, in the lower section of the oesophagus.

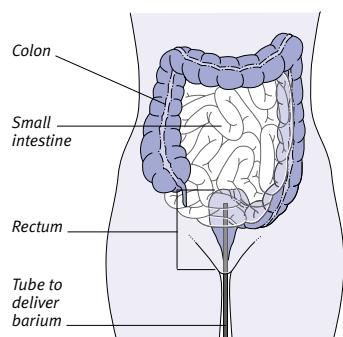

Barium meal result
In this X-ray, a thin film of barium has outlined the stomach lining. The introduction of air into the stomach has revealed the presence of a large tumour.

BARIUM ENEMA

A barium enema is carried out for examination of the large intestine and rectum. In order for an examination to be successful, the large intestine needs to be as empty and clean as possible because faeces can obscure or simulate

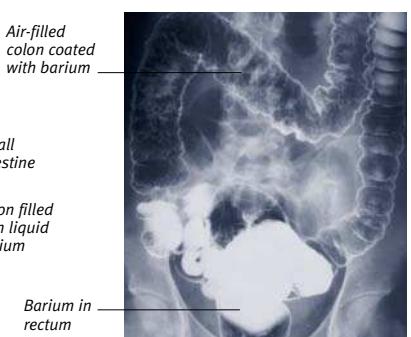

a polyp or tumour. For this reason, the patient's intake of food and fluids is sometimes restricted for a few days before the examination, and laxatives are given to make sure that the bowel is empty prior to the procedure.

**The procedure**

The radiographer or radiologist introduces the barium into the patient's intestine via a tube inserted into the rectum. The patient lies on his or her left side while the barium is infused. He or she then turns on to the other side, front, and back, and X-rays are taken.

**Single-contrast result**

In single-contrast barium enemas, the section of intestine to be examined is filled with liquid barium. Because barium is opaque to X-rays, it provides an outline image that shows up prominent abnormalities such as narrowing.

**Double-contrast result**

In double-contrast, barium and air are introduced into the tract. The barium forms a film on the tract's inner surface only, providing an image of small surface abnormalities that would not be visible using single-contrast.

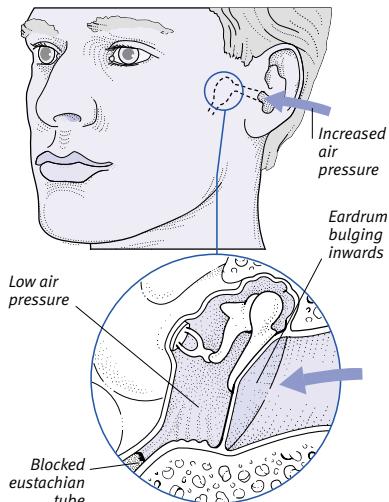

SYMPTOMS

Minor pressure damage in the middle ear may cause pain, hearing loss, and *tinnitus* (ringing in the ears) for a few days; damage in the facial sinuses may also cause pain, and possibly a discharge of mucus or blood. Symptoms usually wear off within hours or days, but treatment may be needed if they worsen or persist. Large changes in pressure can rupture the eardrum (see *eardrum, perforated*).

PREVENTION

Barotrauma can be avoided by vigorous swallowing or by forcibly breathing out with the mouth closed and the nose pinched, which is known as the Valsalva manoeuvre. This action serves to equalize the internal and external pressures in the middle ear and sinuses.

If the eustachian tubes are blocked, as commonly occurs with a cold, use of a nasal spray containing a *decongestant drug* is recommended shortly before the descent of the aircraft. Anyone with a severe head cold should avoid air travel if possible. Infants should be breast- or bottle-fed during descent to encourage swallowing. (See also *aviation medicine*; *scuba-diving medicine*.)

**Mechanism of barotrauma**

The diagram above shows the location of the middle ear and the pressure changes that occur when the eustachian tube is blocked and there is an increase in surrounding air pressure.

barrel chest

A prominent, rounded chest that is sometimes the result of lung distension in people with longstanding *emphysema* (enlarged air sacs in the lungs). Lung distension leads to an increase in distance between the front and back of the

chest, thereby resulting in a change in the shape of the chest wall. (See also *pulmonary disease, chronic obstructive*.)

Barrett's oesophagus

A complication of long-term gastro-oesophageal reflux (see *acid reflux*), in which the cells that line the lower part of the oesophagus are replaced by cells that are normally found in the stomach. People with Barrett's oesophagus are at increased risk of developing cancer of the oesophagus (see *oesophagus, cancer of*). The condition may be monitored regularly by *endoscopy* (internal examination using a viewing instrument) of the oesophagus.

barrier cream

A cream that is used to protect the skin against the effects of irritant substances and excessive exposure to water. (See also *sunscreens*.)

barrier method

A method of preventing pregnancy by blocking the passage of sperm to the uterus (see *contraception, barrier methods of*). An example of a barrier method is the use of a condom or a diaphragm.

barrier nursing

The nursing technique by which a patient with an infectious disease is prevented from infecting other people (see *isolation*). In reverse barrier nursing, a patient with reduced ability to fight infections (for example, because of an *immunodeficiency disorder* or following certain types of surgery) is protected against outside infection. (See also *aseptic technique*.)

bartholinitis

An infection of the *Bartholin's glands* at the entrance to the *vagina*. The disorder, which may be due to a *sexually transmitted infection* such as *gonorrhoea*, causes an intensely painful red swelling at the opening of the gland ducts. Treatment is with *antibiotic drugs, analgesic drugs*, and warm baths.

Bartholinitis sometimes leads to the formation of an abscess (see *Bartholin's abscess*) or a painless cyst, known as a Bartholin's cyst, which may become infected. Abscesses are drained under general anaesthesia (see *anaesthesia, general*). Recurrent abscesses or infected cysts may require surgery to convert the duct into an open pouch (see *marsupialization*) or remove the gland completely.

Bartholin's abscess

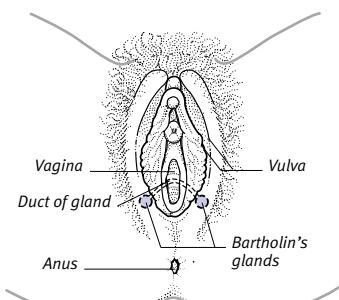

The formation of pus in one or both of the *Bartholin's glands*, which are located on either side of the vulva (the folds of flesh that surround the opening of the vagina). Bartholin's abscesses develop as a result of bacterial infection of the glands (see *bartholinitis*).

Bartholin's glands

A pair of oval, pea-sized glands whose ducts open into the vulva (the folds of flesh that surround the opening of the vagina). During sexual arousal, the Bartholin's glands secrete a fluid that lubricates the vulval region. Infection of these glands causes *bartholinitis* or the development of a *Bartholin's abscess*.

BARTHOLIN'S GLANDS

These glands are located on each side of the entrance to the vagina.

**basal cell carcinoma**

A type of skin cancer, also known as a rodent ulcer or BCC, that occurs most commonly on the face or neck, but can affect any part of the body. The cells of the tumour closely resemble, and are possibly derived from, cells in the basal (innermost) skin layer.

Basal cell carcinoma is caused by skin damage from the ultraviolet radiation in sunlight. Fair-skinned people over the age of 50 are most commonly affected by this form of cancer; dark-skinned people are protected by the larger amount of *melanin* (a pigment that absorbs ultraviolet radiation) in their skin. The incidence of basal cell carcinoma is much higher among people living in sunny climates, especially those who have outdoor occupations; in parts of the US and Australia, over half the white population has had a basal cell carcinoma by the age of 75.

SYMPOTMS

The majority of basal cell carcinomas occur on the face, often at the side of an eye or on the nose. It starts as a small, flat nodule and grows slowly, eventually breaking down at the centre to form a shallow ulcer with raised edges.

Diagnosis is confirmed through a biopsy (removal of a small sample of cells for microscopic analysis). Without treatment, the tumour gradually invades and destroys the surrounding tissues, but it virtually never spreads to other parts of the body.

TREATMENT

Treatment of basal cell carcinoma is usually with surgery (or in some cases *radiotherapy*) and is often completely successful. *Plastic surgery* may also be required, however, depending on the size and site of the tumour.

PREVENTION

The risk of developing this form of skin cancer can be reduced by avoiding over-exposure to strong sunlight, by using *sunscreens*, and by wearing protective clothing such as sun hats. People who have previously had a basal cell carcinoma may develop further tumours and should be especially alert to any new changes in their skin. (See also *melanoma, malignant; squamous cell carcinoma; sunlight, adverse effects of*.)

basal ganglia

Paired nerve cell clusters deep within the cerebrum (the main mass of the *brain*) and the upper part of the brain-stem. The basal ganglia play a vital part in producing smooth, continuous muscular actions and in stopping and starting movement. Any disease or degeneration affecting the basal ganglia and their connections may lead to the appearance of involuntary movements, trembling, and weakness, as occur in *Parkinson's disease*.

basal metabolic rate (BMR)

The rate at which energy is used by the body just to maintain vital functions. Such vital functions include breathing, circulation, and digestion. (See also *energy requirements; metabolism*).

base

See *alkali*.

basement membrane

The thin membrane that lies directly beneath the *epithelium* (the layer of cells that covers surfaces of the body and

lines most hollow structures within it). The basement membrane is composed of protein fibres and carbohydrates.

base pair

Part of a *DNA* molecule comprising two chemicals known as nucleotide bases that are linked together by means of hydrogen bonds. A base pair forms one "rung" of the DNA "ladder". There are only two possible pairings of the four bases: guanine always pairs with cytosine and adenine with thymine. The sequence of base pairs in each DNA chain provides the code for the activities of the cell (see *genetic code*). (See also *nucleic acids*.)

basic life support

Resuscitation techniques that may be performed by a first aider (see *rescue breathing; cardiopulmonary resuscitation*). If basic life support measures fail to restore a normal heartbeat and spontaneous breathing, *advanced life support* must then be administered by trained medical personnel.

basilar membrane

A membrane within the cochlea (the inner *ear* structure containing the receptor for hearing). Sound waves cause the basilar membrane to vibrate, stimulating sensory hair cells to send electrical signals to the brain.

basophil

A type of *white blood cell* that plays a part in inflammatory and allergic reactions.

Batten's disease

One of a group of hereditary metabolic diseases (see *metabolism, inborn errors of*) to which *Tay-Sachs disease* also belongs. In Batten's disease, abnormal fatty substances accumulate in the cells of the *nervous system*, causing progressive dementia, worsening seizures, and loss of vision. Symptoms of the condition usually first appear during early childhood.

There is no known treatment for Batten's disease, which is generally fatal during childhood.

Bazin's disease

A rare disorder, mainly affecting young women, in which tender swellings develop under the skin in the calves. In most cases no cause can be found, although Bazin's disease may sometimes be linked to *tuberculosis*.

B-cell

See *B-lymphocyte*.

BCG vaccination

A vaccine that gives immunity against *tuberculosis*. The BCG vaccine is prepared from an artificially weakened strain of bovine (cattle) tubercle bacilli, the rod-shaped *bacteria* that are responsible for causing tuberculosis. The letters BCG stand for "bacille Calmette-Guérin", after the two men who developed the tuberculosis vaccine.

WHY IT IS DONE

The BCG vaccine is given to people who are at risk of tuberculosis and to those whose tuberculin test is negative, indicating that they are likely to have no immunity to the disease. People at risk include health workers, contacts of people with tuberculosis, and immigrants from countries where there is a high rate of tuberculosis. Infants born to immigrants in this category are immunized, without having a tuberculin test, within a few days of birth. The vaccine is also recommended for children aged 10 to 14 years for whom the tuberculin test is negative.

HOW IT IS DONE

The vaccine is usually injected into the upper arm. About six weeks later, a small pustule appears. This normally heals completely, leaving a small scar, but can occasionally develop into a chronic *ulcer* (open sore).

Becker's muscular dystrophy

A type of *muscular dystrophy*.

beclometasone

A *corticosteroid drug* that is used in the treatment of *asthma* and hay fever (see *rhinitis, allergic*). When prescribed as a nasal spray, beclometasone controls the symptoms of these conditions by reducing inflammation and the production of mucus in the lining of the nose. Prescribed as an inhaler for the treatment of asthma, the drug reduces inflammation of the airways, thereby controlling wheezing and coughing.

Beclometasone is often given with *bronchodilator drugs* in the management of asthma. A severe asthma attack may require the dose to be increased. The action of beclometasone is slow, however, and its full effect takes several days to occur. Possible adverse effects of the drug include hoarseness, throat irritation, and, on rare occasions, fungal infections in the mouth.

Bclometasone is also prescribed in the form of a cream or as an ointment to treat inflammation of the skin resulting from *eczema*.

bclometasone

The former name for the corticosteroid drug *bclometasone*.

Beconase

A brand name for a nasal spray that contains the corticosteroid drug *bclometasone*. Beconase is used to treat hay fever (see *rhinitis, allergic*) and also some other nasal allergies.

Becotide

A brand name for an inhaled form of the corticosteroid drug *bclometasone* that is used to treat *asthma*.

becquerel

A unit of radioactivity (see *radiation units*).

bed bath

A method of washing a bedridden person. A small area is washed and dried at a time, while the rest of the body is kept covered to prevent chilling.

bedbug

A flat, wingless, brown insect that is about 5 mm long and 3 mm wide. Bedbugs live in furniture and furnishings, especially in beds and carpets, emerging at night to feed on humans by sucking their blood. Bedbugs are not known to transmit disease, but their bites are itchy and they may develop into sores that become infected.

bedpan

A metal, plastic, or fibre container into which a patient can defaecate or urinate without getting out of bed.

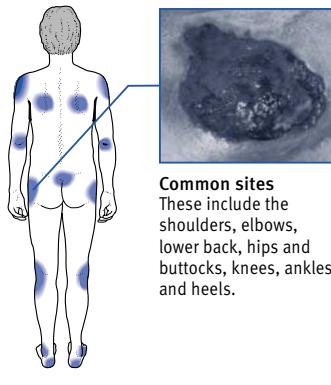

bed rest

A term used to describe periods spent in bed. Bed rest is sometimes part of the treatment for certain illnesses, such as *rheumatic fever*, and for some types of injury, such as a fractured vertebra.

Prolonged bed rest carries risks such as muscle wasting, *bedsores*, and development of blood clots in the legs. Bed rest was once considered an essential part of the treatment of many common conditions, but it is now avoided when possible. Patients are usually encouraged to be mobile as soon as they are able following illness or surgery.

PREVENTING BEDSORES

Once a bedsore has developed it will heal only if pressure on it is minimized, so good nursing care of a bedridden or immobile patient is crucial. The patient's position should be changed at least every two hours; and it is important to wash and dry pressure areas carefully, especially if there is incontinence. Barrier creams can be used for additional protection.

bedridden

A term used to describe a person who is unable to leave bed due to illness or injury. People most likely to be bedridden are the very elderly, the terminally ill, and those paralysed as the result of an accident.

bedsore

Also known as a decubitus ulcer or pressure sore, an ulcer that forms on the skin of patients who are unconscious or immobile. Common sites for bedsores include the shoulders, elbows, lower back, hips, buttocks, ankles, and heels.

CAUSES

Bedsores may develop following a *stroke* or *spinal injuries* that result in loss of sensation. Incontinence (see *incontinence, urinary*), if it results in constantly wet skin, may also be a causative factor.

SYMPOTMS

Bedsores start as red, painful areas that become purple before the skin starts to break down, producing open sores. At this stage, the sores may become infected and take a long time to heal.

TREATMENT AND PREVENTION

Deep, chronic *ulcers* may require treatment with *antibiotic drugs* and, in some cases, *plastic surgery*. Good nursing care, including changing the patient's position regularly, skin care, protection of

vulnerable areas, and use of cushions and special mattresses, should prevent bedsores from developing in most cases.

bedwetting

The common name for poor bladder control at night (see *enuresis, nocturnal*).

bee stings

See *insect stings*.

behavioural problems in children

Behavioural problems range from mild and short-lived periods of unacceptable behaviour, which are common in most children, to more severe problems such as conduct disorders and refusal to go to school. Behavioural problems may occasionally occur in any child; specialist management is called for when the problems become frequent and disrupt school and/or family life. Some behavioural problems can occur whatever the family or home situation of the child. In some cases, however, stressful external events, such as moving home or parental divorce, may produce periods of problem behaviour.

Behavioural problems that are common in young children include sleeping problems, such as waking repeatedly in the night. In toddlers, *breath-holding attacks, tantrums, separation anxiety, and head-banging* are problems best dealt with by a consistent and controlled approach. Problems with *toilet-training*

BEHAVIOURAL PROBLEMS BY AGE

- **Babies up to 18 months**
Sleeping and feeding difficulties, colic, crying

- **Toddlers and children 1–4 years**
Head-banging, tantrums, biting, breath-holding attacks, separation anxiety, poor social interaction, difficulty in changing from one activity to another, toilet training problems

- **Early childhood 4–8 years**
Nail-biting, thumb-sucking, aggression, clinginess, anxiety about illness and death, nightmare, enuresis

- **Middle childhood/adolescence 9–18 years**
Lying, stealing, smoking, truancy, disobedience, aggression, low achievement in school, drug or alcohol use, running away, sexual promiscuity

are usually avoided if the training is delayed until the child is physically and emotionally ready.

In children between the ages of four and eight years, minor behavioural problems, such as *thumb-sucking* and nail-biting, clinginess, bedwetting (see *enuresis, nocturnal*), and disruption during the night due to *nightmares*, are so common as to be almost normal. Such problems are best dealt with by using a positive approach that concentrates on rewarding good behaviour. In most cases, the child grows out of the problem, but medical help from a child guidance counsellor or a child psychiatrist may occasionally be needed.

behaviourism

An American school of *psychology* founded by John Broadus Watson early in the 20th century. He argued that, because behaviour, rather than experience, was all that could be observed in others, it should constitute the sole basis of psychology.

behaviour therapy

A collection of techniques, based on psychological theory, that are used to change abnormal behaviour or to treat anxiety. Behaviour therapy is based on two main ideas: that repeated exposure to a feared experience under safe conditions will render it less threatening, and that desirable behaviour can be encouraged by using a system of rewards, often self-administered.

TYPES

Specific behaviour therapy techniques include exposure therapy (also known as desensitization), flooding, response prevention, and modelling.

Exposure therapy A technique that is commonly used to treat phobic disorders, such as *agoraphobia* (a fear of open spaces and/or public places), animal phobias, and fear of flying. It consists of exposing the patient to the cause of the anxiety in stages: for example, the therapist may accompany an agoraphobic patient on a short journey. At the same time, the patient is taught to cope with anxiety symptoms by using relaxation techniques. The intensity of the exposure is increased, until eventually, he or she is able to deal with the full situation.

Flooding In flooding, the patient is confronted directly and for a lengthy period with the anxiety-provoking stimulus. He or she is supported by the therapist until the fear is reduced. This technique

can be emotionally traumatic and is now used less commonly.

Response prevention The patient is prevented from carrying out an obsessional task. For example, someone with a handwashing compulsion is prevented from carrying out the washing rituals. This technique is used in combination with other methods.

Modelling In this approach, the therapist acts as a model for the patient, performing the anxiety-provoking activity first, and encouraging the patient to copy.

behaviour, types A and B

Behaviours characteristic of two personality types described in the early 1970s, when studies were performed to examine the behaviour patterns of people with coronary artery disease.

It was proposed that a particular behaviour pattern (called Type A) was associated with increased vulnerability to stress-related illnesses, such as *hypertension* (high blood pressure). Type A personalities are said to feel constantly under pressure to perform many tasks at the same time, and to be competitive and self-critical. They are also impatient and easily irritated by others. In contrast to this, people with Type B personalities are said to be calmer and more relaxed.

Behçet's syndrome

A rare, multisystem disorder with recurrent *mouth ulcers* and *genital ulcers* and inflammation of the eyes, skin, joints, blood vessels, brain, and intestines.

The cause of Behçet's syndrome is unknown, but the disorder is strongly associated with HLA-B51, a genetically determined *histocompatibility antigen*. It affects twice as many men as women. Treatment of Behçet's syndrome is often difficult and may involve *corticosteroid drugs* and *immunosuppressant drugs*. The condition often becomes long term.

belching

The noisy return of air from the stomach through the mouth. Swallowing air is usually an unconscious habit, which may result from eating or drinking too much and/or too quickly. Occasionally, belching may help to alleviate discomfort caused by indigestion.

belladonna

An extract of the deadly nightshade plant that has, since ancient times, been used medicinally. Belladonna contains *alkaloids* (substances containing nitrogen), such

as *atropine*, that are used as *antispasmodic drugs* to treat gastrointestinal disturbances. (See also *anticholinergic drugs*.)

Bell's palsy

The most common form of *facial palsy* (facial muscle weakness).

Bence-Jones protein

An abnormal protein found in the urine of people with *multiple myeloma*, which is a cancer affecting one type of cell in the bone marrow.

bendrofluazide

The former name for the diuretic drug *bendroflumethiazide*.

bendroflumethiazide

A thiazide *diuretic drug* that is used to treat *hypertension* (high blood pressure) and *heart failure*.

bends

The nonmedical term for *decompression sickness*. The term is used especially to refer to the severe bone and joint pains that are a common symptom in divers who rise to the surface too rapidly.

benign

A term used to describe a disease that is relatively harmless. When used to refer to tumours, benign means noncancerous tumours that do not invade or destroy local tissues and do not spread to other sites within the body.

benign prostatic hyperplasia (BPH)

A medical term for noncancerous enlargement of the prostate gland (see *prostate, enlarged*).

Bennett's fracture

A fracture of the base of the thumb, which is often accompanied by partial dislocation of the joint.

benorilate

A *nonsteroidal anti-inflammatory drug* (NSAID) that contains *aspirin* and *paracetamol*. Benorilate is mainly used to relieve joint pain and stiffness in *osteoarthritis* and *rheumatoid arthritis*. Side effects of benorilate are not usually serious, but the aspirin in the drug may cause nausea, indigestion, or bleeding from the stomach lining.

benorylate

The former spelling of the nonsteroidal anti-inflammatory drug *benorilate*.

benzalkonium chloride

A preservative that is widely used in eye-drops and products such as cosmetics and mouth washes.

benzocaine

A local anaesthetic (see *anaesthesia, local*) commonly used as an ingredient in over-the-counter preparations for relieving the pain of conditions such as *mouth ulcers* and *sore throat*.

benzodiazepine drugs

COMMON DRUGS

SLEEPING DRUGS • Flunitrazepam • Flurazepam

• Loprazolam • Lormetazepam • Nitrazepam

• Temazepam

SEDATIVES • Alprazolam • Chlordiazepoxide

• Clorazepate • Diazepam • Lorazepam

• Oxazepam

A group of sedative drugs given for short periods either as *sleeping drugs* for *insomnia* or to control the symptoms of *anxiety* (see *tranquillizer drugs*). Common benzodiazepine drugs include diazepam, which is used as a tranquillizer, and nitrazepam, which is used to relieve insomnia. Benzodiazepine drugs are also used in the management of alcohol withdrawal and in the short-term control of an epileptic seizure.

HOW THEY WORK

Benzodiazepine drugs promote sleep and relieve anxiety by interfering with chemical activity in the brain and nervous system. This reduces the communication between nerve cells and depresses brain activity.

POSSIBLE ADVERSE EFFECTS

Adverse effects of benzodiazepines include excessive daytime drowsiness, dizziness, and forgetfulness. Unsteadiness and slowed reactions may also occur. If taken with alcohol, benzodiazepines may increase the alcohol's effect to a dangerous extent.

After as little as two weeks, users of a benzodiazepine drug may become psychologically and physically dependent on the drug. For this reason, most doctors are now reluctant to prescribe the drugs unless they are absolutely necessary, and then only for a maximum of three weeks.

When benzodiazepine treatment is stopped suddenly, withdrawal symptoms, such as anxiety, restlessness, and nightmares may occur. People who have been taking benzodiazepine drugs long term need to have them gradually withdrawn over the course of several

months to prevent withdrawal symptoms. Benzodiazepines are sometimes abused for their sedative effects.

benzoyl peroxide

An *antiseptic* agent used in the treatment of *acne* and fungal skin infections (see *fungal infections*). In acne, benzoyl peroxide also works by removing the surface layer of skin, thereby unblocking sebaceous glands.

benzylpenicillin

A type of *penicillin drug* that is given by injection.

bereavement

The emotional reaction following the death of a loved one. The expression of grief is individual to each person, but there are recognized stages of bereavement, each of which is characterized by a particular attitude.

STAGES OF BEREAVEMENT

In the first stage of bereavement, which may last from three days to three months, there is often a feeling of numbness and an unwillingness to recognize the death. These emotions are defence mechanisms against admitting, and therefore accepting, the loss and the associated pain. Often, the reality of the death does not penetrate completely at this time, and many people continue to behave as though the dead person were still alive. Hallucinations, in which the deceased person is seen or sensed, are a common experience among the recently bereaved. This sensation can be quite comforting for some people, but others may find it disturbing.

Once the numbness wears off, the person may be overwhelmed by feelings of anxiety, anger, and despair that can develop into a depressive illness (see *depression*). Gastrointestinal disturbances, insomnia, malaise, agitation, and tearfulness are also common.

Gradually, but usually within two years, the bereaved person adjusts to the loss and begins to look more towards the future. This process can involve periods of pain and despair, alternating with periods of enthusiasm and interest.

SUPPORT AND COUNSELLING

Family and friends can often provide the support a bereaved person needs. Outside help is sometimes required and may be given by a social worker, health visitor, member of the clergy, or self-help group. For some people, when depression, apathy, and lethargy impede

their chances of recovery, specialized *counselling* or *psychotherapy* is necessary. (See also *stillbirth*.)

beriberi

A nutritional disorder resulting from a lack of *thiamine* (vitamin B₁) in the diet. Thiamine, found in wholemeal cereals, meat, green vegetables, potatoes, and nuts, is essential for the metabolism of carbohydrates. Without it, the brain, the nerves, and the muscles (including the heart muscle) are not able to function properly. In developed countries, the illness is seen only in people who are starving or those who have an extremely restricted diet, such as alcoholics.

SYMPTOMS AND SIGNS

There are two forms of the illness: "dry" and "wet" beriberi. In dry beriberi, thiamine deficiency mainly affects the nerves and skeletal muscles. The symptoms include numbness, a burning sensation in the legs, and muscle wasting. In severe cases, the affected person becomes virtually paralysed, emaciated, and bedridden.

In wet beriberi, the main problem is *heart failure* (the inability of the heart to maintain efficient pumping of blood around the body). This in turn causes *oedema* (swelling caused by fluid accumulation) in the legs and sometimes also in the trunk and face. Other symptoms of wet beriberi include poor appetite, rapid pulse, and breathlessness. Without treatment, heart failure worsens and can lead to death.

TREATMENT

Beriberi is treated with thiamine, given either orally or by injection, which usually brings about a complete cure. A permanent improvement in diet is also required to prevent recurrence.

Bernard–Soulier syndrome

A *genetic disorder* in which platelets (the *blood cells* responsible for initiating blood clotting) do not function properly. The syndrome is characterized by abnormal bleeding in the skin and internal organs.

berry aneurysm

An abnormal swelling that occurs at the junction of *arteries* supplying the brain. Berry aneurysms are usually due to a congenital (present at birth) weakness in the artery wall. They may occasionally rupture, which results in a *subarachnoid haemorrhage*. (See also *aneurysm*; *intracranial aneurysm*.)

berylliosis

An occupational disease that is caused by the inhalation of dust or fumes containing beryllium, a metallic element that is used in high-technology industries such as nuclear energy, electronics, and aerospace. Short exposure to high concentrations of beryllium may lead to an episode of severe *pneumonitis* (lung inflammation). Exposure over a number of years to smaller concentrations may lead to permanent damage to the lungs and the liver.

Treatment with *corticosteroid drugs* can reduce damage to the lungs. In most cases, the introduction of safe working practices prevents exposure to dangerous levels of beryllium.

Best's disease

A *genetic disorder* in which the macula (part of the light-sensitive retina at the back of the eye) is abnormal. The disorder is congenital (present from birth) and results in progressive loss of vision.

beta-blocker drugs

COMMON DRUGS

- CARDIOSELECTIVE** • Atenolol • Betaxolol
- Bisoprolol • Celixprolol • Metoprolol
- NONCARDIOSELECTIVE** • Acebutolol • Carvedilol
- Labetolol • Nadolol • Oxprenolol • Pindolol
- Propranolol • Sotalol • Timolol

A group of drugs, also known as beta-adrenergic blocking agents, prescribed principally to treat heart and circulatory disorders such as *angina pectoris* (pain in the chest due to an insufficient supply of blood to the heart muscle) and *hypertension* (high blood pressure). The drugs block the effects of the *sympathetic nervous system*, which releases *adrenaline* (epinephrine) and *noradrenaline* (norepinephrine) at nerve endings known as beta receptors.

There are two types of beta receptor: β_1 and β_2 . β_1 receptors are present mainly in the heart and β_2 are found in the lungs, blood vessels, and elsewhere in the body. Certain beta-blockers (such as atenolol, bisoprolol and metoprolol) are termed cardioselective and, because they act mostly on β_1 receptors, are used principally to treat heart disease such as angina, hypertension, and cardiac *arrhythmia* (abnormal heartbeat). These drugs are sometimes given following a *myocardial infarction* (heart attack) in order to reduce the likelihood of further damage to the heart muscle.

HOW BETA-BLOCKERS WORK

Beta-blockers block specific sites on body tissues where neurotransmitters (chemicals released from nerve endings) bind. These sites are called beta receptors, and there are two types: β_1 receptors, found in heart tissue, and β_2 receptors, found in the lungs, blood vessels, and other tissues. At these receptors, two chemicals, adrenaline (epinephrine) and noradrenaline (norepinephrine), are released from nerve endings in the sympathetic nervous system, the part of the involuntary nervous system that enables the body to deal with stress, anxiety, and exercise. These neurotransmitters bind to beta receptors to increase the force and speed of the heartbeat, to dilate the airways to increase air flow to the lungs, and to dilate blood vessels.

Cardioselective beta-blockers bind predominantly to β_1 receptors; noncardioselective beta-blockers bind

to both types. Beta-blockers slow the heart rate and reduce the force of contraction of heart muscle. These effects can be used to slow a fast heart rate and regulate abnormal rhythms.

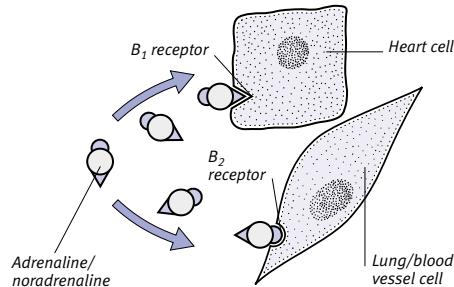

Beta-blockers prevent attacks of *angina pectoris* by reducing the work performed by the heart muscle and therefore the heart's oxygen requirement. High blood pressure is reduced because the rate and force at which the heart pumps blood into the circulation is lowered.

The effect of blocking beta receptors on muscles elsewhere in the body is to reduce the muscle tremor of anxiety and an overactive thyroid gland.

Beta-blockers may help to reduce the frequency of migraine attacks by preventing the dilation of blood vessels surrounding the brain, which is what causes the headache. In glaucoma they lower pressure in the eye by reducing fluid production in the eyeball.

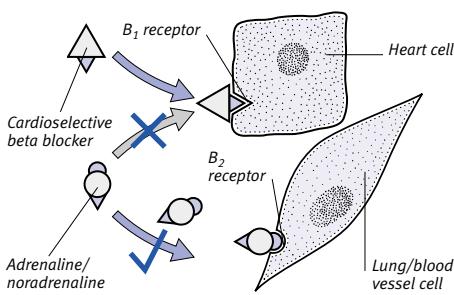

Normal

Adrenaline (epinephrine) and noradrenaline (norepinephrine) can be released either from the adrenal gland or from sympathetic nerve endings. They bind to β_1 and β_2 receptors in tissues around the body.

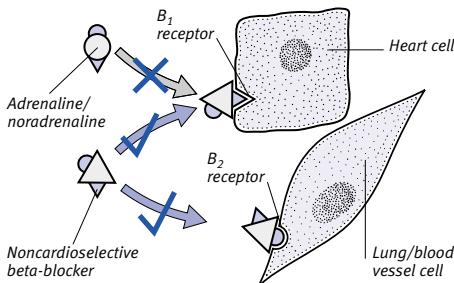

Cardioselective beta-blockers

Cardioselective beta-blockers occupy predominantly β_1 receptors, preventing adrenaline and noradrenaline from binding to them. This reduces the stimulating action of adrenaline and noradrenaline on heart tissue. Cardioselective beta-blockers do not block β_2 receptors, thereby allowing adrenaline (epinephrine)/noradrenaline (norepinephrine) to act on other tissues around the body.

Noncardioselective beta-blockers

Noncardioselective beta-blockers occupy both β_1 and β_2 receptors, reducing the stimulating action of adrenaline (epinephrine) and noradrenaline (norepinephrine) on tissues around the body.

Other types of beta-blocker, such as oxprenolol, propranolol, and timolol, may be given to prevent *migraine* attacks by acting on blood vessels in the head. They are also used to reduce the physical symptoms of *anxiety* and to control the symptoms of *thyrotoxicosis* (an overactive thyroid gland). Beta-blockers such as timolol are sometimes given in the form of eye-drops to treat *glaucoma*; they work by lowering the fluid pressure within the eyeball. (See also the illustrated box.)

POSSIBLE ADVERSE EFFECTS

Beta-blocker drugs may reduce an individual's capacity for strenuous exercise. They may worsen the symptoms of *asthma*, *bronchitis*, or other forms of lung disease. They may also reduce the flow of blood to the limbs, causing cold hands and feet. In addition, sleep disturbance and depression can be side effects of beta-blockers. Anyone taking beta-blockers should not suddenly stop; a severe recurrence of previous symptoms and a significant rise in blood pressure may result.

betahistine

A drug that is used in the treatment of the inner-ear disorder *Ménière's disease*. Betahistine reduces the frequency and severity of the characteristic attacks of nausea and vertigo.

beta interferon

A type of *interferon* (a protein produced naturally by body cells) sometimes used in the treatment of *multiple sclerosis*.

beta-lactam antibiotics

A group of *antibiotic drugs* that includes the penicillins and the cephalosporins. Beta-lactam antibiotics work by altering chemical activity in bacteria, thereby killing them.

beta-lactamase

An enzyme, also known as *lactamase*, that inactivates antibiotic drugs such as penicillins. Bacteria that are able to produce this enzyme are therefore resistant to treatment with these kinds of antibiotic drugs.

betamethasone

A *corticosteroid drug* that is used in the treatment of inflammation. Betamethasone is applied to the skin as a cream to treat contact *dermatitis* and *eczema*. The drug is also prescribed as nasal spray to treat allergic *rhinitis* (hay fever)

and is taken by mouth to treat some cases of *asthma* and *arthritis*.

Adverse effects of betamethasone are unlikely with short-term use. However, prolonged topical use of the drug can cause thinning of the skin and may aggravate any infection that has developed. Taken orally over a prolonged period or in high doses, betamethasone can cause adverse effects typical of other corticosteroid drugs.

betel nut

The seed of the tropical palm *ARECA CAT-ECHU*, which, when chewed, acts as a stimulant and digestant. Betel nut is commonly used throughout India and Southeast Asia.

Betnovate

A brand name for the corticosteroid drug *betamethasone*, which is used in topical preparations.

bezafibrate

A *lipid-lowering drug* used to reduce blood cholesterol levels.

bezoar

A ball of food and mucus, vegetable fibre, hair, or other indigestible material in the stomach. Trichobezoars, which are composed of hair, may form in the stomachs of children or emotionally disturbed adults who nibble at, or pull out and swallow, their hair.

Symptoms include loss of appetite, constipation, nausea and vomiting, and abdominal pain. If trichobezoars pass into the intestines, they may cause a blockage (see *intestine, obstruction of*). Bezoars can be removed by *endoscopy* (a procedure in which a flexible viewing tube is passed down the digestive tract) or by conventional surgery.

bi-

A prefix meaning two or twice, as in bilateral (two-sided).

bicarbonate of soda

See *sodium bicarbonate*.

biceps muscle

The name that is given to any muscle that originates as two separate parts, which then fuse. The term biceps muscle is commonly used to refer to the biceps brachii muscle of the upper arm, which bends the arm at the elbow and rotates the forearm. Another example of a biceps muscle is the biceps femoris

muscle, located at the back of the thigh, which bends the leg at the knee and extends the thigh.

bicornuate uterus

The term that is used to describe an abnormally shaped uterus (womb) that divides into two halves in its upper part. Bicornuate literally means "having two horns".

bicuspid

A term meaning to have two cusps (curved, pointed structures). Bicuspid describes certain *heart valves* and is used as an alternative name for a premolar tooth (see *teeth*).

bifocal

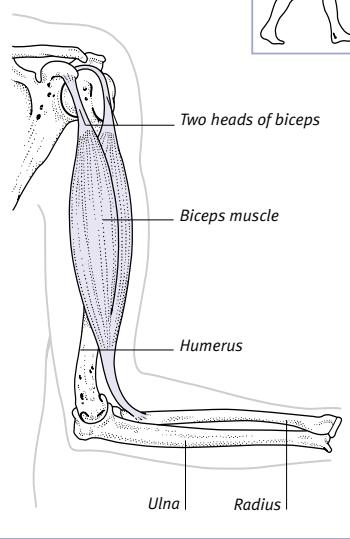

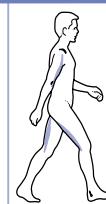

A spectacle lens with two different focal lengths. Glasses that have bifocal lenses make corrections both for close and for distant vision. (See also *myopia*; *hypermetropia*.)

biguanides

Oral hypoglycaemic drugs (see *hypoglycaemics, oral*) used in the treatment of type 2 (non-insulin-dependent) *diabetes mellitus*. Metformin, which is the only available type of biguanide drug, reduces the production of glucose

LOCATION OF BICEPS

There are four biceps muscles in the body: one in each upper arm and one on the back of each thigh.

(sugar) in the liver and also increases the uptake of glucose by the body's cells. (See also *antidiabetic drugs*.)

bilateral

A term that means affecting both sides of the body, or affecting both organs if they are paired (for example, both ears in bilateral deafness).

bile

A greenish-brown alkaline liquid that is secreted by the *liver*. Bile carries away waste products formed in the liver and also helps to break down fats in the small intestine for digestion.

The waste products in bile include the pigments *bilirubin* and biliverdin, which give bile its greenish-brown colour; bile salts, which aid in the breakdown and absorption of fats; and *cholesterol*. Bile passes out of the liver through the *bile ducts* and is then concentrated and stored in the gallbladder. After a meal, bile is expelled and enters the duodenum (the first section of the small intestine) via the common bile duct. Most of the bile salts are later reabsorbed into the bloodstream to be recycled by the liver into bile. Bile pigments are excreted in the faeces. (See also *biliary system; colestyramine*.)

bile duct

Any of the ducts through which *bile* is carried from the *liver* to the gallbladder and then on to the duodenum (the first section of the small intestine).

The bile duct system forms a network of tubular canals. Canaliculi (small canals) surround the liver cells and collect the bile. The canaliculi join together to form ducts of increasing size. The ducts emerge from the liver as the two hepatic ducts, which join within or just outside the liver to form the common hepatic duct. The cystic duct branches off to the gallbladder; from this point the common hepatic duct becomes the common bile duct and leads into the duodenum. (See also *biliary system*.)

bile duct cancer

See *cholangiocarcinoma*.

bile duct obstruction

A blockage or constriction of a bile duct (see *biliary system*). Obstruction of a bile duct results in the accumulation of bile in the liver (*cholestasis*) and *jaundice* (yellowing of the skin and the whites of the eyes) due to a buildup of *bilirubin*

(bile pigment) in the blood. Prolonged obstruction of the bile duct can lead to secondary *biliary cirrhosis*, which is a serious form of liver disease.

CAUSES

The most common cause of bile duct obstruction is *gallstones*. Other causes include a tumour affecting the pancreas (see *pancreas, cancer of*) and cancer that has spread from elsewhere in the body. *Cholangiocarcinoma* (cancer of the bile ducts) is a rare cause of a blockage. Bile duct obstruction is known to be a rare side effect of certain drugs. It may also be caused by *cholangitis* (inflammation of the bile ducts), trauma (such as injury during surgery), and, rarely, by *flukes* or worms.

SYMPTOMS

Bile duct obstruction causes "obstructive" jaundice, which is characterized by pale-coloured faeces, dark urine, and a yellow skin colour. There may also be itching. Other symptoms of bile duct obstruction depend on the cause of the blockage; for example, there may be abdominal pain (with gallstones) or weight loss (with cancer).

TREATMENT

Treatment depends on the cause, but surgery is sometimes necessary. Gallstones may be removed by means of *ERCP* (an X-ray procedure that uses a viewing tube called an endoscope with instruments attached to it).

bilharzia

Another name for the tropical parasitic disease *schistosomiasis*.

biliary atresia

A rare *congenital* disorder in which some or all of the *bile ducts* fail to develop or develop abnormally. As a result, *bile* is unable to drain from the liver (see *cholestasis*). Unless the atresia can be treated, secondary *biliary cirrhosis* (a serious liver disorder) will develop and may prove fatal. Symptoms include *jaundice*, usually beginning a week after birth, and the passing of dark urine and pale faeces. Treatment is by surgery to bypass the ducts. If this fails, or if the jaundice recurs, a *liver transplant* is required.

biliary cirrhosis

An uncommon form of liver *cirrhosis* that results from problems with the bile ducts. There are two types of biliary cirrhosis. One is an *autoimmune disorder* and is known as primary biliary cirrho-

sis. Secondary biliary cirrhosis occurs as a result of a longstanding blockage. In both types of the condition, liver function is impaired due to *cholestasis* (accumulation of bile in the liver).

Primary biliary cirrhosis principally affects middle-aged women and seems to be linked with a malfunction of the *immune system*. In this disorder, the bile ducts within the liver become inflamed and are destroyed. Symptoms include itching, *jaundice* (a yellowish discolouration of the skin and the whites of the eyes), an enlarged liver, and sometimes abdominal pain, fatty diarrhoea, and *xanthomatosis* (deposits of fatty material under the skin). *Osteoporosis* may also develop. Symptoms of liver cirrhosis and *liver failure* may occur after a few years. Drugs can be used to minimize complications and to relieve symptoms such as itching, but a *liver transplant* is the only cure.

Secondary biliary cirrhosis results from prolonged *bile duct obstruction* or *biliary atresia* (abnormal bile ducts). Symptoms and signs include abdominal pain and tenderness, liver enlargement, fevers and chills, and sometimes blood abnormalities. Treatment is the same as for bile duct obstruction.

biliary colic

A severe pain in the upper right quadrant of the abdomen that is usually caused by the gallbladder's attempts to expel *gallstones* or by the movement of a stone in the *bile ducts*. The pain may be felt in the right shoulder (see *referred pain*) or may penetrate to the centre of the back. Episodes of biliary colic often last for several hours and may recur, particularly after meals.

Injections of an *analgesic drug* and *anti-spasmodic drug* may be given to relieve the colic. Tests such as *cholecystography* or *ultrasound scanning* can confirm the presence of gallstones, in which case *cholecystectomy* (surgical removal of the gallbladder) may be performed.

biliary system

The organs and ducts in which *bile* is formed, concentrated, and carried from the *liver* to the duodenum (the first part of the small intestine). Bile is secreted by liver cells and collected by a network of *bile ducts* that carry the bile out of the liver via the hepatic duct. The cystic duct branches off the hepatic duct and leads to the gallbladder, where the bile is concentrated and stored. Beyond this

junction, the hepatic duct becomes the common bile duct, which opens into the duodenum at a controlled orifice known as the ampulla of Vater. The presence of fat in the duodenum following a meal prompts the secretion of a hormone that opens the ampulla of Vater. This causes contraction of the gallbladder, which squeezes stored bile into the duodenum.

The main disorders affecting the biliary system are *gallstones*, congenital *biliary atresia* and *bile duct obstruction*. (See also *gallbladder, disorders of*.)

biliousness

A condition in which bile is brought up to the mouth from the stomach. Biliousness is also used as a nonmedical term for nausea and vomiting.

bilirubin

The main pigment in *bile*. Bilirubin is produced by the breakdown of *haemoglobin*, the pigment in red blood cells. Very high levels of bilirubin cause the yellow pigmentation of *jaundice*. Products formed from the breakdown of bilirubin make faeces brown.

Billings' method

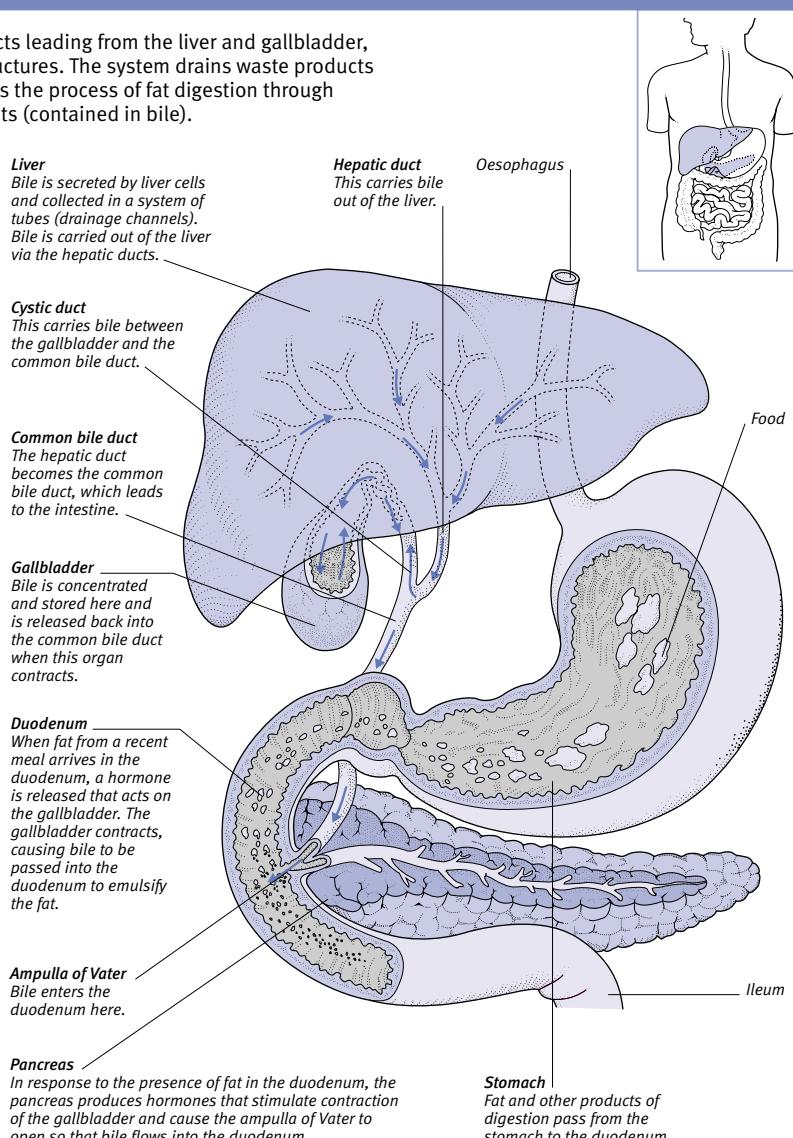

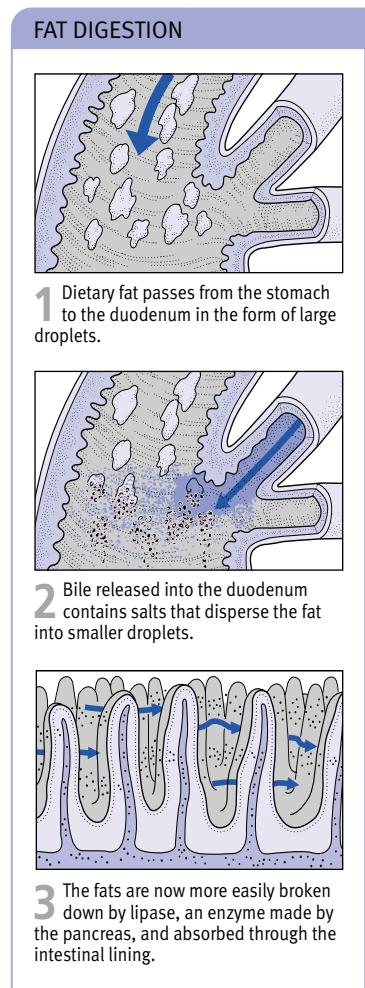

A technique (also known as the mucus inspection method) in which a woman notes changes in the characteristics of mucus produced by her cervix. The technique is employed to predict ovulation for the purposes of *contraception* or *family planning*.

Billroth's operation

A type of partial *gastrectomy* in which the lower part of the stomach is surgically removed. Previously used in the treatment of *peptic ulcers*, the operation

FUNCTION OF THE BILIARY SYSTEM

The biliary system consists of the bile ducts leading from the liver and gallbladder, the gallbladder itself, and associated structures. The system drains waste products from the liver into the duodenum and aids the process of fat digestion through controlled release of fat-emulsifying agents (contained in bile).

is now rarely performed due to the introduction of newer, less invasive treatment, often using *antibiotic drugs*.

Binet test

The first *intelligence test* that attempted to measure higher mental functions rather than more primitive abilities. The Binet test was devised in 1905.

binge-purge syndrome

An alternative term for the eating disorder *bulimia*.

bio-

A prefix describing a relationship to life, as in biology, the science of life.

bioavailability

The proportion of a drug that reaches the target organs and tissues, usually expressed as a percentage of the dose administered. Intravenous administration of a drug results in 100 per cent bioavailability because the drug is injected directly into the bloodstream. Drugs taken orally have a much lower bioavailability. Preparations that have equal bioavailabilities are described as bioequivalent. (See also *drug*.)

biochemistry

A science that studies the chemistry of living organisms, including human beings. The human body is made up of millions of cells that require nutrients and energy, and which grow, multiply, and die. The chemical processes that are involved in providing these cells with energy, eliminating their wastes, repairing damage, promoting cell growth, and causing both normal and abnormal cell division are all studied by biochemists, the specialists in the field.

Life is maintained by a huge number of chemical reactions that are carried out inside cells. These reactions link together in a complex way and together make up the *metabolism* of the body. The reactions that produce energy and break down food and body structures are termed catabolism; those that build up body structures and store food are termed anabolism. Overall regulation of these chemical processes is a principal function of *hormones* which are secreted into the bloodstream by the *endocrine glands*; regulation of individual reactions is carried out by *enzymes* (substances that promote biochemical reactions).

Certain vital chemical processes take place in every single cell in the body.

Other, more specific, chemical processes are confined to specialized cells that make up the tissues of particular organs. For example, liver cells store and chemically modify the digestion products of food; kidney cells help to control the amounts of various substances (such as certain minerals) in the blood, as well as regulating the total amount of fluid in the body.

A constant interchange of substances occurs between the cell fluids and the blood and urine. Biochemists can learn a great deal about the chemical changes occurring inside the body's cells by regularly taking, and comparing, precise measurements of the various minerals, gases, enzymes, hormones, and proteins in the different fluids of the body.

Such biochemical tests may be used to make, or to confirm, a diagnosis, as well as to screen for a particular disease and to monitor its progress. The most commonly used biochemical tests are performed on *blood*; such tests include *liver function tests* and *kidney function tests*. Biochemical tests can also be performed on urine (see *urinalysis*) as well as on all other body fluids.

bioengineering

See *biomechanical engineering*.

biofeedback training

A technique in which a person uses information about a normally unconscious body function, such as blood pressure, to gain conscious control over that function. This training may help to treat stress-related conditions, including certain types of *hypertension* (high blood pressure), *anxiety*, and *migraine*.

HOW IT IS DONE

The doctor connects the patient to a recording instrument that can measure one of the unconscious body activities, such as blood pressure, heart rate, muscle tension, the quantity of sweat on the skin, brain waves, or stomach acidity. The patient receives information (feedback) on the changing levels of these activities from changes in the instrument's signals, for example a flashing light or sound changing tone.

After some experience with the technique, the person starts to become aware of how he or she is feeling whenever there is a change of signal. By using *relaxation techniques*, the person learns to change the signals by conscious control of the function. Once acquired, control can be exercised without the instrument.

biological clock

A popular term for the inherent timing mechanism that supposedly controls physiological processes and cycles in living organisms. (See also *biorhythms*.)

biology

The scientific study of all living organisms, including animals, plants, and microorganisms (single-celled organisms). Biology involves the study of the structure and functions of living organisms, their relationships with other organisms, and the ways in which they interact with their environment. (See also *biochemistry*; *microbiology*.)

biomechanical engineering

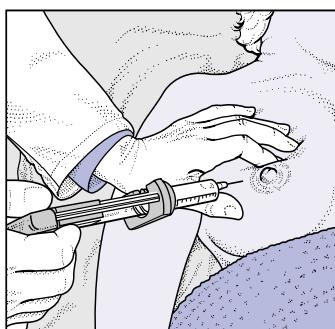

A discipline that applies engineering methods and principles to the body to explain how it functions and to treat disorders. Applications include the design of artificial joints and heart valves, pacemakers, and kidney dialysis machines.

biopsy

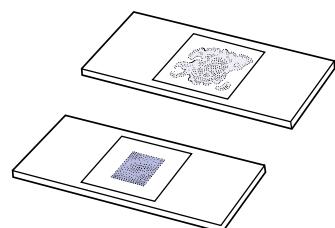

A diagnostic test involving the removal of small amounts of tissue or cells from the body for microscopic examination. A biopsy is an accurate method of diagnosing many illnesses, including cancer. Microscopic examination of tissue (see *histology*) or of cells (see *cytology*) usually gives a correct diagnosis.

HOW IT IS DONE

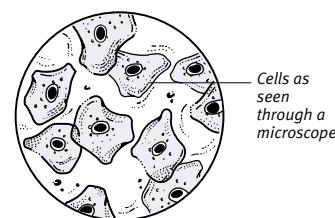

There are several types of biopsy. In excisional biopsy, the whole abnormal area is removed for study. Incisional biopsy involves cutting away a small sample of skin or muscle for analysis. In a needle biopsy, a needle is inserted through the skin and into the organ or tumour to be investigated. Aspiration biopsy uses a needle and syringe to remove cells from a lump (see box). Guided biopsy uses *ultrasound scanning* or *CT scanning* to locate the area of tissue to be biopsied and follow the progress of the needle. In endoscopic biopsy, an *endoscope* (viewing tube) is passed into the organ to be investigated and an attachment is used to take a sample from the lining of accessible hollow structures such as the lungs, stomach, and bladder. In an open biopsy, a surgeon opens a body cavity to reveal a diseased organ or tumour and removes a sample. Prompt analysis, in some cases by *frozen section* (in which the tissue is frozen and thinly sliced), can enable the surgeon to decide whether to remove the entire diseased area immediately.

ASPIRATION BIOPSY

1 A fine needle attached to a syringe is inserted into the lump, and fluid or cells are sucked out to be examined under a microscope. The syringe can be held in a device that withdraws the plunger. Usually no anaesthetic is necessary, but local anaesthetic may be sometimes be used.

2 Before examination any fluid may be spun at high speed in a centrifuge and a small amount placed on a slide.

3 The cells are then fixed (preserved) and finally stained for viewing. The cytologist examines individual cells for abnormalities, paying particular attention to the size, shape, and structure of the nucleus.

OBTAINING RESULTS

Biopsy samples are analysed by *staining*; dyes are used to show up structures or identify constituents such as *antibodies* or *enzymes*. Tissue may be tested with specific antibodies in the investigation of infection and inflammation. In some cases, a tissue *culture* (cultivation of tissue cells in a growing medium) may be required. (See also *endometrial biopsy*; *excision*; *kidney biopsy*; *liver biopsy*.)

biorhythms

A term used to describe physiological functions that vary in a rhythmic way (for example, the menstrual cycle, which repeats approximately every 28 days in fertile women).

Most biorhythms are based on a daily, or circadian (24-hour), cycle. Our bodies are governed by an internal clock, which is itself regulated by *hormones* (chemicals released into the circulation by *endocrine glands*). Periods of sleepiness and wakefulness may be affected by the level of *melatonin* secreted by the pineal gland in the brain. Release of melatonin is stimulated by darkness and suppressed by light. Cortisol, a hormone that is secreted by the adrenal glands, also reflects sleeping and waking states, being low in the evening and high in the morning.

When the normal regular division between night and day is distorted by air travel to a distant time zone, the body's internal clock is disrupted and the result is *jet-lag*.

biosynthesis

The formation of chemical compounds by a living organism.

biotechnology

The use of living organisms such as *bacteria* in industry and science (for example, in drug production).

bioterrorism

The use of disease-causing organisms as an act of violence and intimidation. Examples of such organisms are *anthrax* spores and the *smallpox* virus.

biotin

A vitamin of the B complex (see *vitamin B complex*) that is essential for the breakdown of fats.

bisphosphonate drugs

See *bisphosphonate drugs*.

bipolar disorder

An illness, commonly known as *manic-depressive illness*, that is characterized by swings in mood from severe depression to overexcitability and vice versa.

bird-fancier's lung

A form of allergic *alveolitis* (inflammation of the lungs) caused by inhalation of dust particles from bird droppings. The disease is also sometimes known as pigeon-fancier's lung.

birth

See *childbirth*.

birth canal

The passage through the pelvis, running from the cervix (the neck of the womb) to the vaginal opening, through which the baby passes during *childbirth*.

birth control

Limitation of the number of children born, either to an individual or within a population. *Family planning* allows men and women to choose if and when to have children; *contraception* can prevent unwanted pregnancies.

birth defects

Abnormalities that are obvious at birth or detectable early in infancy. Also called *congenital defects*, they encompass both minor abnormalities, such as *birthmarks*, and serious disorders such as *spina bifida* (failure of the spinal column to close properly). Birth defects may occur as the result of a variety of factors, but in most cases no obvious cause can be found.

CHROMOSOME DEFECTS

Some children are born with more or fewer than the normal 23 pairs of *chromosomes* (threadlike structures in the cell nuclei that carry the genetic information for normal development). *Down's syndrome*, a condition in which there is an extra copy of one of the chromosomes, is one of the most common *chromosomal abnormalities*.

GENETIC OR HEREDITARY DEFECTS

These may be inherited from one or both parents (see *gene*; *genetic disorders*). Genetic defects obvious at birth include *albinism* (lack of normal pigmentation in the skin, hair, and eyes) and *achondroplasia* (abnormally short stature).

DRUGS AND OTHER HARMFUL AGENTS

Certain drugs and chemicals (known as *teratogens*) can damage the fetus if the mother takes or is exposed to them during early pregnancy. Teratogenic drugs include *thalidomide* (now rarely prescribed) and *isotretinoin*, which is used in the treatment of severe *acne*. Alcohol can affect the development of the brain and face (see *fetal alcohol syndrome*).

IRRADIATION

Irradiation of the embryo at an early stage of development, for example, if a woman is X-rayed before she is aware of her pregnancy, can cause abnormalities.

INFECTIONS

If a woman contracts certain infections during pregnancy, there is a chance that

they may cause birth defects. For example, *rubella* (German measles) in early pregnancy can cause fetal abnormalities, including deafness, cataract (clouding of the lens of the eye), and heart disease. *Toxoplasmosis* (infection with a parasite found in cats' faeces), can also be passed on to the fetus, causing damage to the eyes, liver, and other organs.

OTHER COMMON DEFECTS

Abnormalities in the embryo's development can damage the brain and spinal cord, causing defects such as spina bifida and *hydrocephalus* (a buildup of fluid in the brain). In congenital heart disorders (see *heart disease, congenital*), there is a structural abnormality in the heart that may interfere with normal blood flow. *Cleft lip and palate* result from a failure of the two sides of the fetal face and palate to join completely.

DETECTION

Ultrasound scanning and blood tests during pregnancy can identify women at high risk of having a baby with a birth defect. Further tests such as *chorionic villus sampling*, *amniocentesis*, or *fetoscopy* may then be carried out.

PREVENTION

Some birth defects can be prevented, or the risks minimized; for example, by rubella immunization before pregnancy or avoiding teratogens during pregnancy.

birthing chair

A specially designed chair to support a woman during *childbirth*. In the opinion of many doctors, sitting, as opposed to lying down, can help to shorten labour.

birth injury

Damage sustained by a baby during *childbirth*. Minor injuries, such as bruising and swelling of the scalp during a vaginal delivery (see *cephalhaematoma*) are common. More serious injury can occur, particularly if the baby is large and has difficulty passing through the birth canal. A *breech delivery* may result in injury to nerves in the baby's shoulder, causing temporary paralysis in the arm. The face may be paralysed temporarily if the facial nerve is traumatized by forceps during delivery. Fractured bones are another hazard of difficult deliveries, but the bones usually heal easily. (See also *birth defects; brain damage*.)

birthmark

An area of discoloured skin that is present at birth, or appears very soon afterwards. Birthmarks include *moles*,

freckles, and other types of melanocytic *naevi* (a variety of flat, brown to blue-grey skin patches), strawberry marks (bright red, usually protuberant areas), and port-wine stains (purple-red, flat, often large areas). The latter two are types of *haemangioma* (malformation of blood vessels). Strawberry marks often increase in size in the first year, but most disappear after the age of nine. Port-wine stains seldom fade, but some of them can be reduced by *laser treatment* during adulthood.

Birthmark

Strawberry marks, a common type of birthmark caused by malformation of blood vessels, are usually bright red, protuberant, and spongy.

birthpool

A pool of warm water in which a woman can sit to help relieve pain during labour (see *childbirth*).

birth, premature

See *prematurity*.

birth, preterm

See *preterm birth*.

birth rate

A measurement of the number of births in a particular year in relation to the size of the population.

birthweight

A baby's weight at birth, which usually ranges from 2.5 to 4.5 kg. Birthweight depends on a number of factors, including the size and ethnic origin of the parents. Baby boys weigh, on average, slightly more than baby girls. Babies who weigh less than 2.5 kg at birth are considered to be of low birthweight. Causes include *prematurity* and undernourishment in the uterus (because the mother had *pre-eclampsia*, for example). Abnormally high birthweight may be due to unrecognized or poorly controlled *diabetes mellitus* in the mother.

bisacodyl

A type of stimulant *laxative drug* that works by stimulating the intestinal wall into contracting, increasing the speed at which faecal matter passes through.

bisexuality

Sexual interest in members of both sexes that may or may not involve sexual activity.

bismuth

A metal, salts of which are used in tablets to treat *peptic ulcer* and in creams and suppositories to treat *haemorrhoids* (piles). Bismuth preparations taken by mouth may colour the faeces black. The tongue may darken and, occasionally, nausea and vomiting may occur.

bisphosphonate drugs

Drugs used to slow bone metabolism (for example, in *Paget's disease*) and to reduce the high calcium levels in the blood that are associated with destruction of bone by secondary cancerous growths. Bisphosphonate drugs may also be used in the prevention or treatment of *osteoporosis*.

bite

See *occlusion*.

bites, animal

Any injury inflicted by the mouthparts of an animal, which may range from the puncture wounds of bloodsucking insects to the massive injuries caused by shark or crocodile attacks. Teeth, especially those of carnivores, can inflict widespread mechanical injury. Severe injuries and lacerations to major blood vessels can lead to heavy blood loss and physiological *shock*. Serious infection may occur as a result of bacteria in the animal's mouth being transferred in the bite, and *tetanus* is a particular hazard. In countries where *rabies* is present, any mammal may potentially harbour the rabies virus and transmit it via a bite.

TREATMENT

Medical advice should be sought for all but minor injuries, and in all cases if there is a risk of rabies. The treatment usually includes cleaning and examination of the wound. The wound will usually be left open and dressed, rather than stitched, as closing it can encourage the multiplication of bacteria. Preventive *antibiotic drug* treatment and an anti-tetanus injection may also be given. Antirabies vaccine is given, together with

immunoglobulin, if there is any possibility that the animal could be infected with the rabies virus. (See also *bites, human; insect bites; snake bites; spider bites; venomous bites and stings*.)

bites, human

Wounds that are caused by one person biting another. Human bites rarely result in serious tissue damage or blood loss; but infection from any microorganisms in the mouth is likely, particularly if the bite is deep. For example, there is a risk of *tetanus* infection, and transmission of *hepatitis B*, *herpes simplex*, and *HIV* through a human bite is a theoretical hazard.

Bitot's spots

Grey, foamy patches that appear on the *conjunctiva* (the mucous membrane covering the front of the eye). Bitot's spots, which are made up of keratinized (horny) cells, are associated with *vitamin A* deficiency.

black death

The medieval name for bubonic *plague*, which in past epidemics killed 50 per cent of its victims. One feature of the disease is bleeding under the skin, causing bluish-black bruises, hence the name.

black eye

A dark discolouration of the skin around the eye, usually following an injury. The discolouration is due to blood collecting under the skin (see *bruise*). Because the skin around the eye is loose and thin, bruising is darker than on other parts of the body. A cold compress held over the eye can help to relieve the discomfort.

blackhead

Also called a comedo, a semi-solid, black-capped plug of keratin and sebum that blocks the outlet of a sebaceous (oil-forming) gland in the skin. Blackheads occur most commonly on the face, chest, shoulders, and back, and

they are associated with increased sebaceous gland activity. They are one of the features of most types of *acne*.

blackout

A common term for loss of consciousness (see *fainting*).

black teeth

See *discoloured teeth*.

blackwater fever

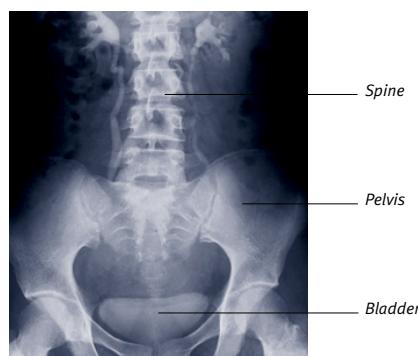

An occasional, life-threatening complication of falciparum *malaria* (the most dangerous form of malaria). Symptoms include loss of consciousness, fever, vomiting, and very dark urine (due to pigment from destroyed *red blood cells* being filtered into the urine).

bladder

The hollow, muscular organ situated in the lower abdomen that acts as a reservoir for *urine*. The bladder lies within,

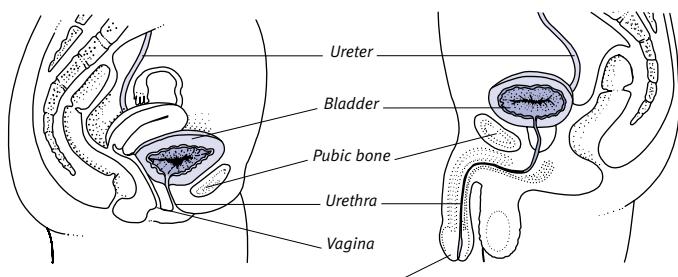

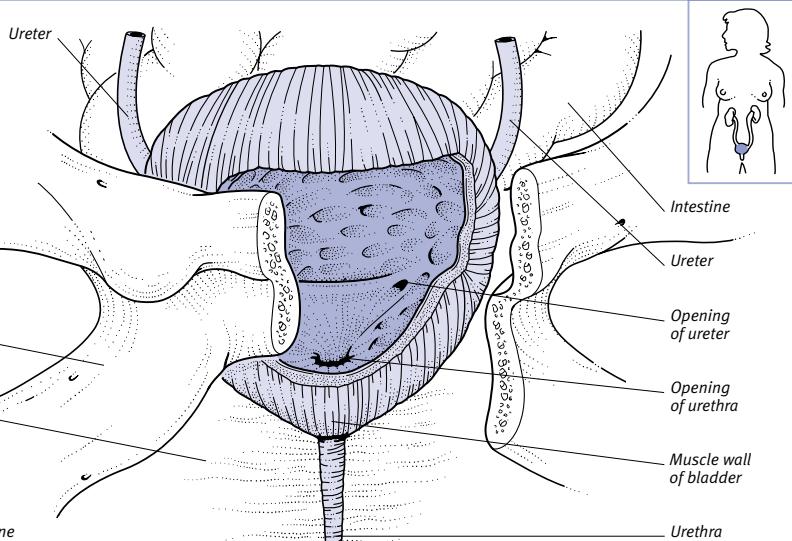

ANATOMY OF THE BLADDER

The bladder is a hollow organ that holds urine. It is situated behind the pubic bone and is protected by the pelvis. The ureters carry urine to the bladder from the kidneys. When the sphincter at the lowest part of the bladder is relaxed, urine is passed into the urethra and out of the body.

Intravenous urography

This special X-ray technique shows clearly the position of the bladder in the pelvis.

and is protected by, the *pelvis*. The average adult bladder can hold about 0.5 litres of urine before the need to pass urine is felt.

The bladder walls consist of muscle and an inner lining. Two tubes called *ureters* carry urine to the bladder from the kidneys. At the lowest point of the bladder is the opening into the *urethra* (outflow tube), known as the bladder neck. This is normally kept closed by a ring of muscle (the urethral sphincter).

FUNCTION

The bladder's function is to collect and store urine until it can be expelled from the body. Full control over bladder function takes several years to develop. In infants, emptying of the bladder is an entirely automatic, or *reflex*, reaction. When the bladder fills with urine and is stretched beyond a certain point, nerve signals are sent to the spinal cord. Signals from the spinal cord then cause the urethral sphincter to relax and the principal bladder muscle to contract, thereby expelling urine via the urethra.

Children develop complete bladder control at varying ages. Most are dry at night by the age of five years, but some take longer (see *enuresis, nocturnal*).

Defective bladder function, leading to problems such as incontinence (see *incontinence, urinary*) and *urinary retention*, can have a variety of causes. (See also *bladder disorders* box.)

bladder cancer

See *bladder tumours*.

bladder outflow obstruction

See *prostate, enlarged; urinary retention*.

bladder tumours

Growths originating in the inner lining of the bladder. *Papillomas* (small wart-like growths) often recur and eventually become cancerous. Other, more malignant, growths may extend not only into the bladder cavity, but also through the bladder wall to involve nearby organs, such as the colon, rectum, prostate gland, or uterus. Bladder cancer is more common in smokers and workers in the dye and rubber industries.

SYMPTOMS

Haematuria (blood in the urine) is the main symptom of bladder cancer. A tumour may obstruct the point at which a ureter enters the bladder, causing back pressure and pain in the kidney region, or the urethral exit, causing difficulty in passing, or retaining, urine.

DIAGNOSIS AND TREATMENT

Bladder tumours are diagnosed using *cystoscopy* (passage of a viewing tube up the urethra into the bladder) and biopsy (tissue sampling for microscopic analysis) of the abnormal area.

If they are small, the tumours can be treated by heat or removed surgically. Tumours tend to recur within the bladder, so regular follow-up cystoscopy is usually necessary. Bladder tumours that have spread through the bladder wall may be treated by *radiotherapy* or by the removal of part or all of the bladder.

Blalock shunt

A surgical procedure in which a connection is made between one of the two subclavian arteries (which normally deliver oxygen-rich blood to the neck and arms) and one of the pulmonary arteries (which carry blood from the right side of the heart to the lungs for oxygenation). The shunt may be used as a temporary treatment for congenital heart disorders, such as *tetralogy of Fallot*, in which oxygen-depleted blood is diverted back to the heart before it reaches the lungs. The shunt redirects the

DISORDERS OF THE BLADDER

The most important causes of bladder problems are infection, tumours, calculi (stones), and impairment of the bladder's nerve supply.

Infection

Bacterial infection of the bladder, which causes inflammation of the bladder wall (see *cystitis*), is particularly common in women. The short female urethra makes it relatively easy for bacteria to enter from outside the body. In men, infection is usually associated with obstruction of urine flow from the bladder by, for example an enlarged prostate gland (see *prostate, enlarged*) or bladder tumours.

Tumours

Bladder tumours may be cancerous or noncancerous and are more common in men than in women. They are usually painless in the early stages, the first symptoms being blood in the urine (see *haematuria*) or *urinary retention*, in which the bladder cannot be emptied. All bladder tumours need careful follow-up because, left untreated, noncancerous bladder tumours may become cancerous.

Calculi

Bladder stones (see *calculus, urinary tract*) are mostly caused by the crystallization of substances, such as calcium, in the urine. They mainly affect men and usually result from a longstanding urinary tract infection and/or incomplete emptying of the bladder.

Nerve impairment

Damage to the nerves controlling the bladder can prevent normal bladder function and lead either to incontinence (see *incontinence, urinary*) or to urinary

retention. The most common cause is spinal-cord injury or tumours. Bladder control can be affected by nerve degeneration in conditions such as *diabetes mellitus, multiple sclerosis, or dementia*.

Other disorders

An unstable or *irritable bladder* is a common condition, particularly in women, in whom the bladder wall is especially sensitive to being stretched. Weakness of the muscles at the bladder neck, causing *stress incontinence*, is also common in women, particularly after childbirth. Tension or anxiety can cause frequent urination.

In children, delayed bladder control (see *enuresis, nocturnal*) is most often due to delayed maturation of the nervous system. Injury to the bladder is rare but may occur if the pelvis is fractured when the bladder is full.

INVESTIGATION

Various methods are used to investigate bladder disorders. Urinary tract infection is diagnosed by tests on a sample of urine. The bladder can be viewed directly by *cystoscopy* (insertion of a viewing tube). *Ultrasound scanning* is often performed, particularly if stones are suspected. X-ray procedures include micturating *cystourethrography*, which normally shows only the bladder and urethra, and intravenous *urography*, which shows the whole urinary tract except the urethra. *Urodynamics*, which may involve X-rays, are studies carried out to investigate bladder control problems. *Cystometry* measures bladder capacity in relation to pressure.

oxygen-depleted blood to the lungs. The improved blood oxygen levels allow the child to survive and grow until corrective surgery is possible.

blond diet

An easily digested diet that is free from possible irritants to the digestive tract, such as spicy foods and raw vegetable fibre. A bland diet is often advised following abdominal surgery or for people with gastrointestinal disorders.

blast cell

An immature *cell* that later develops into a specialized cell. For example, *white blood cells* begin as blast cells in the bone marrow and eventually form different types of mature white blood cells that are then released into the bloodstream. The presence of certain blast cells may indicate illness. For example, blast cells are found in the blood in acute leukaemia (see *leukaemia, acute*). (See also *stem cell*.)

blast injury

Tissue damage due to the effects of blast waves generated by an explosion. The eardrums and digestive tract are particularly at risk; the air within the ear and hollow parts of the gut transmits the waves in all directions, often resulting in severe damage.

blastocyst

A cell cluster that develops from a fertilized *ovum* and grows into an *embryo* (see *fertilization*).

blastomycosis

A type of *fungal infection* that can affect the lungs and other internal organs.

bleaching, dental

A cosmetic procedure for lightening certain types of *discoloured teeth*, including nonvital "dead" teeth. The surface of the affected tooth is painted with oxidizing agents and then exposed to ultraviolet light. A home procedure, consisting of trays loaded with bleaching material, is also available but is slower.

bleb

Another term for a *blister*.

bleeding

Loss of blood from the *circulatory system*, which may be caused by damage to the blood vessels or by a *bleeding disorder*. Bleeding may be visible (external) or

concealed (internal). Rapid loss of more than 10 per cent of the blood volume can cause symptoms of *shock*, with fainting, pallor, and sweating.

The speed with which blood flows from a cut depends on the type of vessel damaged: blood usually oozes from a capillary, flows from a vein, and spurts from an artery. If an injury does not break open the skin, the blood collects around the damaged blood vessels just beneath the skin and forms a *bruise*.

Any lost blood that mixes with other body fluids such as sputum (phlegm) or urine will usually be noticed quite readily; bleeding from the lining of the digestive tract may make vomit or faeces appear darker than usual. Internal bleeding may not be discovered until severe *anaemia* develops.

bleeding disorders

A group of conditions characterized by bleeding in the absence of injury or by abnormally prolonged and excessive bleeding following injury. Bleeding disorders are the result of defects in the mechanisms by which bleeding is normally stopped: the coagulation of blood, the plugging of damaged blood vessels by platelets (the smallest type of blood cell), and the constriction of blood vessels (see *blood clotting*).

Defects in the coagulation system tend to cause deep bleeding into the gastrointestinal tract, muscles, and joint cavities. Defects of the platelets or blood vessels usually cause superficial bleeding into the skin, the gums, or the lining of the intestine or the urinary tract.

COAGULATION DEFECTS

These disorders are usually due to a deficiency of or abnormality in the *enzymes* (coagulation factors) that are involved in blood clotting. Clot formation is very slow and the clots are weak and do not seal blood vessels securely. Coagulation defects may be *congenital* (present at birth) or may be acquired later in life.

Congenital The main congenital coagulation defects are *haemophilia*, *Christmas disease*, and *von Willebrand's disease*. In all of these, one coagulation factor is either absent from the blood or present only in small amounts. Haemophilia and Christmas disease are similar disorders, resulting from deficiencies of two different coagulation factors: factor VIII and factor IX respectively. Inheritance of these disorders is sex-linked (see *genetic disorders*) and normally only males are

affected. Von Willebrand's disease is an inherited disorder in which there is a platelet and a factor VIII defect; it affects both sexes about equally.

Individuals with one of these disorders may suffer from bruising, internal bleeding, abnormally heavy menstrual periods, and excessive bleeding from wounds. In severe cases, there may be recurrent bleeding into joints, such as the knee.

Acquired Acquired defects of blood coagulation factors may develop at any age due to severe liver disease, digestive system disorders that prevent the absorption of *vitamin K* (which is needed to make certain coagulation factors), or the use of *anticoagulant drugs*.

Disseminated intravascular coagulation (DIC) is an acquired disorder that is complex and serious. It may be the result of an underlying infection or of a cancerous tumour. In this condition, platelets accumulate and clots develop within small blood vessels; coagulation factors are used up faster than they are able to be replaced, and severe bleeding may result.

Tests and treatment Coagulation disorders are investigated by *blood-clotting tests*. If such a disorder is severe, it is treated by replacing the missing factor. Factors are extracted from fresh blood or from fresh frozen plasma, or genetically engineered factors may be used. Paradoxically, anticoagulants are sometimes used to suppress excess clotting activity in DIC, which results in a reduction in bleeding.

PLATELET DEFECTS

Bleeding may occur if there are too few platelets in the blood, a condition called *thrombocytopenia*. The main feature of this disorder is surface bleeding into the skin and gums, and there are multiple small bruises.

Occasionally, the platelets are present in normal numbers but function abnormally, causing bleeding. Platelet defects may be inherited, they may be associated with the use of certain drugs (including *aspirin*), or arise as a complication of certain bone marrow disorders such as *leukaemia*. Platelets can be destroyed by *autoimmune disorders* that may have been triggered by an infection or by drug treatment.

Platelet defects are investigated by blood tests. Bleeding due to a lack of platelets may be treated with intravenous platelet transfusions. In some cases, oral *corticosteroid drugs* are prescribed.

BLOOD VESSEL DEFECTS

In rare cases, abnormal bleeding is the result of a blood-vessel defect or *scurvy* (a disorder that is caused by a deficiency of *vitamin C*). Elderly people and patients on long-term courses of *corticosteroid drugs* may suffer mild abnormal bruising due to loss of skin support to the smallest blood vessels. Treatment is rarely required in these cases.

bleeding, dysfunctional uterine

Abnormal bleeding from the *uterus* (womb) with no obvious cause. (See also *menorrhagia*).

bleeding gums

See *gingivitis*.

bleeding, occult

Bleeding that is not obvious to the naked eye (such as that which occurs within the intestine) and that may be detected only by tests. (See also *occult blood, faecal*).

bleeding time

An assessment of the functioning of platelets (the tiny cell fragments within the blood that play a vital role in *blood clotting*) by measuring the speed at which they form plugs to stem bleeding from damaged blood vessels. Two small cuts are made in the forearm and the time taken for the bleeding from these cuts to stop is recorded.

blepharitis

Inflammation of the eyelids, with redness, irritation, and scaly skin at the lid margins. Blepharitis may cause burning and discomfort in the eyes and flakes or crusts on the lashes. The condition is common, tends to recur, and is sometimes associated with dandruff of the scalp or *eczema*. Severe blepharitis may lead to *corneal ulcers*. In many cases, treatment of associated dandruff with an antifungal shampoo will result in improvement of the blepharitis.

blepharoplasty

A cosmetic operation to remove drooping, wrinkled skin from the upper and/or lower eyelids. Blepharoplasty is usually performed under local anaesthetic (see *anaesthesia, local*).

blepharospasm

Prolonged, involuntary contraction of one of the muscles controlling the eyelids, causing them to close. It may be

Appearance before (top) and after (bottom)

Blepharoplasty involves the removal of a crescent-shaped section of skin and underlying fat from each eyelid.

due to *photophobia* (abnormal sensitivity of the eyes to light), to damage to the *cornea* (the transparent dome that forms the front part of the eyeball), or to *dystonia* (abnormal muscle rigidity), for which *botulinum toxin* (a muscle relaxant) treatment is highly effective.

blind loop syndrome

A condition in which a redundant area or dead end (blind loop) in the small intestine becomes colonized with bacteria. The bacteria break down bile salts, which are necessary for the absorption of fat and certain vitamins. This results in poor absorption of fats and abnormal faeces. Blind loop syndrome may result from surgery or a *stricture* (narrowing) in the intestine as a result of a disorder such as *Crohn's disease*. It is characterized by *steatorrhoea* (pale yellow, foul-smelling, fatty, bulky faeces that are difficult to flush away), tiredness, and weight loss. *Antibiotic drug* treatment is usually effective, but the condition may recur if the underlying abnormality cannot be corrected.

blindness

Inability to see. Definitions of blindness and partial sight vary. In the UK, blindness is defined as a corrected *visual acuity* of 3/60 or less, or a *visual field* of no more than 20 degrees, in the better eye.

CAUSES

Loss of vision may result from injury to, or disease or degeneration of, the eyeball; the optic nerve or the nerve pathways that connect the eye to the brain; or the brain itself.

Eyeball Normal vision depends on an uninterrupted passage of light from the front of the eye to the light-sensitive retina at the back. Anything that prevents light from reaching the retina can cause blindness.

Various disorders can lead to the clouding of the cornea at the front of the eye. These disorders include *Sjögren's syndrome* (in which the eyes become excessively dry), *vitamin A deficiency*, chemical damage, infections, and injury. *Corneal ulcers*, which most commonly develop after severe infections, can cause blindness due to scarring of the cornea. *Uveitis* (inflammation of the iris, ciliary body, or choroid), can also cause loss of vision.

Cataract (cloudiness of the lens) is another common cause of blindness. It is usually the result of the lens becoming less transparent in old age, but is occasionally present from birth or develops in childhood.

Diabetes mellitus, *hypertension* (high blood pressure), or injury can all cause bleeding into the cavity of the eyeball and a subsequent loss of vision. Bleeding into the fluid in front of the lens (see *hyphaema*) or behind the lens (see *vitreous haemorrhage*) can also result in loss of vision.

Disorders of the retina that may result in blindness include age-related *macular degeneration* (degeneration of the central area of the retina, which occurs in old age); *retinopathy* due to diabetes or to hypertension; *retinal artery occlusion* or *retinal vein occlusion* (blockage of the blood flow to and from the retina); *retinal detachment*; certain types of tumour, such as *retinoblastoma* and malignant melanoma affecting the eye (see *melanoma, malignant*); and *retinal haemorrhage* (bleeding into the retina), caused by diabetes, hypertension, vascular disease, or injury.

In *glaucoma*, excessive fluid pressure within the eyeball causes degeneration of nerve fibres at the front end of the optic nerve.

Nerve pathways The light energy that is received by the retina is transformed into nerve impulses that travel along the optic nerve and nerve pathways into the brain. Loss of vision may result if the conduction of these nerve impulses is impaired.

Reasons for damage to nerve pathways include pressure caused by a tumour in the orbit (the bony cavity that contains the eyeball); a reduced blood supply to

the optic nerve, which may be caused by diabetes mellitus, hypertension, a tumour, injury, or *temporal arteritis* (inflammation of arteries in the scalp); *optic neuritis* (inflammation of the optic nerve that may occur in *multiple sclerosis*); the toxic (poisonous) effects of certain chemicals; and certain nutritional deficiencies.

Brain Nerve impulses from the retina eventually arrive in a region of the *cerebrum* (the main mass of the brain) called the visual cortex. Blindness can result if there is pressure on the visual cortex from a *brain tumour* or a *brain haemorrhage*, or if the blood supply to the visual cortex has been reduced following a *stroke*.

DIAGNOSIS AND TREATMENT

It is frequently possible to detect the cause of blindness by direct examination of the eye, using such techniques as *ophthalmoscopy*, *slit-lamp examination*, and *tonometry*. The conduction of nerve impulses can be measured by means of *evoked responses*.

Treatment of blindness depends on the underlying cause. If the loss of vision cannot be corrected, the patient may then be registered as legally blind or partially sighted, and will become eligible for certain benefits and services. (See also *eye; vision, loss of*.)

blind spot

The small, oval-shaped area on the retina of the eye where the optic nerve leaves the eyeball. The area is not sensitive to light because it has no light receptors

(nerve endings responsive to light). The blind spot can also be used to describe the part of the *visual field* in which objects cannot be detected.

blister

A collection of fluid beneath the outer layer of the skin that forms a raised area. The fluid is serum that has leaked from blood vessels in underlying skin layers after minor damage; it provides protection for the damaged tissue.

Common causes of blisters are *burns* and friction. Blisters may also occur in some skin diseases, including *eczema*, *epidermolysis bullosa*, *impetigo*, *erythema multiforme*, *pemphigus*, *pemphigoid*, and *dermatitis herpetiformis*, and in some types of *porphyria*. Small blisters develop in *chickenpox*, *herpes zoster* (shingles), and *herpes simplex*. Blisters are generally best left intact; large or unexplained blisters need medical attention.

bloating

Distension of the abdomen, commonly due to wind in the stomach or intestine (see *abdominal swelling*).

blocked nose

See *nasal congestion; nasal obstruction*.

blocking

The inability to express true feelings or thoughts, usually due to emotional or mental conflict. In Freudian-based *psychotherapy*, blocking is thought to result from the repression of painful emotions in early life. A very specific form of thought blocking occurs in *schizophrenia*: trains of thought are persistently interrupted involuntarily to be replaced by unrelated new ones.

blood

The red fluid that circulates in the body's veins, arteries, and capillaries. Blood is pumped by the heart via the arteries to the lungs and all other tissues and is then returned to the heart in veins (see *circulatory system*). Blood is the body's transport system and also plays an important role in the defence against infection. An average adult has about 5 litres of blood.

Almost half the blood's volume consists of *blood cells*, including red blood cells (erythrocytes), which carry oxygen to the tissues; white blood cells (leukocytes), which defend the body against infection; and platelets (thrombocytes), which are involved in *blood clotting*. The

rest of the blood volume is made up of plasma, a watery, straw-coloured fluid containing proteins, sugars, fats, salts, and minerals.

Nutrients are transported in the bloodstream to the tissues after absorption from the intestinal tract or after release from storage depots such as the liver. Waste products, including *urea* and *bilirubin*, are carried in the plasma to the kidneys and liver respectively.

Plasma proteins include fibrinogen, which is involved in blood clotting; *immunoglobulins* (also called antibodies) and *complement*, which are part of the *immune system*; and *albumin*. Hormones are also transported in the blood to their target organs.

blood-brain barrier

A system of tight, impermeable junctions between the cells that form the walls of the capillaries (tiny blood vessels) within the *central nervous system*. The blood-brain barrier has a protective function; it allows only certain substances and drugs in the bloodstream to gain access to the central nervous system, especially to the brain.

blood cells

Cells, also called blood corpuscles, that are present in blood for most or part of their lifespan. They include red blood cells (which make up about 45 per cent of the volume of normal blood), white blood cells, and platelets. All blood cells are made in the bone marrow by a series of divisions from a single type of cell called a *stem cell*.

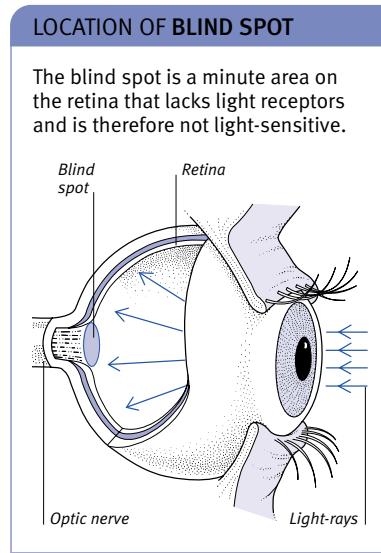

RED BLOOD CELLS

These cells are also known as RBCs, red blood corpuscles, or erythrocytes. They transport oxygen from the lungs to the tissues (see *respiration*).

Formation Red blood cells are formed from stem cells in the bone marrow by a process called *erythropoiesis*, which takes about five days. Their formation requires an adequate supply of nutrients, including iron, amino acids, and the vitamins B_{12} and folic acid. The rate at which RBCs are formed is influenced by a hormone called *erythropoietin*, which is produced by the kidneys.

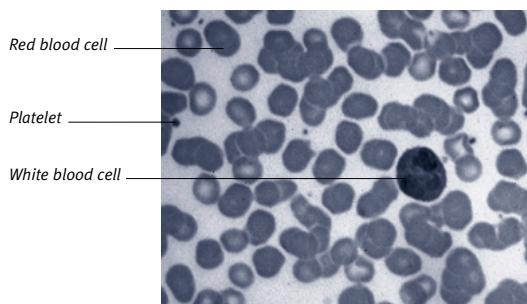

Immature red blood cells that have just been released into the bloodstream from the bone marrow are called *reticulocytes*; within two to four days, these develop into mature cells.

Structure and function In 1 ml of blood there are approximately 5 million red

CONSTITUENTS OF BLOOD

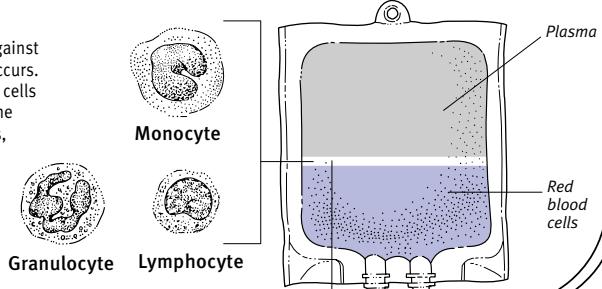

Blood is pumped around the body in veins and arteries, transporting oxygen from the lungs to the tissues and carbon dioxide from the tissues to the lungs. Blood also carries nutrients such as sugars, fats, and proteins that have been absorbed from the intestine and hormones produced by a variety of glands. Waste products that are released from cells are carried in the blood to be broken down in the liver or excreted from the kidneys.

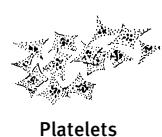

Normal blood smear
This is the appearance of normal blood under a microscope. The dominant feature is the abundance of red blood cells, which make up almost half of the volume of blood. One white blood cell (a lymphocyte) can be clearly seen; the platelets are the tiny dark particles.

White blood cells

These cells protect the body against infection and fight it when it occurs. They are bigger than red blood cells but fewer in number. Each of the three main types (granulocytes, monocytes, and lymphocytes) plays a different role in dealing with infection.

**Platelets**

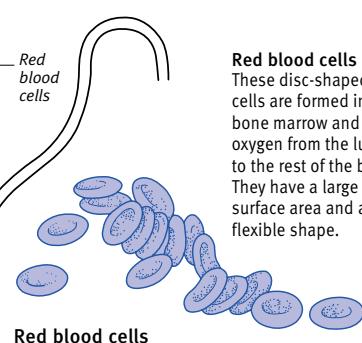

The smallest type of blood cell produced in the bone marrow. They play an important role in blood clotting.

Platelets

Plasma

The fluid part of the blood that consists mostly of water. It carries substances such as proteins, fats, glucose, and salts.

**Red blood cells**

These disc-shaped cells are formed in the bone marrow and carry oxygen from the lungs to the rest of the body. They have a large surface area and a flexible shape.

blood cells, each of which is disc-shaped, about 0.0075 mm in diameter, and thicker around the edge than at the centre. This shape gives each cell a relatively large surface area, which helps it absorb and release oxygen molecules, and allows it to distort as it squeezes through narrow blood vessels. The surface structure of red blood cells varies slightly among individuals, and this provides the basis for classifying blood into groups (see *blood groups*).

RBCs are packed with large quantities of *haemoglobin*, a pigmented protein that contains iron. Haemoglobin binds (combines chemically) with oxygen to form oxyhaemoglobin, which carries oxygen to body tissues. Oxyhaemoglobin is responsible for the bright red coloration of oxygenated blood, which flows mainly through the arteries. Most venous blood is darker because it contains the unbound (deoxygenated) form of haemoglobin.

Every RBC also contains *enzymes* (substances that promote biochemical

reactions), minerals, and sugars that provide energy for the cell's *metabolism* (chemical processes) and maintain its shape, structure, and elasticity.

Aging and destruction The normal lifespan of RBCs in the circulation is about 120 days. As they age, their internal chemical machinery wears out, they lose elasticity, and they become trapped in small blood vessels in the spleen and other organs; they are then destroyed by a type of white blood cell called a macrophage. Most of the components of haemoglobin molecules are reused, but some are broken down to form the waste product *bilirubin*.

Disorders Abnormalities can occur in the rate at which RBCs are produced or destroyed; in their numbers; and in their shape, size, and haemoglobin content, all of which may cause forms of *anaemia* and *polycythaemia* (see *blood disorders* box).

WHITE BLOOD CELLS

These are also called WBCs, white blood corpuscles, or leukocytes. They protect

the body against infection and fight infection when it occurs. White blood cells are bigger than red blood cells (up to 0.015 mm in diameter) but are far less numerous (about 7,500 per ml of blood). They generally spend a shorter part of their lifespan than red blood cells in the blood itself. The three main types of WBC are granulocytes (also called polymorphonuclear leukocytes), monocytes, and lymphocytes.

Granulocytes Granulocytes are further classified as neutrophils, eosinophils, or basophils, each type having a specific role. The most important are neutrophils, which isolate and destroy invading bacteria. Neutrophils remain in the blood for only about six to nine hours before moving through blood-vessel walls into tissues. Eosinophils play a part in allergic reactions and increase in numbers in response to certain parasitic infections. Basophils are involved in inflammatory and allergic reactions.

Monocytes These cells also play an important role in the *immune system*.

DISORDERS OF THE BLOOD

Abnormalities can occur in any of the components of blood: in red blood cells, white blood cells, platelets, and the numerous constituents of plasma.

There are various types of *anaemia* (a reduced level of the oxygen-carrying pigment haemoglobin in the blood), which is by far the most common blood disorder. Some abnormalities of the blood are inherited; others may be the result of various diseases, such as cancer, or be caused by poisoning by infective organisms, toxins, or drugs.

Genetic disorders

Some blood disorders are inherited (genetic) and are present from birth (congenital). Such disorders include *sickle cell anaemia* and *thalassaemia*, in which the red blood cells are abnormally fragile, and *haemophilia*, in which there is a deficiency of one of the blood clotting factors.

Sickle-cell anaemia

This electron micrograph shows a red blood cell deformed by sickle-cell anaemia (left). On the right is another red cell that has started to sickle.

Nutritional disorders

Heavy or persistent blood loss, most commonly as a result of menstruation, may mean that iron (an essential component of the red cell pigment haemoglobin) is lost faster than it can be replaced in the diet (see *anaemia, iron-deficiency*). Deficiencies of the vitamins B₁₂ or folic acid interfere with the production of red blood cells in bone marrow and give rise to abnormally large, deformed red blood cells (see *blood, anaemia, megaloblastic*).

Cancer

There are various types of bone marrow cancer, all of which affect the blood. *Leukaemia* causes an overgrowth of abnormal white blood cells and destroys healthy bone marrow. In *polycythaemia*, too many red blood cells are produced. Another bone marrow cancer, *multiple myeloma*, can cause an excess of certain proteins in the blood plasma. Secondary deposits that have spread from cancers elsewhere in the body may also involve the bone marrow.

Clotting disorders

Defects in the blood platelets and in blood clotting mechanisms may lead to *bleeding disorders*, such as *haemophilia* and *disseminated intravascular coagulation (DIC)*. Liver disease may cause deficiencies of some clotting factors. Unwanted clot formation (see *thrombosis*) may have any of a variety of causes, such as a mutation

in the gene that controls production of a clotting factor (see *factor V*, for example) or use of oral contraceptives. People with *Hughes' syndrome* are also at increased risk of thrombosis.

Other disorders

Blood poisoning may be caused by the multiplication of bacteria in the blood (see *septicaemia*) or by the toxins released by bacteria (see *toxaemia*). Poisoning can also be caused by toxins such as carbon monoxide and lead.

Some drugs can cause blood abnormalities. For example, thiazide diuretic drugs may depress the production of white blood cells and/or platelets; methotrexate may interfere with red cell production; and too high a dose of anticoagulant drugs can cause abnormal bleeding.

Albumin, which is an important protein in blood plasma, may become deficient as a result of either liver or kidney disease.

INVESTIGATION

Blood disorders are investigated principally by various blood tests, such as *blood count*, *blood film*, and *blood-clotting tests*. Levels of vitamins and minerals, such as iron, may also be measured. In some cases, a bone marrow *biopsy* may also be required.

They circulate in the bloodstream for about one to three days.

Lymphocytes Lymphocytes are usually formed in the lymph nodes, rather than in the bone marrow. They play an important role in the immune system, roving throughout the body between the bloodstream, the lymph nodes, and the channels between lymph nodes. Lymphocyte cells may survive for anywhere between three months and ten years.

There are two principal types of lymphocyte: T-lymphocytes (or T-cells) and B-lymphocytes (or B-cells). T-lymphocytes are responsible for delayed hypersensitivity reactions (see *allergy*) and are also involved in protection against cancer. T-lymphocytes manufacture chemicals, called lymphokines, which affect the functioning of other

cells. T-lymphocytes can be classified according to their surface marker proteins. For example, T-lymphocytes with CD4 surface marker proteins are particularly important in monitoring HIV infection. In addition, T-lymphocytes moderate the activity of B-lymphocytes, which form the antibodies that can act to prevent a second attack of certain infectious diseases.

Disorders The *leukaemias* are *blood disorders* in which there is uncontrolled overproduction of white blood cells in the bone marrow. Other disorders arise when white blood cells are not produced in sufficient numbers.

PLATELETS

Platelets, which are also called thrombocytes, are the smallest type of blood cell (0.002 mm to 0.003 mm in diameter).

There are about 250,000 of them per cubic mm of blood. Like other blood cells, they originate in the bone marrow. Platelets survive in the blood for about nine days.

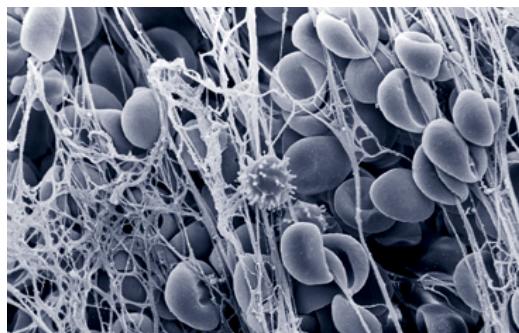

Function Platelets circulate in the blood in an inactive state until brought into action by certain circumstances, when they begin to stick to blood-vessel walls and to each other. These activities play an important part in *blood clotting*, which helps wounds to heal. However, the accumulation of platelets can, occasionally, lead to the formation of clots in blood vessels (see *thrombosis*).

BLOOD CELLS IN DIAGNOSIS

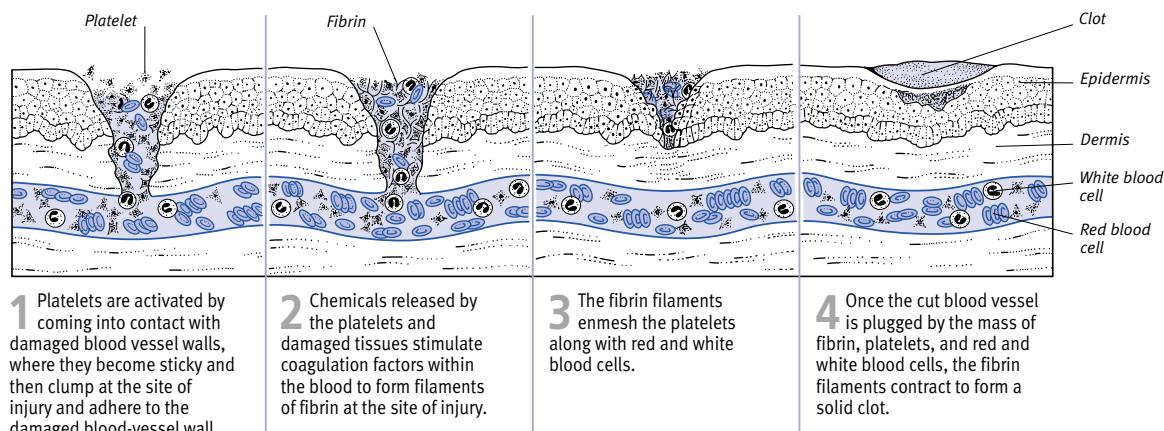

The numbers, shapes, and appearance of the various types of blood cell are of great value in the diagnosis of disease (see *blood count*; *blood film*).

HOW BLOOD CLOTS

Clotting describes the solidification of blood anywhere in the body. Clotting occurs almost immediately at the site of a cut and helps to limit blood loss by sealing damaged blood vessels. However, if abnormal clotting occurs in major blood vessels, a heart attack, stroke, or other disorder may occur. The clotting process has two main parts – platelet activation and the formation of fibrin filaments.

Red blood cells enmeshed in fibrin filaments
Fibrin is formed by a chemical change from a soluble protein, fibrinogen, which is present in the blood. The fibrin molecules aggregate to form long filaments, which enmesh blood cells (see left) to form a solid clot. The conversion of fibrinogen to fibrin is the last step of the “coagulation cascade”, a series of reactions in the blood that are triggered by injury to the tissues and activation of platelets.

**blood clot**

See *thrombus*.

blood clotting

The process of blood solidification. Blood clotting is important in stemming bleeding from damaged blood vessels. However, blood clots can also form inside major blood vessels, leading to a *myocardial infarction* (heart attack) or to a *stroke* (see *thrombosis*).

CLOTTING MECHANISM

When a blood vessel is damaged, it constricts immediately to reduce blood flow to the area. The damage sets off a series of chemical reactions, leading to the formation of a clot to seal the injury. First, platelets around the injury site are activated, becoming sticky and adhering to the blood-vessel wall. The activated platelets then release chemicals that, in turn, activate coagulation factors. These factors, together with *vitamin K*, act on fibrinogen, a substance found in blood, converting it to fibrin. Strands of fibrin form a kind of meshwork, which traps red blood cells to form a clot.

ANTICLOTTING MECHANISMS

There are several anticoagulation mechanisms that prevent the formation of unwanted blood clots. These mechanisms include prostacyclin (a *prostaglandin*), which prevents platelet aggregation (the first stage of blood clotting), and plasmin, which breaks down fibrin (see *fibrinolysis*). Blood flow washes away active coagulation factors; and the liver deactivates excess coagulation factors.

CLOTTING DEFECTS

Defects in blood clotting may result in *bleeding disorders*. Excessive clotting, or thrombosis, may be due to an inherited increase or defect in a coagulation factor (see *factor V*); the use of oral contraceptives; a decrease in the level of enzymes that inhibit coagulation; or sluggish blood flow through a particular area. Treatment is usually with *anticoagulant drugs* such as heparin or warfarin.

blood-clotting tests

Laboratory tests used to screen for and diagnose *bleeding disorders*. Such disorders usually result from deficiencies or

abnormalities of blood coagulation factors or of platelets (see *blood clotting*). The tests are also used to monitor treatment with *anticoagulant drugs*; excessive doses of these drugs could cause bleeding. (See also *international normalized ratio*.)

blood count

A test, also called full blood count, that measures the *haemoglobin* concentration and the numbers of red blood cells, white blood cells, and platelets in 1 cu. mm of blood. The proportion of various white blood cells is measured and the size and shape of the red and white cells is also noted.

A blood count is the most commonly performed blood test and is important for diagnosing *anaemia* or confirming the presence of an infection to which cells in the blood have responded. It is also used to diagnose disorders such as *leukaemia* and *thrombocytopenia* (abnormally low platelet levels).

About 1 to 2 ml of blood is required for a blood count, which is usually performed by an automatic analyser.

blood culture

A laboratory test performed on a sample of *blood* to determine the presence of microorganisms such as bacteria. (See also *culture*.)

blood donation

The process of giving blood for use in *blood transfusion*. Blood donors give up to 500 ml of blood (about one-tenth of total blood volume), usually about twice a year. Donated blood is routinely tested for a range of infectious agents, such as *hepatitis B* and *hepatitis C*, and antibodies to *HIV*. After being classified into *blood groups*, the blood is stored in a blood bank, either whole or separated into its components (see *blood products*).

Apheresis is a specific type of blood donation in which only a particular component of blood (such as plasma, platelets, or white blood cells) is withdrawn from the donor.

blood film

A test that involves smearing a drop of blood on to a glass slide for examination under a microscope. The blood film is stained with dyes to make the blood cells show up clearly.

The test allows the shape and appearance of blood cells to be checked for any abnormality, for example the sickle-shaped red blood cells characteristic of *sickle cell anaemia*. The relative proportions of the different types of white blood cells can also be counted. This examination, known as a differential white cell count, may be helpful in diagnosing infection or *leukaemia*. Blood films are also used in diagnosing infections in which the parasites can be seen inside the red blood cells; an example of such an infection is *malaria*.

Blood film tests are usually carried out together with a full *blood count*.

blood gases

Measurement of the concentrations of oxygen and carbon dioxide in the blood. The acidity–alkalinity (pH) and bicarbonate levels are also measured. The test is carried out on a sample of blood that has been taken from an artery, usually at the wrist or the groin. It is useful in diagnosing and monitoring *respiratory failure*. Bicarbonate and acidity reflect the *acid–base balance* of the body, which may be disturbed in conditions such as diabetic ketoacidosis, aspirin poisoning, *hyperventilation* (overbreathing), or repeated vomiting.

Blood oxygen can also be monitored continuously without the need to take blood samples by using an *oximeter*.

blood glucose

The level of *glucose* in the blood. Abnormally high blood glucose (sometimes called *blood sugar*) levels may be an indication of *diabetes mellitus*. (See also *hyperglycaemia*; *hypoglycaemia*.)

blood glucose monitoring

A method of analysing a person's blood *glucose* (sugar) levels that requires only a drop of blood taken from a pinprick on the fingertip. The blood is applied to a test strip, which has an area impregnated with a chemical that reacts with the glucose in the blood sample. The glucose level is shown either by a visible colour change on the strip or by placing the strip in a digital meter. People with *diabetes mellitus* must perform regular blood glucose monitoring tests to monitor their blood glucose control. (See also *hyperglycaemia*; *hypoglycaemia*.)

blood groups

Systems of classifying blood according to the different *antigens* (marker proteins) on the surface of *red blood cells* (RBCs) and the *antibodies* in the blood plasma. The antigens affect the ability of the RBCs to provoke an *immune response*. The two principal blood grouping systems used are the ABO system and the rhesus system.

ABO GROUPS

In this system, the presence or absence of two types of antigen (A and B) on the

		BLOOD GROUP COMPATIBILITY			
		Donor blood group			
		A	B	AB	O
Recipient blood group	A	○	●	●	○
	B	●	○	●	○
	AB	○	○	○	○
	O	●	●	●	○

Key ○ Compatible ● Incompatible

surface of the red blood cells determines a person's blood group. People with the A antigen (blood group A) have anti-B antibodies; people with the B antigen (blood group B) have anti-A antibodies; those with both antigens (blood group AB) have neither type of antibody; and those with neither antigen (blood group O) have both types of antibody.

RHESUS FACTORS

The rhesus system involves several antigens, the most important of which is called factor D. People with this factor are Rh-positive; those without it are Rh-negative. The importance of the Rh group relates mainly to pregnancy in Rh-negative women because, if the baby is Rh-positive, the mother may form antibodies against the baby's blood (see *rhesus incompatibility*).

USES

Blood group typing is essential for safe *blood transfusion*. The ABO and rhesus groups are used to categorize blood stored in blood banks, so that donor blood that is compatible with that of the patient can be selected before transfusion takes place.

Because a person's blood group is inherited, identification of blood group may be used in paternity testing. Genetic analysis allows identification of the blood of a criminal suspect with virtual certainty (see *genetic fingerprinting*).

blood level

The concentration of a given substance in the blood plasma or serum that may be measured by *blood tests*.

blood loss

See *bleeding*.

blood poisoning

A common name for *septicaemia* with *toxaemia*, a life-threatening illness that is caused by multiplication of bacteria and formation of toxins in the bloodstream. Septicaemia may occur as a complication of an infection in an organ or tissue. In some infective conditions, *septic shock* may be caused by toxins that are released by bacteria. Treatment for blood poisoning is with *antibiotic drugs* and intensive therapy for shock. (See also *bacteraemia*.)

blood pressure

The pressure exerted by the flow of blood through the main arteries. The pressure at two different phases is measured. Systolic, the higher pressure, is

MEASURING BLOOD PRESSURE

Blood pressure measurement is a routine part of a physical examination. A sphygmomanometer measures blood pressure as systolic (the top figure), when the heart contracts, and diastolic, when the heart relaxes. An inflatable cuff attached to the sphygmomanometer is wrapped around the upper arm and deflated while a doctor listens to the blood flow through an artery, using a stethoscope.

Sphygmomanometer

created by the contraction of the ventricles of the *heart*. Diastolic, the lower pressure, is recorded during relaxation of the ventricles between heartbeats; it reflects the resistance of all the small arteries in the body and the load against which the heart must work. The pressure wave that is transmitted along the arteries with each heartbeat is easily felt as the *pulse*.

Blood pressure is measured using a *sphygmomanometer* and is expressed as millimetres of mercury (mmHg). Blood pressure varies with age, between individuals, and at different times in the same individual. A healthy young adult usually has a blood pressure reading, at rest, of about 120/80 (120 mmHg systolic and 80 mmHg diastolic pressure). A sustained level of high blood pressure is called *hypertension*; abnormally low pressure is termed *hypotension*.

blood products

Donated blood (see *blood donation*) that is separated into its components: red cells, white cells, platelets, and plasma. Each blood product has a specific lifespan and use in *blood transfusion*. Packed red cells (blood that has most of the plasma removed) are used to treat individuals with some forms of chronic *anaemia* and babies with *haemolytic disease of the newborn*. Washed red cells (with white blood cells and/or plasma proteins removed) are used when a person requires repeated transfusions since there is less risk of an *allergy* to any of the blood components developing.

Platelets may be given through transfusions for those people who have blood-clotting disorders. Patients who have life-threatening infections may be treated with granulocytes, a type of white blood cell. Fresh frozen plasma is

used to correct many types of *bleeding disorder* because plasma contains all the clotting factors. Plasma substitutes may be used to treat *shock* that has occurred as a result of severe blood loss, until sufficient compatible whole blood becomes available. Purified albumin preparations are used for people who have *nephrotic syndrome* and chronic liver disease.

Concentrates of blood clotting factors VIII and IX are used in the treatment of the conditions *haemophilia* and *Christmas disease*. *Immunoglobulins* (also called antibodies), which are extracted from blood plasma, can be given by injection (see *immunoglobulin injection*) to protect those people who are unable to produce their own antibodies or have already been exposed to an infectious agent. Immunoglobulins may also be given to provide short-term protection against *hepatitis A*. Immunoglobulins are given in large doses to treat certain *autoimmune disorders*.

blood smear

See *blood film*.

blood sugar

See *blood glucose*.

blood test, haematological

Analysis of a sample of blood to provide information about its cells and proteins and the chemicals, gases, antigens, and antibodies it contains. Haematological blood tests are used to check respiratory function, the immune system, the metabolism, hormonal balance, and the health of the major organs. The tests look at the numbers, appearance, shape, and size, of blood cells and assess the function of clotting factors in the blood.

TYPES

Important haematological blood tests are *blood count* and *blood group* tests if a blood transfusion is needed. Biochemical tests measure chemicals in the blood (see *acid-base balance*; *kidney function tests*; and *liver function tests*). Microbiological tests (see *immunoassay*) look for microorganisms that are in the blood, such as in septicæmia. Immunological tests also look for antibodies in the blood, which may confirm immunity to an infection.

blood transfusion

The infusion of large volumes of blood or of *blood products* directly into the bloodstream to remedy severe blood loss or to correct chronic *anaemia*. In an exchange blood transfusion, nearly all of the recipient's blood is replaced by donor blood.

HOW IT IS DONE

Before a transfusion, a sample of the recipient's blood is taken to identify his or her *blood group*, which is then matched with suitable donor blood. The donor blood is transfused into an arm vein through a plastic cannula (a tube with a smooth tip). Usually, each unit (about 500 ml) of blood is given over one to four hours; in an emergency, 500 ml may be given within a couple of minutes. The blood pressure, body temperature, and pulse of the patient are monitored during the procedure.

COMPLICATIONS

If mismatched blood is accidentally introduced into the circulation, antibodies in the recipient's blood may cause the donor cells to burst, leading to *shock* or *kidney failure*. Less severe reactions can produce fever, chills, or a rash. Reactions can also occur as the result of an allergy to a particular component of the transfused blood.

The risk of infection is extremely small. All blood used for transfusion is carefully screened for a number of infectious agents, including *HIV* (the *AIDS* virus) and *hepatitis B* and *hepatitis C*.

In elderly or in severely anaemic patients, blood transfusion can overload the circulation, leading to heart failure. In patients with chronic anaemia who need regular transfusions over the course of many years, excess iron may accumulate (a condition called *haemosiderosis*) and damage organs such as the heart, liver, and pancreas. Treatment with the drug *desferrioxamine* to remove excess iron may be needed in this case.

blood transfusion, autologous

The use of a person's own blood, which had been donated at an earlier time, for *blood transfusion*. Autologous transfusion eliminates the slight but serious risk of contracting an infectious illness from contaminated blood. Another advantage is that there is no risk of a reaction occurring as a result of incompatibility between donor and recipient blood.

Up to 2.5 litres of a person's blood can be removed and stored in several sessions up to three days before planned surgery. There must be at least four days between each session. Blood may also be taken during surgery. The blood is filtered and returned to the body.

blood transfusion, incompatible

A *blood transfusion* in which the recipient's blood and the donor's blood are mismatched. As a result, *antibodies* that are present in the recipient's circulation lead to destruction of the transfused *red blood cells*. This can have serious consequences, including *kidney failure* and occasionally even death. Careful cross-matching of blood in the laboratory make incompatible transfusions rare.

blood vessels

A general term for arteries, veins, and capillaries (see *circulatory system*).

Bloom's syndrome

A *genetic disorder* that is most commonly found among people of East European Jewish descent. Physical characteristics of the syndrome include short stature, a butterfly-shaped red rash on the face, and *photosensitivity* (an abnormal reaction to sunlight). Individuals with Bloom's syndrome may also be at increased risk of certain cancers, such as *leukaemia*.

blue baby

An infant with a cyanotic (bluish) complexion, especially visible on the lips and tongue, caused by a relative lack of oxygen in the blood. This is usually due to a structural defect of the heart or the major arteries leaving the heart. Such defects may need to be corrected surgically (see *heart disease, congenital*).

blue bloater

An outdated term to describe a person with bluish lips and tongue and *oedema* (a buildup of fluid in the tissues). The cause is long-term lung damage that has led to heart failure (see *pulmonary disease, chronic obstructive*).

blue naevus

A type of *naevus* (skin blemish) with a dark blue or black coloration and a clearly defined border. Blue naevi are noncancerous and they are made up of a collection of pigment-producing cells called *melanocytes*.

blurred vision

Indistinct, or fuzzy, visual images. Blurred vision, which should not be confused with *double vision* (diplopia), can occur in one eye or both, for episodes of varying lengths of time, and can develop gradually or suddenly. The usual cause of longstanding blurred vision is a refractive error such as *astigmatism* (unequal curvature of the front of the eye), *hypermetropia* (longsightedness), or *myopia* (shortsightedness), all of which can be corrected by glasses or contact lenses. After the age of 40, *presbyopia* (reduced ability to focus on near objects) becomes more common.

Vision may also be blurred or impaired as a result of damage, disease, or abnormalities of parts of the eye or its connections to the brain. Blurred vision as a result of disease is most commonly caused by *cataract* or *retinopathy*.

blushing

Brief reddening of the face, and sometimes the neck, caused by widening of the blood vessels close to the skin's surface. Blushing is often an involuntary reaction to embarrassment. In some women, blushing is a feature of the *hot flushes* that occur during the *menopause*. Flushing of the face also occurs in association with *carcinoid syndrome*.

B-lymphocyte

A type of *white blood cell*, also referred to as a B-cell. B-lymphocytes play a vital part in the *immune system*, the body's natural defence mechanism, by producing *antibodies* (special proteins) to find and destroy harmful microorganisms.

BMI

The abbreviation for *body mass index*.

BMR

The abbreviation for *basal metabolic rate*.

BM-test 1-44

A brand-named *blood glucose monitoring* test strip for analysing the blood glucose level in *diabetes mellitus*. The strip is sensitive to blood glucose levels ranging from 1 mmol to 44 mmol.

body contour surgery

Surgery that is performed to remove excess fat, skin, or both, from various parts of the body, especially from the abdomen, the thighs, and the buttocks. One of the most commonly used operations is abdominal wall reduction, also called abdominoplasty, which involves removing excess skin and fat from the abdominal area.

To minimize scarring, a less invasive procedure, such as suction lipectomy (liposuction), may be performed. In this operation, a rigid hollow tube is inserted through a small incision in the skin and is used to break up large areas of fat. The fat can then be sucked out through the instrument.

All body contour surgery carries a risk of complications, including wound infection. Minor irregularities and some dimpling of the skin commonly occur following liposuction.

body dysmorphic disorder

A psychiatric disorder in which a person suffers intense anxiety about an imagined defect in part of his or her body.

body image

A person's perception of the different parts of his or her own body.

body mass index (BMI)

An indicator of healthy body weight. BMI is calculated by dividing weight in kilograms by the square of height in metres. The normal range is 20 to 25.

body odour

The smell caused by the action of *bacteria* on sweat. It is most noticeable in the armpits and around the genital area, where the *apocrine glands* contain proteins and fatty materials favourable to bacterial growth.

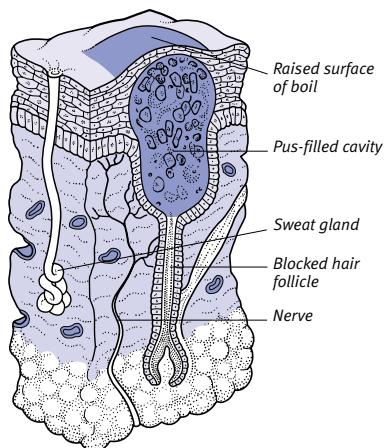

body temperature

See *temperature*.

boil

An inflamed, pus-filled area of skin, usually an infected hair follicle. A more severe and extensive form of boil involving several hair follicles is known as a *carbuncle*. The usual cause of a boil is infection with the bacterium *STAPHYLOCOCCUS AUREUS*. Recurrent boils may occur in people with known or unrecognized *diabetes mellitus* or in those with other conditions in which general resistance to infection is impaired.

Treatment sometimes involves *antibiotic drugs*. However, a boil that is opened surgically to release the pus usually heals rapidly without the need for drug treatment.

Cross-section of a boil

Following bacterial infection of the hair follicle, there is a buildup of pus, and a raised tender lump appears on the surface of the skin.

bolus

A soft mass of chewed food that is produced by the action of the tongue, the teeth, and the saliva to facilitate swallowing of the food. The term bolus is also used to describe a single dose of a drug that is rapidly injected into a vein.

bonding

The reciprocal process by which a strong tie, both psychological and emotional, is established between a parent and a newborn child. The process of

The bonding process

By the maintenance of close physical contact, bonding gradually becomes established.

bonding may be delayed if a baby is premature or ill and has to be separated from his or her parents immediately after birth (for example, by being placed in an incubator).

bonding, dental

Techniques that use plastic resins and acrylic or porcelain veneers to repair, restore, or cosmetically improve the teeth. Dental bonding may sometimes be used as an alternative to crowning (see *crown, dental*) and can also be used to protect the teeth.

bone

The structural material of the *skeleton* that provides a rigid framework for the muscles and protects certain organs of the body. In combination with the joints and the muscles, the bones form the locomotor system.

STRUCTURE

Bone consists of several layers. The surface has a thin covering known as the *periosteum*, a membrane that contains a network of blood vessels and nerves. Beneath the periosteum is an inner shell of hard (also called compact or cortical) bone composed of columns of bone cells (osteoclasts and osteoblasts). Each column has a central hollow (haversian canal) that is important for the nutrition, growth, and repair of the bone. The direction of the haversian canals corresponds with the mechanical forces acting on the bone.

Inside the hard shell, bone has a central meshlike structure (which is known as spongy, cancellous, or trabecular bone). The cavity in the centre of certain bones, and the spaces in spongy bone, contain *bone marrow*, in which the red blood cells, platelets, and most of the white blood cells are formed.

GROWTH

Bone is continuously reabsorbed by osteoclasts and replaced by osteoblasts. The osteoblasts encourage deposition of calcium phosphate on the protein framework of the bone; the osteoclasts remove it. The actions of these cells are controlled by growth hormone, secreted by the pituitary gland, the sex hormones oestrogen and testosterone, the adrenal hormones, the thyroid hormone thyrocalcitonin, and parathyroid hormone. These hormones also work to maintain the level of calcium in the blood.

Most bones begin to develop in the embryo during the fifth or sixth week of pregnancy, at which time they take

the form of *cartilage*. This cartilage begins to be replaced by hard bone, in a process known as *ossification*, at around the seventh or eighth week of pregnancy; this process is not complete until early adult life. At birth, many bones consist mainly of cartilage, which ossifies later in life. The *epiphyses* (the growing ends of the long bones) are separated from the bone shaft (*diaphysis*) by the epiphyseal plate. Some bones in the body, such as certain skull bones, do not develop from cartilage, and these are known as membranous bones.

bone abscess

A localized collection of pus in a bone (see *osteomyelitis*).

bone age

A measure of skeletal maturity used to assess physical development in children. X-rays, which show how much bones have grown in a particular body area, are used to determine bone age. (See also *age*.)

bone cancer

Malignant growth in bone. Bone cancer may originate in the bone itself (primary bone cancer) or, more commonly, may occur as a result of cancer spreading from elsewhere in the body (secondary, or metastatic, bone cancer).

PRIMARY BONE CANCER

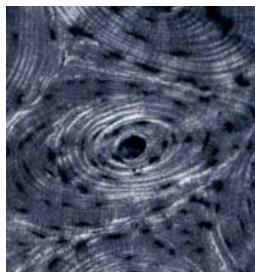

Cancers that originate in the bone are rare; the type of primary bone cancer that occurs most often is *osteosarcoma*. Other types include *chondrosarcoma* and *fibrosarcoma*. Cancers can also start in the bone marrow, but these are not usually considered to be bone cancers (see *multiple myeloma* and *leukaemia*). The treatment of primary bone cancer will depend on the extent to which the disease has spread. If it remains confined to bone, it may be possible to remove the cancer and fill the defect with a *bone graft*. In other cases, amputation may be recommended. *Radiotherapy* or *chemotherapy*, or both, may also be needed.

SECONDARY BONE CANCERS

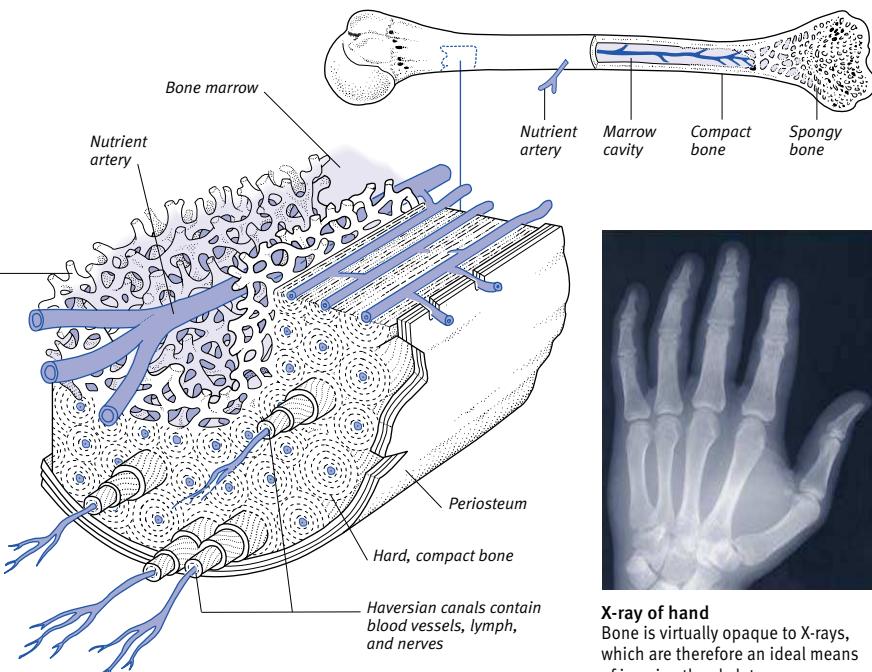

The cancers that spread most readily to form secondary bone cancer are those of the breast, lung, prostate, thyroid, and kidney. These bone metastases occur commonly in the spine, pelvis, ribs, and skull. Pain is usually the main symptom. Affected bones are abnormally fragile and may fracture easily. Bone cancer that affects the spine may cause collapse or crushing of vertebrae, damaging the

STRUCTURE OF BONE

Bone consists of several layers: a thin, membranous surface and an inner, dense shell surrounding spongy material in which the bone marrow lies.

Microscopic image of bone
A Haversian canal is clearly visible in the centre of this micrograph of compact bone.

X-ray of hand
Bone is virtually opaque to X-rays, which are therefore an ideal means of imaging the skeleton.

spinal cord and causing weakness or paralysis of one or more limbs.

Secondary bone cancers from the breast and prostate gland may respond to treatment with *hormone antagonists*. In other cases, local treatment with radiotherapy is often effective in relieving pain caused by the tumour.

bone conduction

A method of transmitting sound that is tested during investigation into the cause of impaired *hearing*.

A vibrating tuning fork is held next to the ear. The base of the fork is then placed against the bone behind the ear. If the deafness is the result of an outer- or middle-ear problem (*conductive deafness*), the sound will be heard better when the tuning fork is held behind the ear. The bone transmits sound directly to the inner ear, bypassing the outer and middle ear. (See also *deafness; hearing tests*.)

bone cyst

An abnormal cavity in a bone. Bone cysts typically develop at one end of a long bone and may be discovered only by chance after a fracture at the site of the cyst. Minor surgery to scrape out the

cyst and fill the cavity with bone chips usually cures the condition; many small cysts do not actually require treatment.

bone density

The compactness of *bone* tissue in relation to its volume. A decrease in bone density is a normal part of aging. However, excessive loss of bone density (see *osteoporosis*) can lead to *fractures*. An increase in bone density (see *osteosclerosis*) occurs in some disorders, such as *osteopetrosis* and *Paget's disease*. Bone density is measured by *densitometry*, a technique that uses low-dose X-rays.

bone graft

A surgical operation in which small pieces of bone are taken from one part of the body in order to repair or replace abnormal or missing bone elsewhere. The bone graft eventually dies, but it acts as a scaffold upon which strong new bone grows.

Bone is most commonly taken from the iliac crests (upper parts of the hipbones). They contain a large amount of inner, spongy bone, which is very useful for getting grafts to "take". Other common sources are the ribs (for curved bone) and the ulna in the forearm.

bone imaging

Techniques for providing pictures that show the structure or function of bones. *X-ray* images are commonly used for diagnosing fractures and injuries. More detailed information is provided by *tomography*, *CT scanning*, or *MRI*, which can show tumours, infections, and the effects of diseased bone on the surrounding tissues. *Radionuclide scanning* detects areas in the skeleton in which there is high bone-cell activity. This type of scanning is used mainly to determine whether cancer has spread to the bones.

bone marrow

The soft fatty tissue found in bone cavities; it may be red or yellow. Red bone marrow is present in all bones at birth and is the factory for most *blood cells*. During the teens, red bone marrow is gradually replaced in some bones by less active yellow marrow. In adults, red marrow is confined principally to the spine, sternum, (breastbone), pelvis (hip bones), ribs, scapulae (shoulderblades), clavicles (collarbones), and skull bones.

Stem cells within the red marrow are stimulated to form blood cells by the hormone *erythropoietin*. Yellow marrow is composed mainly of connective

DISORDERS OF BONE

Bone is affected by the same types of disorders as other body tissues, but its hard, rigid structure makes for extra complications. If a bone receives a direct blow or suffers from repeated stress, it may *fracture*. If it becomes infected (due to *osteomyelitis* or a *bone abscess*, for example), the resulting inflammation may interfere with the blood supply, leading to death of part of the bone.

Genetic disorders

Several inherited conditions may affect bone growth; these include *achondroplasia* and *osteogenesis imperfecta*. Such disorders often result in short stature.

Nutritional disorders

Lack of calcium and vitamin D in the diet may result in *rickets* in children and *osteomalacia* in adults; in both conditions the bones become soft and lose their shape.

Hormonal disorders

If the pituitary gland produces excess growth hormone before puberty, this results in excessive growth of the bones

tissue and fat. If the body needs to increase its rate of blood formation, some of the yellow marrow will be replaced by red. Sometimes marrow fails to produce sufficient numbers of normal blood cells, as occurs in aplastic anaemia (see *anaemia, aplastic*) or when marrow has been displaced by tumour cells. In other cases, marrow may overproduce certain blood cells, as occurs in *polycythaemia* and *leukaemia*.

bone marrow biopsy

A procedure to obtain a sample of cells from the bone marrow (an aspiration biopsy) or a small core of bone with marrow inside (a trephine biopsy). The sample is usually taken, under local *anaesthesia*, from the sternum (breast-bone) or iliac crests (upper part of the hip-bones). Microscopic examination gives information on the development of the blood components and on the presence of cells foreign to the marrow. It is useful in the diagnosis of many blood disorders, including *leukaemia* and *anaemia*. It can also show whether bone marrow has been invaded by *lymphoma* or cells from other tumours.

and other organs, leading to *gigantism*. Excess parathyroid hormone may lead to *bone cysts*. *Osteoporosis* (loss of bone density) is common in women following the menopause, when oestrogen levels fall.

Tumours

Several different types of cancerous and noncancerous growth can arise from bone (see *bone cancer* and *bone tumour*). In addition, the bones are a common site for secondary tumours (metastases) that have spread from cancerous tumours elsewhere in the body.

Other disorders

Paget's disease involves thickening of some areas of the bones, while other areas become spongy.

INVESTIGATION

Bone disorders are investigated using imaging techniques such as *X-rays*, *CT scanning*, *radionuclide scanning*, and *densitometry*; by *biopsy*; and *blood tests*.

bone marrow transplant

The technique of using normal red *bone marrow* to replace cancerous, defective, or diseased bone marrow in a patient. In allogeneic bone marrow transplantation (BMT), healthy marrow is taken from a donor with a very similar tissue-type to the recipient's (often a brother or sister). In autologous BMT, the patient's own healthy bone marrow is harvested while his or her disease is in remission and is reinfused at a later time. Generally, BMT is used only in the treatment of serious, potentially life-threatening blood and immune system disorders, including aplastic anaemia (see *anaemia, aplastic*), *sickle cell anaemia*, and *leukaemia*.

An alternative treatment is *stem-cell* transplantation, in which cells from the umbilical cord of a newborn baby or the bloodstream of an adult are transplanted instead of bone marrow.

HOW IT IS DONE

Before transplantation, all of the recipient's bone marrow is destroyed with *cytotoxic drugs* or radiation in order to prevent rejection of the donated cells and to kill any cancer cells present. The donor bone marrow is transfused into

the circulation from where cells find their way to the bone marrow cavities and start to grow.

In autologous BMT, the patient's bone marrow is stored by *cryopreservation* (freezing). Before being frozen, the marrow is usually treated to eliminate any undetected cancerous cells. If the patient's disease recurs, the stored bone marrow can then be reinfused.

COMPLICATIONS

The major risks with BMT are infection during the recovery period and rejection (known as *graft-versus-host disease*, or GVHD). *Immunosuppressant drugs* are used to prevent and treat rejection. The risk of GVHD may be reduced by removing the T-cells (see *T-lymphocyte*) from the marrow using monoclonal antibodies (see *antibody, monoclonal*) before it is reinfused. GVHD does not occur with autologous BMT or with stem-cell transplantation.

bone metastases

Cancerous *tumours* in bone, also known as secondary bone cancers, that have spread from a cancer in another part of the body (see *bone cancer*). The bones of the ribs, pelvis, skull, and spine are particularly affected.

bone pain

An unpleasant sensation (see *pain*) felt in a part of the skeleton (see *musculoskeletal pain*). Bone pain is frequently described as constant and gnawing, and it may disturb sleep. There are many possible causes of bone pain, including trauma of the bone (see *fracture*), infection (see *osteomyelitis*), disorders of the bone itself (such as *Paget's disease*), and *bone tumours*. (See also *osteoid osteoma*; *osteomalacia*; *sickle cell anaemia*.)

bone resorption

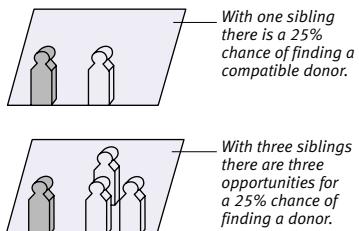

Loss of *bone* tissue. Bone resorption and the laying down of new bone tissue are continuous processes. With increasing age, resorption exceeds new bone formation, and the bone tissue gradually becomes thinner. However, in certain disorders (for example, *osteoporosis*), resorption takes place more rapidly and to a greater extent, causing weakening of bone and increased risk of *fractures*.

bone tumour

A bone swelling that may be cancerous (see *bone cancer*) or noncancerous. The most common type of noncancerous bone tumour is an *osteochondroma*.

PERFORMING A BONE MARROW TRANSPLANT

Normal bone marrow is used to replace malignant or defective marrow. In the allogeneic procedure, healthy marrow is taken from a donor. In the autologous procedure, the patient's own healthy marrow is used.

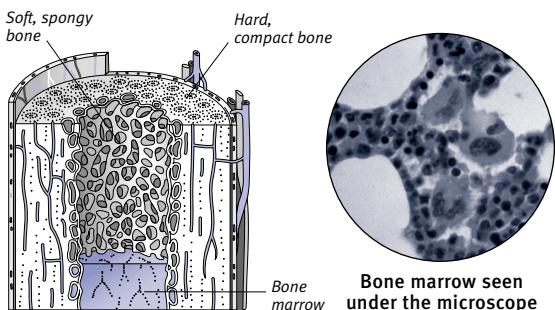

Finding a donor

The more siblings one has, the greater the chance of finding a donor. With three or more siblings, the chances are good.

SITES OF BONE MARROW

Red or yellow in colour, bone marrow is a soft, fatty tissue found in the cavities of bones. In newborn babies, red bone marrow is present in all bones; during the teen years, most is replaced by yellow marrow. The marrow used for transplants is red.

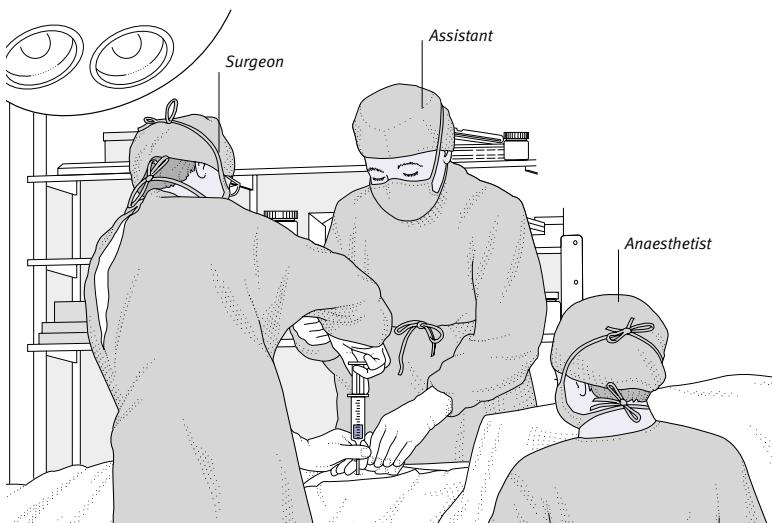

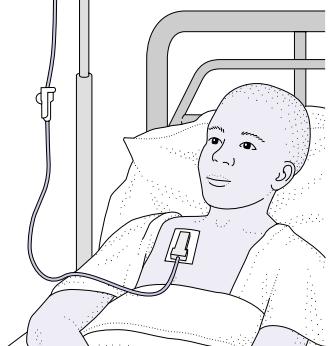

1 Before transplantation, all the recipient's bone marrow is destroyed by treatment with drugs or radiation. Destroying the marrow kills any cancer cells.

2 Using general anaesthesia, bone marrow is aspirated from the donor's iliac crests and/or sternum. Up to one litre is removed. The transplanted marrow grows quickly to occupy the bone spaces.

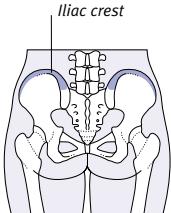

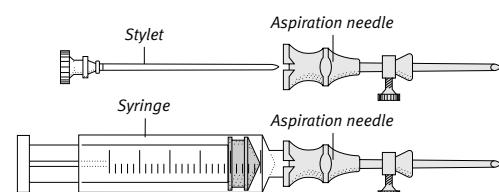

3 After aspiration, the bone marrow is transfused intravenously into the patient. The bone marrow cells find their way through the circulation into the patient's marrow cavities, where they start to grow.

DONOR ASPIRATION

With the donor lying face down, a hollow aspiration needle, which has a stylet (a thin, sharp lance) within it, is introduced into the bone (iliac crests).

The stylet is then removed. Bone marrow is sucked out through the cortex into a syringe connected to the needle.

Other types of bone tumour are *osteoma* and *chondroma* (see *chondromatosis*). Treatment is needed only if the tumour becomes large or causes symptoms by pressing on other structures. In such cases, it can be removed by surgery. Osteoclastoma (also called a giant cell tumour), which usually occurs in the arm or leg of a young adult, is tender and painful and has to be removed.

booster

A follow-up dose of *vaccine*, given to reinforce or prolong immunity after an initial course of *immunization*.

borborygmi

The medical name for *bowel sounds* that are audible without a stethoscope.

borderline personality disorder

A personality disorder that falls between neurotic and psychotic levels. Mood changes are often rapid and inappropriate. Angry outbursts are common, as are impulsive, self-damaging acts such as gambling or suicide attempts.

Bordetella pertussis

A species of *bacteria* that may infect the human respiratory tract and is responsible for causing *whooping cough*.

Bornholm disease

One of the various names for epidemic *pleurodynia*, an infectious viral disease that is characterized by severe chest pains and fever.

Borrelia

A genus of spiral-shaped *bacteria* transmitted through tick bites (see *ticks and disease*). *BORRELIA* species cause *relapsing fever* (an infectious disease characterized by recurrent bouts of fever) and also *Lyme disease*.

bottle-feeding

Infant feeding using a milk preparation usually based on modified cow's milk. This formula milk contains similar proportions of protein, fat, lactose (milk sugar), and minerals to those in human milk, but it lacks the protective antibodies that are present in breast milk. Vitamins are added.

In some cases, medical problems in the mother or child may make *breast-feeding* impossible or undesirable, in which case bottle-feeding is recommended. However, bottle-fed babies are at higher risk of gastrointestinal infec-

tions than breast-fed babies and may be more likely to develop allergic disorders. (See also *feeding, infant*.)

Botox

A brand name for the drug *botulinum toxin*, which is used to treat muscle spasm in conditions such as *cerebral palsy*. Botox is also used for cosmetic reasons to reduce the appearance of wrinkles in the skin.

botulinum toxin

A potentially lethal toxin produced by the bacterium *CLOSTRIDIUM BOTULINUM* (see *botulism*). In tiny doses, botulinum toxin is used as a *muscle-relaxant drug* to control muscle spasms in some disorders (see *blepharospasm; facial spasm*). It is also increasingly used for cosmetic purposes; when injected into facial muscles, botulinum toxin temporarily reduces wrinkles.

botulism

A rare but serious form of poisoning caused by eating improperly canned or preserved food contaminated with a toxin produced by the bacterium *CLOSTRIDIUM BOTULINUM*. The toxin causes progressive muscular paralysis as well as other disturbances of the central and peripheral nervous system. *CLOSTRIDIUM BOTULINUM* produces spores that resist boiling, salting, smoking, and some forms of pickling. These spores, which multiply only in the absence of air, thrive in canned or poorly preserved food. Ingestion of even minute amounts of toxin can lead to severe poisoning.

SYMPTOMS

The symptoms of botulism first occur within 8 to 36 hours of ingesting contaminated food. They include difficulty in swallowing and speaking; nausea and vomiting; and double vision. Prompt treatment is vital.

In infants, the toxin can form within the body after the ingestion of foods contaminated with the bacterium, such as honey. (See also *food poisoning*.)

Bouchard's node

A bony swelling that forms on the joint in the middle of the finger in a person suffering from *osteoarthritis*. (See also *Heberden's node*.)

bougie

A rod-shaped instrument used for insertion into tubular organs, such as the urethra, during investigations or treat-

ment. It may also be used to stretch a narrowed area. There are various types of bougie; they can be either hollow or solid, and most are slightly flexible.

bovine spongiform encephalopathy (BSE)

A neurological disorder in cattle that can be transmitted to humans through the consumption of infected meat, causing *Creutzfeldt-Jakob disease*. (See also *encephalopathy*.)

bowel

A common name for the large and/or small *intestines*.

bowel disorders

Any disorder that affects the *intestine*. Common bowel disorders are *inflammatory bowel disease* and *irritable bowel syndrome (IBS)*. (See also *intestine disorders box; intestine, cancer of; intestine, obstruction of; intestine, tumours of*.)

bowel movements, abnormal

See *faeces, abnormal*.

bowel sounds

Sounds made by the passage of air and fluid through the *intestine*. Absent or abnormal bowel sounds may indicate a disorder. Those that are audible without a stethoscope are known as *borborygmi* and are a normal part of the digestive process, but they may be exaggerated by anxiety and some intestinal disorders.

Bowen's disease

A rare skin disorder that is characterized by the formation of a flat patch of red, scaly skin, most commonly on the face or the hands. Bowen's disease may become cancerous.

Treatment involves surgical removal of the diseased skin, or its destruction by freezing or *cauterization*.

bowleg

An outward curving of bones in the legs that results in wide separation of the knees when the feet are together. Bowlegs are common in very young children, and they are a normal part of development. In most cases, the curve straightens as the child grows. If the bowing is severe, is on one side only, or persists beyond the age of three, a doctor should be consulted. Surgery may be needed. Rarely, leg deformity is a result of bone disease, particularly *rickets* (a vitamin D deficiency) in children.

Bowman's capsule

A cup-shaped membrane within the kidney's *nephron* containing a *glomerulus* (a cluster of tiny blood vessels called capillaries). Here, blood is filtered into the kidney tubule.

BP

The abbreviation for *blood pressure*.

brace, dental

See *orthodontic appliances*.

brace, orthopaedic

An appliance worn to support part of the body or hold it in a fixed position. A brace may be used to correct or halt the development of a deformity, to aid mobility, or to relieve pain. (See also *caliper splint; corset; splint*.)

brachial artery

The *artery* that runs down the inner side of the upper arm, between the armpit and the elbow.

brachialgia

Pain or stiffness in the arm that is often accompanied by pain, tingling and/or numbness of the hands or fingers, and weak hand grip. It may be a symptom of underlying disorders such as *frozen shoulder* or nerve compression from *cervical osteoarthritis*.

brachial plexus

A group of large nerve trunks formed from nerve roots of the lower part of the cervical spine (in the neck) and upper part of the thoracic spine (in the chest). These nerve trunks divide into the musculocutaneous, axillary, median, ulnar, and radial nerves, which control muscles in and receive sensation from the arm and the hand. Injuries to the brachial plexus can cause loss of movement and sensation in the arm.

In severe injuries, there may be damage to both the upper and the lower nerve roots of the brachial plexus, producing complete paralysis of the arm. The paralysis may be temporary if the stretching was not severe enough to tear nerve fibres. It may be possible to repair nerve roots that have been torn by nerve grafting, which is a *microsurgery* procedure, but if a nerve root has become separated from the spinal cord, surgical repair will not be successful. Apart from injuries, the brachial plexus may be compressed by the presence of a *cervical rib* (extra rib).

brachytherapy

A type of *radiotherapy*.

bradycardia

An abnormally slow heart rate. Most people have a heart rate of between 60 and 100 beats per minute. Many athletes and healthy people who exercise regularly and vigorously have slower rates. In others, bradycardia may indicate an underlying disorder such as *hypothyroidism* or *heart block*. Bradycardia may also occur as a result of taking *beta-blocker drugs*. Profound or sudden bradycardia may cause a drop in blood pressure that results in fainting (see *vasovagal attack*).

bradykinin

A *polypeptide* (protein molecule) that forms naturally in the blood as part of the inflammatory process. Bradykinin is a powerful vasodilator (it causes the widening of blood vessels). Bradykinin also allows fluid to leak from the blood vessels; stimulates pain receptors; and causes contraction of the smooth muscle in internal organs such as the lungs or intestines.

Braille

A system of embossed dots, now accepted for all written languages, that enables blind people to read and write. The system is based on six raised dots, which can be combined in different ways to form symbols.

There are two types of Braille. In grade I, each symbol represents an individual letter or punctuation mark. In grade II, which is the more widely used, symbols represent common letter combinations or words.

brain

The major organ of the *nervous system*, located in the *cranium* (skull). The brain receives, sorts, and interprets sensations from the nerves that extend from the *central nervous system* (brain and spinal cord) to the rest of the body; it initiates and coordinates nerve signals involved in activities such as speech, movement, thought, and emotion.

An adult brain weighs about 1.4 kg and has three main structures: the *brainstem*; the *cerebellum*; and the largest part, the *cerebrum*, which consists of left and right hemispheres.

CEREBRUM

Each hemisphere in the cerebrum has an outer layer called the cortex, consist-

ing of grey matter, which is rich in nerve-cell bodies and is the main region in the brain for conscious thought, sensation, and movement. Beneath the cortex are tracts of nerve fibres called white matter, and, deeper within the hemispheres, are the *basal ganglia* (paired nerve cell clusters). The surface of each of the hemispheres is divided by fissures (sulci) and folds (gyri) into distinct lobes (occipital, frontal, parietal, and temporal lobes), named after the skull bones that overlie them. A thick band of nerve fibres called the *corpus callosum* connects the hemispheres.

The cerebrum encloses a central group of structures including the *thalamus* and the *hypothalamus*, which has close connections with the *pituitary gland*. Encircling the thalamus is a complex of nerve centres called the *limbic system*. These structures act as links between parts of the cerebrum and the brainstem lying beneath the thalamus.

BRAINSTEM AND CEREBELLUM

The brainstem is concerned mainly with the control of vital functions such as breathing and blood pressure. The cerebellum at the back of the brain controls balance, posture, and muscular coordination. Both of these regions operate at a subconscious level.

MENINGES AND CEREBROSPINAL FLUID

The brain and spinal cord are encased in three layers of membranes known as *meninges*. *Cerebrospinal fluid* circulates between these membrane layers and within the four main brain cavities, which are known as *ventricles*. This fluid helps to nourish and cushion the brain.

BLOOD SUPPLY

The brain as a whole has an extensive blood supply. Blood comes from a circle of arteries fed by the internal *carotid arteries* (which run up each side of the front of the neck to enter the base of the skull) and from two vertebral arteries that run parallel to the spinal cord. The brain receives about 20 per cent of the blood from the heart's output.

brain abscess

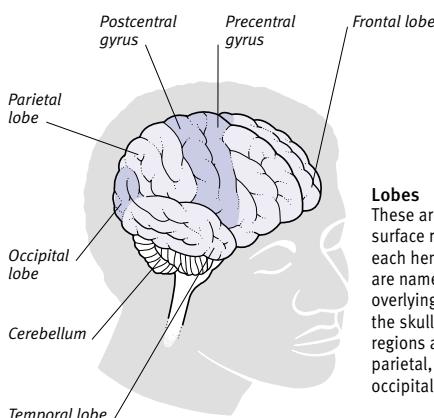

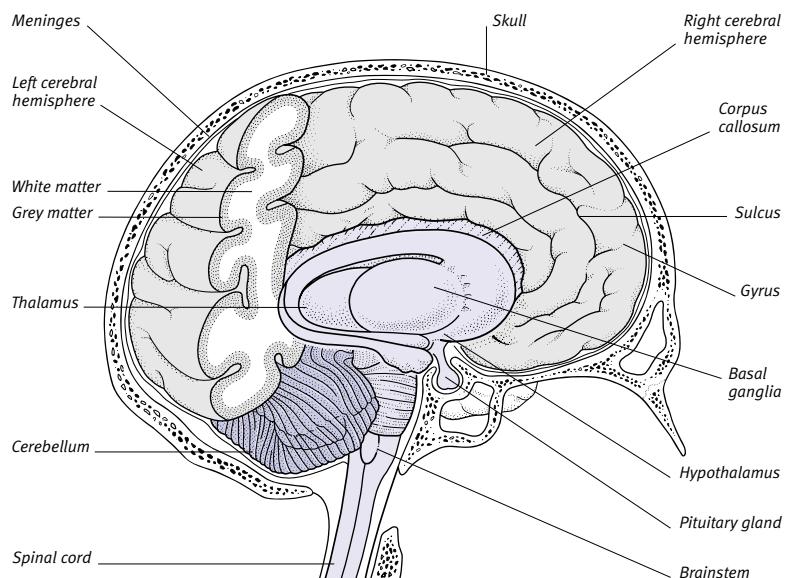

A collection of pus, surrounded by inflamed tissues, within the brain or on its surface. The most common sites are the frontal and temporal lobes of the *cerebrum* in the forebrain.

Brain abscesses may occur after a head injury, but most cases result from the spread of infection from elsewhere in the body, such as the middle ear or the sinuses. Another cause of a brain

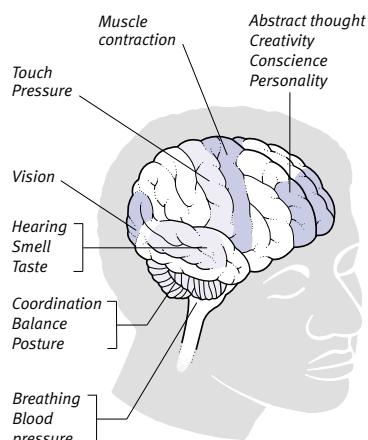

STRUCTURE OF THE BRAIN

The brain has three main parts: the brainstem (an extension of the spinal cord), the cerebellum, and the cerebrum, much of which consists of the two large cerebral hemispheres. Each hemisphere consists of an outer layer, or cortex, which is rich in nerve cells and called grey matter, and inner areas rich in nerve fibres, called white matter. The surface of each hemisphere is thrown into folds called gyri, separated by fissures called sulci. The two hemispheres are linked by a thick band of nerve fibres, the corpus callosum. Deep within the forebrain are various central structures, which include the thalamus, hypothalamus, basal ganglia, and pituitary gland.

The brain has the consistency of jelly and, in adults, weighs about 1.4 kg. It is protected by membranous coverings (known as meninges) within the skull.

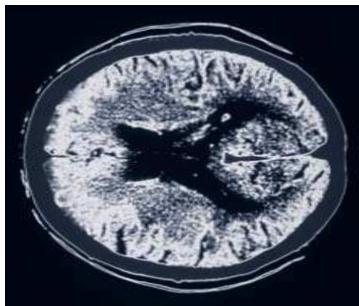

Lobes
These are broad surface regions of each hemisphere that are named after the overlying bones of the skull. The four main regions are the frontal, parietal, temporal, and occipital lobes.

Special areas
Some areas of the brain are associated with specific functions – for example, the occipital lobe with vision and the cerebellum with balance and coordination. Touch and pressure sensation is perceived within the postcentral gyrus. Muscle movements are controlled from the precentral gyrus; speech is controlled from an area in the frontal lobe of the dominant hemisphere.

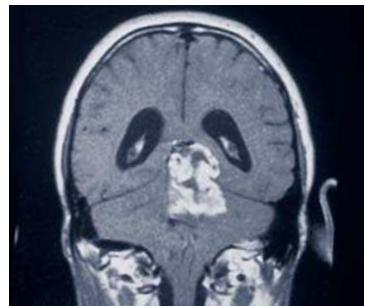

IMAGING THE BRAIN

**CT scanning**

CT scans produce images as “slices” through the head. The scan above shows bleeding into the brain tissue (a cerebral haemorrhage).

**Angiography**

This technique makes blood vessels clearly visible. The angiogram above shows the carotid artery and its branches.

**Magnetic resonance imaging**

MRI produces three-dimensional or cross-sectional images. This MRI shows a tumour (the white area to the right of centre) in the cerebellum.

abscess is an infection following a penetrating brain injury. Multiple brain abscesses may occur as a result of blood-borne infection, most commonly in patients with a heart-valve infection (see *endocarditis*).

Symptoms of a brain abscess include headache, drowsiness, vomiting, visual disturbances, fever, and seizures. There may also be other symptoms, such as speech disturbances, that are due to local pressure. Treatment is with *antibiotic drugs* and surgery. A *craniotomy* may be needed to open and drain the abscess. Untreated, brain abscesses can cause permanent damage and can be fatal. Despite treatment, scarring can cause *epilepsy* in some cases.

brain contusion

Bruising of the brain accompanied by loss of consciousness, which occurs as the result of an injury. (See also *brain damage; concussion*.)

brain damage

Degeneration or death of nerve cells and tracts within the brain that may be localized to a particular area of the brain or may be diffuse.

DIFFUSE DAMAGE

One of the most common causes of diffuse brain damage is prolonged cerebral *hypoxia* (an insufficient supply of oxygen to the brain), which may occur in a baby during a difficult birth. Other causes of diffuse damage to the brain tissue include *cardiac arrest* (cessation of the heartbeat), *respiratory arrest* (cessation of breathing), drowning, certain types of poisoning, and *status epilepticus* (prolonged seizures). Diffuse damage may also occur gradually as a result of exposure to environmental pollutants, such as lead or mercury compounds (see *Minamata disease*), or if nerve-cell poisons build up in the brain, as occurs in untreated *phenylketonuria*. Other possible causes of diffuse brain damage include brain infections such as *encephalitis*.

LOCALIZED DAMAGE

Localized brain damage may occur as the result of a *head injury*, *stroke* (damage to part of the brain caused by an interruption to its blood supply), *brain tumour*, or *brain abscess*. At birth, a raised blood level of bilirubin (see *haemolytic disease of the newborn*) can cause local damage to the *basal ganglia*

deep within the brain. This leads to a condition called *kernicterus*. Brain damage that occurs before, during, or after birth may result in *cerebral palsy*.

OUTCOME

Diffuse damage to the brain may result in *learning difficulties* and severe physical disability. Localized brain damage may cause specific deficits in brain function, such as disturbances of movement or speech (see *speech disorders*). Nerve cells and tracts in the brain and spinal cord cannot repair themselves once they have been damaged, but some return of function may be possible with training, as patients learn to use other parts of the brain. (See also *Structure of the brain* box.)

brain death

The irreversible cessation of all functions of the brain, including those of the brainstem. (See also *death*.)

brain failure

See *brain syndrome, organic*.

brain haemorrhage

Bleeding within or around the brain caused either by injury or by the spontaneous rupture of a blood vessel. There

DISORDERS OF THE BRAIN

Defects and disorders of the brain have numerous causes, including infection, injury, *brain tumour*, or a lack of blood or oxygen (see *hypoxia*). Brain cells destroyed by injury or disease cannot be replaced, so any resulting loss in function can be difficult to reverse.

Because the brain is encased within the skull, any space-occupying tumour, *brain abscess*, or *haematoma* (large blood clot) creates raised pressure, which can impair the function of the whole brain.

Brain disorders that are localized in a small region may affect a specific function, such as speech (see *aphasia*). However, more often, damage is more diffuse and the symptoms can be varied and numerous.

The brain may also be damaged by a blow to the head (see *head injury*).

Congenital defects

Some brain disorders are congenital (present from birth) due to genetic or chromosomal disorders, as in *Down's syndrome*. Structural defects during fetal development include *hydrocephalus*

(water on the brain) and *anencephaly* (congenital absence of the brain).

Impaired blood and oxygen supply

Brain cells can survive only a few minutes without oxygen. A reduced supply may occur at birth, causing *cerebral palsy*. Later in life, choking or arrest of breathing and heartbeat can cause hypoxia (oxygen lack).

From middle age onwards, *cerebro-vascular disease*, which impairs the blood supply to one or more regions of the brain, is the most important cause of brain disorders. If an artery within the brain becomes blocked or ruptures, leading to haemorrhage, the result is a *stroke*.

Infection

Encephalitis (infection within the brain) may be due to a virus. *Meningitis* (infection of the membranes surrounding the brain) is generally due to bacterial infection.

Creutzfeldt-Jakob disease is a rare, fatal brain disease associated with an infective agent called a prion, which, in some cases, has been linked with *bovine spongiform encephalopathy* (BSE), a disease in cattle.

Degenerative disorders

Multiple sclerosis is a progressive disease of the brain and spinal cord. Degenerative brain diseases include *Alzheimer's disease* and *Parkinson's disease*.

Other disorders

Emotional or behavioural disorders are often called psychiatric illnesses, but the distinction between these and neurological disorders is unclear. In many illnesses, such as *depression* and *schizophrenia*, there may be an underlying disturbance of brain chemistry.

INVESTIGATION

Procedures used to investigate brain disorders and function include tests of reflexes and of mental and physical abilities. Electrical activity may be measured with an *EEG*. Physical abnormalities can be found using *brain imaging* techniques such as *angiography*, *CT scanning*, or *MRI*.

are four possible types of brain haemorrhage: *subdural*, *extradural*, *subarachnoid*, and *intracerebral* (see the illustrated box). Extradural and subdural haemorrhages are usually caused by a blow to the head (see *head injury*). Subarachnoid and intracerebral haemorrhages tend to occur spontaneously due to rupture of *aneurysms* or small blood vessels in the brain.

brain imaging

Techniques that can provide pictures of the brain. Brain imaging techniques are used to detect injury or disease of the brain and include *X-rays*, *angiography*, *CT scanning*, *MRI* (magnetic resonance imaging), *PET* (positron emission tomography) scanning, and *SPECT* (single photon emission CT).

INVESTIGATION OF BRAIN STRUCTURE

CT scanning gives images of the brain substance; it provides clear pictures of the ventricles (fluid-filled cavities) and can reveal tumours, blood clots, strokes, *aneurysms*, and abscesses.

MRI (magnetic resonance imaging) produces very detailed images of the brain's structure. This technique is also used to detect patches of abnormal brain tissue, as seen in *multiple sclerosis*.

Angiography involves the injection of a contrast medium that shows up the blood vessels in the brain on *X-ray*. It is used to investigate aneurysms and other circulatory disorders.

INVESTIGATION OF BRAIN FUNCTION

PET and *SPECT* scanning are specialized forms of *radionuclide scanning* that use small amounts of radioactive material to provide information about brain function as well as structure. They enable blood flow and metabolic activity in the brain to be measured.

Functional magnetic resonance imaging (*fMRI*) can be used to determine which parts of the brain are activated by different sensations or activities, such as sight or movement of the fingers. This technique is used to assess how the brain is working.

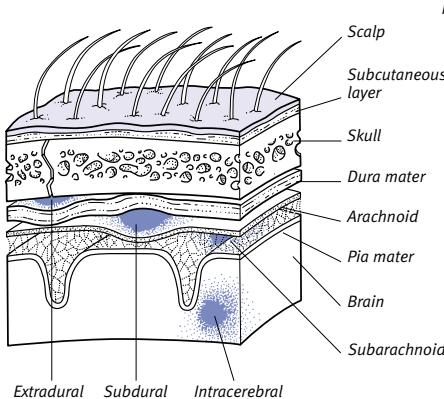

Ultrasound scanning, through the fontanelles (holes where the skull bones have yet to fuse), can detect bleeding in the brain only in premature or very young babies; ultrasound waves cannot penetrate the bones of a mature skull.

brainstem

A stalk of nerve tissue that forms the lowest part of the brain and links with the spinal cord. The brainstem acts partly as a highway for messages travelling

SITES OF BRAIN HAEMORRHAGE

Haemorrhages within the skull fall into four main categories – extradural, subdural, subarachnoid, and intracerebral – according to the site of the bleeding in relation to the brain and its protective coverings (the meninges). The causes and effects of the bleeding and the outlook for the patient vary depending on which category the haemorrhage falls into.

Intracerebral haemorrhage
This CT scan shows bleeding in the brain tissue (cerebral haemorrhage).

between other parts of the brain and spinal cord. It also connects with 10 of the 12 pairs of *cranial nerves* (which emerge directly from the underside of the brain) and controls basic functions such as breathing, vomiting, and eye reflexes. Brainstem activities are below the level of consciousness, and they operate mainly on an automatic basis.

STRUCTURE

The brainstem is composed of three main parts: the midbrain, pons, and medulla. Attached to the back of the brainstem is a separate part of the brain, the *cerebellum*, which is concerned with balance and coordinated movement. Running longitudinally through the middle of the brainstem is a canal; this widens in the pons and medulla to form the fourth ventricle (cavity) of the brain, which contains the circulating *cerebrospinal fluid*.

Midbrain The midbrain is the smallest section of the brainstem. This part contains the nuclei (nerve-cell centres) of the third and fourth cranial nerves, which control eye movements and the size and reactions of the pupil. It also contains cell groups, such as the *substantia nigra*, involved in smooth coordination of limb movements.

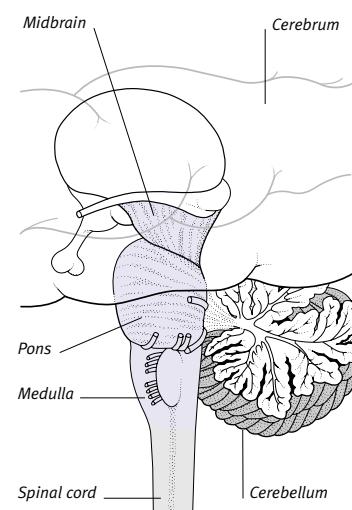

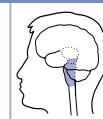

Pons The pons contains thick bundles of nerve fibres that connect with the *cerebellum*. It also houses the nuclei for the fifth to eighth cranial nerves, and relays sensory information from the ear, face, and teeth, as well as the signals that

move the jaw, adjust facial expressions, and produce some eye movements.

Medulla The medulla resembles a thick extension of the spinal cord. It contains the nuclei of the ninth to 12th cranial nerves, by which it receives and relays taste sensations from the tongue and

LOCATION OF THE BRAINSTEM

The brainstem is a 7.5 cm-long stalk of nerve cells and fibres that joins the upper spinal cord to the rest of the brain.

relays signals to muscles involved in speech and in tongue and neck movements. The medulla also contains the "vital centres" (groups of nerve cells that regulate the heartbeat, breathing, blood pressure, and digestion (information on which is relayed via the 10th cranial nerve (see *vagus nerve*).

Reticular formation Throughout the brainstem are numerous nerve-cell groups known collectively as the reticular formation. This network alerts the higher brain centres to sensory stimuli that may require a conscious response. Our sleep/wake cycle is controlled by the reticular formation.

DISORDERS

The brainstem is susceptible to the same disorders that afflict the rest of the central nervous system (see *brain, disorders of*). Damage to the medulla's vital centres is rapidly fatal; damage to the reticular formation may cause *coma*. Damage to specific cranial nerve nuclei can sometimes lead to specific effects. For example, damage to the seventh cranial nerve (the facial nerve) leads to *facial palsy*. Degeneration of the substantia nigra in the midbrain is thought to be a cause of *Parkinson's disease*.

brain syndrome, organic

Disorder of consciousness, intellect, or mental functioning that is of organic (physical), as opposed to psychiatric, origin. Possible causes include degenerative diseases, most notably *Alzheimer's disease*; infections; certain drugs; or the effects of injury, *stroke*, or tumour.

SYMPOTMS

Symptoms of acute organic brain syndrome range from mild confusion to stupor or *coma*. They may also include disorientation, memory loss, hallucinations, and delusions (see *delirium*). In the chronic form, there is a progressive decline in intellect, memory, and behaviour (see *dementia*). Treatment is more likely to be successful with the acute form. In chronic cases, irreversible brain damage may already have occurred. (See also *psychosis*.)

brain tumour

An abnormal growth in or on the brain. Although they are not always cancerous, all brain tumours are serious due to the buildup of pressure they cause within the brain and the compression of adjoining brain areas, both of which may occur as the tumour grows and expands. Expansion of a brain tumour

within the rigid skull may also result in damage to the normal tissue that surrounds the tumour.

TYPES

Brain tumours may be primary growths arising directly from tissues within the skull or metastases (secondary growths) that have spread via the bloodstream from cancerous tumours elsewhere in the body, particularly from those in the lung or breast.

The cause of primary brain tumours is not known. About 60 per cent are *gliomas* (which are frequently cancerous), and arise from the brain tissue. Other primary tumours include *meningiomas*, which arise from the meningeal membranes covering the brain; *acoustic neuromas*, which arise from the acoustic nerve; and *pituitary tumours*, which arise from the tissue of the pituitary gland. Most of these tumours are noncancerous, but their relatively large size can cause local tissue damage.

Some types of primary brain tumour affect mainly children. These include two types of glioma called *medulloblastoma* and cerebellar *astrocytoma*. Primary brain tumours virtually never spread (metastasize) outside the central nervous system.

Secondary growths (metastases) are always cancerous and may be found in more than one organ.

SYMPTOMS

Compression of brain tissue or nerve tracts near the tumour may cause muscle weakness, loss of vision, or other sensory disturbances, speech difficulties, and epileptic seizures.

The presence of a growing tumour can increase pressure within the skull, causing headache, visual disturbances, vomiting, and impaired mental functioning. *Hydrocephalus* (excess fluid in the brain) may occur if the circulation of cerebrospinal fluid is obstructed by the tumour.

DIAGNOSIS AND TREATMENT

Many different *brain imaging* techniques may be used to locate the site of a brain tumour and to establish its size and the extent of its spread.

In some cases, complete removal of a brain tumour may be possible using guidance from MRI scanning during surgery. In such cases, the patient may be cured. However, many cancerous growths are inaccessible or too extensive for removal. In cases where a tumour cannot be completely removed, as much as possible of it will be cut away to relieve pressure.

For primary and secondary tumours, *radiotherapy* or *anticancer drugs* may also be given. *Corticosteroid drugs* are often prescribed temporarily to reduce the size of a tumour and any associated swelling of brain tissues.

bran

The fibrous outer covering of grain that cannot be digested. The fibre is used as a bulk-forming *laxative* to prevent constipation (see *fibre, dietary*).

branchial disorders

Disorders due to abnormal development, in an embryo, of the branchial arches (paired segmented ridges of tissue in each side of the throat). Such disorders include branchial cyst and branchial fistula.

A branchial cyst is a soft swelling, containing fluid that may be either clear or puslike, that appears on the side of the neck in early adulthood. Treatment of a branchial cyst is usually with surgical removal.

A branchial fistula occurs between the back of the throat and the external surface of the neck, where it appears as a small hole, usually noted at birth. A hole in the neck that does not extend to the back of the throat is a branchial cleft sinus. A branchial fistula or cleft sinus may discharge mucus or pus and may be removed surgically.

brash, water

See *waterbrash*.

Braxton Hicks' contractions

Short relatively painless contractions of the uterus during pregnancy. They may be felt in late pregnancy and are sometimes mistaken for labour pains.

BRCA 1 and BRCA 2

Two of the abnormal *genes* that are thought to be responsible for inherited *breast cancer*. Women with these genes may also have an increased risk of ovarian cancer (see *ovary, cancer of*).

breakbone fever

A tropical viral illness, which is also called *dengue*, that is spread by mosquitoes. The symptoms include high fever and severe joint and muscle pain.

breakthrough bleeding

Bleeding or staining ("spotting") from the vagina between menstrual periods in women taking an oral contraceptive.

The bleeding is most common during the first few months of taking the pill and is caused by incomplete suppression of the monthly buildup of the *endometrium* (lining of the uterus). (See also *vaginal bleeding*.)

breast

Either of the two mammary glands, which, in women, provide milk to nourish a baby and are secondary *sexual characteristics*. The male breast is an immature version of the female breast.

DEVELOPMENT AND STRUCTURE

At puberty, a girl's breasts begin to develop: the areola (the circular area of pigmented skin around the nipple) swells and the nipple enlarges. This is followed by an increase in glandular tissue and fat.

The adult female breast consists of between 15 and 20 lobes of milk-secreting glands embedded in fatty tissue. The ducts of these glands have their outlet in the nipple. The areolar skin contains sweat glands, sebaceous glands, and hair follicles. Bands of fine ligaments determine the breast's height and shape.

The size, shape, and general appearance of a woman's breasts may vary throughout the menstrual cycle, during pregnancy and lactation, and following the menopause.

BREAST FUNCTION

During pregnancy, the hormones *oestrogen* and *progesterone*, which are secreted by the ovaries and placenta, cause the milk-producing glands in the breasts to develop and to become active. These two hormones also cause the nipples to enlarge.

Just before and immediately after childbirth, the glands in the breast produce a watery fluid known as *colostrum*. The production of this fluid is replaced by milk production a few days later. Milk production and release are stimulated by the hormone *prolactin*.

breast abscess

A collection of pus in the mammary gland, usually in a woman who is lactating (producing milk). Breast abscesses develop if acute *mastitis* (inflammation of the breast) is not treated promptly and occur most commonly during the month after a woman's first delivery.

The initial symptoms of a breast abscess are the same as those of acute mastitis. The abscess develops in one area, which becomes very firm, red, and extremely painful. Treatment involves

antibiotic drugs and repeated *aspiration* (withdrawal by suction) of the pus using a needle and syringe. In rare cases, surgical drainage may be needed.

breast awareness

A woman's familiarity with the appearance and feel of her breasts, which allows her to recognize both normal and abnormal changes. Doctors recommend that women develop "awareness" in order to improve the chances of detecting *breast cancer* at an early stage. (See also *breast self-examination*.)

breastbone

The common name for the *sternum*, the front part of the *thorax* (chest).

breast cancer

A cancerous tumour of the breast. Breast cancer is the most common type of cancer in nonsmoking women and the second most common type, after lung cancer, in women who smoke. One woman in every 12 who live to old age will develop breast cancer at some point in her life. Breast cancer can also

rarely develop in men. The advancement of techniques for early diagnosis and treatment of breast cancer has improved overall survival rates.

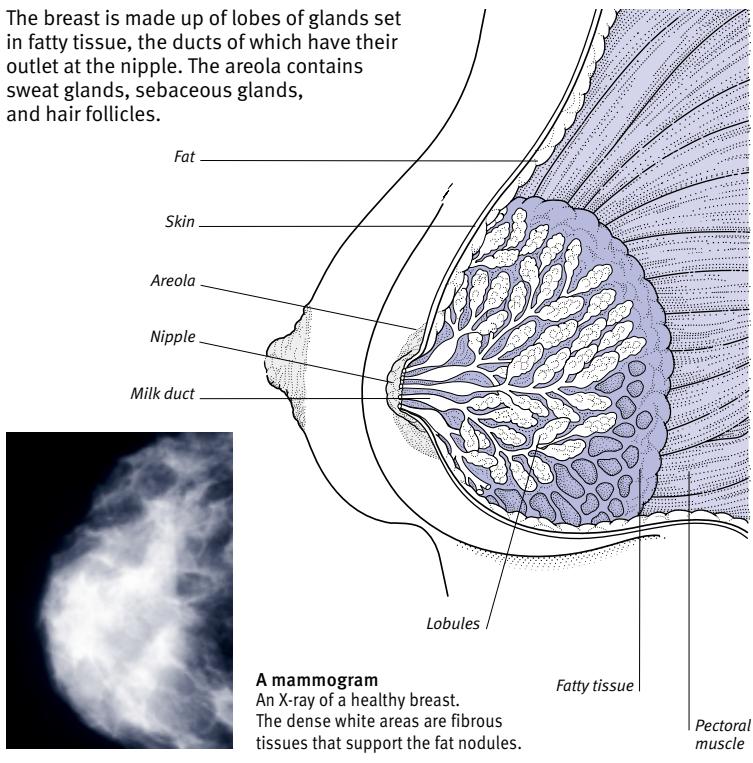

CAUSES

Current theories regarding the causes of breast cancer are focused on hormonal and genetic influences. However, the principal risk factor is age, with a woman's chances of developing the disease doubling every ten years of her life.

The incidence of breast cancer is known to be raised in women whose menstrual periods began at an early age and in those whose *menopause* was late to commence. The risk is also higher in women who did not have children or those who had their first child late in life. Women whose mothers or sisters have had breast cancer are also at an increased risk. Diet may also play a part; breast cancer is more common in countries in which the typical diet contains a lot of fat. Studies have shown that *hormone replacement therapy (HRT)* slightly increases the chances of developing breast cancer; the risk increases with the length of time that HRT has been taken.

THE FEMALE BREAST

The breast is made up of lobes of glands set in fatty tissue, the ducts of which have their outlet at the nipple. The areola contains sweat glands, sebaceous glands, and hair follicles.

DISORDERS OF THE BREAST

Disorders of the breast are mostly minor and respond to treatment. Problems are most commonly caused by infection, hormonal changes, and tumours.

Infection

Mastitis (bacterial infection of breast tissue) often occurs with breast-feeding, usually due to a blocked milk duct. Untreated, it may lead to a *breast abscess*.

Hormonal changes

Breast pain and tenderness is common just before menstruation or when a woman is taking hormones. Before menstruation, breasts may increase in size and become lumpy. Such lumps shrink when menstruation is over. Hormonal disorders may, rarely, cause *galactorrhoea* (abnormal production of milk). In men, *gynaecomastia* (abnormal

breast development) may occur as a result of hormonal disturbance or treatment with certain drugs.

Tumours

The majority of *breast lumps* are non-cancerous tumours, such as *cysts* (fluid-filled sacs) and *fibroadenomas* (thickened areas of milk-producing tissue). More rarely, *breast cancer* may occur.

INVESTIGATION

Disorders of the breast may be discovered during *breast self-examination* or physical examination by a doctor. Special investigations for the breast include *biopsy* (removal of a small sample of tissue for analysis) and *mammography*.

Breast cancer in women under the age of 50 may be linked to genetic factors and various genes, including *BRCA 1* and *BRCA 2*, have been identified. These genes seem to account for some of the breast cancers that occur within families. Women with one or more relatives who have developed the disease in their 30s or 40s may wish to seek specialist genetic advice.

SYMPTOMS AND SIGNS

The first sign of breast cancer is often a painless lump. However, it is important to note that nine out of ten breast lumps are not cancerous. Other symptoms of breast cancer may include a dark discharge from the nipple, retraction (indentation) of the nipple, and an area of dimpled, creased skin over the lump. In the majority of cases, only one breast is affected.

An abnormality may sometimes be detected during a routine *mammography*, which is offered every three years to all women between the ages of 50 and 65.

INVESTIGATION AND TREATMENT

If a lump is detected in the breast, an imaging procedure, such as *mammography* or *ultrasound scanning*, will be carried out. Cells will then be collected from the lump by needle *aspiration* (withdrawal by suction) or *biopsy* (surgical removal of a small sample of tissue for analysis).

A small cancerous tumour that is not thought to have spread outside the

breast is removed surgically, along with a surrounding margin of normal tissue. *Lymph nodes* in the armpit are usually removed at the same time. Larger cancers may require *mastectomy* (surgical removal of the whole breast). Surgery can be combined with or followed by *mammoplasty* (breast reconstruction) to help reduce the psychosexual impact of the disease.

Any further treatment depends on the size of the tumour; whether or not there is evidence of spread to the lymph nodes; and the sensitivity of the tumour cells to hormones, which is assessed in the laboratory using a technique known as oestrogen receptor testing. The woman's age and whether or not she has gone through the menopause are also significant factors in determining appropriate treatment.

After surgery, most women have a course of *radiotherapy* to any remaining breast tissue and to the armpit, and/or *chemotherapy* (treatment with *anticancer drugs*). *Tamoxifen*, an oral anti-oestrogen drug, is commonly prescribed for five years following surgery for breast cancer to reduce the risk of recurrence. Women who are approaching the menopause may be offered treatment to bring on an early menopause if the tumour is oestrogen-sensitive.

Secondary tumours in other parts of the body, which may be present at the time of the initial diagnosis or may

develop years after apparently successful treatment, are treated with anticancer drugs and hormones.

OUTLOOK

A complete cure or years of good health can usually be expected after treatment for early breast cancer. Regular check-ups are required to detect recurrence or the development of a new cancer in the other breast. Mammograms should be performed periodically for this reason. If the cancer recurs, it can be controlled, sometimes for years, by drugs and/or radiotherapy. (See also *breast self-examination*.)

breast cyst

A fluid-filled lump that forms within the milk-producing tissue of the breast. Breast cysts most commonly affect women in their 30s and 40s, especially in the years leading up to the *menopause*. A lump can be diagnosed as a cyst by *ultrasound scanning*, a *mammography*, or by withdrawing fluid from it with a syringe and needle (see *aspiration*), which usually results in the lump disappearing. About half of all women with a breast cyst will develop future cysts. Any new breast lump should be seen by a doctor to confirm the diagnosis.

breast enlargement surgery

A type of *mammoplasty*.

breast-feeding

The natural method of infant feeding during the period between birth and weaning. Human milk contains the ideal balance of nutrients for a baby and provides valuable *antibodies* (proteins made by the immune system) against infections. For the first few days after birth, the breasts produce a watery fluid known as *colostrum*. Milk flow is stimulated by the baby's sucking and is usually established in three to four days.

Breast-feeding problems may occur as a result of engorged breasts and cracked nipples or if the baby has problems sucking; a breast-feeding advisor may be able to help with these difficulties. Breast-feeding can sometimes cause an infection (see *mastitis*) that leads to a *breast abscess*. In such cases, treatment with *antibiotic drugs* may mean that it is possible to continue breast-feeding.

breast implant

An artificial structure surgically introduced into the breast to increase its size (see *mammoplasty*).

breast lump

Any mass, swelling, or cyst that can be felt in the breast tissue. At least 90 per cent of lumps are noncancerous; the rest are cancerous (see *breast cancer*).

Many women have generally lumpy breasts, with the lumps more obvious before a period. Once known as *fibrocystic disease* or *fibroadenosis*, this is now considered to be a variation of normal. Lumpy breasts do not increase the risk of breast cancer, but any new or distinct lump should be medically assessed. In a young woman, a single lump is likely to be a noncancerous *fibroadenoma*. This growth is usually round, firm, and rubbery, causes no pain, and can be moved about beneath the skin. In an older woman, a lump is more likely to be a noncancerous, fluid-filled *breast cyst*.

Breast awareness and regular *breast self-examination* may help to detect any changes. Treatment depends on the cause and type of lump. Cysts can be drained in a simple outpatient procedure. Other lumps may need to be removed surgically.

breast pump

A device that is used to draw milk from overfull breasts during lactation (see *breast-feeding*). A breast pump may also be used to express milk for future use or to feed a baby who is unable to suckle.

breast reconstruction

See *mammoplasty*.

breast reduction

See *mammoplasty*.

breast self-examination

A visual and manual examination carried out by a woman to detect lumps and other changes in her breasts that might be a sign of early *breast cancer*.

To carry out self-examination, the breasts should be checked in a mirror for any dimpling of the skin, changes in the appearance of the nipples, or changes in breast size and shape. Then, placing one arm behind the head, and using small, circular movements, the breast should be gently but firmly pressed. The entire breast, armpit area, and nipple should be examined.

By performing regular self-examination, a woman is able to familiarize herself with the appearance and feel of her breasts (see *breast awareness*); any abnormal changes should be reported to a doctor without delay.

breast tenderness

Soreness or tenderness of the breasts, frequently accompanied by a feeling of fullness. Breast tenderness is extremely common. In most women it is cyclical, varying in severity in response to the hormonal changes of the menstrual cycle. The breasts are usually most tender before a period (see *premenstrual syndrome*). The condition tends to affect both breasts and may be aggravated by stress or caffeine. Breast tenderness may also be noncyclical, caused by muscle strain or *mastitis*. During lactation, it may be due to engorgement of the breasts with milk. Rarely, tenderness may be due to a *breast cyst* or to *breast cancer*. Examination by a doctor will exclude any underlying problems.

Women with large breasts are more likely to suffer from both cyclical and noncyclical breast tenderness.

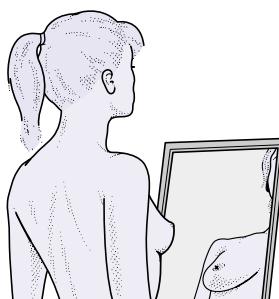

Cyclical tenderness may be relieved by reduced caffeine intake, relaxation exercises for stress, a well-fitting bra, or weight loss to reduce breast size. If these measures do not work, hormonal treatment may be recommended.

breath-holding attacks

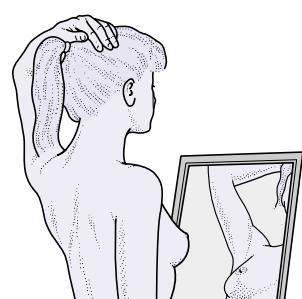

Periods during which a toddler holds his or her breath, usually as an expression of pain, frustration, or anger. The child usually becomes red or even blue in the face after a few seconds, and may faint. Breathing quickly resumes as a natural reflex, ending the attack. Breath-holding does not cause damage and is usually outgrown.

breathing

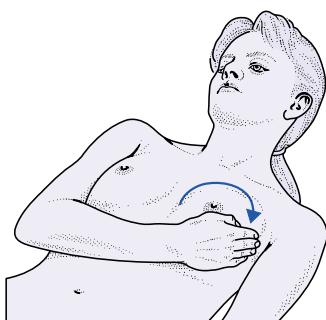

The process by which air passes into and out of the lungs to allow the blood to take up *oxygen* and dispose of *carbon dioxide*.

BREAST SELF-EXAMINATION

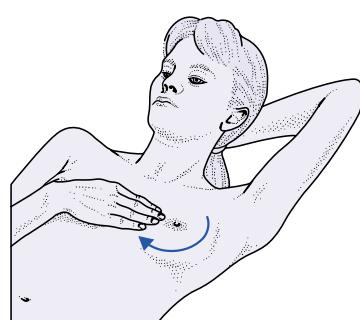

1 On a regular basis, examine your breasts in a mirror and become familiar with their general appearance. With your arms by your side, look at your breasts and be alert to any changes to the nipples or to the shape and size of the breasts.

2 Raise each arm in turn above your head, looking for changes in appearance. Turn from side to side, looking at the outline of the breasts for any changes. Examine the skin surface for peculiarities. Orange-peel texture could indicate the presence of a lump.

3 Lie on your back with a pillow under your shoulders and head, and one arm by your side. Using the flat of your other hand, and the pads of your fingers, work around the breast in firm, small circular movements.

4 Raise your arm above your head on one side and feel around the entire breast, including the nipple. Feel also along the top of the collarbone and into the armpit. Repeat the process for the other breast.

dioxide. Breathing is controlled by the respiratory centre in the *brainstem*. On inhalation, the diaphragm contracts and flattens. The intercostal muscles (between the ribs) contract and pull the ribcage up and out. The resulting increase in volume in the chest cavity causes the lungs to expand, and the reduced pressure draws air into the lungs. On exhalation, the chest muscles and diaphragm relax, causing the ribcage to sink and the lungs to contract, squeezing air out.

In normal, quiet breathing, less than a tenth of the air in the lungs passes out to be replaced by the same amount of fresh air (the tidal volume). This new air mixes with the stale air (the residual volume) already held in the lungs. The normal breathing rate for an adult at rest is 13 to 17 breaths per minute. (See also *respiration*.)

breathing difficulty

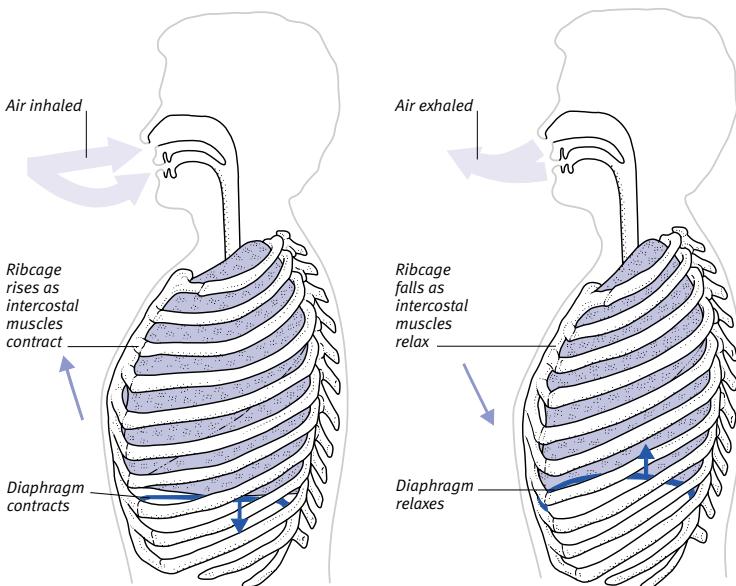

Laboured or distressed breathing that includes a change in the rate and depth of breathing or a feeling of breathlessness. Some degree of breathlessness is normal after exercise, particularly in unfit or overweight people. Breathlessness at rest is always abnormal and is usually due to disorders that affect the airways (see *asthma*), lungs (see *pulmonary disease, chronic obstructive*), or cardiovascular system (see *heart failure*). Severe anxiety can result in breathlessness, even when the lungs are normal (see *hyperventilation*). Damage to the breathing centre in the brainstem due to a *stroke* or *head injury* can affect breathing. This may also happen as a side effect of certain drugs. Ventilator assistance is sometimes needed.

At high altitudes, the lungs have to work harder in order to provide the body with sufficient oxygen (see *mountain sickness*). Breathlessness may occur in severe anaemia because abnormal or low levels of the oxygen-carrying pigment *haemoglobin* means that the lungs need to work harder to supply the body with oxygen. Breathing difficulty that intensifies on exertion may be caused by reduced circulation of blood through the lungs. This may be due to *heart failure* (reduced pumping efficiency of the heart), *pulmonary embolism* (blockage of blood vessels in the lungs by clots), or *pulmonary hypertension* (increased pressure in the arteries in the lungs).

Breathing difficulty due to air-flow obstruction may be caused by chronic

BREATHING

In an adult, inhalation and exhalation occur between 13 and 17 times a minute at rest and up to 80 times a minute during vigorous exertion. A normal, resting inhalation takes in about 400 ml of air; a deep breath, up to 4 litres.

Inhalation

Air is drawn into the lungs as the intercostal muscles (between the ribs) contract, causing the ribcage to rise, and the diaphragm contracts and flattens.

Exhalation

Air is expelled from the lungs as the intercostal muscles relax, causing the ribcage to fall, and the diaphragm relaxes and resumes its domed shape.

bronchitis, asthma, an allergic reaction, or *lung cancer*. Breathing difficulty may also be due to inefficient transfer of oxygen from the lungs into the bloodstream. Temporary damage to the lung tissue may be due to *pneumonia*, *pneumothorax* (collapsed lung), *pulmonary oedema* (fluid in the lung), or *pleural effusion* (fluid around the lung). Permanent lung damage may be due to *emphysema*, a condition in which the small air sacs in the lungs are destroyed.

Chest pain (for example, due to a broken rib) that is made worse by chest or lung movement can make normal breathing difficult and painful, as can *pleurisy* (inflammation of the membrane that lines the lungs and chest cavity). Pleurisy is associated with pain in the lower chest and often in the shoulder tip on the affected side.

Abnormalities of the skeletal structure of the thorax (chest), such as severe *scoliosis* or *kyphosis*, may cause difficulty in breathing by impairing the normal movements of the ribcage.

breathing exercises

Techniques for learning to control the rate and depth of breathing. They aim to teach people to inhale through the nose, while expanding the chest, and then to exhale fully through the mouth, while contracting the abdominal muscles. The exercises are used after chest surgery and for people with chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*), who often tend to have difficulty breathing effectively. Breathing exercises can also help people with *anxiety disorders* and may also help to relieve the symptoms of *asthma*.

In *yoga*, deep, rhythmic breathing is used to achieve a state of relaxation. During *childbirth*, breathing exercises can relax the mother and may also help to control the contractions of the uterus and reduce pain. (See also *physiotherapy*.)

breathing stoppage

The cessation of *breathing* (see *apnoea*). Breathing may be stopped by an *airway obstruction*, by damage to the brainstem

(for example, following a *stroke*), by *Cheyne–Stokes respiration*, and, in children, by *breath-holding attacks*.

B**breathlessness**

A feeling of laboured breathing. Breathlessness is a normal response to exercise or exertion, but may also be caused by some underlying disorders (see *breathing difficulty*).

breath test

A procedure used to check for infection of the digestive tract by *HELICOBACTER PYLORI*, the bacterium associated with *peptic ulcers*. The test involves drinking a substance that can be broken down by the bacterium. The breakdown process produces a chemical that passes into the bloodstream and is then breathed out. A machine detects the substance's presence in the breath, confirming infection with the bacterium.

breech delivery

A birth in which the fetus presents buttocks first. Many fetuses lie in a breech position before week 32 of pregnancy, but most of them turn by week 36. The three per cent that do not turn may be in one of three types of breech presentation: in a complete breech, the fetus is curled up; in a frank breech, the fetus's legs are extended and the feet are close to the face; in a footling breech, one or both feet are positioned over the cervix. In many twin pregnancies, one twin is in a breech position.

A mother whose fetus is in a breech presentation may be offered a procedure to turn the fetus around after week 36 of pregnancy, because this usually makes birth easier. In some breech deliveries, a *caesarean section* may be recommended.

bridge, dental

False teeth attached to natural teeth on either side of a gap left by one or more missing teeth (see the illustrated box). Adhesive bridges, which are attached to, but do not damage, the teeth on either side of the gap are now available in certain situations. (See also *denture*.)

Bright's disease

An alternative name for the kidney disorder *glomerulonephritis*.

Briquet's syndrome

An alternative name for *somatization disorder*, a psychiatric illness.

brittle bones

Bones with an increased tendency to fracture. They are a feature of *osteoporosis* and may occur in people who are taking *corticosteroid drugs*, are immobile, or have certain hormonal disorders. In *osteomalacia*, the bones are soft and tend both to become deformed and to fracture. The inherited disorder *osteogenesis imperfecta* is a rare cause of brittle bones and frequent fractures and is usually detected in infancy.

brittle diabetes

A former term for type 1 (insulin-dependent) *diabetes mellitus* in which it is difficult to maintain blood sugar levels within an acceptable range.

Broca's area

An area of the cerebral cortex (the outer layer of the *brain*) that is responsible for speech origination. Damage to Broca's area may result in *aphasia* (complete loss of previously acquired language skills).

Brodmann areas

Areas of the cerebral cortex (outer layer of the *brain*), that are numbered one to 47. Each area contains nerve cells that correspond to specific functions, such as sight, hearing, and movement.

broken leg

See *femur, fracture of, fibula; tibia*.

broken nose

Fracture of the nasal bones or dislocation of the cartilage that forms the bridge of the nose (see *nose, broken*).

broken tooth

See *fracture, dental*.

broken veins

A term that is commonly used to refer to *telangiectasia*, in which small blood vessels under the surface of the skin enlarge and give the impression of being "broken".

bromides

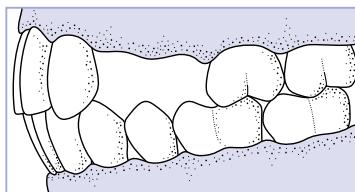

Substances formerly used as *sedative drugs* or as *anticonvulsant drugs* in the treatment of *epilepsy*. Bromides are no longer used due to their side effects, which include serious disturbance of brain function that may lead to *coma*.

bromocriptine

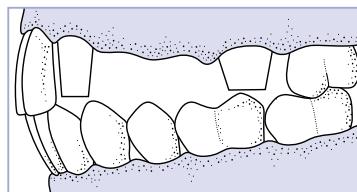

A drug used to suppress production of *prolactin* (a hormone) to treat conditions such as noncancerous pituitary tumours (see *prolactinomas; acromegaly*). Bromocriptine may also be used to suppress

FITTING A BRIDGE

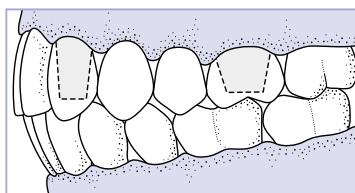

The most common type of bridge consists of one or more false teeth attached to a crown on each side of a gap. The natural teeth are shaped to receive the crowns, which are then cemented into place.

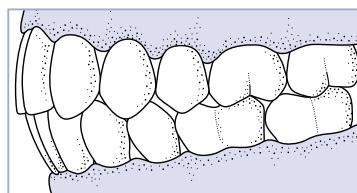

1 Two complete teeth are missing. A bridge of two false teeth and two crowns can be attached.

2 The two healthy teeth are shaped so that they can receive the crowns on either side of the gap.

3 The bridge, which is mounted on a cast-metal subframe (not shown), is cemented on to the healthy teeth on either side of the gap.

4 The finished bridge is in position, showing the new porcelain teeth; the metal base to which they are cemented is concealed.

milk production after childbirth and to treat *Parkinson's disease*. Side effects include nausea and vomiting; high doses may cause drowsiness and confusion.

bronchial asthma

See *asthma*.

bronchiectasis

A lung disorder in which one or more bronchi (air passages leading from the trachea) are abnormally widened and distorted, with damaged linings. Bronchiectasis commonly develops during childhood and was once associated with infections such as *measles* and *pertussis* (whooping cough). The condition may also be a complication of *cystic fibrosis*. Bronchiectasis results in pockets of long-term infection within the airways and the continuous production of large volumes of green or yellow sputum (phlegm). Extensive bronchiectasis may cause shortness of breath.

Symptoms are usually controlled with *antibiotic drugs* and *postural drainage*, a technique that clears secretions from the lungs. If the condition is confined to one area of lung, surgical removal of the damaged area may be recommended.

bronchiole

One of many small airways of the *lungs*. Bronchioles branch from larger airways (bronchi) and subdivide into progressively smaller tubes before reaching the alveoli (see *alveolus, pulmonary*), where gases are exchanged.

bronchiolitis

An acute viral infection of the lungs, mainly affecting babies and young children, in which the bronchioles (the airways branching off the bronchi) become inflamed. A common cause is the respiratory syncytial virus (RSV).

Symptoms of bronchiolitis include rapid breathing, a cough, and fever. No treatment may be necessary but, in severe cases, hospital admission is necessary so that *oxygen therapy* can be given. If treatment is prompt, recovery is usually within a few days. *Antibiotic drugs* may be given to prevent a secondary bacterial infection.

bronchitis

A disorder in which the bronchi, the large air passages to the lungs, are inflamed. Bronchitis results in a cough that may produce considerable quantities of sputum (phlegm) and may be

acute or chronic. Both types are more common in smokers and in areas with high atmospheric pollution. (See also *bronchitis, acute; bronchitis, chronic*.)

bronchitis, acute

A form of *bronchitis*, usually due to a viral infection, that develops suddenly but often clears up within a few days. Bacterial infection of the airways may be a complication. Smokers, babies, the elderly, and people with lung disease are particularly susceptible. Symptoms include wheezing, shortness of breath, and a cough producing yellow or green sputum. There may also be pain behind the sternum (breastbone) and fever.

Symptoms may be relieved by drinking plenty of fluids and inhaling steam or using a humidifier. Most cases clear up without further treatment, but acute bronchitis may be serious in people who already have lung damage.

bronchitis, chronic

Smoking-induced inflammation of the airways associated with *emphysema*, in which the air sacs in the lungs are destroyed. The combination of chronic bronchitis and emphysema is known as chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*). Symptoms include a productive cough and progressive breathlessness.

bronchoconstrictor

A substance that causes narrowing of the airways. Bronchoconstrictors, such as *histamine*, are released during an allergic reaction (see *allergy*) and may provoke an *asthma* attack. The effect can be reversed by a *bronchodilator drug*.

bronchodilator drugs

COMMON DRUGS

SYMPATHOMIMETICS • Bambuterol • Eformoterol
• Ephedrine • Epinephrine • Fenoterol
• Salbutamol • Salmeterol • Terbutaline

ANTICHOLINERGICS • Ipratropium bromide
• Oxitropium

XANTHINES • Aminophylline • Theophylline

Drugs that widen the bronchioles (small airways in the lungs) to improve air flow and breathing. They are especially used to treat *asthma* and chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*), in which the lungs are inflamed and damaged.

TYPES

There are three main types of bronchodilator drug. Sympathomimetics (such

as *salbutamol*) are used primarily for the rapid relief of *breathing difficulty*. *Anticholinergics* (such as *ipratropium*) and *xanthines* (such as *aminophylline*) are more frequently used for the long-term prevention of attacks of breathing difficulty. Bronchodilators can be given by *inhaler*, in tablet form, or, in severe cases, by *nebulizer* or injection.

SIDE EFFECTS

The main side effects of sympathomimetics are palpitations and trembling. Anticholinergics may cause dry mouth, blurred vision, and, rarely, difficulty in passing urine. Xanthines may cause headaches, nausea, and palpitations.

bronchography

An *X-ray* procedure used for examining the bronchi, which are the two main air passages of the lungs. Once used to diagnose *bronchiectasis* (widening and distortion of the bronchi), this method has now been largely replaced by other imaging techniques, especially *CT scanning*, and by *bronchoscopy*.

bronchopneumonia

The most common form of *pneumonia*. In bronchopneumonia, inflammation is spread throughout the lungs in small patches around the airways; in lobar pneumonia, it is confined to one lobe.

bronchoscopy

Examination of the bronchi, the main airways of the lungs (see *bronchus*), by means of an *endoscope* (viewing tube) known as a *bronchoscope*. Bronchoscopes may be rigid or flexible.

WHY IT IS DONE

Bronchoscopy is performed to inspect the bronchi for abnormalities, such as *lung cancer* and *tuberculosis*; to collect samples of mucus; to obtain cells; and to take *biopsy* samples from the airways or lungs. A bronchoscope with special attachments is used to carry out treatments such as removing inhaled foreign bodies, destroying abnormal growths, and sealing off damaged blood vessels. (See also *Bronchoscopy* box, overleaf.)

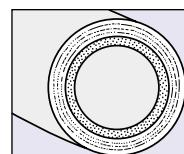

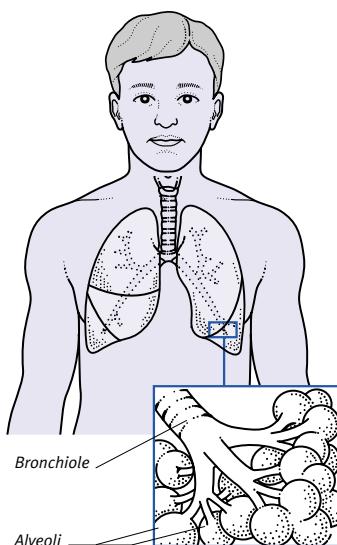

bronchospasm

Temporary narrowing of the bronchi (the air passages to the lungs). Bronchospasm is caused by contraction of the muscles in the walls of the bronchi, by inflammation of the lining of the bronchi, or by a combination of both. Contraction may be triggered by the release of substances during an allergic

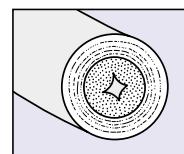

HOW BRONCHODILATORS WORK

When bronchioles become narrow following contraction of the muscle layer and swelling of the mucous lining, the passage of air is impeded. Bronchodilator drugs relax the muscles surrounding bronchioles by acting on the nerve signals that govern muscle activity.

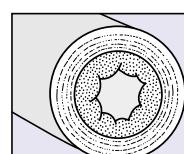

Sympathomimetic and anticholinergic drugs interfere with nerve signals passed to the muscles through the autonomic nervous system. Sympathomimetics enhance the action of neurotransmitters that encourage muscle relaxation. Anticholinergics block the neurotransmitters that trigger muscle contraction. Xanthine drugs relax muscle in the bronchioles by a direct effect on the muscle fibres; however, their precise action is not fully understood.

Normal bronchioles
The muscle surrounding the bronchioles is relaxed, leaving the airway open.

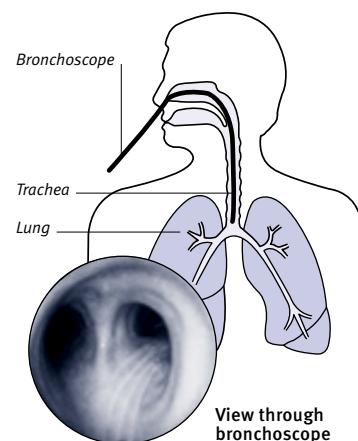

during an asthma attack
The muscle contracts and the lining swells, narrowing the airway.

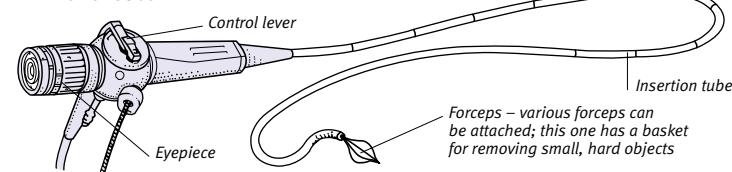

After drug treatment
The muscles relax, opening the airway, but the mucous lining remains swollen.

BRONCHOSCOPY

There are two kinds of bronchoscope. The rigid type is a hollow tube that is passed into the bronchi via the mouth and requires a general anaesthetic. The flexible, fibre-optic bronchoscope (a narrower tube formed from light-transmitting fibres) can be inserted through either the mouth or nose. It is used after giving only a mild sedative and/or local anaesthetic and it reaches farther into the lungs. Both types of bronchoscope can be fitted with forceps for taking tissue samples and the instrument also has attachments for performing laser therapy and cryosurgery. (See also *endoscopy*.)

THE BRONCHOSCOPE

reaction (see *allergy*). When the airways are narrowed, the air is reduced, causing wheezing or coughing.

Asthma is the most common cause of bronchospasm. Other possible causes include respiratory infection, chronic

obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*), in which the lungs are inflamed and damaged, *anaphylactic shock* (a potentially life-threatening hypersensitivity reaction), or allergic reaction to chemicals.

bronchus

A large air passage in a lung. Each lung has one main bronchus, originating at the end of the trachea (windpipe). This main bronchus divides into smaller branches known as segmental bronchi, which further divide into *bronchioles*.

bronchus, cancer of

See *lung cancer*.

bronze diabetes

An outdated term for *haemochromatosis*, a rare genetic disorder in which excess amounts of iron are deposited in tissues.

brown fat

A special type of fat found in infants and some animals. Located mainly between and around the shoulderblades, brown fat provides energy and helps infants to maintain a constant body temperature.

Brown–Sequard syndrome

A combination of symptoms associated with damage to a part of the *spinal cord*. There is loss of pain and temperature sensation on the opposite side of the body below the damage, and weakness and stiffness of muscles below the damage on the same side of the body.

brow presentation

A rare form of *malpresentation* in which the head of the fetus is bent slightly backwards and its brow lies against the

mother's cervix. Vaginal delivery is not possible if this presentation persists throughout labour, and a *caesarean section* is then required.

brucellosis

A rare bacterial infection, caused by various strains of *BRUCELLA*, which may be transmitted to humans from affected cattle, goats, and pigs. The infection may also be transmitted in unpasteurized dairy products.

Brucellosis causes high fever, sweating, poor appetite, joint aches, headache, backache, weakness, and depression. Rarely, severe untreated cases lead to *pneumonia* or *meningitis* (inflammation of the membranes surrounding the brain and spinal cord). In long-term brucellosis, bouts of the illness recur over months or years, and the depression can be severe. The disease is treated with *antibiotic drugs*.

bruise

A discoloured area under the skin caused by leakage of blood from damaged capillaries (tiny blood vessels). The blood initially appears blue or black; as the *haemoglobin* (the red pigment in blood) breaks down, the bruise turns a yellowish colour.

A bruise that does not fade after about week, that appears for no apparent reason, or that is severe after only minor injury, may indicate a *bleeding disorder*. (See also *black eye*; *purpura*.)

bruits

The sounds that are made in the heart, arteries, or veins when the blood circulation becomes turbulent or when it flows abnormally fast. This may happen when blood vessels widen (as in an *aneurysm*), when they become narrowed by disease (as in *arteriosclerosis*), or when heart valves are narrowed or damaged (as in *endocarditis*). Bruits can be heard by a doctor through a *stethoscope*. (See also *carotid bruit*.)

bruxism

Rhythmic grinding or clenching of the teeth that usually occurs during sleep. The main causes are emotional stress and minor discomfort when the teeth are brought together. Continued bruxism may wear away the teeth.

BSE

The abbreviation for *bovine spongiform encephalopathy*.

bubo

An inflamed and swollen *lymph node*, usually in the groin or armpit. Buboes usually occur as the result of a bacterial infection such as *plague* or a *sexually transmitted infection*.

bubonic plague

The most common form of *plague*, characterized by the development of a *bubo* (a swollen lymph node) in the groin or armpit.

buccal

A term that refers to the cheek or mouth. Buccal preparations of some drugs are available. Placed between the cheek and gum, they dissolve and are absorbed directly into the blood circulation.

buck teeth

Prominent upper incisors (front teeth) that protrude from the mouth. Orthodontic treatment of buck teeth involves repositioning the teeth with a removable brace (see *brace, dental*) or a fixed *orthodontic appliance*.

Budd-Chiari syndrome

A rare disorder in which the veins draining blood from the liver become blocked or narrowed. Blood accumulates in the liver, which swells. *Liver failure* and *portal hypertension* (raised pressure in the vein carrying blood to the liver) result.

Treatment is aimed at removing the cause of the obstruction, which may be a blood clot, pressure on the veins from a liver tumour, or a congenital (present from birth) abnormality of the veins. In most cases, treatment has only a limited effect and, unless a *liver transplant* can be carried out, the disease is generally fatal within two years.

budesonide

A *corticosteroid drug* used in the prevention of bronchial *asthma* attacks. Budesonide is administered using an *inhaler*. Adverse effects, which include hoarseness, throat irritation and, rarely, fungal infections, can be reduced by rinsing the mouth after administration.

Buerger's disease

A rare disorder, also known as *thromboangiitis obliterans*, in which the nerves, arteries, and veins in the legs, and sometimes the arms, become severely inflamed. The blood supply to the toes and fingers becomes cut off, eventually

causing *gangrene* (tissue death). Buerger's disease is most common in men under the age of 45 who smoke heavily.

buffalo hump

A lump of fat under the skin on the back of the neck. A buffalo hump may develop following long-term treatment with high doses of *corticosteroid drugs* or as a result of *Cushing's syndrome*.

building-related illnesses

Another term for the group of symptoms known as *sick building syndrome*.

bulbar palsy

Weakness of the muscles involved in talking and swallowing, causing slurred speech, hoarseness, difficulty in swallowing, and choking on food and drink. Bulbar palsy may be caused by damage to the muscles' nerve supply, as in *motor neuron disease*, or disease of the muscles themselves, as in *muscular dystrophy*.

bulimia

A psychiatric illness that is characterized by bouts of overeating, usually followed by self-induced vomiting or excessive use of *laxatives*. Most people suffering from bulimia are girls or women between the ages of 15 and 30. In some cases, the symptoms coexist with those of *anorexia nervosa*.

Repeated vomiting can lead to dehydration and loss of potassium, causing weakness and cramps, and also causes tooth damage due to the gastric acid in vomit. Treatment of bulimia includes supervision and regulation of the person's eating habits, *psychotherapy*, and, in some cases, antidepressant drugs (see *selective serotonin reuptake inhibitors*).

bulk-forming agent

A type of *antidiarrhoeal drug* that absorbs water, making stools less liquid. Bulk-forming agents are also used as *laxatives*, stimulating bowel movement by softening faeces and increasing their bulk.

bulla

A large air- or fluid-filled bubble that is usually found in the lungs or skin. Lung bullae in young adults are usually *congenital* (present from birth). In later life, lung bullae develop in patients with *emphysema*, a disorder in which the air sacs in the lungs are gradually destroyed. Skin bullae are large, fluid-filled *blisters* with a variety of causes, including the bullous disease *pemphigus*.

bull-neck

Swelling of the neck caused by severely swollen *lymph glands*, often related to infections in the tonsils and throat. (See also *diphtheria*.)

bullous pemphigoid

An alternative term for *pemphigoid*, a skin disease in which large, tense blisters develop.

bumetanide

A powerful, short-acting loop *diuretic drug* used to treat *oedema* (accumulation of fluid in tissues) resulting from *heart failure*, *nephrotic syndrome* (damage to the kidney's filtering units), or *cirrhosis*. It may be given by injection for the emergency treatment of *pulmonary oedema* (fluid in the lungs). Side effects may include rash and muscle pain.

bundle

Also known as a fascicle, a cluster of nerve or muscle fibres.

bundle branch block

See *heart block*.

bunion

A thickened pad of tissue or a fluid-filled bursa (sac) overlying a deformed big-toe joint. The underlying cause is

HOW BUNIONS FORM

A bunion results from the rubbing of a shoe against an abnormal outward projection of the joint at the base of the big toe (a *hallux valgus*), leading to irritation and inflammation. The joint abnormality is often due to wearing narrow, pointed shoes with high heels, although it can also result from an inherited weakness in the joint.

Bunion

Valgus deformity of the joint between the first metatarsal bone and the adjoining phalanx.

an abnormal outward projection of the big toe called a *hallux valgus*. Small bunions can usually be remedied by wearing well-fitting shoes and a special toe pad to straighten the big toe. Large bunions may require surgery to realign the joint and relieve the pressure.

buphthalmos

A large, prominent eyeball in an infant due to congenital *glaucoma* (increased pressure inside the eyeball). The condition is usually treated with surgery to reduce the pressure; otherwise, the child's sight is progressively damaged.

bupivacaine

A long-acting local anaesthetic (see *anaesthesia, local*) often used as a *nerve block* during *childbirth* and in *epidural anaesthesia* and *spinal anaesthesia*. Side effects are uncommon, but high doses may cause blood pressure to fall.

bupropion

Another name for *amfebutamone*, a drug used as an aid to stopping smoking.

Burkitt's lymphoma

A cancer of lymph tissues (see *lymphatic system*) characterized by tumours within the jaw and/or the abdomen. The condition almost exclusively affects children living in the low-lying, moist, tropical regions of Africa and New Guinea. *Anti-cancer drugs* or *radiotherapy* give a partial or complete cure in about 80 per cent of cases. (See also *lymphoma*.)

burns

Tissue damage caused by contact with heat, electricity, chemicals, or radiation. Burns are classified, according to the severity of skin damage, as first-, second-, or third-degree (or superficial, partial thickness, or full thickness).

FIRST-DEGREE BURNS

A first-degree burn causes reddening of the skin and affects only the epidermis, (topmost layer of skin). These type of burns usually heal quickly, but the damaged skin may peel away after a day or two. *Sunburn* is a common example of a first-degree burn.

SECOND-DEGREE BURNS

A second-degree burn extends into, and damages, the dermis (deep layer of skin), sometimes causing the formation of blisters. Because some of the dermis is left to recover, these type of burns usually heal without leaving scars, unless they are very deep.

THIRD-DEGREE BURNS

A third-degree burn destroys the full skin thickness and may extend to the muscle layer beneath the skin. The affected area will look white or charred; if the burn is very deep, muscles and bones may be exposed. Even if very localized, third-degree burns will need specialist treatment and possibly skin grafts to prevent scarring.

ELECTRICAL BURNS

Electrical burns can cause extensive tissue damage with minimal external skin damage. The electric current may cause heart damage.

EFFECTS AND COMPLICATIONS

Extensive first-degree burns (such as sunburn) cause pain, restlessness, fever, and headache, but are not life-threatening. A second- or third-degree burn that affects more than ten per cent of the body surface causes *shock*, with lowered blood pressure and a rapid pulse, due to massive fluid loss from the burned area. Shock may be fatal if this fluid is not replaced intravenously.

When the skin is burned it can no longer protect the body from contamination by airborne bacteria. The infection of extensive burns may cause fatal complications if effective treatment with *antibiotic drugs* is not available.

Victims who have inhaled smoke may develop inflammation of the lungs and may need specialist care for burns of the eyes and respiratory passages.

TREATMENT

A burn is covered with a non-stick dressing to keep the area moist. *Analgesic drugs* are given if necessary and antibiotics are prescribed if there is any infection. For extensive second-degree burns, which may be slow to heal or carry a high risk of infection, a topical antibacterial agent, such as silver sulphadiazine, is used. Third-degree burns always require *skin grafts*, which are used early to minimize scarring. Extensive burns may require *plastic surgery*.

burping

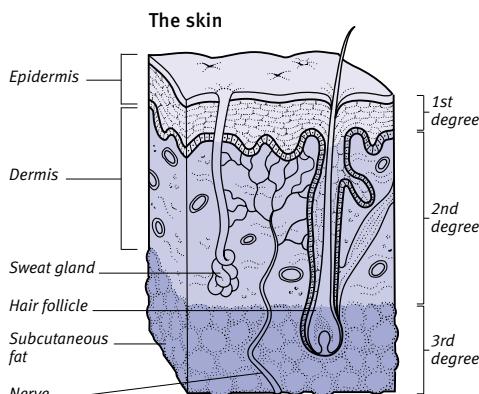

Another term for *belching*.

burr hole

A hole made in the skull by a special drill with a rounded tip (burr). The hole relieves pressure on the brain that often results from bleeding inside the skull, usually due to a *head injury*. Burr holes may be part of a *craniotomy* (in which a section of skull is removed for access to the brain) and may be life-saving.

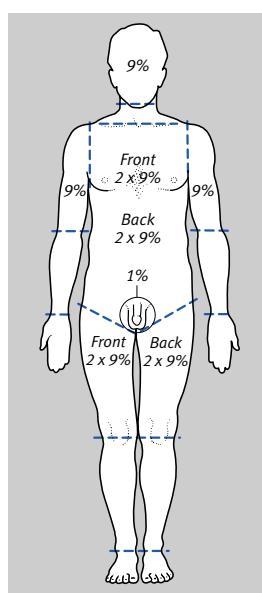

BURNS

Superficial burns cause the skin to redden and peel but, unless extensive, need no treatment. Burns that blister usually heal well but can be fatal if they affect a large area of the body. Burns that extend beyond the skin layers may damage fat, nerves, and muscle; and healing is slow because they are likely to require skin grafting.

Degrees of burns

Burns are divided into three categories. First-degree (or superficial) burns affect the epidermis and the skin may peel; second-degree (or partial thickness) burns cause blisters; third-degree (or full thickness) burns destroy the whole of the skin's thickness and require special treatment.

Skin surface area

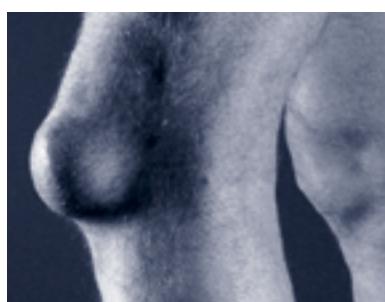

For assessment of burns, the body is divided roughly into nine per cent areas. This varies slightly in young children because the head is larger in relation to the body.

bursa

A fluid-filled sac that acts as a cushion at a pressure point, often where a tendon or muscle crosses bone or other muscles. The important bursae are found around the knee, elbow, and shoulder joints.

bursitis

Inflammation of a *bursa* (a fluid-filled sac) causing pain and swelling. Bursitis may result from pressure, friction, or injury to the membrane surrounding a joint, or to infection. Prepatellar bursitis

Pre-patellar bursitis

This condition, which is caused by inflammation of a bursa, produces a fluid-filled swelling in front of the kneecap.

(also known as housemaid's knee), for example, is the result of prolonged kneeling on a hard surface. Treatment is by avoiding further pressure and by taking *nonsteroidal anti-inflammatory drugs*. *Antibiotic drugs* may be necessary if the bursa is infected.

buserelin

A synthetic form of the hormone *gonadorelin* that is used to treat *endometriosis* (a disease of the lining of the uterus), infertility, and cancer of the prostate.

butterfly rash

A skin eruption, also called a butterfly patch, that is characteristic of systemic *lupus erythematosus* (see *rash*).

buzzer and pad system

A device used to treat bedwetting (see *enuresis, nocturnal*). A pad that detects moisture is placed in the bed and is attached to a buzzer that sounds when the pad becomes wet with urine. The person is woken up as soon as he or she starts to pass urine and gradually learns to wake up before starting to pass urine.

bypass operations

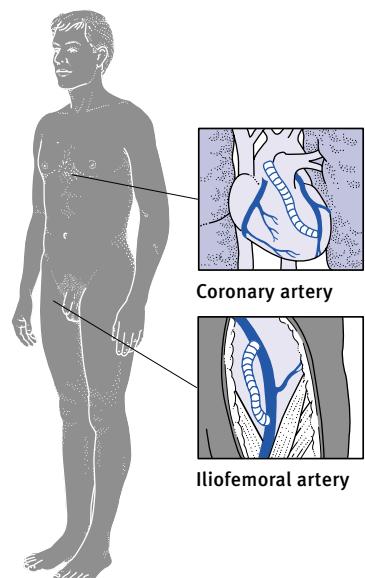

Surgical procedures that are used to bypass blockages or narrowing. The term bypass usually refers to operations on arteries, although blockages in the digestive system can also be treated with bypass operations.

The most common type of bypass operation is *coronary artery bypass*, which is used to treat *coronary artery disease*, (a condition in which the arteries have become blocked or narrowed by *atherosclerosis*). Obstructions can be bypassed by using sections of healthy artery or vein from elsewhere in the body or using tubing made from a synthetic material such as dacron.

Intestinal bypass operations are most often performed to treat cancer patients in whom the tumour is too extensive to be removed surgically. The blocked area is bypassed by joining the sections of bowel above and below the blockage.

byssinosis

A lung disease caused by the dust that is produced during the processing of flax, cotton, hemp, or sisal. Byssinosis causes a feeling of tightness in the chest and shortness of breath that may become chronic (of long duration) if exposure to the agent continues. *Bronchodilator drugs* and other drugs used to treat asthma can relieve the symptoms; good ventilation and equipment such as masks reduce the risk.

Common bypass locations

The coronary artery and the iliofemoral vessels are the most common locations for bypasses.

C

cachexia

A condition of severe weight loss and decline in health caused by a serious underlying disease, such as cancer or tuberculosis, or by starvation.

cadaver

A dead human body used as a source of transplant organs or for anatomical study and dissection.

cadmium poisoning

The toxic effects of cadmium, a tinlike metal. Poisoning as a result of inhalation of cadmium fumes is an industrial hazard, the effects of which depend on the duration and severity of exposure. Eating vegetables grown in cadmium-rich soil, or the consumption of food or drink stored in cadmium-lined containers, can also cause poisoning.

Short-term exposure to cadmium may lead to *pneumonitis* (inflammation of the lungs). Exposure over a long period can lead to urinary tract *calculi* (stones), *kidney failure*, or *emphysema* (a form of permanent lung damage).

caecum

The first section of the large intestine, joining the *ileum* (the end of the small intestine) to the ascending *colon*. The *appendix* projects from the caecum. (See also *digestive system*).

caesarean section

An operation to deliver a baby from the mother's uterus through a horizontal or, less commonly, a vertical incision in the abdomen. A caesarean section is performed if vaginal delivery would be difficult or dangerous for the mother or the baby. Increasingly, women who do not want to go through labour are also opting to have the operation.

A caesarean section may be performed using either an *epidural anaesthesia* or *general anaesthesia* (see *anaesthesia, general*). The procedure for performing a caesarean section is shown in the illustrated box (see opposite page).

After the operation, the mother is given *analgesic drugs* (painkillers) as required. If there are no complications, she and the baby can usually leave hospital about a week after the operation.

café au lait spots

Coffee-coloured patches on the skin that may occur on any part of the body. Café au lait spots are usually oval in shape and may measure several centimetres across. Generally, the presence of a few of these spots is not significant. However, larger numbers of them may be a sign of *neurofibromatosis*, a hereditary disorder of the sheaths that surround nerve fibres.

caffeine

A *stimulant drug* that is found in coffee, tea, cocoa, and cola drinks. Caffeine reduces fatigue, improves concentration, makes the heart pump blood faster, and has a diuretic effect.

CAFFEINE LEVELS

The strength and preparation method determine exact amounts of caffeine present (in mg per cup).

Drink	Caffeine
Tea, weak	50mg
Tea, strong	80mg
Coffee, weak	80mg
Coffee, strong	200mg
Cocoa	10–17mg
Cola	43–75mg

Large quantities of caffeine may produce side effects such as agitation and tremors. A regular high intake may lead to increased *tolerance*, so that people need to increase their caffeine intake to obtain the equivalent stimulant effect. In people who consume large amounts of caffeine, withdrawal symptoms (see *withdrawal syndrome*), such as headaches and tiredness, may occur after a few hours without caffeine.

Caffeine may be used in some drug preparations, particularly in combination with *analgesic drugs* (painkillers) and with *ergotamine* in preventive treatments for migraine.

caisson disease

An alternative term for *decompression sickness*. It usually occurs when a person surfaces too quickly after a deep dive.

calamine

A preparation of zinc oxide and iron oxide that is applied to the skin as an ointment, lotion, or dusting powder to relieve irritation and itching. Calamine has a protective, cooling, and drying effect. It may be combined with a local anaesthetic (see *anaesthesia, local*), *corticosteroid drug*, or *antihistamine drug*.

calcaneal bursitis

Inflammation of the bursa (fluid-filled pad) that cushions the *calcaneus* and prevents friction at the back of the heel (see *bursitis*). The condition causes pain and swelling but usually clears up with rest and *anti-inflammatory drugs*.

calcaneus

The heel bone. The calcaneus is one of the tarsal bones and is the largest bone in the *foot*. The *Achilles tendon* runs between the back of the calcaneus and the calf muscles; it controls upward and downward movements of the foot.

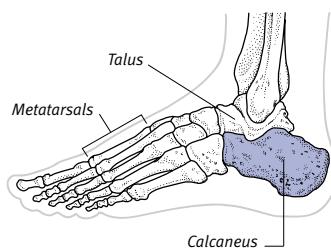

DISORDERS

The calcaneus may be fractured by a fall from a height on to the heel. Minor fractures do not usually cause problems and can be treated by placing the affected foot and leg in a *cast*. A more serious fracture, with compression of the bone, may cause permanent damage to the joints involved in turning the foot in and out, leading to pain and stiffness that are aggravated by walking.

The point at which the Achilles tendon joins the calcaneus may become strained by excessive or prolonged stress from the pull of the tendon (in some *running injuries*, for example). In children, this area may be inflamed and painful (see *osteochondrosis*) because the bone is still growing.

LOCATION OF THE CALCANEUS

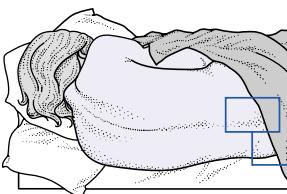

The calcaneus is the largest of the tarsal bones. It projects backwards beyond the leg bones.

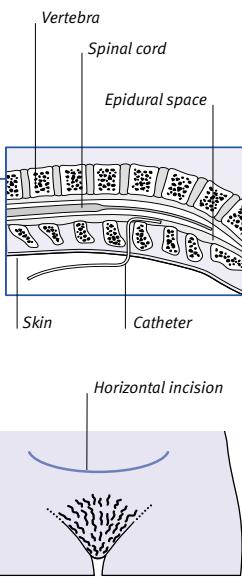

PROCEDURE FOR A CAESAREAN SECTION

A caesarean section allows delivery of a baby through a horizontal or vertical cut in the abdominal and uterine walls. The mother is given epidural anaesthesia, so that she remains conscious during the procedure, or general anaesthesia.

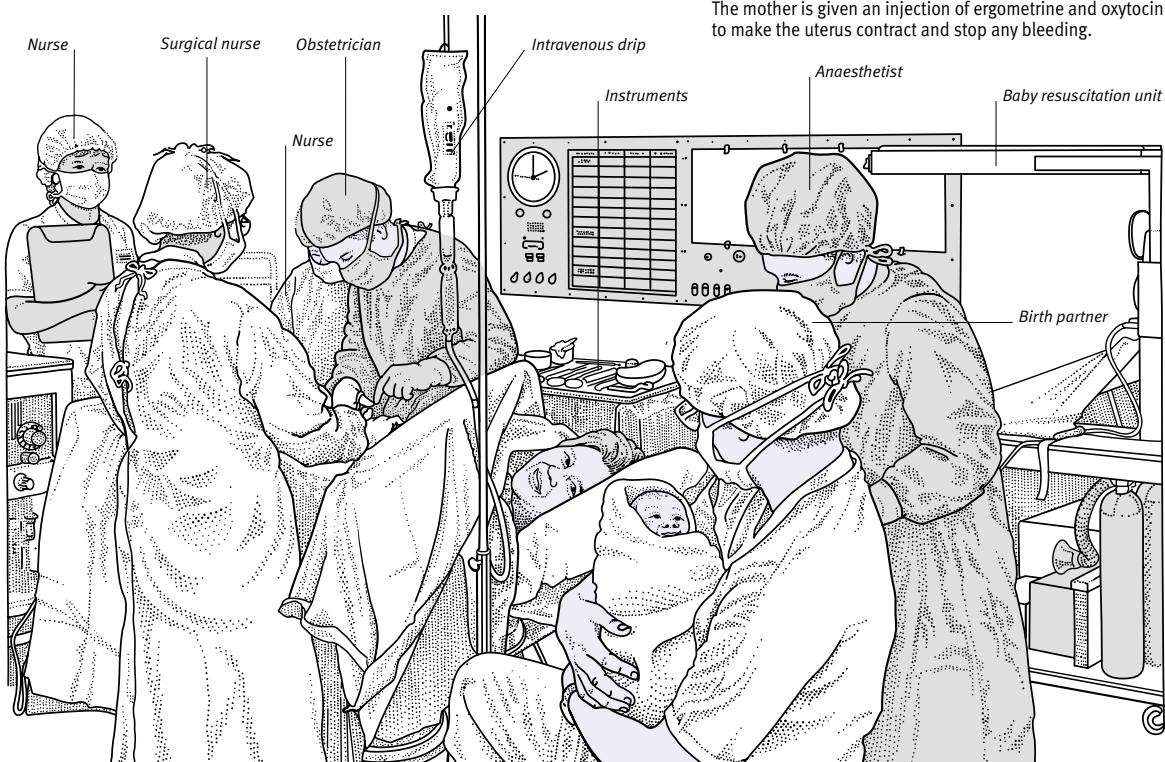

HOW IT IS DONE

1 First, epidural anaesthesia is carried out to temporarily numb the abdomen by deadening the nerves leading to it. A needle is introduced into the epidural space and a catheter is threaded through it. A local anaesthetic is injected down the *catheter*. A catheter is also inserted into the bladder to empty it.

2 The abdomen is then opened, usually through a horizontal incision made just above the pubic bone. This type of cut heals most effectively. The resulting scar is hardly noticeable and comes below the "bikini line".

WHY IT IS DONE

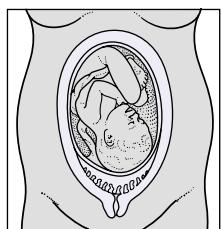

A caesarean can be elective (planned) in cases of breech presentation; placenta praevia (where the placenta is lying close to or across the cervix); the mother's ill health; or, most commonly, if there were problems in previous caesareans that still exist (such as the mother having a small pelvis).

Breech presentation

Elective caesarean is sometimes requested by the parents for social reasons.

An emergency caesarean is needed in cases of *fetal distress* (lack of oxygen); unsuccessful induction of labour; or bleeding (such as in placental abruption (premature separation) or placenta praevia).

Placenta praevia

3 The amniotic fluid is drained off by suction. The baby is delivered through an incision in the lower part of the uterus. The umbilical cord is cut and the afterbirth removed. The incisions in the uterus and abdomen are then sewn up. The mother is given an injection of ergometrine and oxytocin to make the uterus contract and stop any bleeding.

The tendons of the sole of the foot are fixed under the calcaneus, and the associated muscles are important in supporting the arches of the foot. Inflammation around these tendons (as occurs in plantar fasciitis) causes pain and tenderness under the heel when standing or walking. A calcaneal spur (a bony protrusion) occurs in some people with plantar fasciitis and also, occasionally, in those with healthy feet.

calciferol

A former name for vitamin D₂. This vitamin is now more commonly known as ergocalciferol (see *vitamin D*).

calcification

The deposition of *calcium* salts in body tissues. Calcification is part of the normal processes of bone and teeth formation and the healing of fractures. It also occurs in injured muscles, in arteries affected by *atherosclerosis*, and when blood calcium levels are raised by disorders of the *parathyroid glands*.

calcification, dental

The deposition of *calcium* salts in developing teeth. Primary teeth (see *eruption of teeth*) begin to calcify in a fetus at between three and six months gestation. Calcification of permanent teeth (other than the wisdom teeth) begins between birth and four years.

Certain tooth conditions can cause abnormal calcification. In amelogenesis imperfecta, an enamel disorder (see *hypoplasia, enamel*), teeth have a thin, grooved covering due to incomplete calcification. Another cause is absorption of high levels of fluoride (see *fluorosis*) and drugs, such as *tetracycline*, that are taken in pregnancy.

calcinosis

The abnormal deposition of *calcium* salts in the skin, muscles, or *connective tissues*, forming *nodules*. Calcinosis occurs in connective tissue disorders such as *scleroderma*. (See also *calcification*.)

calcipotriol

A derivative of *vitamin D* that is used in topical treatments for the skin condition *psoriasis*.

calcitonin

A *hormone* produced by the *thyroid gland* that helps to control blood *calcium* levels by slowing the rate at which calcium is lost from the bones.

WHY IT IS USED

A synthetic form of calcitonin used in the treatment of *Paget's disease*, in which the bones grow abnormally and become deformed, causing pain and an increased risk of fracture. Injections of calcitonin can generally halt abnormal bone formation in about a week and can relieve pain within a few months.

Calcitonin is also used in the treatment of *hypercalcaemia* (abnormally high levels of calcium in the blood), which may be caused by overactivity of the *parathyroid glands* or by *bone cancer*. It helps to relieve the nausea and vomiting that result from hypercalcaemia by rapidly reducing the level of calcium circulating in the blood.

SIDE EFFECTS

Calcitonin causes minimal side effects. Gastrointestinal reactions, such as nausea, vomiting, and diarrhoea, usually diminish with continued use.

calcium

The body's most abundant mineral, calcium is essential for cell function, muscle contraction, the transmission of nerve impulses from nerve endings to muscle fibres, and for *blood clotting*. Calcium phosphate is the hard, basic constituent of teeth and bones. Dietary sources of calcium include dairy products, eggs, and green, leafy vegetables.

CONTROL OF CALCIUM LEVELS

Vitamin D and certain hormones help to control the overall amount of calcium in the body. They act by regulating the amount of calcium that is absorbed from food and the amount filtered out from the blood by the kidneys and excreted in the urine.

The levels of calcium in the blood are controlled by the actions of two hormones: parathyroid hormone, which is produced by the *parathyroid glands*, and *calcitonin*, which is produced by the thyroid gland. When the level of calcium in the blood falls to a low level, the parathyroid glands release more parathyroid hormone, which raises the blood calcium level by helping to release calcium from the enormous reservoir in the bones. When the blood calcium level rises significantly, the thyroid gland releases more calcitonin. This hormone counteracts the effects of parathyroid hormone, thereby lowering the level of calcium in the blood.

DISORDERS OF CALCIUM METABOLISM

Abnormally high levels of calcium in the blood (*hypercalcaemia*) or abnor-

mally low levels (*hypocalcaemia*) may seriously disrupt cell function, particularly in muscles and nerves. (See also *mineral supplements*.)

calcium carbonate

A *calcium* salt used in some *antacid drugs*, which can be taken for the treatment of indigestion.

calcium channel blockers

COMMON DRUGS

- Amlodipine • Diltiazem • Felodipine
- Isradipine • Lacidipine • Lercanidipine
- Nicardipine • Nifedipine • Verapamil

Drugs used in the treatment of *angina pectoris* (chest pain due to impaired blood supply to the heart muscle), *hypertension* (high blood pressure), and certain types of cardiac *arrhythmia* (irregular heartbeat).

HOW THEY WORK

Calcium channel blockers work by interfering with the movement of *calcium* across the membranes of muscle cells in blood vessels and in the heart muscle itself. This action decreases the work of the heart in pumping blood, reduces the pressure of blood flow through the body, and improves blood circulation through the heart muscle.

The drugs also slow the passage of nerve impulses through the heart's internal conduction system, which helps to correct certain types of arrhythmia.

SIDE EFFECTS

The side effects of calcium channel blockers are mainly related to their action of increasing the blood flow through tissues. These effects include headaches, swollen ankles, flushing, and dizziness. Adverse effects tend to diminish with continued treatment.

calculus

A hard deposit in the body. Calculus may form on the surface of the teeth (see *calculus, dental*). Alternatively, it may be a small, hard, crystalline mass that forms in a body cavity from certain substances in fluids such as bile, urine, or saliva. Such calculi (also called stones) can occur in the gallbladder and bile ducts (see *gallstones*), kidneys, ureters, bladder (see *calculus, urinary tract*), or in the salivary ducts.

Although some calculi do not cause any symptoms, some can cause severe pain, in which case they may need to be dissolved, shattered, or surgically removed from the body cavity.

calculus, dental

A hard, crust-like deposit, also called tartar, found on the crowns and roots of the teeth. Calculus forms when mineral salts in saliva are deposited in existing *plaque*, a coating of mucus and debris that forms on the teeth.

TYPES

There are two types of dental calculus. Supragingival calculus is a yellowish or white deposit that forms above the gum margin, on the crowns of teeth in areas close to the openings of *salivary gland* ducts. Subgingival calculus forms below the gum margin, is more evenly distributed around all the teeth, and is brown or black.

Both types of calculus are hard and are therefore difficult to remove; the subgingival variety may be more difficult to remove because of its location and degree of calcification.

EFFECTS AND TREATMENT

The toxins present in calculus can lead to gum inflammation (see *gingivitis*), which may progress to destruction of the supporting tissues (see *periodontitis*). Calculus should be removed on a regular basis by professional *scaling*. Careful attention to *oral hygiene* may reduce the recurrence of dental calculus.

calculus, urinary tract

A stone in the kidneys, ureters, or bladder that is formed from crystallized substances in the urine.

TYPES AND CAUSES

Kidney and ureteral stones Most stones that form in the kidneys and ureters are composed of calcium oxalate or other salts crystallized from the urine. These stones may be associated with a diet that is rich in oxalates (which are found, for example, in leafy vegetables and tea); high levels of *calcium* in the blood due to *hyperparathyroidism* (overactivity of the parathyroid glands); or chronic dehydration.

Other types of kidney or ureteral stone are associated with *gout* and certain cancers. Stones that develop in these locations due to chronic *urinary tract infection* are termed "infective". Kidney stones that fill the entire network of urine-collecting ducts at the top of the ureter are called "staghorn" calculi, due to their shape.

Bladder stones In developing countries, bladder stones usually occur as a result of dietary deficiencies. In developed countries, they are usually caused by an obstruction to urine flow from the

bladder and/or a longstanding urinary tract infection. The composition of the stones is related to the acidity or alkalinity of the urine.

SYMPTOMS

The most common symptom of a stone in the kidney or ureter is *renal colic*, a severe pain in the back, under the ribs, that often spreads into the groin. This pain may be accompanied by nausea and vomiting. There may also be *haematuria* (blood in the urine). A bladder stone usually causes difficulty in passing urine.

DIAGNOSIS AND TREATMENT

Investigation of a suspected calculus usually starts with microscopic examination of the urine, which may reveal red blood cells and the presence of crystals. The degree of acidity or alkalinity of the urine may reflect the type of stone involved. The site of a stone

can usually be confirmed by intravenous *urography*. Some stones, particularly those containing calcium, are visible on a plain abdominal X-ray.

Renal colic is treated with bed rest and an *analgesic drug* (painkiller). With an adequate fluid intake, small stones are usually passed in the urine without causing problems. The first line of treatment for larger stones in the urinary tract is often *lithotripsy*, a procedure that uses ultrasonic waves or shock waves to disintegrate the stones. Alternatively, *cystoscopy* can be used to crush and remove stones in the bladder and lower ureter. In some cases, surgery may be needed to remove the stones.

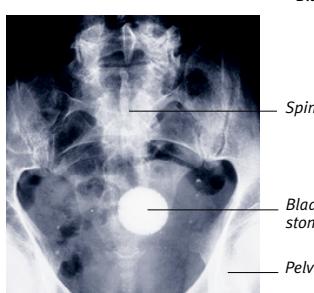

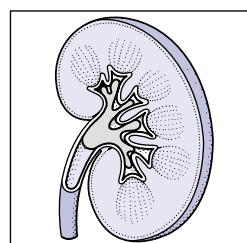

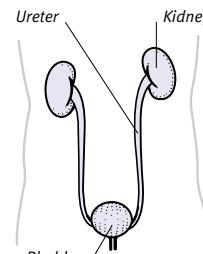

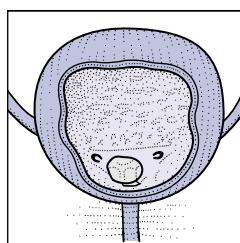

calendar method

A method of *contraception*, also called the rhythm method, based on abstaining from sexual intercourse around the

URINARY TRACT CALCULI

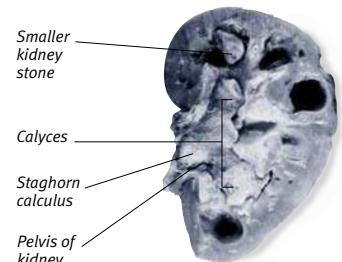

Calculi form in the urinary tract when certain substances in the urine become overly concentrated. The substances form crystals, which grow into stones. Some stones may be associated with recurrent episodes of *urinary tract infection*. Symptoms vary according to the site of the stone. Small stones may be passed in the urine and cause no symptoms. Some stones, however, may

lodge in a ureter, causing *renal colic* (a sudden, severe pain in the small of the back that moves towards the groin) and *haematuria* (blood in the urine). In the bladder, stones may settle over the outlet, which can cause difficulty in passing urine, a poor flow rate, and dribbling. Any obstruction to urine flow may result in rapid kidney damage and acute, severe infection (*pyelonephritis*).

X-ray of a bladder stone

A large bladder stone, such as the one that can be clearly seen in this X-ray, can make the passing of urine both difficult and painful.

Staghorn calculus

Here, a staghorn calculus has filled the entire pelvis and calyces of the kidney, producing a cast of them. A smaller stone has formed in the medulla (central area).

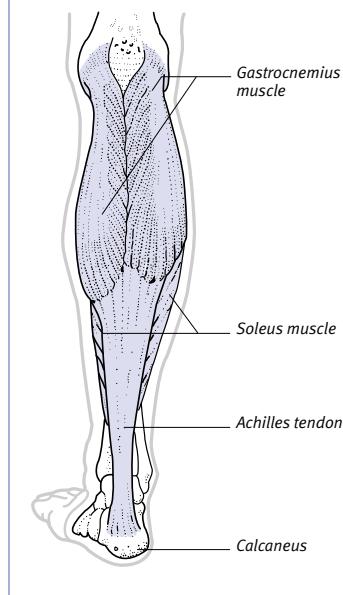

time of *ovulation* (the release of an egg from a woman's ovary). This time is calculated on the basis of the length of her previous menstrual cycles. The calendar method is unreliable because a woman's menstrual cycle may vary. There are now more scientific and effective contraceptive methods of this type (see *contraception, natural methods*).

calf muscles

The muscles extending from the back of the knee to the heel. The gastrocnemius muscle starts behind the knee and forms the bulky part of the calf; beneath it lies the soleus muscle which starts at the back of the *tibia* (shin). These two muscles join to form the *Achilles tendon*, which connects them to the heel. Contraction of the calf muscles pulls the heel up and is important in walking, running, and jumping.

LOCATION OF CALF MUSCLES

The gastrocnemius muscle and the soleus muscle at the back of the leg join to form the Achilles tendon.

calf pain

Various disorders may be responsible for pain in the calf. Common causes include *cramp*, muscle strain, and *sciatica* (inflammation of the sciatic nerve). More rarely, pain in the calf muscles may be due to blood clots in leg veins (see *thrombosis, deep vein*). This disorder is a particular risk if a person has been

immobile for a long time – for example, after surgery or during a long journey by air. Another possible problem is *claudication* (cramping pain often due to narrowing of the arteries). In this last condition, pain is often caused by walking and relieved by rest.

caliper splint

An *orthopaedic* device that corrects or controls a deformed leg or supports a leg weakened by a muscular disorder, allowing an affected person to stand and walk. For example, a person who has lost the ability to flex the foot upward and, as a result, drags the toes on the ground with each step can be fitted with a splint that keeps the foot permanently at right angles to the leg, thereby allowing walking.

A caliper splint consists of one or two vertical metal rods attached to leather or metal rings that are worn around the affected limb. A splint extending just below the knee is sufficient to control the position of the ankle. Longer splints may be jointed to allow movement of the knee.

callosity

See *callus, skin*.

callus, bony

A diffuse growth of new, soft bone that forms as part of the healing process in a *fracture*. As healing continues, the callus is replaced by harder bone, and the original shape of the bone is restored.

callus, skin

An area of thickened skin, usually on the hands or feet, caused by regular or prolonged pressure or friction. A *corn* is a callus on a toe. If corns are painful, the thickened skin can be pared away by a chiropodist using a scalpel.

caloric test

A method of finding out whether the *labyrinth* in the inner ear is diseased. A caloric test may be performed as part of investigations into *vertigo* (dizziness) and hearing loss.

The outer-ear canal is briefly flooded with water of different temperatures, above and below normal body temperature. This flooding sets up convection currents in the semicircular canals in the inner ear. If the labyrinth is normal, *nystagmus* (rapid reflex flickering of the eyes) occurs for a predictable period. If the labyrinth is diseased, this response

is either absent or reduced. The presence and duration of nystagmus may be observed directly or recorded electrically using *electronystagmography*.

calorie

A unit of energy. One calorie is the amount of energy that is needed to raise the temperature of 1 gram of water by 1°C. The term "calorie" is also used in medicine and *dietetics* to mean "kilocalorie", which is a larger unit of energy equal to 1,000 calories.

Normally, when a person's calorie intake matches the amount of energy expended, body weight remains constant. If intake exceeds expenditure, weight is usually gained; if expenditure exceeds intake, weight is usually lost. In general, fats contain more calories than proteins or carbohydrates.

Energy can also be measured in joules: 1 calorie equals 4.2 joules. (See also *calorimetry; diet and disease*.)

calorie requirements

See *energy requirements*.

calorimetry

The measurement of the *calorie* (energy) value of foods or the energy expenditure of a person. In direct calorimetry, a small measure of food is burned up inside a sealed container, which is immersed in water. The resultant rise in water temperature is used to calculate the calorie value.

Energy production in humans can be measured by oxygen uptake. Every litre of oxygen taken into the body produces 4.8 kilocalories of energy. The level of energy production is calculated by comparing the percentage of oxygen in air that is inhaled and exhaled.

Calpol

A brand name for paediatric preparations containing the *analgesic drug* (painkiller) *paracetamol*.

camouflaging preparations

Creams or powders that are applied to the skin to conceal skin disfigurements, such as *birthmarks* and scars.

Campbell de Morgan's spot

A small (1–3 mm), bright red, domed spot, also known as a *cherry angioma*, that appears on the trunk or limbs. A Campbell de Morgan's spot is a type of *haemangioma* (a noncancerous blemish). The spots are harmless. They are

caused by weakening of the walls of capillaries in the dermis (the inner layer of the skin). Campbell de Morgan's spots are common in adults, especially elderly people.

Campylobacter

A group of bacteria that are among the most common causes of gastrointestinal disorders. Campylobacter bacteria are harboured by animals and can be passed on to humans through contaminated food, especially in poultry, causing *food poisoning*. These bacteria also cause a form of *colitis*, an inflammatory disease of the colon.

canal

A narrow tubular passage or channel in the body, such as the *ear canal*, which leads from the outer to the middle ear, or the alimentary canal, which is part of the *digestive system*.

cancer

Any of a group of diseases that are characterized by the abnormal and unrestrained growth of cells in body organs or tissues. Cancerous tumours can form in any tissue in the body, but they most commonly develop in major organs, such as in the lungs, breasts, intestines, skin, stomach, or pancreas. Cancerous tumours can also develop in the nasal sinuses, the testes or ovaries, or the lips or tongue. Cancers may also develop in the tissues of the bone marrow that form blood cells (see *leukaemia*) and in the lymphatic system, the muscles, or the bones.

Cancers differ from benign (non-cancerous) *neoplasms* (growths) in that they spread and infiltrate surrounding normal tissue. The tumours can cause blockages in hollow organs, such as within the digestive tract. They can also destroy nerves and erode bone. Cancer cells may also spread through the blood vessels or lymphatic system to other organs to form secondary tumours, known as metastases (see *metastasis*).

CAUSES

Tumour-forming cells develop when the *oncogenes* (genes controlling cell growth and multiplication) in a cell or cells undergo a series of changes. A small group of abnormal cells develop that divide more rapidly than normal, lack differentiation (they no longer perform their specialized task), and may escape the normal control of hormones and nerves.

Possible causes of cancer include environmental factors (such as sunlight and pollutants), alcohol consumption, dietary factors, and, most particularly, smoking, which is responsible for more cancers than any other agent. All of these factors may provoke critical changes within body cells in people who are already susceptible to developing cancer. Susceptibility to certain cancers may be inherited.

SYMPTOMS

Cancer symptoms depend on the site of the growth, the tissue of origin, and the extent of the tumour. They may be a direct feature of the growth (for example, lumps or skin changes) or may result from disruption of the function of a vital organ or blockage of a part of the body by the tumour. Unexplained weight loss is a feature of many different types of cancer.

DIAGNOSIS

Screening tests (see *cancer screening*) are increasingly being used to detect early signs of certain types of cancer in people who are thought to be at risk. Early detection of cancer optimizes the chance of a cure; for this reason, screening for breast cancer, cancer of the cervix, and intestinal cancer has

reduced mortality from these tumours. Diagnosis of cancer after symptoms have appeared is based on a physical examination, and confirmed by *biopsy* (removal of a sample of abnormal tissue for microscopic analysis) and imaging tests.

There are four main types of procedure used to detect cancer: *cytology* (cell) tests, imaging techniques, chemical tests, and direct inspection.

TREATMENT AND OUTLOOK

Many cancers are now curable, usually by combinations of surgery, *radiotherapy*, and *anticancer drugs*. For details of a specific type of cancer, refer to the article on that organ (for example, see *lung cancer*; *stomach cancer*).

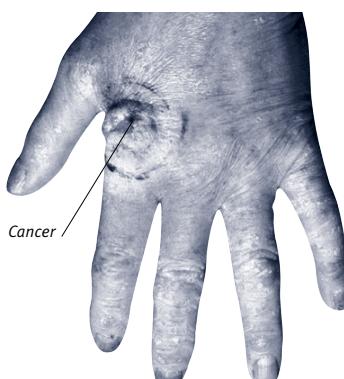

cancerphobia

An intense fear of developing cancer, out of proportion to the actual risk, that significantly affects the life of the sufferer. An individual who has cancerphobia may become convinced that symptoms such as headaches, skin problems, constipation, or difficulty in swallowing, are signs of cancer. Patterns of behaviour that are typical of *obsessive-compulsive disorder* (such as prolonged washing rituals) may be adopted in an attempt to reduce the

TREATMENT OF CANCER

The treatment of many cancers is still primarily surgical. Excision of an early tumour will often give a complete cure. There may be small, undetectable metastases (secondary tumours) at the time of operation, so surgery is commonly combined with radiotherapy and anticancer drugs. The aim of these

treatments is to suppress or arrest the rate of cell division in any tumour cells left after surgery. Anticancer drugs often have unpleasant side effects because it is sometimes difficult to direct specific drugs to their target, and normal cells and tissues may be disrupted along with the tumour cells.

Before radiotherapy
The photograph shows a skin cancer on the back of the hand before treatment.

After radiotherapy
This was the appearance a few weeks later, after a course of radiotherapy.

TESTS USED TO DETECT CANCER		
Cytology tests	These tests reveal the presence of abnormal cells. One example is the <i>cervical smear test</i> , an investigation in which cells are scraped from the cervix (neck of the uterus) and examined microscopically to detect	potential or early cancer of the cervix. Another example is urine cytology, used to detect bladder cancer. Cells can also be removed from solid lumps; this procedure is often carried out on breast lumps.
Imaging techniques	Imaging tests can sometimes reveal changes in the appearance of tissue that are suggestive of cancer. One such test is a low-dose X-ray used in <i>mammography</i> to detect early breast cancer. Another is <i>ultrasound scanning</i> ; for example, pelvic	ultrasound scans can detect cancer of the ovary. CT scanning and MRI provide detailed images of internal anatomy and are particularly useful for showing inaccessible areas, such as the brain and the back of the abdominal cavity.
Chemical tests	Tests on blood, urine, or faeces can show the presence of substances suggestive of cancer. For example, microscopic amounts of blood in the	faeces may be due to cancer of the colon; high blood levels of prostate specific antigen (PSA) are sometimes due to prostate cancer.
Viewing techniques	Viewing tests involve looking inside a hollow organ using an <i>endoscope</i> (a tube with a viewing lens). They are usually performed only when cancer is already suspected. Examples	include <i>colonoscopy</i> , <i>gastroscopy</i> , <i>cystoscopy</i> , and <i>laparoscopy</i> (viewing of the colon, stomach, bladder, and abdominal cavity, respectively).

risk of cancer. *Psychotherapy*, including *behaviour therapy*, may be of benefit. (See also *phobia*.)

cancer screening

Tests that are carried out to detect cancer before symptoms have developed. Cancer screening is used particularly for groups of people who are thought to be susceptible because of their age, occupation, lifestyle, or genetic predisposition. Early detection often increases the chance of a cure. Tests for cancers of the cervix (see *cervical smear test*), breast (see *mammography*), bladder, and colon have proved effective in reducing mortality from these conditions.

cancrum

The medical term for cancer or ulceration. It mainly refers to the mouth and lips, when the condition is known as *cancrum oris*. (See also *noma*.)

candidiasis

Infection by the fungus *CANDIDA ALBICANS*, also known as thrush or moniliasis. Candidiasis affects areas of mucous membrane in the body, most commonly the vagina and the inside of the mouth. In infants, candidiasis can occur in conjunction with *nappy rash*.

CAUSES

The fungus is normally present in the mouth and the vagina, but in some

situations it may multiply excessively. Candidiasis may occur if *antibiotic drugs* destroy the harmless bacteria that control the growth of the fungus, or if the body's resistance to infection is lowered. Certain disorders, for example *diabetes mellitus*, and the hormonal changes that occur during pregnancy or with *oral contraceptives*, may also encourage growth of the fungus.

Candidiasis can be contracted by having sexual intercourse with an infected partner. The infection is far more common in women than in men.

SYMPOTMS

Symptoms of vaginal infection include a thick, white discharge, genital irritation, and discomfort on passing urine. Less commonly, the penis is infected, usually causing *balanitis* (inflammation of the head of the penis). Oral candidiasis produces sore, creamy-yellow, raised patches inside the mouth.

Candidiasis may spread from the genitals or mouth to other moist areas of the body. It may also affect the gastrointestinal tract, especially in people with impaired immune systems, such as those taking *immunosuppressant drugs* or who have HIV (the virus that leads to *AIDS*).

DIAGNOSIS AND TREATMENT

Candidiasis is diagnosed by examination of a sample taken from the white discharge or from patches.

The condition is treated topically with *antifungal drugs* such as clotrimazole or with oral antifungals. The drugs are given in the form of creams, vaginal pessaries, or throat lozenges. Treatment of candidiasis is usually successful, but the condition may recur.

Canesten cream

A brand name for the *antifungal drug* clotrimazole, used to treat fungal infections of the skin and genitals (for example, *candidiasis*).

canine tooth

See *teeth*.

cannabis

A preparation that is derived from the hemp plant *CANNABIS SATIVA* and usually used to produce euphoria and hallucinations (see *marijuana*).

cannula

A smooth, blunt-ended tube that is inserted into a blood vessel, lymphatic vessel, or body cavity, in order to introduce or withdraw fluids.

Cannulas are used for *blood transfusions* and *intravenous infusions* and for draining *pleural effusions* (fluid around the lungs). If necessary, a cannula may be left in place for several days if continuous testing of, or introduction of, fluids is required.

canthus

The anatomical term for the corner of the eye (the angle at which the upper and lower eyelids meet).

capacity, iron-binding

A measure of the level of transferrin, a protein that acts in addition to *haemoglobin* (the oxygen-carrying pigment in the blood) to bind and transport iron in the blood. Measuring iron-binding capacity may help to establish the cause of *anaemia* (a reduced level of haemoglobin in the blood).

Transferrin is formed mainly in the *liver*. The amount produced is determined by the amount of iron that is stored in the body. When iron stores are low, as occurs in iron-deficiency anaemia (see *anaemia*, *iron-deficiency*), more transferrin is produced to enable the blood to carry as much iron as possible. The level of transferrin and the iron-binding capacity of the blood are thereby raised, although the level of iron in the body is low.

capacity, vital

The maximum volume of air, usually around 4.5 litres, that can be expelled from the lungs following maximum inhalation. Vital capacity is measured as part of lung function tests (see *pulmonary function tests*).

cap, cervical

A flexible contraceptive device that is placed directly over the *cervix* to prevent sperm from entering it (see *contraception, barrier methods of*).

cap, duodenal

See *duodenal cap*.

Capgras' syndrome

The delusion (false belief) that a relative or friend has been replaced by an identical impostor. Capgras' syndrome, also known as the "illusion of doubles", is seen most frequently in patients with paranoid *schizophrenia* but can also occur in some organic brain disorders (see *brain syndrome, organic*) and *affective disorders*.

capillary

Any of the vessels that carry blood between the smallest arteries, or arterioles, and the smallest veins, or venules (see *circulatory system*). Capillaries form a fine network throughout the body's organs and tissues. Their thin walls are permeable; as a result, they allow blood and cells to exchange constituents such as oxygen, glucose, carbon dioxide, and water (see *respiration*).

Capillaries open and close to blood flow according to the requirements of different organs for oxygen and nutrients. For example, when a person is running, most of the capillaries in the leg muscles are open, but at rest many are closed. The opening and closing of skin capillaries helps to regulate *temperature*. The blood flow through each capillary is controlled by a tiny circle of muscle at its entrance.

DISORDERS

A direct blow to an area of the body may rupture the capillary walls, causing bleeding under the skin, which in turn results in swelling and bruising.

Capillaries become more fragile in elderly people, in people taking high doses of *corticosteroid drugs*, and in those suffering from *scurvy* (vitamin C deficiency). All such people have a tendency to develop *purpura* (small areas of bleeding under the skin which often appear as reddish-purple patches).

capillary haemangioma

See *haemangioma*.

Caplan's syndrome

A combination of *rheumatoid arthritis* and *pneumoconiosis* (a lung disorder that is caused by inhalation of certain mineral dusts). In Caplan's syndrome, large areas of fibrous (scar) tissue form in the lungs, often causing severe shortness of breath.

capping, dental

See *crown, dental*.

capsule

An anatomical structure enclosing an organ or body part. For example, the liver, kidneys, joints, and eye lenses are all enclosed in capsules.

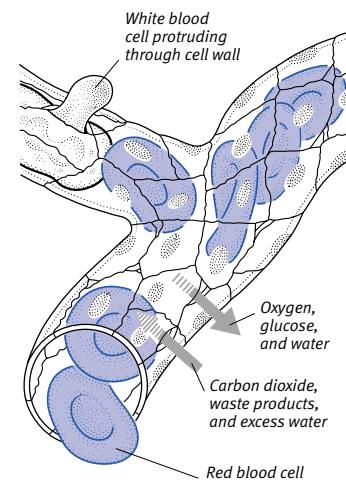

The term "capsule" is also used to describe a soluble, elongated shell, usually made of gelatine, which contains a drug to be taken by mouth. The coating of some capsules prevents potentially irritant drugs from being released into the stomach, or allows drugs to be released slowly to enable them to be taken less frequently.

capsulitis

Inflammation of a *capsule*, a structure that encloses an organ or joint. One example of capsulitis is *frozen shoulder*.

STRUCTURE OF CAPILLARIES

These minute blood vessels have thin, permeable walls, which allow the transfer of oxygen, glucose, and water from blood to tissues.

**captopril**

An *ACE inhibitor drug*. These drugs are used in the treatment of *hypertension* (high blood pressure), *heart failure*, and *diabetic nephropathy* (kidney damage).

caput

The Latin word for head. The term is commonly used of the *caput succedaneum*: a soft, temporary swelling in the scalp of newborn babies, which is caused by pressure during labour. The word "caput" was once also used to refer to the face, skull, and associated organs; to the origin of a muscle; or to any enlarged extremity, such as the *caput femoris*, the head of the femur (thigh bone).

carbamazepine

An *anticonvulsant drug* that is chemically related to the *tricyclic antidepressants*. Taken orally or as suppositories, carbamazepine reduces the frequency of seizures that are caused by abnormal nerve signals in the brain and is used mainly in the long-term treatment of *epilepsy*. The drug is also prescribed to relieve *neuralgia* (intermittent severe pain caused by nerve damage or irritation) and as a mood-stabilizing drug in the treatment of psychiatric disorders such as *mania*.

carbaryl

An insecticide used to treat head *lice* and *crab lice*. Carbaryl is applied topically as a liquid; however, it must not come into contact with the eyes or with areas of broken skin.

carbenoxolone

An *ulcer-healing drug* that is used to treat inflammation and ulceration of the oesophagus, but which has now largely been superseded by antibiotics and by proton pump inhibitors. A gel containing carbenoxolone is commonly used to relieve mouth ulcers.

carbimazole

A drug that is used to treat *hyperthyroidism* (overactivity of the thyroid gland). Carbimazole is slow to take effect, so *beta-blockers* may be given to relieve symptoms in the interim.

Long-term treatment with carbimazole may reduce the production of blood cells by the bone marrow, so regular blood counts are required. Side effects may include headaches, dizziness, joint pain, and nausea.

carbocisteine

A type of *mucolytic drug* that is used to thin sputum, making it easier to cough up. Carbocisteine may be helpful in chronic obstructive pulmonary disease (see *pulmonary disease*, *chronic obstructive*) and *cystic fibrosis*.

carbohydrates

A group of compounds, including starches (complex carbohydrates) and sugars (simple carbohydrates), that are composed of carbon, hydrogen, and oxygen and supply the body with its main source of energy.

TYPES AND SOURCES

Carbohydrates are found in fruits, cereals, and root vegetables. They fall into two main groups: available carbohydrates and unavailable carbohydrates.

The main available carbohydrates are starches and sugars, which are metabolized into glucose for the body's use. Unavailable carbohydrates include cellulose, which cannot be broken down by digestive enzymes and makes up the bulk of dietary fibre (see *fibre, dietary*).

CARBOHYDRATE METABOLISM

The different types of carbohydrates are processed by the body in different ways. Monosaccharides (also known as simple sugars), which include glucose (grape sugar), galactose (a milk sugar), and fructose (fruit sugar), can all be absorbed, unchanged, into the bloodstream, whereas disaccharides (also known as "double" sugars), including sucrose, maltose, and lactose (a milk sugar), need to be broken down into simple sugars before they are absorbed. Starches also have to be broken down

into simple sugars before they can be absorbed by the body. This process is carried out by enzymes (chemical catalysts) in the digestive tract.

The simple sugars (mainly glucose) are then absorbed through the intestinal wall and into the bloodstream for distribution throughout the body. Some glucose is burned up immediately (see *metabolism*) in order to generate energy for cells that need a constant supply, such as brain cells and red blood cells. Galactose and fructose are converted to glucose in the liver to be used by body cells. Surplus glucose is transported to the liver, muscles, and fat cells where it is converted into *glycogen* and fat for storage.

When blood glucose levels are high, glucose storage is stimulated by *insulin*, a hormone that is secreted by the *pancreas*. When blood glucose levels become low, insulin secretion diminishes and *glucagon*, another hormone produced by the pancreas, stimulates the conversion of stored glycogen to glucose for release into the bloodstream. Fat cannot be converted to glucose, although it can be used as a fuel to conserve glucose.

In the disorder *diabetes mellitus*, carbohydrate metabolism is disturbed by a deficiency of insulin.

carbolic acid

See *phenol*.

carbon

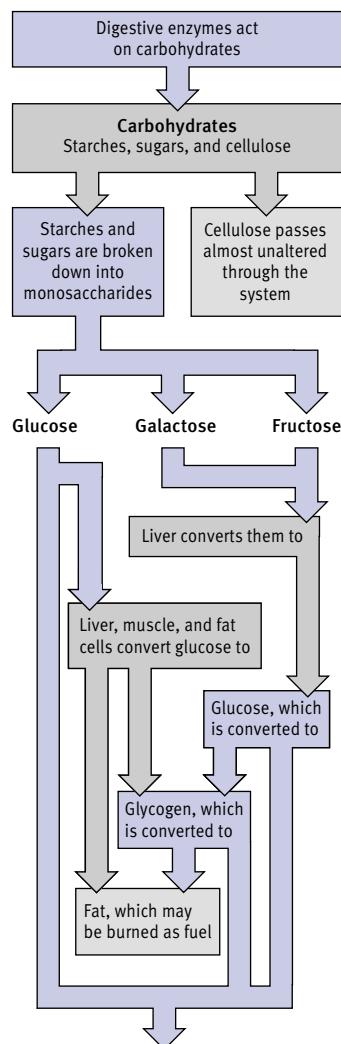

A nonmetallic element that is present in all the fundamental molecules of living organisms, such as *proteins*, *fats*, and *carbohydrates*, and well as in some inorganic molecules, such as *carbon dioxide*, *carbon monoxide*, and *sodium bicarbonate*. Pure carbon is the major constituent of diamond, coal, charcoal, and graphite.

carbon dioxide (CO_2)

A colourless, odourless gas. Carbon dioxide consists of one carbon atom linked to two oxygen atoms and has the chemical formula CO_2 . The gas is present in small amounts in the air and is an important by-product of *metabolism* in cells. It is produced by the breakdown of substances such as carbohydrates and fats to produce energy. It is then carried in the bloodstream to the lungs, where it is exhaled.

Carbon dioxide helps to control the rate of respiration: when a person exer-

CARBOHYDRATE METABOLISM

cises, CO_2 levels in the blood rise, causing the person to breathe more rapidly in order to expel carbon dioxide and to take in more *oxygen*.

Carbon dioxide that is compressed and cooled to -75°C becomes solid *dry ice*, which is used in *cryosurgery* (destruction of diseased tissues by freezing).

carbon monoxide (CO)

A colourless, odourless, poisonous gas. Carbon monoxide consists of one carbon atom linked to one oxygen atom and has the chemical formula CO. It

toxin is present in vehicle exhaust fumes and is produced by inefficient burning of coal, gas, or oil.

POISONING

Carbon monoxide is toxic because it binds with *haemoglobin* (the oxygen-carrying molecule in red blood cells), which prevents the blood from carrying oxygen to the body tissues. As a result, the tissues are deprived of oxygen, and asphyxiation occurs. The initial symptoms of acute high-level carbon monoxide poisoning include dizziness, headache, nausea, and faintness. Continued inhalation of the gas may lead to loss of consciousness, permanent brain damage, and even death. Low-level exposure to carbon monoxide over a period of time may cause fatigue, nausea, diarrhoea, abdominal pain, and general malaise.

carbon tetrachloride (CCl_4)

A colourless, poisonous, volatile chemical with a characteristic odour. Carbon tetrachloride consists of one carbon atom linked to four chlorine atoms and has the chemical formula CCl_4 . Formerly used in domestic dry-cleaning fluids, its use is now restricted to industry.

Carbon tetrachloride is an extremely dangerous chemical, and it can cause dizziness, confusion, and liver and kidney damage if a significant amount of the chemical is inhaled or swallowed. (See also *household poisons*.)

carbuncle

A cluster of interconnected *boils* (painful, pus-filled, inflamed hair roots). Carbuncles are usually caused by infection with the bacterium *STAPHYLOCOCCUS AUREUS*. The back of the neck and the buttocks are the most common sites. The swellings mainly affect people with reduced immunity, particularly those with *diabetes mellitus*.

Treatment is usually with an *antibiotic drug*. In addition, the application of hot *compresses* may encourage the pus-filled heads of the boils to burst, which relieves pain. Occasionally, incision and drainage (together with removal of the core of the carbuncle) may be necessary if a carbuncle is persistent, and drainage and healing have not occurred spontaneously.

carcinogen

Any agent that is capable of causing *cancer*, such as tobacco smoke, high-energy *radiation*, or asbestos fibres.

CHEMICAL CARCINOGENS

Chemicals form the largest group of carcinogens. Major types include polycyclic aromatic hydrocarbons (PAHs), which occur in tobacco smoke, pitch, tar fumes, and soot. Exposure to PAHs may lead to cancer of the respiratory system or skin. In addition, certain aromatic amines used in the chemical and rubber industries may cause bladder cancer after prolonged exposure.

PHYSICAL CARCINOGENS

The best-known physical carcinogen is high-energy radiation, such as nuclear radiation and *X-rays*. Radiation may also come from *ultraviolet light*, for example in sunlight. Another known physical carcinogen is asbestos (see *asbestos-related diseases*).

Exposure to radiation may cause cancerous changes in cells, especially in cells that divide quickly; for example changes in the precursors of white blood cells in the bone marrow causes *leukaemia*. The level of risk depends on the dosage and duration of exposure to the carcinogen. Over many years, exposure to ultraviolet radiation in sunlight can cause skin cancer.

BIOLOGICAL CARCINOGENS

Only a few biological agents are known to cause cancer in humans. *SCHISTOSOMA HAEMATOBIUM*, one of the blood flukes responsible for the tropical disease *schistosomiasis*, can cause cancer of the bladder; and *ASPERGILLUS FLAVUS*, a fungus that produces the poison *aflatoxin* in stored peanuts and grain, is believed to cause liver cancer.

Viruses that are associated with cancer include some strains of the human papilloma virus, which are linked to cancer of the cervix; the hepatitis B and C viruses, which are linked to liver cancer; and some types of herpes virus, which are associated with *Kaposi's sarcoma* and *Burkitt's lymphoma*.

AVOIDANCE OF CARCINOGENS

In industry, known carcinogens may be banned. Alternatively, as in the nuclear industry and in hospital X-ray departments, they may be allowed only if their use is considered essential, if exposure to them is strictly limited, and if regular medical screening is provided for workers using them.

Outside industry, people are exposed to very few known, unavoidable, high-risk carcinogens. Any substance that could possibly be carcinogenic, such as a food additive, a cosmetic, or a chemical for use in drugs, must be carefully

screened by an official body (such as the Medicines Control Agency, which assesses drugs in the UK) before it is allowed to be manufactured.

carcinogenesis

The development of a *cancer* caused by the action of *carcinogens* (factors that cause cancer) on normal cells.

Carcinogens are believed to alter the DNA in cells, particularly in *oncogenes* (genes that control the growth and division of cells). An altered cell divides abnormally fast, passing on the genetic changes to all of its offspring cells. Thus, a group of cells is established that is not affected by the body's normal restraints on growth.

carcinoid syndrome

A rare condition caused by an intestinal or lung tumour, called a carcinoid, which secretes excessive amounts of the hormone *serotonin* and often also other chemicals, such as *bradykinin*. Carcinoid syndrome is characterized by bouts of facial flushing, diarrhoea, and wheezing, but symptoms usually occur only if the tumour has spread to the liver or has arisen in a lung.

Carcinoid tumours in the intestine, lung, and, more rarely, the liver are sometimes removed surgically, but, in most cases, surgery is unlikely to be of benefit. In these circumstances, symptoms may be relieved by drugs such as *octreotide*, which often inhibits the growth of the tumour.

carcinoid tumour

A type of hormone-secreting cancerous tumour. Carcinoids most often occur in the small intestine or rectum but occasionally also develop in the lungs. (See also *carcinoid syndrome*.)

carcinoma

Any cancerous tumour (see *cancer*) that arises from cells in the covering surface layer or lining membrane of an organ. A carcinoma is distinguished from a *sarcoma*, which is a cancer arising in bone, muscle, or connective tissue. The most common cancers of the lungs, breast, stomach, skin, cervix, colon, and rectum are carcinomas.

carcinoma in situ

The earliest, usually curable, stage of a cancer. In this stage, the disease has not yet spread from the surface layer of cells in an organ or other tissue.

carcinomatosis

The presence of cancerous tissue in different sites of the body due to the spread of *cancer* cells from a primary (original) cancerous tumour.

SYMPOTMS

The symptoms of carcinomatosis may include weight loss, lack of energy, and various other problems depending on the sites of the metastases (secondary tumours). For example, metastases in the lungs may cause coughing and breathlessness; those that develop in the liver may cause jaundice.

DIAGNOSIS AND TREATMENT

A diagnosis of carcinomatosis may be confirmed by *X-rays* or by *radionuclide scanning* of the bones and lungs, by biochemical tests, or in the course of an operation. *Anticancer drugs* or *radiotherapy* may be given to destroy the metastases. The condition will not be improved by removing the primary tumour unless the tumour is producing a hormone that directly stimulates the growth of metastases.

cardiac aneurysm

Ballooning of an area of a ventricle (lower chamber) of the heart, usually as a result of damage following a *myocardial infarction* (heart attack). (See also *ventricular aneurysm*.)

cardiac arrest

A halt in the pumping action of the heart. Cardiac arrest occurs when the heart's rhythmic muscular contractions stop, and usually results from abnormal electrical activity. It causes sudden collapse, loss of consciousness, and the absence of pulse and breathing.

CAUSES

The most common cause of cardiac arrest is a *myocardial infarction* (heart attack). Other possible causes include *respiratory arrest*, *electrical injury*, loss of blood, *hypothermia*, drug overdose, and *anaphylactic shock* (an extremely severe type of allergic reaction).

DIAGNOSIS AND TREATMENT

The survival of the patient depends on prompt restoration of the heartbeat and the oxygen supply to the brain. *Cardiopulmonary resuscitation* may be used to maintain the circulation until the heartbeat resumes.

A diagnosis of cardiac arrest can only be confirmed by monitoring the electrical activity of the heart using *ECG*. This helps medical personnel distinguish between ventricular fibrillation

(the rapid, uncoordinated contraction of individual heart muscle fibres) and asystole (the complete absence of heart muscle activity), which are the two abnormalities of heart rhythm that can lead to cardiac arrest.

Ventricular fibrillation may be corrected by *defibrillation* (the application of an electric shock to the heart). Asystole is more difficult to reverse but may respond to injection of *adrenaline* or to an electrical *pacemaker*.

OUTLOOK

In general, recovery after ventricular fibrillation is more likely than after a cardiac arrest triggered by asystole.

cardiac arrhythmia

See *arrhythmia*, *cardiac*.

cardiac asthma

Difficulty in breathing that is similar to asthma but is the result of *pulmonary oedema* (fluid on the lungs); the oedema, in turn, is due to *heart failure* (the inability of the heart to cope with its workload). Attacks of cardiac asthma usually occur at night. The disorder is not related to bronchial *asthma* and requires different treatment.

cardiac catheter

See *catheterization*, *cardiac*.

cardiac cycle

The sequence of events, lasting for less than a second, that make up each beat of the *heart*. A heartbeat has three phases: diastole, atrial systole, and ventricular systole. In diastole, the heart relaxes. During atrial systole, the *atria* (upper chambers of the heart) contract, and in ventricular systole, the *ventricles* (the heart's lower chambers) contract. The *sinoatrial node* (the heart's natural pacemaker) regulates the timing of the phases by sending electrical impulses to the atria and the ventricles.

cardiac dysrhythmia

See *dysrhythmia*, *cardiac*.

cardiac massage

Rhythmic compression of the heart. Cardiac massage is performed when the heart has stopped beating, in order to maintain blood circulation, especially to vital organs such as the brain. It involves repeatedly squeezing the heart to force blood out of it and into the circulatory system, then releasing the pressure on the heart so that it fills

with blood again. Cardiac massage is continued until the heart resumes beating or the person is declared dead.

There are two main types: *external cardiac massage*, which involves pressing on the chest to squeeze the heart, and *internal cardiac massage*, when the exposed heart is massaged by hand. (See also *cardiopulmonary resuscitation*.)

cardiac muscle

See *muscle*.

cardiac neurosis

Excessive anxiety about the condition of the heart. Cardiac neurosis usually follows a *myocardial infarction* (heart attack) or heart surgery, but sometimes occurs when the person has had no previous heart trouble.

A person who has cardiac neurosis experiences symptoms that are typical of heart disease, such as breathlessness and chest pain, and may be reluctant to exercise or work for fear of having a heart attack. Medical investigation reveals no physical problem, however.

Psychotherapy may help an affected person to overcome the anxiety and resume a normal, active life.

cardiac oedema

An abnormal build-up of fluid in body tissues that is caused by *heart failure* (inability of the heart to cope with its workload). (See also *oedema*.)

cardiac output

The volume of blood pumped by the heart each minute. Cardiac output is a measure that is used to assess how efficiently the heart is working. At rest, a healthy adult's heart pumps between 2.5 and 4.5 litres of blood per minute. During exercise, however, this figure may rise to as much as 30 litres per minute. A low output during exercise may indicate damage to the heart muscle or major blood loss.

cardiac stress test

One of a group of tests used to assess the function of the *heart* in people who experience chest pain, breathlessness, or palpitations during exercise. A cardiac stress test establishes whether the patient has *coronary artery disease* (in which the blood supply to the heart muscle is impaired).

An *ECG* machine records the patterns of the heart's electrical activity while the heart is stressed. This is usually

achieved by the patient exercising on a treadmill or stationary bicycle. Specific changes in the electrical pattern as exercise levels increase indicate *angina pectoris* (chest pain due to impaired blood supply to the heart muscle).

Cardiac stress testing may also be used in conjunction with *radionuclide scanning* in order to identify damaged areas of heart muscle.

cardiology

The study of the function of the *heart* and the investigation, diagnosis, and medical treatment of disorders of the heart and blood vessels, such as *atherosclerosis* (fat deposits on the artery walls) and *hypertension* (high blood pressure).

Some disorders reduce the pumping efficiency of the heart. They include arrhythmias (abnormalities in the rate or rhythm of the heartbeat; see *arrhythmia, cardiac*), *coronary artery disease* (in which the blood supply to the heart muscle is impaired), *cardiomyopathy* (in which the heart muscle itself is abnormal), and *heart valve* disorders.

Some babies are born with structural defects of the heart and/or the major blood vessels that emerge from it (see *heart disease, congenital*). Diseases of the lungs and blood vessels can also have adverse effects on heart function.

Many people with heart problems are treated by their general practitioners, but some may be referred to a cardiologist (a heart specialist). Investigations may include tests such as *echocardiography* (viewing the structure and movement of the heart using ultrasound) and detailed interpretation of *ECGs* (electrocardiograms, which measure the electrical activity of the heart). If coronary artery disease is suspected, the cardiologist may perform coronary *angiography* (taking X-ray images of blood vessels) and possibly widen any blocked blood vessels (see *angioplasty, balloon*). A cardiologist may, in turn, refer a patient to a cardiovascular surgeon if surgical treatment is required.

cardiomegaly

Enlargement of the *heart*. This condition may take the form of *hypertrophy* (thickening) of the heart muscle or of dilatation (increase in volume) of one or more of the heart chambers.

CAUSES

Hypertrophy of the heart muscle occurs in conditions in which the heart has to work harder than normal to

pump blood. These disorders include *hypertension* (high blood pressure), which causes the wall of the left ventricle to thicken; *pulmonary hypertension* (raised blood pressure in the lungs), in which the wall of the right ventricle thickens; and one type of *cardiomyopathy* (disease of the heart muscle), in which the walls of one or both ventricles may thicken.

Dilation of a heart chamber may be due to heart valve incompetence (failure of a valve to close properly after a contraction). In *aortic insufficiency*, failure of the aortic valve to close completely allows blood to flow back from the aorta into the left ventricle after each contraction, eventually enlarging the chamber.

SYMPTOMS

Symptoms of cardiomegaly may not occur until the heart has enlarged to the point where it cannot cope with additional stress (for example, as a result of exercise or infection). The heart's reduced pumping efficiency leads to *heart failure*, with symptoms of breathlessness and ankle swelling.

DIAGNOSIS AND TREATMENT

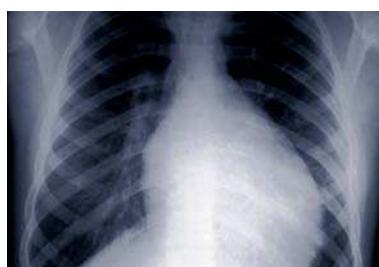

Cardiomegaly is diagnosed by a physical examination, *chest X-ray*, and *ECG* (measurement of the electrical activity of the heart). Treatment is directed at the underlying cause.

cardiomyopathy

Any disease of the heart muscle that weakens the force of cardiac contractions, thereby reducing the efficiency of blood circulation. Cardiomyopathies may be the result of infectious, metabolic, nutritional, toxic, autoimmune, or degenerative disorders. However, in many cases, the cause is unknown.

TYPES

There are three principal forms of the condition: hypertrophic, dilated, and restrictive cardiomyopathy.

Chest X-ray showing cardiomegaly

The heart has become greatly enlarged as a result of the heart-muscle abnormality.

In hypertrophic cardiomyopathy, the heart muscle is abnormally thickened. This condition is usually inherited.

In dilated cardiomyopathy, which is often of unknown cause, *metabolism* (chemical activity) of the heart muscle cells is abnormal and the heart's walls tend to balloon out under pressure.

Restrictive cardiomyopathy is a condition in which the heart walls are unusually inflexible, so that the heart cannot fill sufficiently with blood. It is often caused by scarring of the endocardium (the inner lining of the heart) or by *amyloidosis* (infiltration of the muscle with a starchlike substance).

SYMPTOMS AND SIGNS

Symptoms of cardiomyopathy include fatigue, palpitations, and chest pain. Palpitations may be due to an abnormal heart rhythm such as *atrial fibrillation* (rapid, uncoordinated contractions of the upper chambers of the heart).

The condition may lead to *heart failure*, in which the pumping action of the heart becomes less efficient. Symptoms of heart failure include breathing difficulty and *oedema* (abnormal fluid accumulation in body tissues).

DIAGNOSIS

A *chest X-ray* may show enlargement of the heart, and *echocardiography* (an ultrasound technique for imaging the structure and movement of the heart) may show thickened heart muscle. A *biopsy* (small tissue sample removed for microscopic analysis) of heart muscle may reveal muscle cell abnormalities.

TREATMENT

Symptoms of cardiomyopathy may be treated with *diuretic drugs* to control heart failure and *antiarrhythmic drugs* to correct the abnormal heart rhythm. In many cases, heart muscle function deteriorates, and the only remaining option is a *heart transplant*.

cardiopulmonary bypass

The procedure by which the circulation of blood around the body is maintained while the heart is stopped during heart surgery. A *heart-lung machine* is used to maintain the supply of oxygenated blood to the body tissues.

cardiopulmonary resuscitation

The administration of life-saving measures to a person who has suffered a *cardiac arrest* (in which the heart stops pumping blood). A person in cardiac arrest shows no sign of breathing and has no detectable pulse or heartbeat.

Brain damage is likely if the brain is starved of blood, and therefore oxygen, for more than three to four minutes.

First, mouth-to-mouth resuscitation (see *rescue breathing*) is given in order to restart the casualty's breathing. If this step fails, repeated chest compressions, using the heel of the hand, are applied to the lower part of the breastbone (see *external cardiac massage*) until emergency medical help arrives. These measures are used alternately to restore blood circulation to the brain.

cardiotocography

See *fetal heart monitoring*.

cardiovascular

A term that means "pertaining to the heart and blood vessels".

cardiovascular disorders

Disorders of the heart (see *heart disorders* box), blood vessels, and blood circulation (see *arteries, disorders of, veins, disorders of*).

cardiovascular surgery

The branch of surgery that is concerned with the heart and blood vessels. Cardiovascular surgery can be divided into two main areas.

One area, sometimes called cardiothoracic surgery, includes operations to prevent or repair damage to the heart itself and to the major blood vessels within the chest cavity. Cardiothoracic surgery is used, for example, to help treat damage due to congenital heart disease (see *heart disease, congenital*) or a *myocardial infarction* (heart attack).

The second area, which is known as vascular surgery, is concerned with the treatment of blood vessels elsewhere in the body, such as in the legs. (See also *heart valve surgery, coronary artery bypass, and heart transplant*.)

cardioversion

An alternative name for *defibrillation*.

carditis

A general term for inflammation of any part of the heart or its linings. There are three types. *Myocarditis* (inflammation of the heart muscle) is usually caused by a viral infection. *Endocarditis* (inflammation of the internal lining of the heart) is usually due to a bacterial infection. *Pericarditis* (inflammation of the outer covering of the heart) is usually the result of a viral or bacterial

infection but may be associated with a *myocardial infarction* (heart attack) or an autoimmune disorder, such as *systemic lupus erythematosus*.

caries, dental

The gradual erosion of enamel (the hard covering of a tooth) and dentine (the softer substance that lies beneath the enamel). This condition is more commonly known as tooth decay.

CAUSES

The main cause of dental caries is *plaque*, a sticky substance consisting of food deposits, saliva by-products, and bacteria that collects on the surface of teeth. The breakdown of food deposits by bacteria creates acid that eats into the enamel to form cavities. Left unchecked, decay spreads to the dentine, and as the cavity enlarges, bacteria may invade and destroy the pulp tissue at the core of the tooth.

SYMPOTMS

Initial decay usually occurs on the grinding surfaces of the back teeth and on areas around the gum line. In the

early stages, dental caries does not usually cause any symptoms. Advanced decay causes toothache (see *pulpitis*), however, which may be aggravated by eating very sweet, hot, or cold food. Sometimes advanced decay can also cause halitosis (bad breath).

TREATMENT

Treatment consists of drilling away the area of decay and filling the cavity (see *filling, dental*). In advanced decay, it may be necessary to remove the infected pulp and replace it with a filling (see *root-canal treatment*) or to extract the tooth (see *extraction, dental*).

PREVENTION

The risk of dental caries occurring is reduced by cutting down on sugar consumption, practising good *oral hygiene*, and visiting the dentist regularly. Water *fluoridation* and the use of fluoride toothpaste also helps to prevent caries.

carminative

A medicine that relieves abdominal wind (*flatulence*). Carminatives are used in the treatment of *colic*.

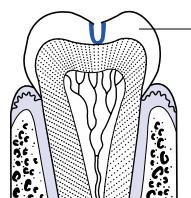

CAUSES OF CARIES (TOOTH DECAY)

The primary cause of tooth decay is dental *plaque*, a sticky substance that forms on the teeth. Plaque consists of food remains, saliva by-products, and the bacteria that live in the mouth. The bacteria feed mainly on the fermentable carbohydrates (simple sugars and starches) in food, and, in breaking them down, create an acid that gradually destroys enamel, forming a cavity. If the process is not checked, the dentine is eroded next, enlarging the cavity and enabling the bacteria to invade the pulp at the centre of the tooth.

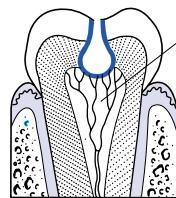

Micrograph of dental caries

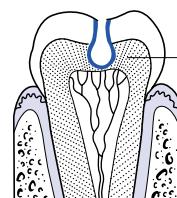

The surface enamel of this decaying molar tooth is being broken down.

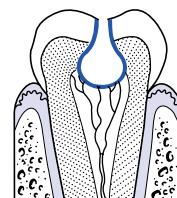

- 1** Acid produced in the breakdown of food gradually destroys enamel, forming a cavity.

- 2** Unchecked, decay spreads to the dentine.

- 3** The cavity continues to enlarge, enabling the bacteria to invade exposed pulp at the tooth's centre.

- 4** If untreated, the infected pulp will die and the tooth will be destroyed.

carotenaemia

A harmless condition in which blood levels of *carotene*, an orange pigment in certain vegetables, are very high as a result of excessive intake of these foods. Carotenaemia may cause temporary yellowing of the skin, especially on the palms and soles. Unlike *jaundice*, carotenaemia does not cause yellowing of the whites of the eyes.

carotene

A yellow or orange pigment found in carrots, tomatoes, and leafy green vegetables. The most important form of carotene is beta-carotene, an *antioxidant*. Beta-carotene is converted in the intestines into retinol (see *vitamin A*), which is essential for vision and healthy skin. Excessive intake of foods containing carotene may cause *carotenaemia* (temporary yellowing of the skin).

carotid artery

Any of the main arteries of the neck and head. There are two common carotid arteries (left and right), each of which divides into two main branches (internal and external).

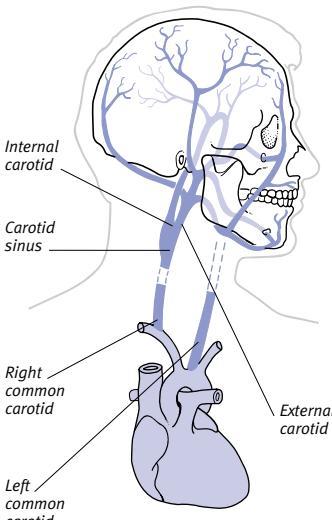

The left carotid artery arises from the *aorta* and runs up the neck on the left side of the *trachea* (windpipe). The right carotid artery arises from the subclavian artery (which branches off the aorta) and follows a similar route on the right side of the neck. Just above the level of the *larynx* (voicebox), each carotid artery divides to form an external carotid artery and an internal carotid artery.

The external arteries have multiple branches that supply most of the tissues in the face, scalp, mouth, and jaws. The internal arteries enter the skull to supply the brain and eyes. At the base of the brain, branches of the two internal carotids and the basilar artery join to form a ring of blood vessels called the circle of Willis. Narrowing of these vessels may be associated with *transient ischaemic attack (TIA)*; obstruction of them causes a *stroke*.

The carotid arteries have two specialized sensory regions in the neck: the carotid sinus, which monitors blood pressure, and the carotid body, which monitors the oxygen content of the blood and helps to regulate breathing. The carotid artery is one of the points at which the *pulse* can be measured. (See also *carotid bruit*; *carotid doppler scanning*; *carotid sinus syndrome*.)

LOCATION OF CAROTID ARTERY

The common carotid artery runs up each side of the neck and divides to form internal and external branches.

carotid bruit

An abnormal noise in a *carotid artery* (one of the major arteries supplying the neck and head), which is due to turbulent blood flow. A doctor can hear the noise with a stethoscope placed on the side of a person's neck, over the artery. A carotid bruit indicates narrowing (stenosis) of the artery, usually due to fatty deposits on the blood vessel lining (see *atherosclerosis*).

carotid doppler scanning

A method for assessing blood flow through the *carotid arteries* (the major arteries supplying the neck and head) by the use of *ultrasound scanning*. Carotid doppler scanning is used to investigate certain disorders, such as carotid artery stenosis (narrowing of the artery), *transient ischaemic attacks*, and *stroke*, that may be the result of narrowing of the common carotid arteries and their branches.

An ultrasound transducer is moved over each side of the neck in the area of the carotid arteries. The transducer emits ultrasound waves, which are reflected off the moving blood cells and blood-vessel walls to produce an image on a screen. This image reveals any narrowing of the arteries or turbulence in blood flow.

carotid sinus syndrome

A condition mainly affecting elderly people, in which the carotid sinus, a structure within the common *carotid artery* of the neck that regulates blood pressure, is overly sensitive.

The carotid sinus is a pocket in the artery at the point where the vessel divides to form two branches. It contains sensors that continually monitor blood pressure. When the blood pressure is raised, the sinus sends messages to the brain, which signals blood vessels to widen and the heart rate to slow, thus lowering the pressure.

In carotid sinus syndrome, the sinus reacts too readily: simply turning the neck suddenly or coughing can trigger the sensors. As a result, the brain slows the heart rate and lowers blood pressure excessively, causing the affected person to faint. This problem may be avoided by the insertion of a *pacemaker*, which will help to maintain a normal heart rate, overriding any inappropriate messages from the carotid sinus.

carpal tunnel syndrome

Numbness, tingling, and pain in the thumb, index finger, and middle fingers. Carpal tunnel syndrome is caused by compression of the *median nerve* at the wrist. The carpal tunnel, through which the nerve passes, is a narrow gap formed by the carpal bones of the wrist and a ligament that lies over them. The condition may affect one or both of the hands and is sometimes accompanied by weakness in the thumb. Symptoms may be worse at night.

CAUSES

Carpal tunnel syndrome is common among people who use computer keyboards, who make constant, repetitive hand movements. The condition also occurs without obvious cause in middle-aged women. In addition, it is quite common in pregnancy; in women who have begun using *oral contraceptives*; in those who suffer from *premenstrual syndrome*; and in men and women who suffer from *rheumatoid arthritis*, *myxedema* (thickening and coarsening of the skin and other body tissues), and *acromegaly* (a condition in which there is abnormal enlargement of the skull, jaw, hands, feet, and internal organs).

TREATMENT

The condition often disappears without any treatment. Persistent symptoms may be treated by the injection of a *corticosteroid drug* under the ligament.

CARPOPEDAL SPASM

Alternatively, the ligament may be cut surgically in order to relieve pressure on the nerve.

carpopedal spasm

Involuntary contraction of muscles in the hands and feet. Carpopedal spasm is due to low levels of calcium in the blood. This problem, in turn, may be caused by *hyperventilation* (abnormally rapid breathing) or by disorders such as *hypoparathyroidism*.

carpus

The eight bones of the wrist.

carrier

A person who is able to pass on an infectious or inherited disease without actually suffering from it themselves.

car sickness

See *motion sickness*.

cartilage

A type of *connective tissue* (a material that holds body structures together) made up of varying amounts of the gel-like substance *collagen*. Cartilage is not as hard as *bone*, but it nevertheless forms an important structural component of various parts of the skeletal system, including the *joints*. Much of the fetal skeleton is formed entirely of

cartilage. During childhood, the cartilage is gradually converted to bone by a process known as *ossification*.

TYPES

There are three main types of cartilage: hyaline cartilage, fibrocartilage, and elastic cartilage. Each type is composed of a different proportion of collagen and has a particular function.

Hyaline cartilage is a tough, smooth tissue that lines the surfaces of joints, such as the knee, providing an almost frictionless layer over the bony parts of the joint. If the lining becomes worn (as occurs in *osteoarthritis*) or damaged, the movement of that joint may be painful or severely restricted.

Fibrocartilage contains a large proportion of collagen and is solid and strong. This type of cartilage makes up the discs that are situated between the bones of the spine (see *disc*, *intervertebral*). It also forms the shock-absorbing pads of tissue within joints.

Elastic cartilage is soft and rubbery. It is found in structures such as the outer ear and the *epiglottis*.

caruncle

A general term for a small, fleshy swelling. Caruncles can be normal, such as the red, raised tissue in the inner corner of the eye. Some are abnormal, appearing as polyp-like growths; this type may be found, for example, at the opening of the urethra (the tube by which urine leaves the bladder).

Casal's necklace

A red rash forming a clearly defined ring around the neck. It is a symptom of *pellagra*, a disorder caused by lack of the B vitamin niacin in the diet.

cascara

A type of stimulant *laxative drug*, which can be used when rapid onset of action is needed. Cascara is now rarely used.

caseous abscess

An *abscess* (collection of pus) containing matter that resembles curds or cottage cheese. Caseous abscesses are most commonly due to *tuberculosis*.

cast

A rigid casing applied to a limb or other part of the body to hold a broken bone or dislocated joint in position as it heals. Most casts are made of bandages impregnated with resin or *plaster of Paris*, which are applied while wet and

harden as they dry. Casts are removed using an electric saw that cuts through the cast but does not damage the skin.

castor oil

A colourless or yellow-tinged oil that is obtained from the leaves of the castor oil plant, *RICINUS COMMUNIS*. If taken orally, castor oil irritates the lining of the small intestine and has a powerful laxative action that completely empties the bowel. Zinc and castor oil are combined in a soothing ointment to treat conditions such as *nappy rash*.

castration

The surgical removal of the testes (see *orchidectomy*). The term "castration" is sometimes also used to refer to removal of the ovaries (see *oophorectomy*).

Castration is performed when the testes or ovaries are diseased. It may also be carried out in order to reduce the level of *testosterone* (a male sex hormone produced in the testes) or of *oestrogen* (a female sex hormone produced in the ovaries) in people who have certain types of *cancer* that are stimulated by these hormones.

Orchidectomy and oophorectomy are performed less frequently since the introduction of *gonadorelin* analogues, which are drugs that also act to reduce the amount of testosterone and oestrogen produced by the body.

catabolism

A chemical process by which constituents of food stored in the body (for example, fats) are broken down, releasing energy into the body cells (see *biochemistry*; *metabolism*).

catalepsy

A physical state in which the muscles of the face, body, and limbs stay in a semi-rigid, statuelike position for minutes, hours, or even days. Catalepsy sometimes occurs in people who have *schizophrenia* or *epilepsy* but may also be due to brain disease or certain drugs.

catalyst

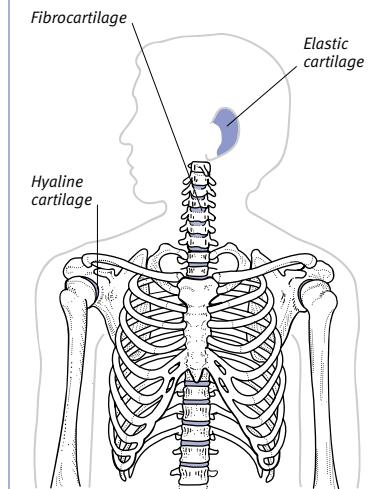

A substance, such as an *enzyme*, that increases the rate of a chemical reaction without being permanently changed itself by that reaction.

cataplexy

A sudden loss of muscle tone, causing an involuntary collapse without loss of consciousness. Triggered by intense

TYPES OF CARTILAGE

The three main types of cartilage have different amounts of collagen, vary in toughness and elasticity, and exist at different sites in the body.

emotion, particularly laughter, it occurs almost exclusively in sufferers of sleep disorders such as *narcolepsy*.

cataract

Loss of transparency of the *lens* of the *eye*, as a result of changes in its protein fibres. At an advanced stage, the front part of the lens becomes densely opaque, but the cataract never causes total blindness. A densely opalescent lens will still transmit light, but the clarity and detail of the image will be lost. Cataract usually occurs in both eyes, but in most cases one eye is more seriously affected than the other.

CAUSES

Almost everyone over 65 has some degree of cataract; the condition might be considered part of the normal aging process. Regular exposure to *ultraviolet light* increases the risk.

Other causes of cataract include an injury to the eye, particularly if a foreign body enters the lens. Cataract is also common in people with *diabetes mellitus* and may develop at an earlier age if blood sugar levels are not well controlled. Long-term use of *corticosteroid drugs* may contribute to cataract.

Congenital cataract may be due to an infection of the mother in early pregnancy, especially with *rubella* (German measles), or to the toxic effects of certain drugs in pregnancy. It may also be associated with *Down's syndrome* or the rare genetic disorder *galactosaemia*.

SYMPTOMS

Cataract is entirely painless and causes only visual symptoms. The onset of symptoms is almost imperceptible, although night driving may be affected in the early stages. There is slow, progressive loss of visual acuity (increasing blurring of vision). The person may become shortsighted and notice disturbances in colour perception.

TREATMENT

When vision has become significantly impaired, *cataract surgery* is performed to remove the lens and replace it with an implant. Provided the eye is otherwise healthy, cataract surgery generally gives excellent results.

cataract surgery

Removal of the *lens* from the eye. Cataract surgery is done to restore sight in people whose vision is impaired by a *cataract*. The lens is usually replaced with a plastic implant during the operation. Alternatively, for young people

and those with other eye disorders, a contact lens or spectacle lens fitted after the operation may be preferable.

catarrh

Oversecretion of mucus by inflamed *mucous membranes* (see *rhinitis*), sinuses (see *sinusitus*) or air passages.

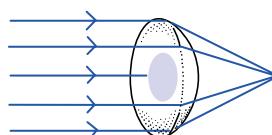

catatonia

A state in which a person becomes mute or adopts a bizarre, rigid pose. The eyes usually remain open and the person may seem awake, but they make no voluntary movements. The state is seen in a rare form of *schizophrenia* and some types of brain disease.

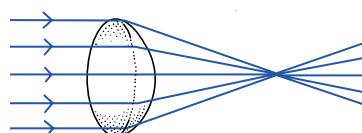

PROCEDURE FOR CATARACT SURGERY

In a normal, healthy lens there is no interference with the passage of light rays. Even when peripheral opacities develop, vision is not limited until the central zone is affected. Dense nuclear

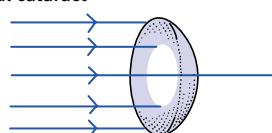

Dense nuclear cataract

Normal lens

Peripheral cataract

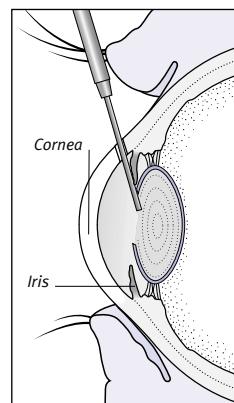

opacities, however, such as that shown on the right, cause deteriorating vision. The affected lens cannot be restored to its former transparency, hence the need for surgical replacement.

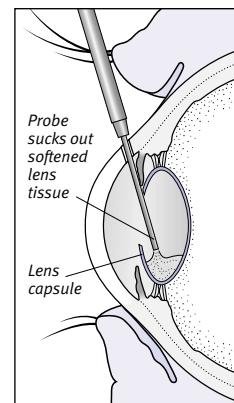

Appearance of cataract

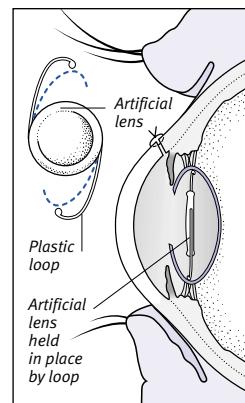

In preparation for surgery, measurements are taken of the cornea and the eye's length to calculate the power of the lens implant that will be needed to restore vision fully. The operation may be performed using general or local anaesthesia; there is no pain in either case. Instruments of remarkable delicacy and precision are used for the procedure, usually with the help of microscope magnification.

1 An ultrasound probe is inserted into the lens capsule through a small incision in the cornea. The incision is made using a diamond tipped instrument.

2 The ultrasound probe softens the lens by emitting sound waves. It then sucks out the softened lens tissue. Only the front part of the lens capsule is removed.

3 An artificial lens is placed inside the lens capsule. The incision in the cornea is left to heal naturally, or it may be closed with a few surgical stitches.

cathartis

A word that means purification or cleansing. The term "catharsis" is used in medicine to refer to the process of cleaning out the bowels. In addition, the term was used by Sigmund Freud in *psychoanalytic theory* to describe the expression of previously repressed feelings and memories. Freud believed that the revival of "forgotten" memories and the expression of the emotions associated with them could bring relief from anxiety, tension, and a variety of other psychological symptoms.

cathartic

A term that means "having the power to purify or cleanse". A cathartic drug stimulates movement of the bowels (see *laxative drugs*).

catheter

A flexible tube that is inserted into the body to drain or introduce fluids or to carry out other functions. Catheters are commonly used to drain urine from the bladder (see *catheterization, urinary*). Other procedures using catheters may be performed in order to investigate the condition of the heart (see *catheterization, cardiac*), to widen obstructed blood vessels, or to control bleeding. (See also *balloon catheter*.)

catheterization, cardiac

A diagnostic procedure in which a fine, sterile *catheter* (flexible tube) is introduced into the heart through a vein or artery in the arm or leg. Cardiac catheterization is used to diagnose and assess the extent of congenital heart disease (see *heart disease, congenital*) and *coronary artery disease*, and to diagnose and treat some disorders of the heart valves (see *valvuloplasty*).

During the procedure, the pressure within the chambers of the heart may be measured, samples of blood and tissue may be taken for laboratory analysis, or a radiopaque dye (a substance that is opaque to X-rays) may be injected into the arteries in order for the cavities of the heart to be visible on an X-ray (see *angiography*).

The procedure causes little discomfort and is performed under local anaesthesia (see *anaesthesia, local*). A small incision is made in an artery or vein near the skin surface, and the catheter is introduced into the vessel. The tube is passed along the blood vessels and into the heart.

catheterization, urinary

The insertion of a sterile *catheter* (a flexible tube) into the *bladder* in order to drain urine from the body.

WHY IT IS DONE

Urinary catheterization is carried out when a person is unable to empty the bladder normally or is incontinent (see *incontinence, urinary*). The procedure is also performed during certain operations in which a full bladder might block the surgeon's view of surrounding organs; in bladder function tests such as *cystometry* and *cystourethrography*; and to monitor urine production in critically ill patients.

HOW IT IS DONE

There are two principal techniques: urethral catheterization (described in the illustrated box below), and suprapubic catheterization.

Suprapubic catheterization is used if it is not possible to pass a catheter up the urethra (for example, if the urethra is abnormally narrow). This form of catheterization involves the insertion of

a catheter into the bladder directly through the abdominal wall, and this is carried out under local anaesthesia (see *anaesthesia, local*).

cation

An *ion* of positive charge. An example of a cation is the sodium ion in saline solution. (See also *electrolyte*.)

cation exchange resin

A type of drug used to remove excess *potassium* that has accumulated in the body because of *renal failure*.

CAT scanning

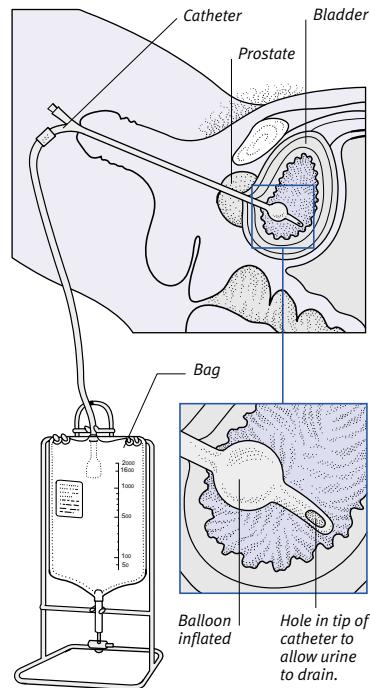

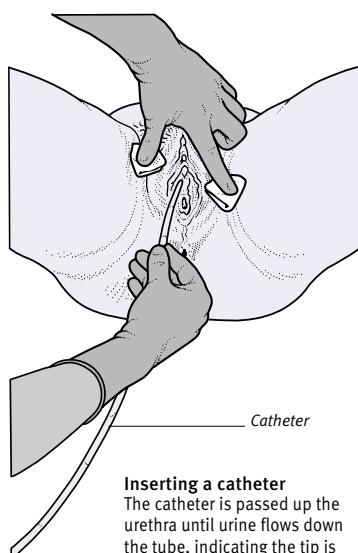

An abbreviation for computerized axial tomographic scanning, which is commonly known as *CT scanning*.

cat-scratch fever

An uncommon disease that develops in people (mostly children) who have suffered a scratch or bite from a cat. The fever is due to infection with a bacterium called *BARTONELLA HENSELAE*.

URETHRAL CATHETERIZATION OF THE BLADDER

A urinary catheter is usually passed into the bladder through the urethra. First, the doctor or nurse cleans the opening of the urethra with antiseptic solution to avoid introducing infection into the urinary tract. He or she then applies a local anaesthetic gel to the urethra. The procedure usually takes about 10 minutes.

SYMPTOMS

The main symptom, appearing three to ten days after the bite or scratch, is a swollen *lymph node* near the affected area. The node may become painful and tender, and an infected blister may develop at the site of the injury. A fever, rash, and headache may occur.

DIAGNOSIS AND TREATMENT

Diagnosis of cat-scratch fever is confirmed by *biopsy* (removal of a small sample of tissue for microscopic analysis) of the swollen lymph node and by a skin test. *Analgesic drugs* (painkillers) may be used to relieve the fever and headache. In most cases, the illness clears up completely within two months.

cats, diseases from

Cats carry various parasites and infectious organisms that can be spread to humans. Some of these are specific to cats; others may also affect dogs.

SPECIFIC DISEASES

The most serious disease that can be contracted from an infected cat is *rabies*. Anyone who is bitten by a cat (or any other animal) in a country where rabies is present should seek medical advice without delay.

Cat-scratch fever is an uncommon illness that is caused by infection with the bacterium *BARTONELLA HENSELAE* following a scratch or bite from a cat.

Cats commonly carry the *protozoan* (single-celled parasite) *TOXOPLASMA GONDII*, which causes the disease *toxoplasmosis*. Infection with the parasite, which is usually from contact with a cat's faeces, is not generally serious, but it can have severe effects in pregnant women. Infections in early pregnancy can lead to *miscarriage* or severe malformation of the fetus. Later in pregnancy, infections can result in nervous system disorders in the fetus and may even lead to blindness in early childhood.

Cat faeces may also carry eggs of the cat roundworm, a possible cause of *toxocariasis*. Rarely, a larva from an ingested roundworm egg migrates to and lodges in an eye, causing deterioration of vision or blindness. Children who have been playing in sand or soil that has been contaminated by cat faeces are at risk of coming into contact with the worm eggs.

Other cat-related disorders in humans include *tinea* (fungal infections of the skin, hair, or nails), particularly ringworm, (ringlike fungal patches, often on the scalp), bites from cat fleas, and

allergic reactions to dander (scales from animal skin, hair, or feathers) that may cause *asthma* or *urticaria* (nettle rash).

PREVENTION

Diseases from cats can be avoided by good hygiene, such as hand-washing, particularly after touching a cat. All pets should have regular worming and flea treatment and veterinary care if ill.

cauda equina

A "spray" of nerve roots resembling a horse's tail that descends from the lower *spinal cord* and occupies the lower third of the spinal canal.

caudal

This word is used to refer to the lower end of the *spine*. The word "caudal" means "of the tail".

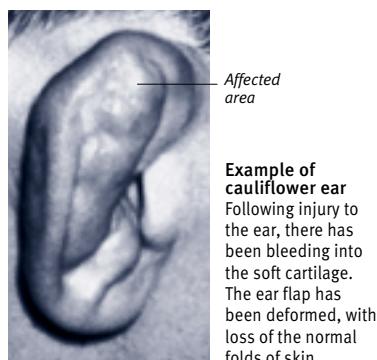

caudal block

A type of *nerve block* in which a local anaesthetic is injected into the lower part of the spinal canal (the central space within the spine). Caudal block may be used to anaesthetize the buttocks and genitals as part of *obstetric* and gynaecological procedures.

cauliflower ear

Painful, swollen distortion of the pinna (ear flap) resulting from blows or friction that have caused bleeding in the soft *cartilage* of the ear.

Immediate treatment following an injury involves the use of ice-packs to reduce the swelling. In severe cases, a doctor may drain blood from the ear and apply a pressure bandage.

**causalgia**

A persistent, burning pain, usually in an arm or leg. Causalgia most often occurs as a result of injury to a nerve by a deep cut, limb *fracture*, or gunshot wound. The skin overlying the painful

area may be red and tender, or blue, cold, and clammy. The condition may be aggravated by light sensations, such as touch, or by emotional factors.

In some cases, treatment with *antidepressant drugs* or *anticonvulsant drugs* is effective. A few people benefit from *sympathectomy*, in which nerves supplying the affected area are severed.

caustic

Describes substances that have a burning or corrosive action on body tissues or a burning taste. An example is caustic soda, the common name for sodium hydroxide. Caustic agents such as silver nitrate are used to destroy warts.

cauterization

The application of a heated instrument to destroy tissues, stop bleeding, or promote healing. Cauterization may be used to treat conditions such as *haemorrhoids* (piles) and *cervical erosion*. It has been largely replaced by *electrocoagulation* (use of high-frequency electric current and, increasingly, laser to seal blood vessels).

Caverject preparations

A brand name for preparations of *alprostadil*, a *prostaglandin drug* used to treat impotence, normally by self-injection.

cavernous sinus thrombosis

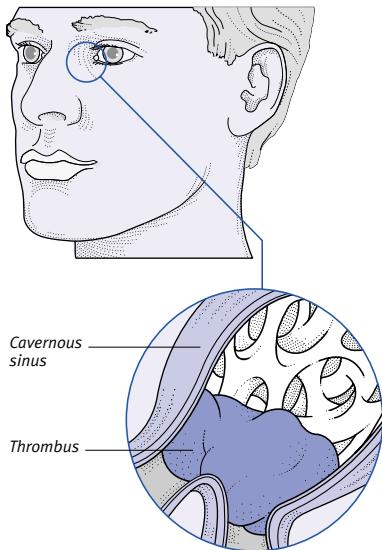

Blockage of a venous *sinus* (a channel for venous blood located deep inside the skull behind an eye socket) by a *thrombus* (an abnormal blood clot). Cavernous sinus thrombosis is usually a complication of a bacterial infection in an area drained by the veins entering the sinus. At first, only the veins behind one eye are affected, but within a few days the thrombosis may spread to the sinus behind the other eye.

CAUSES

Among the infections that can lead to cavernous sinus thrombosis are *cellulitis* (a severe skin infection) of the face, infections of the mouth, eye, or middle ear, *sinusitis* (infection of the air spaces of the facial skull), and *septicaemia* (infection in the bloodstream).

SYMPTOMS

Symptoms of cavernous sinus thrombosis include severe headache, high fever, pain and loss of sensation in and above the affected eye due to the pressure on the fifth cranial nerve, and *proptosis* (protrusion of the eyeball) due to swelling around and behind the eye. In some cases, vision may become blurred

**Thrombus in cavernous sinus**

The clot obstructs blood flow in the cavernous sinus, causing pressure behind the eye socket.

and eye movements may be paralysed due to pressure on the *optic nerve* and other cranial nerves.

TREATMENT

Treatment with *antibiotic drugs* and *anti-coagulant drugs* can save vision. Left untreated, blindness will result, and the infection may eventually prove fatal.

cavity, abdominal

See *abdomen*.

cavity, dental

A hole in a tooth, commonly caused by *dental caries* (see *caries, dental*).

cavity, oral

See *mouth*.

cavity, pelvic

The area of the body that lies below the abdomen, framed by the pelvic bones and lower spine. The pelvic cavity contains the lower digestive and urinary organs, nearly all of the reproductive organs in females, and part of the reproductive system in males.

cavity, pleural

The space between the two layers of the *pleura* (membrane) that lines the chest wall and the outside of the lungs.

CD4 count

A blood test used to monitor *HIV infection* and *AIDS*. The procedure involves counting the number of CD4 *lympho-*

cytes (white blood cells responsible for fighting infection) in a blood sample. CD4 lymphocytes are destroyed by HIV, and reduced levels of these cells indicate the progression of HIV and the eventual development of AIDS.

cefaclor

A common antibiotic that belongs to the group of *cephalosporin drugs*.

cefadroxil

A *cephalosporin drug*, which is used to treat bacterial infections.

cefalexin

A *cephalosporin drug*, which is used to treat bacterial infections.

cefotaxime

A *cephalosporin drug*, which is used to treat bacterial infections.

cefuroxime

A *cephalosporin drug*, which is used to treat bacterial infections.

celecoxib

A COX-2 inhibitor drug (a type of *non-steroidal anti-inflammatory drug*) used to relieve the pain and inflammation of *rheumatoid arthritis* and *osteoarthritis*. Side effects of celecoxib include nausea and diarrhoea. Abdominal discomfort may also occur, but can be minimized by taking the drug with food.

cell

The basic structural unit of all living organisms. The human body comprises billions of cells, which are structurally and functionally integrated to perform the complex tasks necessary for life. In spite of variations in size and function, most of the cells have a similar form.

CELL MEMBRANE

Each cell is a microscopically small bag containing liquid cytoplasm. It is surrounded by a membrane that regulates the passage of useful substances (such as oxygen and nutrients) into the cell and waste materials (such as carbon dioxide) and manufactured substances (such as hormones) out of the cell. Some cells, such as those lining the small intestine, have microvilli, projections that increase the cells' surface area to facilitate absorption.

NUCLEUS

All cells, except red blood cells, have a *nucleus*. The nucleus controls all major cell activities by regulating the amount

and types of *proteins* made in the cell. Inside the nucleus are *chromosomes*, which are made of the nucleic acid *DNA*. This acid contains the instructions for *protein synthesis*, which are carried into the cytoplasm by a type of *RNA* (another nucleic acid) and are decoded in particles called *ribosomes*. The nucleus also contains a spherical structure called the *nucleolus*, which plays a role in the production of ribosomes.

ORGANELLES

In the cytoplasm there are various tiny structures called organelles, each with a particular role. Energy is generated by *mitochondria* breaking down sugars and fatty acids. Substances that would damage the cell if they came into contact with the cytoplasm are contained in particles called *lysosomes* and *peroxisomes*. A system of membranes in the cytoplasm, called the *endoplasmic reticulum*, transports materials through the cell. Flattened sacs called the *Golgi complex* receive and process proteins from the endoplasmic reticulum.

Enzymes and hormones are secreted by vesicles (small saclike structures) at the cell surface. Some waste products and other materials are transported and stored in *vacuoles* (spaces created by the cytoplasm). The cytoplasm has a network of fine tubes (microtubules) and filaments (microfilaments) known as the *cytoskeleton*, which gives the cell a definite shape.

cell death

See *apoptosis*.

cell division

The processes by which cells multiply. *Mitosis* is the most common form of cell division, giving rise to daughter cells identical to the parent cells. *Meiosis* produces egg (see *ovum*) and *sperm* cells that differ from their parent cells in that they have only half the normal number of *chromosomes*.

cellular immunity

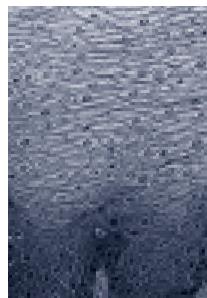

The part of the body's defence mechanisms (see *immune system*) that attacks and destroys harmful cells directly rather than by using *antibodies* (proteins created to combat infection).

Lymphocytes (a type of white blood cell) mount a response against infectious organisms and other abnormal cells, such as cancer cells. There are two main types: T-lymphocytes, which provide cellular immunity, and B-lymphocytes,

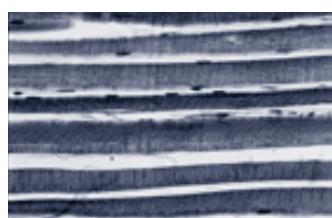

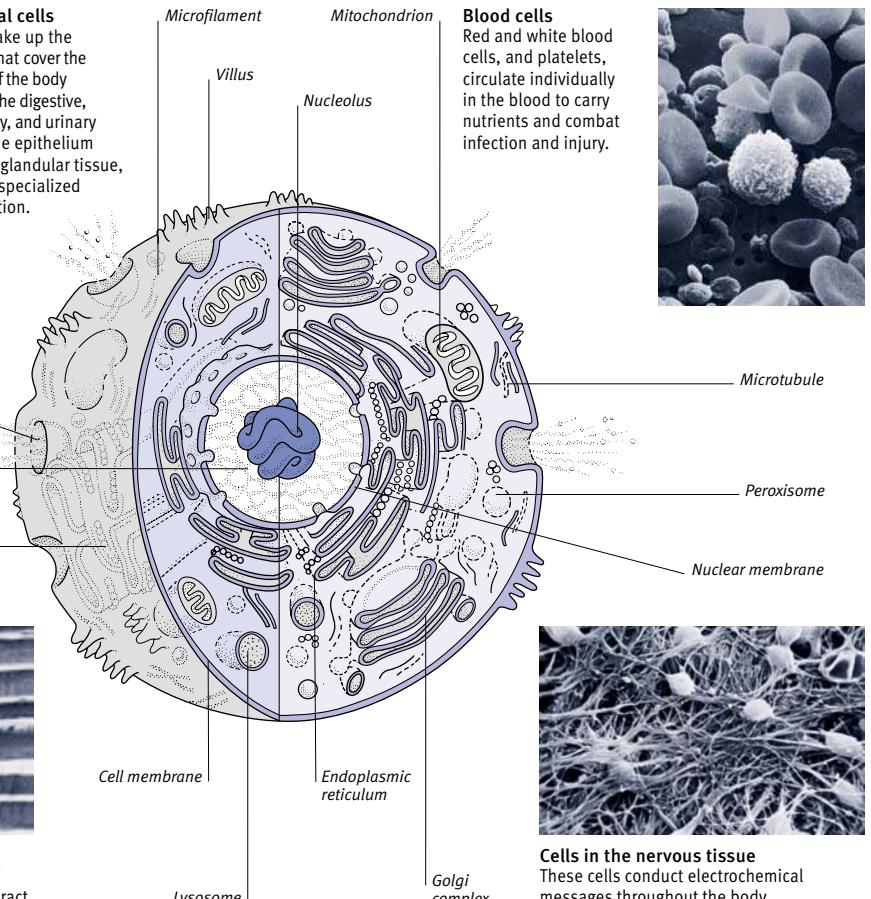

CELL TYPES

Despite their fundamental similarities in structure, the cells of the body are differentiated so that they can perform a variety of specific tasks, such as carrying oxygen (red blood cells), destroying invading microorganisms (white blood cells), and making hormones (secretory cells in glands). Some cells

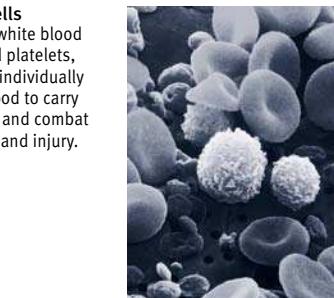

(nerve cells, for instance) cannot be replaced once they have been destroyed, while other cells (those that form toe- and fingernails, for instance) regrow and continue to function even after a person's death. There are four main types of cells, which are grouped according to their primary functions.

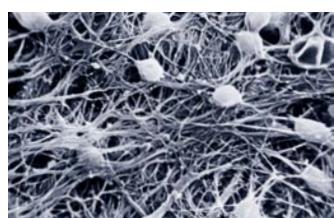

Epithelial cells
These make up the tissues that cover the outside of the body and line the digestive, respiratory, and urinary tracts. The epithelium includes glandular tissue, which is specialized for secretion.

Muscular tissue
Muscle is formed from different types of muscle cells that are specialized to contract.

Blood cells
Red and white blood cells, and platelets, circulate individually in the blood to carry nutrients and combat infection and injury.

Cells in the nervous tissue
These cells conduct electrochemical messages throughout the body.

which produce antibodies. T-lymphocytes recognize specific antigens (substances that the body identifies as foreign), including cancer cells and cells infected by viruses. One group of T-lymphocytes, known as killer T-cells, attach themselves to the abnormal cells and release toxic proteins that destroy them. (See also *humoral immunity*.)

cellular pathology

See *pathology, cellular*.

cellulite

The popular term for the subcutaneous fat that gives the skin a dimpled, or orange-peel, appearance, especially on

the thighs and buttocks. Cellulite usually affects women rather than men and is often attributed to water retention.

cellulitis

A bacterial infection of the skin and the tissues beneath it, which usually affects the lower legs but can occur anywhere on the body. Cellulitis is most commonly caused by streptococci bacteria, which enter the skin via a wound.

SYMPTOMS

There may be fever and chills; and the affected area is hot, red and swollen. Cellulitis is more severe in people with reduced immunity, such as those who have an *immunodeficiency disorder*.

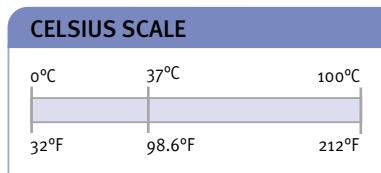

Untreated cellulitis at the site of a wound may progress to *bacteraemia* (bacterial infection of the blood) and *septicaemia* (blood poisoning). Facial infections may spread to the eye socket.

TREATMENT

Treatment of cellulitis is with an *antibiotic drug* such as a *penicillin* drug or *erythromycin*. (See also *erysipelas*.)

cellulose

A *carbohydrate* consisting of chains of glucose (a simple sugar). Cellulose is the main constituent of plant-cell walls. Because it cannot be digested, cellulose is an important source of dietary fibre (see *fibre, dietary*).

Celsius scale

A temperature scale in which the melting point of ice is defined as zero degrees (0°C) and the boiling point of water is 100 degrees (100°C). On this scale, the normal body temperature in humans is 37°C . The scale is named after the Swedish astronomer Anders Celsius (1701–1744). “Centigrade” is an obsolete name for the same scale.

To convert a Celsius temperature to Fahrenheit, multiply the figure by 1.8, then add 32. To convert Fahrenheit to Celsius, subtract 32, then multiply by 0.56. (See also *Fahrenheit scale*.)

cementum

Bonelike tissue surrounding the root of a tooth (see *teeth*).

centigrade scale

The obsolete name for the *Celsius scale*.

centrally acting antihypertensive drugs

A type of *antihypertensive drug* used in the treatment of *hypertension* (high blood pressure). Centrally acting antihypertensives, such as *clonidine* and *methyldopa*, act on the mechanism in the brain that controls blood-vessel size.

central nervous system

The anatomical term for the *brain* and *spinal cord*, often abbreviated to CNS. The central nervous system is made up of neurons (nerve cells) and supporting tissue, and works in tandem with the *peripheral nervous system* (PNS), which carries signals between the CNS and the rest of the body.

The CNS receives sensory information from organs such as the eyes and ears, and from sensory receptors in the body. It analyses this information, then initiates an appropriate motor response in the body, such as contracting a muscle. (See also *nervous system*.)

central venous pressure

The pressure within the right *atrium*, the chamber of the heart that receives oxygen-depleted blood from the body. Central venous pressure is measured by

means of a fine tube, attached to a monitor, that is passed through a vein close to the heart and into the right atrium. By monitoring the pressure, doctors can estimate the volume of blood circulating around the body. This action may be of value following severe haemorrhage and in cases where the blood pressure is too low to deliver an adequate blood supply to organs and tissues (see *shock*).

centrifuge

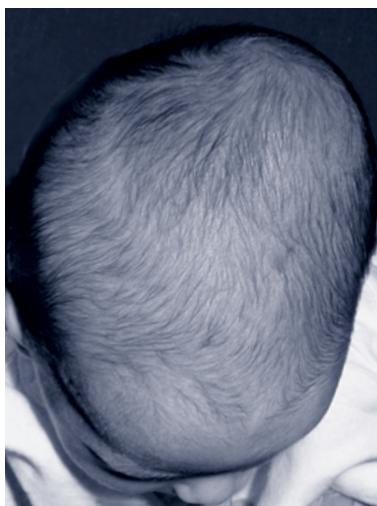

This is a machine that separates the different components of a body fluid for analysis. When a fluid such as blood is spun at high speed around a central axis, groups of particles of varying density, such as red and white blood cells, are separated by centrifugal force and can be analysed independently.

cephalexin

An alternative spelling of cefalexin, a common *cephalosporin drug*.

cephalhaematoma

An extensive, soft swelling on the scalp of a newborn baby. Cephalhaematoma is caused by bleeding into the space between the skull and its fibrous covering (the periosteum or pericranium) due to pressure exerted on the baby's head during delivery. The swelling is neither painful nor serious and it gradually subsides, although this process may take several weeks.

Cephalhaematoma

This baby was born with a cephalhaematoma on one side of the scalp at the back of the head. The condition is not serious and the swelling gradually subsides over a period of a few weeks.

cephalic

Relating to the head, as in cephalic presentation, the head-first position of a baby in the birth canal.

cephalopelvic disproportion

A complication of childbirth (see *childbirth, complications of*) in which the mother's pelvis is too narrow in proportion to the size of the baby's head.

cephalosporin drugs

COMMON DRUGS

- Cefaclor • Cefadroxil • Cefalexin • Cefotaxime
- Cefoxitin • Cefuroxime

A large group of *antibiotic drugs*, derived from the fungus *CEPHALOSPORIUM ACERONIUM*, which are effective against a wide range of infections. Cephalosporins are used to treat ear, throat, and respiratory tract infections and conditions, such as *urinary tract infections* and the sexually transmitted infection *gonorrhoea*, in which the causative bacteria are resistant to other types of antibiotic.

HOW THEY WORK

Cephalosporin drugs interfere with the development of bacterial cell walls and inhibit the production of protein in the bacterial cells. As a result, the bacteria die. Some types of bacteria, however, produce an enzyme (a protein that acts as a catalyst) called beta-lactamase that can inactivate some of the older cephalosporin drugs. Newer cephalosporins are not affected by this enzyme.

SIDE EFFECTS

Occasionally, cephalosporin drugs may cause allergic reactions, such as rash, itching, and fever. Rarely, *anaphylactic shock* (a very severe allergic reaction) occurs. Other side effects include diarrhoea and *blood disorders*.

cerebellar ataxia

Jerky, staggering gait and other uncoordinated movements caused by disease of, or damage to, the *cerebellum*. Other features may include *dysarthria* (slurred speech), hand tremor, and *nystagmus* (abnormal jerky eye movements).

Causes include *stroke*, *multiple sclerosis*, *brain tumour*, damage as a result of *alcohol dependence*, and an inherited disorder of the cerebellum.

cerebellar syndrome

A collection of symptoms, due to certain types of brain disorder, that include tremor, speech disturbance, and abnormal eye movements (*nystagmus*) and gait.

cerebellum

A region of the brain at the back of the skull, behind the *brainstem*. The cerebellum is concerned primarily with the maintenance of posture and balance and the coordination of movement.

STRUCTURE

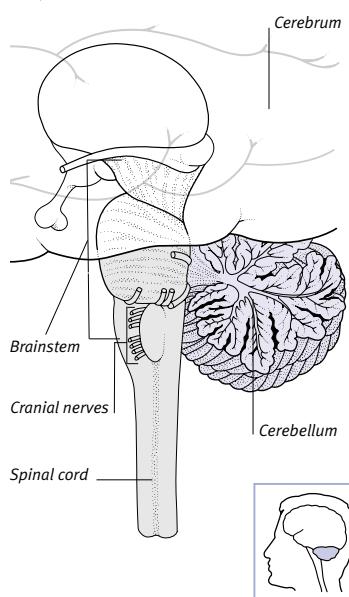

The cerebellum is linked to the *brainstem* by thick nerve tracts. It consists of two hemispheres. From the inner side of each hemisphere arise three nerve fibre stalks, which link with different parts of the brainstem and carry signals between the cerebellum and the rest of the brain. Nerve fibres from the stalks fan out towards the deep folds of the *cortex* (outer part) of each cerebellar hemisphere, which consists of layers of what is often referred to as *grey matter* (interconnected nerve cells).

FUNCTION

Information about the body's posture and the state of contraction or relaxation in its muscles is conveyed from muscle tendons and the labyrinth in the inner ear via the brainstem to the cerebellum. Working with the *basal ganglia* (nerve cell clusters deep within the brain), the cerebellum uses this data to fine tune messages sent to muscles from the motor cortex in the *cerebrum* (the main mass of the brain).

LOCATION OF CEREBELLUM

The cerebellum is situated behind the brainstem and is connected to it by a collection of nerve tracts.

DISORDERS

Disease or damage to the cerebellum may result in *cerebral ataxia*, which is characterized by jerky, staggering gait, slurred speech, and other uncoordinated movements of the body. *Alcohol intoxication* impairs cerebellar function and may produce similar symptoms.

cerebral haemorrhage

Bleeding that occurs within the brain due to a ruptured blood vessel (see *intracerebral haemorrhage; stroke*).

cerebral malaria

A potentially fatal complication of *malaria* (a disease transmitted by mosquitoes) that affects the brain and causes loss of consciousness.

cerebral oedema

An abnormal accumulation of fluid in the *brain*. The resulting compression of brain tissues may cause symptoms such as headache and visual disturbances. There are various causes for cerebral oedema, including injury, *anoxia* (lack of oxygen), and poisoning.

cerebral palsy

A disorder of posture and movement that results from damage to the developing brain before, during, or just after birth, or in early childhood. Cerebral palsy is nonprogressive. The disorder varies in severity from slight clumsiness of hand movement and gait to complete immobility.

CAUSES

In most cases, damage occurs before or at birth, sometimes as a result of cerebral *hypoxia* (an inadequate supply of oxygen to the brain). More rarely, the cause is a maternal infection that spreads to the baby in the uterus.

In rare cases, cerebral palsy is caused by *kernicterus*, which results from an excess of bile pigment in babies with *haemolytic disease of the newborn*. Possible causes after birth include *encephalitis* (inflammation of the brain tissue), *meningitis* (inflammation of the protective membranes covering the brain), *head injury*, or *intracerebral haemorrhage* (bleeding within the brain).

SYMPTOMS

Cerebral palsy may not be recognized until well into the baby's first year. Initially, the infant may have hypotonic (floppy) muscles, be difficult to feed, and show delay in sitting up without support. An affected child may go on

to develop *spastic paralysis* (abnormal muscle stiffness), *athetosis* (involuntary writhing movements), or *ataxia* (loss of coordination and balance). Other nervous system disorders, such as hearing defects or epileptic seizures, may be present. About 70 per cent of children have mental impairment, but the rest are of normal or high intelligence.

DIAGNOSIS AND TREATMENT

If the condition is suspected from the symptoms and from neurological and developmental assessments, imaging tests such as *CT scanning* and *MRI* may be performed to identify brain damage.

Although there is no cure for cerebral palsy, much can be done to help affected children. A team of professionals working with the family can maximize the child's ability to function. *Physiotherapy* can help a child to develop muscular control and maintain balance. *Speech therapy* may improve speech and communication.

cerebral thrombosis

The formation of a *thrombus* (blood clot) in an artery within the brain. The clot may block the artery, cutting off the supply of blood, nutrients, and oxygen to the region of the brain tissue supplied by the artery. This problem may result in a *stroke*.

cerebrospinal fluid

A clear, watery fluid that circulates between the ventricles (cavities) within the *brain*, the central canal in the *spinal cord*, and the space between the brain and spinal cord and their protective coverings, the *meninges*. Cerebrospinal fluid functions as a shock-absorber, helping to prevent or reduce damage to the brain and spinal cord after a blow to the head or back. It contains glucose, proteins, salts, and white blood cells.

Examination of the fluid, samples of which are usually obtained by *lumbar puncture*, is used in the diagnosis of many conditions affecting the brain and spinal cord, including *meningitis* and *subarachnoid haemorrhage*.

Accumulation of cerebrospinal fluid within the skull during the development of the fetus, or in infancy, may cause the skull to become enlarged (a condition known as *hydrocephalus*).

cerebrovascular accident

Any sudden rupture or blockage of a blood vessel in the brain. The problem causes serious bleeding and/or local

obstruction to blood circulation, and leads to a *stroke* (damage to part of the brain due to interrupted blood supply).

Blockage may be due to *thrombosis* (clot formation) or to *embolism* (a clot fragment, or an air bubble carried in the circulation). Rupture of vessels may result in different patterns of bleeding: *intracerebral haemorrhage* (bleeding in the brain) or *subarachnoid haemorrhage* (bleeding around the brain).

cerebrovascular disease

Any disease affecting an artery supplying blood to areas inside the brain. Such diseases include *atherosclerosis* (narrowing of the arteries) and defects in arterial walls that cause *aneurysm* (a balloon-like swelling in an artery).

The disease may eventually cause a *cerebrovascular accident*, which commonly results in a *stroke*. Extensive narrowing of blood vessels throughout the brain can be a cause of *dementia*.

cerebrum

The largest and most developed part of the *brain*, and the site of most conscious and intelligent activities.

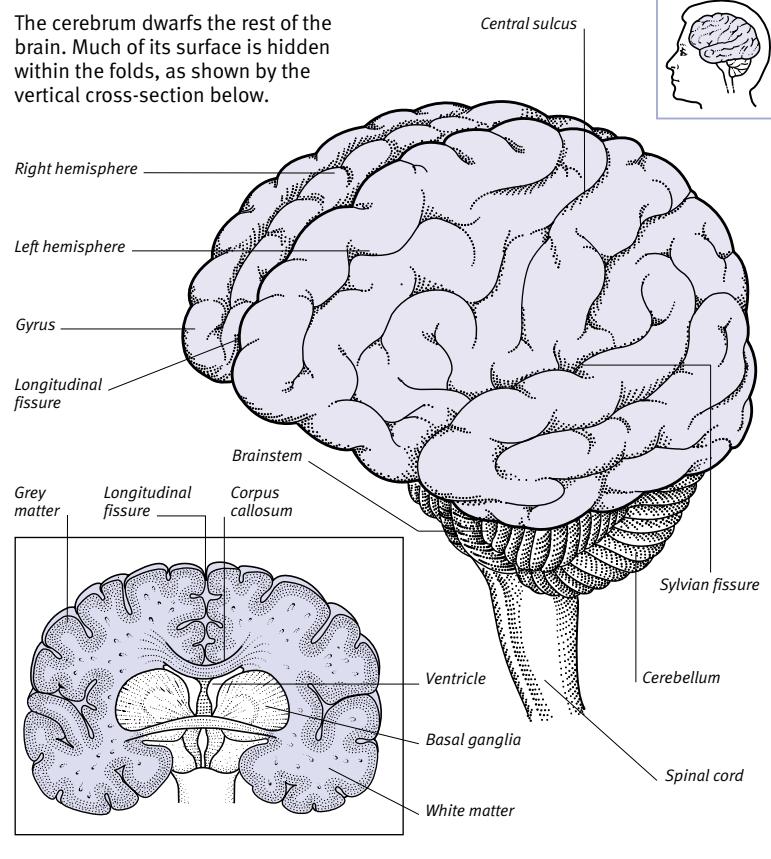

STRUCTURE

The main components of the cerebrum are two large hemispheres that grow out from the upper part of the *brainstem* (an extension of the spinal cord). The surface of the cerebrum is made up of a series of folds called *gyri*, which are separated by fissures called *sulci*, with a deep longitudinal fissure separating the two hemispheres.

The four main surface regions of each hemisphere – the frontal, parietal, temporal, and occipital lobes – are named after the bones that are overlying them. Each hemisphere has a central cavity, called a *ventricle*, that is filled with *cerebrospinal fluid*. This cavity is surrounded by an inner layer, consisting of clusters of nerve cells called the *basal ganglia*. There is a middle layer of *white matter* composed mainly of nerve fibres, which carry information between particular areas of the *cortex* and between the cortex, central brain, and *brainstem*. The outer surface layer of each hemisphere is the *cerebral cortex*, which is also known as the *grey matter*, where much of the sensory information from organs such as the eyes and the ears is processed. A thick band of fibres called the *corpus callosum* carries nerve signals between the two cerebral hemispheres.

STRUCTURE OF THE CEREBRUM

The cerebrum dwarfs the rest of the brain. Much of its surface is hidden within the folds, as shown by the vertical cross-section below.

FUNCTION

Specific sensory processing takes place in separate regions. For example, visual perception is located in a part of the occipital lobe called the *visual cortex*.

The cortex also contains "motor" areas concerned with initiating signals for movements of the skeletal muscles. Linked to the sensory and motor areas of the cortex are association areas. These regions integrate information from various senses and also perform functions such as comprehension and recognition, memory storage and recall, thought, and decision-making.

Some cortical functions are localized to one "dominant" hemisphere (the left in almost all right-handed and many left-handed people). Two clearly defined areas in the dominant hemisphere are *Wernicke's area*, which is responsible for the comprehension of spoken and written language, and *Broca's area*, which is concerned with language expression.

DISORDERS

Damage to particular areas of the cerebrum may cause specific syndromes. For example, damage to the frontal lobe may cause mental apathy, whereas a parietal lobe injury may result in geographical disorientation. Disease of the temporal lobe may cause *amnesia* (memory loss), and visual defects may result from occipital lobe damage.

Quite often, however, cerebral disease causes nonspecific symptoms such as convulsions and headaches.

certification

An outdated term for procedures to commit a person to be compulsorily detained for mental health treatment.

cerumen

The medical term for *earwax*.

Cerumol

A brand-named preparation used for the removal of *earwax*.

cervical

This term can mean either relating to the neck or relating to the *cervix* (the neck of the uterus).

cervical cancer

See *cervix, cancer of*.

cervical dysplasia

Changes in the surface cells of the *cervix* (the neck of the uterus) that may in time become cancerous.

TYPES

There are three grades of cervical dysplasia: mild, moderate, and severe. They are based on the severity of the changes seen in cells obtained from a *cervical smear test*. Abnormalities can also be classified as grades of *cervical intraepithelial neoplasia*. In mild dysplasia, abnormal cells may return to a normal state without treatment. Severe dysplasia, left untreated, may progress to cervical cancer (see *cervix, cancer of*).

CAUSES

The cause is not known, but risk factors include smoking and unprotected sex at an early age or with many partners.

TREATMENT

Treatment depends on the severity of the condition. For mild or moderate dysplasia, the abnormal cells may be destroyed by *laser treatment*, or by freezing at *colposcopy* (inspection of the cervix with a viewing instrument). Alternatively, loop excision (surgical removal of an area of the cervix) may be carried out. If the dysplasia is severe, loop excision or *cone biopsy* are used.

cervical ectopy

A condition affecting the *cervix* (the neck of the uterus) in which a layer of mucus-forming cells that are more characteristic of the inner lining of the cervix appear on its outside surface. There is no loss of tissue or ulceration of the cervix. The tissue may, however, be more fragile, and tend to bleed and secrete more mucus, than normal.

CAUSES

Cervical ectopy may be present from birth. Other possible causes include injury to the cervix during labour and long-term use of *oral contraceptives*.

SYMPOTMS

Most women with cervical ectopy have few or no symptoms. Some, however, experience vaginal bleeding at unexpected times and may have a vaginal discharge. The cervix has a fragile, reddened area on the surface.

DIAGNOSIS AND TREATMENT

The condition is often detected during a routine *cervical smear test*. Only women with symptoms need treatment. Affected tissue may be destroyed using *cauterization* (application of a heated instrument), *cryosurgery* (freezing), *diathermy* (heat), or *laser treatment*.

cervical incompetence

Abnormal weakness of the *cervix* (the neck of the uterus) that can result in recurrent *miscarriages*. Normally, the cervix remains closed until the onset of labour. An incompetent cervix may gradually widen under the weight of the fetus from about the 12th week of pregnancy onwards, or may suddenly open during the second trimester.

DIAGNOSIS AND TREATMENT

The condition is detected by a *pelvic examination* or by *ultrasound scanning*. Treatment is with a suture (stitch) applied like a purse string around the cervix at about the 12th week of pregnancy. The suture is left in position until the pregnancy is at or near full term and is then cut to allow the mother to deliver the baby normally.

cervical intraepithelial neoplasia

Also known as CIN, abnormalities in the cells of the cervix (the neck of the uterus) that may become cancerous. The CIN grading system is used to distinguish levels of change in the surface cells of the cervix. The term is applied to biopsy (tissue) samples taken during *colposcopy*, (inspection of the cervix with a viewing instrument) following an abnormal *cervical smear test*. Grades CIN 1–3 broadly correspond to mild to severe *cervical dysplasia* in the cells obtained from a smear test.

cervical mucus method

A form of contraception based on identifying days on which to abstain from sexual intercourse and thereby avoid pregnancy. This technique involves monitoring the changes in the mucus secreted by a woman's cervix. (See *contraception, natural methods of*.)

cervical osteoarthritis

A degenerative disorder, also called cervical spondylosis, that affects the joints between the cervical *vertebrae* (the bones in the neck). Cervical osteoarthritis mainly occurs in middle-aged and elderly people, but occasionally the

degeneration begins earlier due to an injury, such as a whiplash neck injury sustained in a road traffic accident.

SYMPTOMS

The main symptoms of cervical osteoarthritis are neck pain and stiffness. Pressure on the nerves between affected vertebrae may cause pain in the arms and shoulders, numbness tingling and weakness in the hands. Symptoms tend to flare up from time to time with periods of mild discomfort between.

Other symptoms, such as dizziness, unsteadiness, and double vision when turning the head, may also occur as a result of pressure on blood vessels running through the vertebrae to the brain. Rarely, pressure on the spinal cord can cause weakness or paralysis in the legs and loss of bladder control.

DIAGNOSIS AND TREATMENT

X-rays and other imaging procedures such as *MRI* (a technique that produces cross-sectional or three-dimensional pictures of body structures) are used to diagnose cervical osteoarthritis.

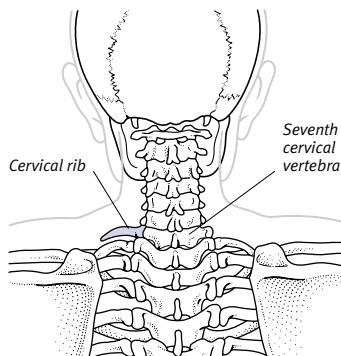

Treatment of severe neck pain and stiffness may include *heat treatment*, supporting the neck in a collar, and the *analgesic drugs* (painkillers). *Physiotherapy* may improve neck posture and movement and is useful when the pain has eased. Pressure on the spinal cord may be relieved by surgery (see *decompression, spinal canal*).

cervical rib

A *congenital* abnormality, which is of unknown cause, in which the lowest of the seven cervical *vertebrae* (neck bones)

LOCATION OF CERVICAL RIB

The overdeveloped seventh cervical vertebra forms a rib parallel to a normal one.

CERVICAL SMEAR TEST

has overdeveloped to form an extra *rib* that lies parallel to and above the first normal rib. The abnormality can vary from a small, bony swelling to a fully developed rib and it may occur on only one or on both sides.

SYMPOTMS

In many cases, there are no symptoms. If the rib presses on the lower *brachial plexus* (the group of nerves passing from the spinal cord into the arm), however, there may be pain, numbness, and pins-and-needles affecting both the forearm and hand.

DIAGNOSIS AND TREATMENT

An *X-ray* will show the presence of a cervical rib, but other possible causes of pain and tingling in the hand or arm (such as *carpal tunnel syndrome* or a *disc prolapse*) still need to be excluded.

Exercises designed to strengthen the shoulder muscles and improve posture may bring relief. Severe or persistent symptoms may, however, require surgery in order to remove the rib.

cervical smear test

A test that is used to detect *cervical dysplasia* (abnormal changes in the cells of the *cervix*, the neck of the uterus) that could develop into cancer (see *cervix*, *cancer of*). A cervical smear test can also detect viral infections of the cervix, such as *herpes simplex*, papilloma (see *warts, genital*), and *CHLAMYDIA TRACHOMATIS*.

WHEN IT IS DONE

A cervical smear test should be carried out within six months after a woman first starts to have sexual intercourse. A repeat test may be carried out between six and twelve months later. If no abnormality is detected on these smears, tests should subsequently be performed at approximately three-yearly intervals until the age of 65.

HOW IT IS DONE

Cervical smear tests are usually performed by doctors or nurses in general practice clinics or at sexual health clinics. A small sample of cells is taken from the surface of the cervix using a spatula or special brush and is examined under a microscope. If all the cells appear normal, nothing further needs to be done. If any cells show dysplasia, this will be graded according to severity, and repeat smear tests and further investigations, such as *colposcopy* (inspection of the cervix with a viewing instrument), may be required.

cervical spondylosis

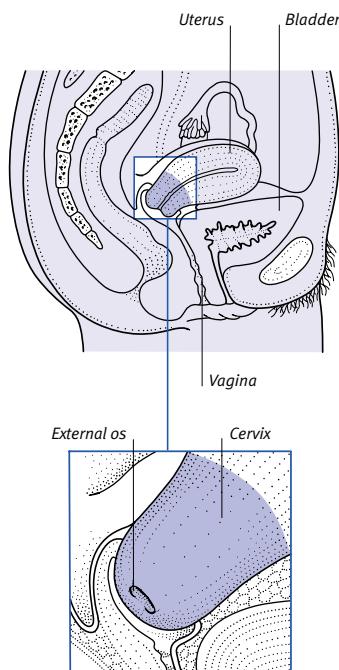

An alternative name for the neck disorder *cervical osteoarthritis*.

cervicitis

Inflammation of the *cervix* (the neck of the uterus). The condition is usually due to a sexually transmitted infection, such as *gonorrhoea*, *chlamydial infections*,

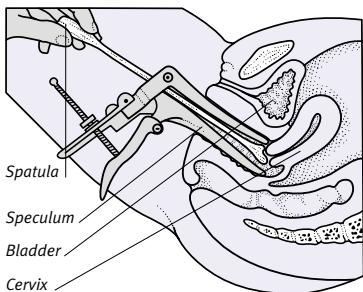

ANATOMY OF THE CERVIX

The cervix contains a central canal for the passage of sperm and menstrual blood and for childbirth. The canal and outer surface of the cervix are lined with two types of cells: mucus-secreting glandular cells and protective squamous cells.

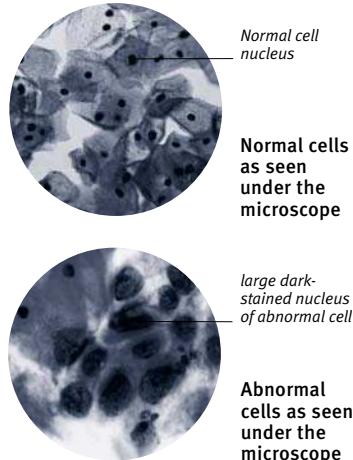

CERVICAL SMEAR

Regular cervical smear tests should begin within six months of a woman first having sexual intercourse, then be done every three years as a matter of routine. The procedure is risk-free, although it may be slightly uncomfortable, and the actual collection of the cells from the cervix takes only a few seconds.

Procedure for cervical smear

The woman lies on her back with her legs bent and relaxed so that they fall open at the knees. The vagina is held open with a speculum. Cells are collected with a spatula or a special brush and either smeared onto a glass slide or put in a preservative for later microscopic examination.

or genital herpes (see *herpes, genital*). However, cervical infection may also result from injury to the cervix during childbirth or surgery.

SYMPTOMS

Cervicitis often does not produce symptoms, although there may be a vaginal discharge, irregular vaginal bleeding, and lower abdominal pain.

COMPLICATIONS

If it is left untreated, cervicitis can spread to cause *endometritis* (inflammation of the lining of the uterus), *salpingitis* (inflammation of the fallopian tubes), or *pelvic inflammatory disease*.

If a pregnant woman has cervicitis, her baby may be infected during delivery, resulting in *neonatal ophthalmia* (eye infection) or, less commonly, *pneumonia* due to chlamydial infection.

DIAGNOSIS AND TREATMENT

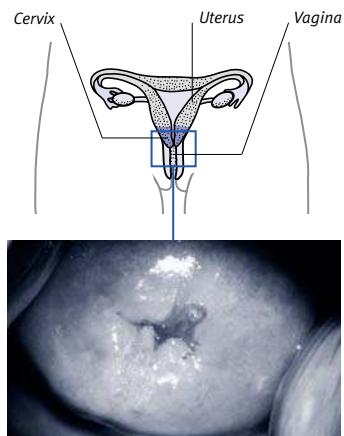

The condition is diagnosed by means of internal examination and by taking swabs of the vaginal discharge, which

are then analysed in order to verify the identity of the organism that is responsible for the condition.

Treatment is with *antibiotic drugs* or *antiviral drugs*. If symptoms persist, the area may be cauterized by *electrocoagulation* (an electric current is applied), *cryotherapy*, (freezing), or *laser treatment*.

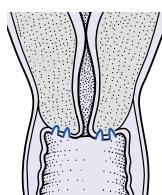

BIOPSY OF THE CERVIX

If a woman has recurrent abnormal smears, colposcopy and punch biopsy or loop excision of the abnormal areas will be carried out. If the areas cannot be seen completely by colposcopy, a larger sample of tissue is removed by cone biopsy. This procedure is used for treatment as well as diagnosis.

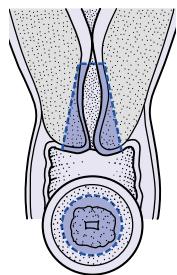

Colposcopic view of cervix

This end-on view of the cervix shows moderate dysplasia (abnormal changes in the cells), with a discharge at the central canal.

Punch biopsy
Small samples are taken from any abnormal area. Bleeding is minimal following a punch biopsy and no stitches are needed.

Cone biopsy
If the abnormal area extends into the cervical canal, out of view of the colposcope, a cone-shaped sample, including abnormal cells, is taken using a scalpel, laser, or, most commonly, loop excision. No stitches are needed.

cervix

A small, cylindrical organ, several centimetres in length and less than 2.5 cm in diameter, comprising the lower part and neck of the *uterus* (womb). The cervix separates the body and cavity of the uterus from the *vagina*. The fibrous, smooth muscle tissue of the cervix creates a form of sphincter (circular muscle), which can stretch open in *pregnancy* and *childbirth*.

FUNCTION

The cervical canal runs through the cervix. It allows the passage of blood during *menstruation* and of *sperm* from the *vagina* into the uterus following sexual intercourse, and forms part of the birth canal during childbirth. After puberty, mucus is secreted by the glandular cells in the canal to assist the entry of sperm into the upper cervix. In addition, the mucus protects the sperm and provides them with energy.

During pregnancy, the internal muscular fibres increase in size, thereby lengthening the cervix and acting as a barrier for the retention of the fetus. Towards the end of pregnancy, the cervix begins to shorten in readiness for labour and delivery. During labour the cervical canal widens up to 10 cm in diameter to allow the baby to pass from the uterus. Soon after childbirth, the muscles in the cervix contract and the canal returns to its original size.

DISORDERS

The cervix may be injured, or may develop infections or other disorders (see *cervix* disorders box, below). Such conditions are usually investigated by means of a *pelvic examination*, a *cervical*

smear test, or swabs taken from the cervix. In cases of suspected cancer or a precancerous condition, a *colposcopy* (inspection of the cervix with a viewing instrument) may be performed.

cervix, cancer of

One of the most common forms of cancer affecting women worldwide. Cancer of the *cervix* (the neck of the uterus) has well-defined precancerous stages in which abnormal changes occur in cells on the surface of the cervix (see *cervical dysplasia*). These type of changes can be detected by a *cervical smear test*. In many cases, this detection allows early treatment leading to a complete cure. If left untreated, however, cancer of the cervix may spread to the organs in the *pelvis*.

TYPES

There are two main types of cervical cancer: the squamous type and a much rarer form called adenocarcinoma.

The squamous type of cervical cancer is thought to be associated with some types of *human papillomavirus* (HPV), which may be contracted during sexual intercourse. The other factors that predispose a woman to developing this type of cancer are smoking, starting to have sex at an early age, having many sexual partners, and having a depressed immune system.

The second type of cervical cancer, adenocarcinoma, sometimes occurs in women who have never had sexual intercourse. Its causes are unknown.

SYMPTOMS

In many cases, cancer of the cervix is detected before symptoms develop. If

DISORDERS OF THE CERVIX

The *cervix* (neck of the uterus) may be susceptible to injuries, infections, tumours, and other conditions.

Injury

Minor injury to the cervix may occur during childbirth, particularly if labour is prolonged. Persistent damage to muscle fibres as a result of injury may lead to *cervical incompetence*.

Infection

The most common cervical infections are sexually transmitted diseases, such as *gonorrhoea*, *chlamydial infections*, and *trichomoniasis*. Viral infections of the

cervix include those due to the *human papillomavirus* and the *herpes simplex virus* (see *warts, genital; herpes, genital*).

Tumours

Polyps are noncancerous growths that occur on the cervix. Cancerous growths (see *cervix, cancer of*) are preceded by changes in the surface cells (*cervical dysplasia*), which can be detected by a *cervical smear test*.

Other disorders

Cervical ectopy is a condition in which mucus-secreting cells form on the outside of the cervix.

the condition is advanced, there may be vaginal bleeding or a bloodstained discharge at unexpected times, such as between periods, after sexual intercourse, or after the menopause. There may be pain if the cancer has spread into the deeper parts of the cervix and then out into the pelvic tissues.

DIAGNOSIS AND TREATMENT

If a smear test has an abnormal result, *colposcopy* (inspection of the cervix with a viewing instrument) or a *cone biopsy* may be carried out.

A localized cancer in its early stages may be destroyed by *electrocoagulation* (application of an electric current), *diathermy* (heat treatment), *laser treatment*, or *cryosurgery* (freezing).

If the cancer has spread into the cervical canal, a cone biopsy may be sufficient to remove all of the diseased tissue. In more advanced cases affecting the pelvic organs, *radiotherapy* may be given. In certain severe cases, radical surgery, in which the bladder, vagina, cervix, uterus, and rectum are removed, may be recommended possibly along with chemotherapy.

cestodes

The scientific name for tapeworms, a group of long, flat, multisegmented parasites (see *tapeworm infestation*).

cetirizine

An *antihistamine drug* that is used to relieve the symptoms of certain conditions such as *allergic rhinitis* (hay fever) and *urticaria* (nettle rash).

cetrimide

An *antiseptic* that is used in many preparations for cleansing the skin.

CFC-free inhalers

Pressurized aerosol *inhalers* (devices for delivering drugs to treat asthma and other lung disorders) in which chlorofluorocarbons, or CFCs (used to propel drugs out of the inhalers), have been replaced by alternative propellants. This change has been made in response to evidence that CFCs are harmful to the ozone layer in the earth's atmosphere.

CFC propellants

See *chlorofluorocarbon propellants*.

Chagas' disease

An infectious parasitic disease found only in parts of South and Central America. Chagas' disease is spread by

insects commonly called cone-nosed or assassin bugs. The *parasites* live in the bloodstream and can affect the heart, intestines, and nervous system.

Symptoms include swelling of the *lymph nodes* and fever. Long-term complications include damage to the heart. The drug nifurtimox kills the parasites but has unpleasant side effects.

chalazion

A round, painless swelling in the upper or lower eyelid caused by obstruction of one of the *meibomian glands*, which lubricate the edges of the eyelids. Chalazions are sometimes called meibomian cysts. They can occur at any age and may be more common in people suffering from the skin conditions *acne*, *rosacea*, or *seborrhoeic dermatitis*.

If the cyst becomes infected, the eyelid becomes more swollen, red, and painful. A large swelling putting pressure on the *cornea* at the front of the eye can cause blurring of vision. About one-third of chalazions disappear without treatment, but large cysts may need to be removed surgically.

A chalazion on the lower lid

Small chalazions often disappear spontaneously. Larger ones may need to be removed surgically.

challenge, food

See *exclusion diet*.

chancre, hard

An *ulcer*, usually on the genitals, that develops during the first stage of *syphilis* (a sexually transmitted infection).

chancroid

A sexually transmitted infection, found mainly in the tropics, that is characterized by enlargement of the lymph nodes in the groin and painful genital *ulcers*. Chancroid is caused by the bacterium *HAEMOPHILUS DUCREYI*. Prompt treatment of the condition with *antibiotic drugs* is usually effective.

change of life

A phrase that is popularly used to describe the *menopause*, in which a drop in hormone levels has a variety of physical and mental repercussions.

chaperone

An individual who accompanies a doctor during the physical examination of a patient. Chaperones provide protection for both doctor and patient against accusations of improper conduct.

The term "chaperone" is also used to refer to a *protein* that helps other proteins to fold up into their correct three-dimensional shapes.

chapped skin

Sore, cracked, rough skin, usually on the hands and face (particularly the lips), caused by dryness. Chapping is caused by the lack, or removal, of the natural oils that keep skin supple. It tends to occur in cold weather, when oil-secreting glands produce less oil, or after repeated washing or wetting.

Chapping can be prevented by wearing protective gloves or applying *barrier creams* before immersing the hands in water, then drying the skin well. Areas of chapped skin can be treated with hand or face cream.

charcoal

A form of carbon that is used in medicine mainly as an adsorbent agent (a substance that binds to toxins) in the emergency treatment of some types of poisoning and drug overdose.

Charcot–Marie–Tooth disease

An inherited muscle-wasting disease of the legs (see *peroneal muscular atrophy*).

Charcot's joint

A joint damaged by repeated injuries that go unnoticed due to loss of sensation in the area (see *neuropathic joint*).

check-up

See *examination, physical*.

cheilitis

Inflammation, cracking, and dryness of the lips. There are several possible causes of cheilitis, including ill-fitting dentures, a local infection, an allergy to cosmetics, excessive sunbathing, or deficiency of riboflavin (vitamin B₂). Treatment is given for the underlying cause; in the meantime, a soothing skin cream can help to relieve the soreness.

chelating agents

Chemicals to treat metal poisoning, which act by combining with metals such as lead, arsenic, and mercury to form less toxic substances. *Penicillamine* is a commonly used chelating agent.

chemical formula

See *formula, chemical*.

chemical pathology

See *pathology, chemical*.

chemist

A pharmacist – a health-care professional who prepares drugs, makes up and supplies prescriptions, and may also give advice on the treatment of common or minor illnesses.

chemosis

Swelling of the *conjunctiva* (the membrane covering the eye and lining the eyelid). Chemosis is most commonly associated with allergic and infective *conjunctivitis*. Treatment may include the use of eyedrops containing an *antihistamine drug* or *antibiotic drug*.

chemotherapy

The term usually used to refer to treatment with *anticancer drugs*. The word “chemotherapy” may also describe the use of *antibiotic drugs* to treat infectious diseases, particularly tuberculosis.

Chemotherapy for cancer works by destroying cancer cells or preventing them from multiplying. The drugs also affect healthy tissues, however, so the treatment is often given in short courses, with drug-free periods in between to allow normal cells to recover. Normal tissues often affected include bone marrow (causing anaemia), the mouth, the intestinal lining, the hair follicles, and the ovaries and testes; sometimes causing severe side effects.

chenodeoxycholic acid

A constituent of *bile* that is necessary for the absorption of fat from the diet and also for the excretion of *cholesterol*.

cherry angioma

An alternative name for a *Campbell de Morgan's spot* (a small, bright red, non-cancerous spot on the trunk or limbs).

cherry-red spot

A red spot that can be seen on the *retina* of infants who have the inherited metabolic disorder *Tay-Sachs disease*.

cherubism

An inherited disease, also known as familial fibrous dysplasia of the jaw. Cherubism is so called because it produces swelling at either side of the jaw, giving the face a cherubic appearance.

chest

The upper part of the trunk. The chest, also known as the *thorax*, extends from the base of the neck down to the *diaphragm muscle*.

chest compression

Another name for *external cardiac massage*. Chest compressions are carried out as part of the life-saving technique *cardiopulmonary resuscitation*.

chest pain

Pain in the chest often has no serious cause, but in some cases it may be a symptom of an underlying disorder requiring urgent treatment. The pain may be in the chest wall (in the skin, the underlying muscles, or the ribs) or in an organ within the chest.

causes

Common causes of pain in the chest wall are a strained muscle or an injury, such as a broken rib. A sharp pain that

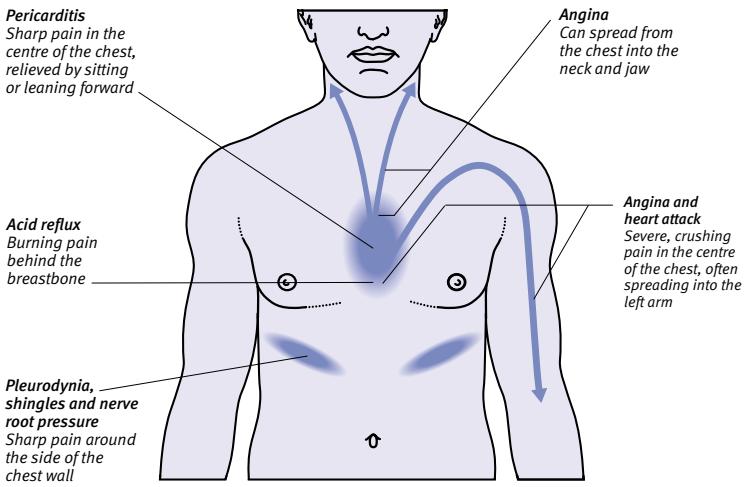

travels from the back of the chest around to the front may be due to pressure on a nerve root where it leaves the spine; nerve compression may result from disorders such as *osteoarthritis* of the *vertebrae*. Pain in the side of the chest may be caused by *pleurodynia* (inflammation of the muscles between the ribs and of the diaphragm muscle, associated with a viral infection). The viral infection *herpes zoster* (shingles) may cause severe pain along the course of a nerve in the chest wall. In *Tietze's syndrome*, inflammation at the junctions of the rib *cartilages* causes pain on the front of the chest wall.

A common cause of pain within the chest is *acid reflux* (regurgitation of acid from the stomach into the *oesophagus*); this problem may cause heartburn, a pain behind the sternum (breastbone). More serious causes include disorders involving the lungs, such as *pleurisy* (inflammation of the membranes surrounding the lungs and lining the inside of the chest wall). Pleurisy may be due to *pneumonia* (inflammation of the lungs due to infection) or, rarely, *pulmonary embolism* (a blood clot that has lodged in an artery in the lung). Cancerous lung tumours (see *lung*

DIAGNOSING CHEST PAIN

To make an accurate diagnosis of the underlying cause, it is important for the patient to describe the location, quality (e.g. burning, pressing, or sharp), severity, and duration of the pain, any factors that relieve it or make it worse, and any other symptoms, such

as breathing difficulty. In addition, the doctor will perform a physical examination, including listening to chest sounds with a stethoscope and feeling for areas of tenderness in the chest wall. He or she may also arrange for other diagnostic procedures to be carried out.

cancer; mesothelioma) may also cause pain as they enlarge in size and press on the *pleura* and the ribs.

Pain in the centre of the chest may be due to a heart disorder. The common disorder *angina pectoris* produces pain that may spread from the chest to the throat, jaw, or arms. It is caused by an inadequate blood supply to the heart, commonly due to *coronary artery disease*. *Myocardial infarction* (heart attack) causes a similar pain to angina but is usually more severe and is not relieved by rest. Acute *pericarditis* (inflammation of the membrane covering the heart) produces severe pain that may be relieved slightly when the person leans forwards. *Mitral valve prolapse* may cause sharp pain, usually on the left side of the chest.

Chest pain may also be a result of *anxiety* and emotional stress (see *hyperventilation; panic attack*).

TREATMENT

The treatment of chest pain depends on the underlying cause. For example, *antibiotic drugs* may be given for chest pain due to pneumonia, and surgery is needed to treat some lung tumours or some cases of coronary artery disease.

chest thrust

A first-aid technique that is used to unblock the airway of a person who is *choking*. Chest thrusts involve standing behind the casualty, reaching around his or her chest, and placing one fist, thumb inwards, against the lower breastbone. The fist is then grasped with the other hand, and the casualty's chest wall is thrust sharply inwards and upwards up to five times. The pressure simulates the coughing reflex and may expel the obstruction.

For an infant, the technique involves the first-aider laying the baby face-upwards and head downwards along his or her forearm, placing two fingertips of the other hand on the baby's lower breastbone, and giving up to five sharp thrusts into the chest.

chest X-ray

One of the most frequently performed medical tests, usually carried out to examine the heart or lungs. Chest X-rays are used to confirm diagnoses of heart disorders, such as enlargement of a heart chamber, or lung diseases, such as tuberculosis or lung cancer. They may also be used to examine the ribs after an injury. The procedure is simple, quick, and painless. (See also *X-rays*.)

Cheyne–Stokes respiration

An abnormal pattern of breathing in which the rate and depth of respiration vary rhythmically. Cheyne–Stokes respiration is characterized by repeated cycles, each lasting a few minutes, of deep, rapid breathing that becomes slower and shallower and then stops for between 10 and 20 seconds.

The pattern of Cheyne–Stokes respiration may be due to a malfunction in the part of the brain that controls breathing (as occurs in some cases of *stroke* and *head injury*). It may be due to *heart failure* or occur in healthy people at high altitude, especially during sleep.

chickenpox

A common, mild infectious disease, also called varicella, most often occurring in children. Symptoms are a rash and slight fever. In adults, chickenpox is uncommon but usually more severe. An attack gives lifelong immunity, but the causative virus remains dormant in nerves and may reappear later in life to cause *herpes zoster* (shingles).

CAUSE AND SYMPTOMS

Chickenpox is caused by the varicella zoster virus, which is spread in airborne droplets. A widespread rash develops two to three weeks after infection and consists of clusters of small, red, itchy spots that become fluid-filled blisters within a few hours. After several days, the blisters dry out to form scabs.

Scratching the blisters can lead to secondary infection and scarring. In adults, or in anyone whose immune system is suppressed by drug treatment or illness, serious complications involving the lungs can occur.

People with chickenpox are highly infectious from about two days before the rash appears to about a week afterwards. Nonimmune pregnant women should be particularly careful to avoid children with chickenpox or anyone with shingles, because the disease may be serious in pregnancy and newborn babies could suffer a severe attack.

TREATMENT

In most cases, no specific treatment is needed. *Paracetamol* helps to reduce fever, and *calamine* lotion may be used to relieve itching. Anyone at high risk who has been exposed to the virus may be given treatment with *immunoglobulin*, which may prevent the condition from developing. In severe cases of chickenpox, in both children and adults, *aciclovir* (an antiviral drug) is given.

chigoe

A painful, itchy swelling, about the size of a pea, caused by a sand flea that lives in sandy soil in Africa and tropical America. When stepped on, the flea penetrates the skin of the feet and lays eggs. Chigoe fleas should be removed with a sterile needle, and the wounds treated with an antiseptic.

chilblain

An itchy, purple-red swelling, usually on a toe or a finger. Chilblains are caused by excessive constriction (narrowing) of small blood vessels below the surface of the skin in cold weather. They are most common in young children and elderly people, and women are more susceptible to them. They generally heal without treatment.

child abuse

Maltreatment of children. Child abuse includes physical injury, *sexual abuse*, emotional mistreatment, and/or neglect; it occurs at all levels of society.

Child abuse can cause severe physical and psychological damage in the victims. In addition, being deprived or ill-treated in childhood may predispose some affected people to repeat the pattern of abuse with their own children.

childbed fever

See *puerperal fever*.

childbirth

The event during which a baby leaves the mother's *uterus* (womb) and enters the outside world. The process of childbirth, known as labour, normally takes place between 38 and 42 weeks of pregnancy, as timed from the mother's last menstrual period.

For most women who receive a high standard of medical care during pregnancy (see *antenatal care*) and delivery, childbirth presents no serious problems. The development of specialized equipment and the availability of *blood transfusions* and *antibiotic drugs* have made childbirth much safer for both mother and baby. In developing countries, however, the number of women who die from childbirth remains high (see *maternal mortality*).

ONSET OF LABOUR

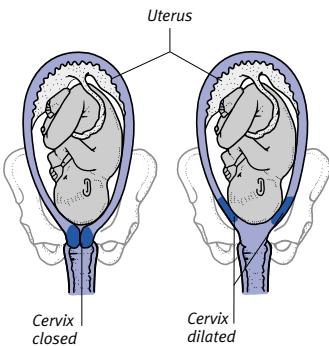

It is often difficult to determine precisely when labour has started. During the last three months of pregnancy, the uterus begins to contract in preparation for the birth. Such contractions, called

STAGES OF CHILDBIRTH

At the onset of labour, painful and regular uterine contractions begin and the cervix (the neck of the womb) starts to dilate (widen). The mother is usually examined vaginally every two to four hours to assess the extent of dilation. The duration of the first stage of labour depends on several factors, but primarily on whether the baby is the mother's first or a subsequent child. *Fetal heart monitoring*

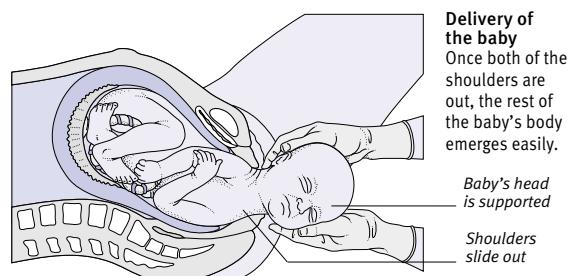

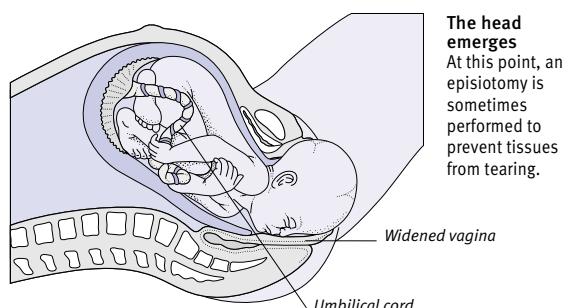

THE FIRST STAGE

With the first contractions, the normally thick, tough cervix becomes thinned and softened and is gradually pulled up until it becomes effaced (merged with the walls of the uterus). The cervix then begins to dilate (stretch open) with each contraction. It is fully dilated when the opening is about 10 cm in diameter. This stage of labour can take 12 hours or more for first babies, but only a few hours for subsequent babies.

THE SECOND STAGE

As the baby's head descends, it reaches the pelvic floor muscles, which cause the head to rotate until eventually the baby's chin is pointing down towards the mother's rectum. As the baby is pushed further down the birth canal, the mother's anus and perineum (the area between the vulva and anus) begin to bulge out, and soon the baby's head can be seen at the opening of the vagina. As the head emerges, the perineal tissues are stretched very thin; sometimes it is necessary to perform an *episiotomy* (cutting of the tissues under local anaesthetic) to prevent them from tearing. As soon as the baby's head emerges, it turns, usually aided by the midwife, so it is once more in line with the body. With the next few contractions, one shoulder is delivered at a time; then the rest of the baby slides out. After delivery, the cord is clamped and cut.

is often carried out, and the frequency, strength, and duration of the mother's contractions are recorded. During the second stage of labour, the contractions become stronger and the woman feels the urge to push; however, she is advised to push only during a contraction. Once the baby is delivered, he or she is usually laid on the mother's abdomen, but may first be warmed, dried, and checked by a midwife or doctor.

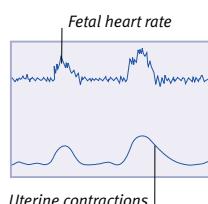

ELECTRONIC FETAL MONITORING

This may be performed if the fetus is at risk, or as a routine check. The fetal heart rate and the mother's uterine contractions are recorded.

Fetal monitoring devices

In the procedure shown above, the baby's heartbeat is detected by a metal plate strapped to the lower belt. A plate beneath the upper belt detects the contractions. An alternative method is to attach an electrode to the baby's head; the electrode is linked to the monitor by a wire passed through the mother's vagina.

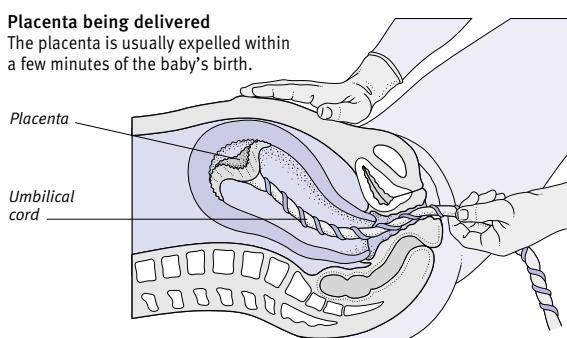

THE THIRD STAGE

Three to 10 minutes after the birth, the placenta (afterbirth) separates from the uterine wall and is removed by gentle traction on the cord. Drugs such as ergometrine or oxytocin may be used to aid its expulsion and to reduce bleeding. Rarely, the placenta may have to be manually removed, under general or epidural anaesthetic, by an obstetrician. Any tears or incisions are cleaned and stitched. This may be done while the mother holds her baby.

Placenta being delivered

The placenta is usually expelled within a few minutes of the baby's birth.

PAIN RELIEF IN LABOUR AND DELIVERY		
Method	Why given	Possible effects on baby
Narcotic analgesics	Routine pain relief during labour	Baby may be less responsive at birth, and may have respiratory problems, but these effects are reversible
Epidural	Routine pain relief during labour, delivery of twins, breech delivery, and caesarean section	Effects are uncommon unless mother's blood pressure falls
Nitrous oxide	Pain relief during labour and delivery; used for short periods only	None
Pudendal block	Forceps delivery	None
Local anaesthetic into perineum	Forceps delivery or episiotomy	None
General anaesthesia	Caesarean section	Baby may show reduced responsiveness at birth

Braxton Hicks' contractions may be mistaken for the onset of labour. However, when the contractions become progressively more painful and occur more regularly and with shorter intervals between, labour has probably started.

At the onset of labour, the *cervix* (the neck of the uterus) becomes thinned and softened and then begins to dilate with each contraction. During this time, there may be a "show", which is when the mucous plug that blocks the cervical canal during pregnancy is expelled as a bloody discharge. "Breaking of the waters", which is the rupture of the *amniotic sac* (the fluid-filled membranous bag that protects the fetus in the uterus), may occur either as a slow trickle of fluid from the vagina or as a sudden gush.

STAGES OF LABOUR

Childbirth occurs in three stages (see illustrated box on p.163 for details).

The first stage of childbirth covers the period lasting from the onset of labour to the point when the woman's cervix is fully dilated, which is when the opening has widened to about 10 cm in diameter. The duration of this stage varies from woman to woman and from birth to birth.

The second stage of labour lasts from full dilation of the cervix until the delivery of the baby. In this stage, the mother feels the urge to push with each strong contraction. As the baby's head descends into the mother's *vagina*,

the baby rotates to face the mother's back. Once the baby's head is delivered, the rest of the body follows with the next contractions. After delivery, the *umbilical cord*, which connects the baby to the *placenta*, is clamped and cut.

In the third stage of labour, the delivery of the placenta (the afterbirth) takes place. This event happens within about ten minutes of the baby's birth.

PAIN RELIEF

Pain relief is available during normal labour and delivery. There are various forms, including opioid *analgesic drugs*, *epidural anaesthesia*, and *pudendal block*. (See also *childbirth, complications of, childbirth, natural*.)

childbirth, complications of

Problems that occur during *labour* and delivery. Complications may affect the mother, the baby, or both. Some are potentially life-threatening, especially to the baby if they impair the baby's oxygen supply (see *fetal distress*).

MATERNAL PROBLEMS

If contractions begin, or if the membranes rupture, before the 37th week of pregnancy, premature labour may occur, with the delivery of a small, immature baby (see *prematurity*).

Premature rupture of the *amniotic sac* (the fluid-filled, membranous bag that protects the fetus in the uterus) can lead to infection in the *uterus*, requiring prompt delivery of the baby and treatment with *antibiotic drugs*.

Slow progress in the first stage of a normal labour may be due to inadequate contractions of the uterus. It is usually treated with intravenous infusions of synthetic *oxytocin*. If the mother cannot push strongly enough, or if the contractions are ineffective in the second stage of labour, the baby may be delivered by *forceps delivery*, *vacuum extraction*, or *caesarean section*.

Rarely, *eclampsia* (convulsions associated with raised blood pressure) may develop during labour. This disorder requires treatment with *anticonvulsant drugs* and oxygen, and a caesarean section will be necessary.

Bleeding before labour (*antepartum haemorrhage*) or during labour may be caused by premature, partial separation of the *placenta* from the wall of the uterus. Less commonly, it may result from a condition called *placenta praevia*, in which the placenta lies over the opening of the *cervix*. Blood loss after the delivery (*postpartum haemorrhage*) is usually due to failure of the uterus to contract after delivery, or to retention of part of the placenta.

FETAL PROBLEMS

If the baby lies in the breech position (see *breech delivery*), or in any other *malpresentation* (not lying in the normal head-down position in the uterus), caesarean section may be necessary.

Multiple pregnancies (see *pregnancy, multiple*) carry an increased risk of problems during delivery due to the difficulty of predicting the position of the second or subsequent babies. It is also more likely that babies in multiple pregnancies will be born prematurely.

FETAL-MATERNAL PROBLEMS

If the mother's pelvis is too small in proportion to the head of her baby (a condition known as *cephalopelvic disproportion*), the baby may have to be delivered by caesarean section.

childbirth, natural

The use of relaxation and other techniques to help cope with pain and minimize the use of drugs and medical intervention during *childbirth*.

child development

The acquisition of physical, mental, and social skills in children. Although there is wide variation in individual rates of progress, most children develop certain skills within predictable age ranges (see the illustrated boxes opposite and overleaf).

FACTORS AFFECTING DEVELOPMENT

The capability for acquiring new skills is dependent upon the maturity of the child's nervous system. Individual rates of maturity are determined genetically and modified by environmental factors in the *uterus* and after birth. For example, premature children miss out on a portion of the growing time in the uterus; therefore, the time that they take to progress should, be calculated from the full-term pregnancy date, not the actual date of birth.

Sight and hearing are both crucial to a child's general developmental progress; any defect in these areas will affect the child's ability to watch, listen, learn, and imitate. Intelligence also affects the speed of development.

Speaking to and playing with children is essential for their language development and to help them practise new physical skills. Introducing children to other children also provides them with a great deal of stimulation.

DEVELOPMENTAL MILESTONES

Development is assessed in early childhood by looking at the child's abilities in four major areas: physical skills; hearing and language; vision and fine movement; and social behaviour and play. Children acquire particular skills at widely recognized stages known as developmental milestones.

All children acquire skills in much the same order (for example, a child will not learn to stand before learning to sit); however, the rate at which these

skills are acquired varies enormously from child to child. A child may develop more rapidly in one area than in another. A more detailed assessment is required only if a child's progress is significantly slower than average or if a parent is concerned for other reasons (see *developmental delay*).

child guidance

A form of care provided by a multidisciplinary diagnosis and advice team, which helps children suffering from emotional or behavioural difficulties (see *behavioural problems in children*). Indications of such problems include poor performance at school, disruptive or withdrawn behaviour, breaking the law, and *drug abuse*.

CHILD DEVELOPMENT: 0–18 MONTHS

Locomotion

By 6 months

Babies can lift up their heads and chests and roll from front to back and back to front. They can sit up with support, bounce up and down, and bear weight on their legs if supported.

9 months

Babies try to crawl, sit without support, and pull themselves up to standing or sitting positions. They can step purposefully on alternate feet if they are supported.

1 year

Children can crawl on hands and knees and walk around furniture (holding on). They may be able to walk alone or with one hand held.

18 months

Children can walk well with feet closer together. They can stoop to pick up objects, run with care, walk upstairs with one hand held, and crawl backwards downstairs.

Vision and fine movement

By 6 months

Babies look intently at everything and everybody. They follow moving objects with their eyes and reach for objects with one or both hands. Objects are transferred from hand to hand and brought to the mouth.

9 months

Babies are visually very alert. Their grasp involves mostly the index and middle fingers. They can manipulate objects with both hands, but have difficulty voluntarily releasing grasped objects.

1 year

Children can grasp small objects well and release grasped objects easily. Both hands are used equally. They can hold a block in each hand and bang the blocks together.

18 months

Children can build a tower of three blocks (when shown), enjoy turning pages of a book, can grip a crayon, scribble, and make dots. They may use one hand more than the other.

Hearing, understanding, and speech

By 6 months

Babies turn their heads to locate sources of sound and have begun to understand the tone of their mother's voice. They enjoy making vowel sounds and tuneful noises. They laugh and squeal.

9 months

Babies listen to sounds and understand "no" and other words. They babble in long strings (making sounds such as ba-ba, da-da, ma-ma) and start using sound to attract attention. (Deaf babies' utterances are monotonous and do not develop in complexity.)

1 year

Children turn when they hear their own name spoken. They have some understanding of how other people feel; they know what most household objects are used for; they may babble meaningfully to themselves; and they may say two or three words.

18 months

Children comprehend short communications spoken directly to them but do not understand the difference between statements, commands, and questions. Vocabulary may contain six to 20 words.

Social behaviour and play

By 6 months

Babies enjoy looking at their images in mirrors and playing peekaboo games. They can grasp objects and can also shake, bang, and otherwise manipulate them. They will not, however, look for objects that are shown and then hidden. They are shy with strangers.

9 months

Babies look for objects that are shown and then hidden, thus showing the beginnings of memory. They imitate hand clapping, wave bye-bye, and show great determination in getting objects. They continue to be shy with strangers.

1 year

Children spend less time putting objects in their mouths and more time releasing objects by throwing them, dropping them, putting them in boxes. They play pat-a-cake and like to be around a familiar adult to whom they demonstrate affection.

18 months

Children actively explore their homes. They enjoy moving things into and out of boxes and looking at picture books. They use spoons and cups and can take off their shoes and socks. They are also determined, impetuous, selfish, and cannot be reasoned with. They alternate between clinging to a familiar adult and struggling to break free.

CHILD DEVELOPMENT: 2–5 YEARS**Locomotion****2 years**

Children can climb furniture and walk up and down stairs (using two feet to each step).

3 years

Children can climb with agility, throw and kick balls, ride tricycles, and run around corners.

4 years

Children walk up and down stairs with one foot on each step, and can stand, walk, and run on tiptoe.

5 years

Children can stand and hop on one foot, and are skilful in rolling, sliding, and swinging.

Vision and fine movement**2 years**

Children can build towers of six or seven blocks, can unscrew a lid, and show a definite right- or left-handedness.

3 years

Children hold crayons with an adult grasp and can undo buttons, but may need help buttoning them up. Their handedness is clearly established.

4 years

Children hold a pencil with a mature grasp, can copy simple letters (i.e. O,T, H or V), and can build a tower of more than 10 blocks.

5 years

Children can match 10 or 12 colours, can copy many more letters, and can draw the full body of a person with a recognizable head and facial features.

Hearing, understanding, and speech**2 years**

Children begin to listen to general conversation. They obey simple instructions and can use 50 or more words meaningfully. They constantly talk to themselves and can put two or more words together to communicate.

3 years

Children listen to conversation and enjoy nursery stories. They understand the difference between statements, commands, and questions. They have large vocabularies and speak clearly in sentences; there may be some errors.

4 years

Children can repeat softly spoken words at a distance of 1 m. They speak fluently and with correct grammar, and can provide their full names, ages, and addresses. They tell long stories, confusing fact and fantasy.

5 years

Children enjoy reciting rhymes, telling stories, and having books read to them.

Social behaviour and play**2 years**

Children ask the names of everything and enjoy participating in nursery rhymes and songs. They ask for food and drink and indicate toilet needs. They begin to play with toys more imaginatively, though they may not like to share them. They are constantly demanding and will throw tantrums if their desires are thwarted.

3 years

Children constantly ask questions. They can dress and undress and eat with a fork and spoon. They are dry and clean during the day and sometimes at night. Three year olds can play with toys imaginatively and will share with others. They can be reasoned with and have fewer tantrums. They are also more affectionate to younger siblings.

4 years

Children continue asking questions constantly. They are more independent and skilful in dressing, undressing, eating, and washing. They need to play with other children and can share with others. They can understand past, present, and future.

5 years

Children ask the meaning of abstract words. They like to build complex structures out of bricks or other objects. They continue in imaginative and dramatic play. They enjoy companionship and understand the need for rules and fair play. They have an understanding of time and are generally sensible, restrained, and independent.

Child guidance professionals include the specialists such as psychiatric social workers, psychiatrists, and psychologists. These people often work closely together in hospital paediatric departments, in schools, or in child-guidance clinics.

Various methods of assessment and therapy may be employed, depending on the age of the child and the problem involved. For young children, *play therapy* may be used to help with diagnosis. Older children may be offered *counselling*, *psychotherapy*, or *group therapy*. *Family therapy* may be of benefit in cases where there are relationship difficulties between child and one or both parents.

chill

A shivering attack accompanied by chattering teeth, pale skin, goose pimples, and feeling cold. Chill frequently precedes a fever. Repeated or severe shivering suggests serious illness.

Chinese medicine

Traditional Chinese medicine is based on the theory that a universal life-force, called chi, manifests itself in the body as two complementary qualities called *yin* and *yang*. According to this belief, vigorous yang and restraining yin must be in balance, and the chi must flow evenly for good health.

Treatments for illness aim to restore the balance between yin and yang and normalize the flow of chi in the body. They include Chinese *herbal medicine*, physical techniques such as *acupressure* and *acupuncture*, and *t'ai chi*.

chiropody

The examination, diagnosis, treatment, and prevention of diseases and malfunctions of the foot and its related structures. Chiropody is concerned with many different types of foot problem, including walking disorders in chil-

dren, ankle injuries in adolescents, fractures in athletes and joggers, *bunions* and *hammer toes* in people of all ages, and the care of ulcers, toenails, and infections of the feet suffered as a complication of *diabetes mellitus*. A person who specializes in chiropody is called a chiropodist.

chiropractic

A system of treatment for a range of disorders, that is based on manipulation of the spine. The main principle of chiropractic is the theory that disease stems from the misalignment of bones, which causes various problems with the nerves and muscles.

chlamydial infections

A group of infectious diseases caused by chlamydiae, a group of bacteria that can multiply only by invading the cells of another life-form.

TYPES

Two main species of chlamydiae cause disease in humans. They can be treated with *antibiotic drugs*.

The first species, *CHLAMYDIA TRACHOMATIS*, is responsible for some sexually transmitted infections, including about half of all cases of *nongonococcal urethritis* in men and *pelvic inflammatory disease* in women. It can also cause the tropical eye disease *trachoma*.

A second species, *CHLAMYDIA PSITTACI*, is responsible for *psittacosis*. This is a rare form of pneumonia that is transmitted to humans from birds.

Chlamydia is also responsible for a type of pneumonia (see *Chlamydia pneumoniae*).

Chlamydia pneumoniae

An infectious organism that can cause a mild form of *pneumonia*, which occurs particularly in young adults.

Chlamydia psittaci

An organism that mainly affects birds but can occasionally spread to people who are in contact with pigeons, parrots, parakeets, or poultry. It causes a type of pneumonia called *psittacosis*.

Chlamydia trachomatis

An organism that belongs to the chlamydiae group and has several strains. In men, it is a major cause of the sexually transmitted infection *nongonococcal urethritis*, which may cause a discharge from the penis. In women, the infection usually causes no symptoms, but can lead to *pelvic inflammatory disease* and possibly *salpingitis* (inflammation of the fallopian tubes). A baby born to a woman with chlamydial infection may acquire an acute eye disorder called neonatal *ophthalmia*.

In some parts of Africa and Asia, certain strains of *CHLAMYDIA TRACHOMATIS* cause *trachoma*, a serious eye disease that is the most common cause of blindness worldwide.

chloasma

A skin condition, also called melasma, in which blotches of pale brown pigmentation appear on the face, notably on the forehead, nose, and cheeks. The condition is aggravated by sunlight. Chloasma sometimes develops during pregnancy. More rarely, it is associated with the menopause or the use of *oral contraceptives*. The areas of abnormal pigmentation usually fade in time, but the condition may recur.

chloral hydrate

A type of *sleeping drug*.

chlorambucil

An *anticancer drug* that is used in the treatment of some types of cancer, such as *Hodgkin's disease*.

chloramphenicol

An *antibiotic drug* commonly used as drops to treat superficial eye infections. Chloramphenicol is also used to treat life-threatening infections of unknown cause. Rarely, tablets or injections are associated with aplastic *anaemia*.

chlorate poisoning

The toxic effects of chemicals called chlorates, which are present in some defoliant weedkillers.

Symptoms of chlorate poisoning include ulcers in the mouth, abdominal pain, and diarrhoea. Chlorates can also cause kidney and liver damage, corrosion of the intestines, and *methaemoglobinæmia* (a harmful chemical change in the blood pigment *haemoglobin*). Even small doses can be fatal; medical help is needed immediately if chlorate poisoning is suspected.

chlordiazepoxide

A *benzodiazepine drug* mainly used in the treatment of *anxiety*.

chlorhexidine

A type of disinfectant mainly used to cleanse the skin before surgery or before taking a blood sample.

chlorine

A poisonous, yellowish-green gas with powerful bleaching and disinfectant properties. If inhaled in even very small amounts, chlorine gas is highly irritating to the lungs; inhalation of large amounts is rapidly fatal.

chlorofluorocarbon propellants

Aerosol propellants, commonly known as CFCs, that contain compounds of gases such as carbon, chlorine, fluorine, and hydrogen. CFCs have contributed to the damage to the ozone layer.

chloroform

A colourless liquid producing a vapour that was formerly used as a general anaesthetic (see *anaesthesia, general*). However, chloroform is associated with liver damage and heart problems and safer drugs are now used instead.

Chloromycetin

A brand name for the antibiotic drug *chloramphenicol*, which is often used in eye and ear preparations.

chloroquine

A drug used mainly in the prevention and treatment of *malaria*. It is also used as an *antirheumatic drug* to treat *rheumatoid arthritis* and *lupus erythematosus*.

Possible side effects of chloroquine include nausea, headache, diarrhoea, rashes, and abdominal pain. Long-term use may damage the retina of the eye.

chlorphenamine

An *antihistamine drug* that is used to treat a number of allergic conditions such as *allergic rhinitis* (hay fever), *allergic conjunctivitis*, *angioedema* (allergic facial swelling) and *urticaria* (nettle rash). Chlorphenamine is also a component of some *cold remedies*.

chlorpheniramine

An alternative name for *chlorphenamine*.

chlorpromazine

A widely prescribed *antipsychotic drug* used to relieve symptoms of major psychotic illnesses such as *schizophrenia* and *mania*. The drug reduces delusional and hallucinatory experiences and may have an effect on irritability and overactivity. It is also used as an *antiemetic drug* to treat nausea and vomiting, especially when these problems are the result of treatment with other drugs, radiotherapy, or anaesthesia.

Chlorpromazine may cause *photosensitivity* (increased sensitivity of the skin to sunlight) and, in some cases, *parkinsonism* (a movement disorder), slow reactions, and blurred vision.

chlorpropamide

A drug that is used to treat *diabetes mellitus* (see *hypoglycaemics, oral*).

choanal atresia

A *congenital* abnormality of the *nose* in which one or both of the nasal cavities are not fully developed.

chocolate cyst

A brown swelling in an *ovary*. Chocolate cysts may develop in *endometriosis*, a condition in which endometrial tissue (which forms the lining of the uterus) is found in sites outside the uterus. The colour is the result of clotted blood within the cysts.

choking

Partial or complete inability to breathe due to an obstruction of the airways. Choking is often caused by food or drink entering the *trachea* (the windpipe) or the bronchi (the main airways to the lungs) instead of passing from the *pharynx* (throat) into the *oesophagus* (gullet). Normally, coughing dislodges the food or drink. An obstruction that partially blocks the airway, and which cannot be dislodged by coughing, is more serious. If the airway is completely blocked, total suffocation will occur if the obstruction is not removed.

If an obstruction cannot be cleared by the use of first-aid techniques, such as the *Heimlich manoeuvre*, or removed by hand, it may be necessary to perform an emergency *tracheostomy* (the making of an incision into the trachea and insertion of a tube through it into the lungs) to restore the airway. The object may then be removed by *laryngoscopy* or *bronchoscopy* (procedures that involve a viewing tube through which instruments are passed).

cholangiocarcinoma

A cancerous growth in one of the *bile ducts*. Cholangiocarcinoma causes *jaundice* and weight loss.

cholangiography

An imaging procedure involving the use of a *contrast medium* (a substance that is opaque to X-rays) to make the *bile ducts* visible on X-rays. It is used to diagnose biliary stones (which are similar to *gallstones*, but they develop in the bile ducts instead of the gallbladder) and narrowing or tumours of the bile ducts. The procedure is being superseded by *ultrasound scanning* and *MRI*, both of which can be used to locate stones.

cholangitis

Inflammation of any of the bile ducts, such as the common bile duct, which leads from the liver and gallbladder to the small intestine (see *biliary system*). There are two forms of the condition: acute ascending cholangitis and sclerosing cholangitis.

ACUTE ASCENDING CHOLANGITIS

This form of cholangitis is usually due to bacterial infection of the duct and its bile. The infection, in turn, generally results from blockage of the duct – for example, by a gallstone (see *bile duct obstruction*). The infection spreads up

the duct and may affect the liver. The main symptoms of acute ascending cholangitis are recurrent bouts of *jaundice*, abdominal pain, chills, and fever.

Mild attacks are treated with *antibiotic drugs* and fluids. Severe attacks may be accompanied by life-threatening *septicaemia* (blood poisoning) and *kidney failure*. In these cases, the infected material may be drained from the bile duct during surgery or *endoscopy* (a procedure in which instruments are passed through a viewing tube).

SCLEROSING CHOLANGITIS

In this rare condition, all the bile ducts within and outside the liver become narrowed. This causes *cholestasis* (stagnation of the bile in the liver), chronic jaundice, and itchiness of the skin, and the liver is progressively damaged.

The drug *colestyramine* may relieve itching. The only other treatment available is a *liver transplant*.

chole-

A prefix that means “relating to the *bile* or the *billary system*”, as in *cholecystitis* (inflammation of the gallbladder).

cholecalciferol

An alternative name for *colecalciferol*, also called vitamin D₃ (see *vitamin D*).

cholecystectomy

Surgical removal of the *gallbladder*. Cholecystectomy is usually performed to deal with the presence of troublesome *gallstones*. It is also used in cases of acute *cholecystitis* (inflammation of the gallbladder) and as an emergency treatment for rupture of the gallbladder or *empyema* (accumulation of pus).

Cholecystectomy may be carried out using conventional surgery or, more commonly, by *minimally invasive surgery* using a *laparoscope* (a type of viewing tube through which instruments can be passed), as shown in the illustrated box opposite.

cholecystitis

Acute or chronic painful inflammation of the *gallbladder*.

CAUSES AND SYMPTOMS

Acute cholecystitis is usually caused by a *gallstone* obstructing the outlet from the gallbladder. The trapped bile inside becomes more concentrated, because water is absorbed from it, and irritates the gallbladder walls. Bacterial infection of the bile may result. The main symptom of acute cholecystitis is

severe, constant pain in the right side of the abdomen under the ribs, accompanied by fever and, occasionally, *jaundice*.

Repeated mild attacks of acute cholecystitis can lead to a chronic form of the condition, in which the gallbladder shrinks, its walls thicken, and it ceases to store bile. Symptoms include indigestion, pains in the upper abdomen, nausea, and belching; they may be aggravated by eating fatty foods.

TREATMENT AND COMPLICATIONS

Treatment of cholecystitis usually involves the use of *analgesic drugs*, *antibiotic drugs*, and an intravenous infusion of nutrients and fluids. In some affected people, complications develop. These may include *peritonitis* (inflammation of the lining of the abdominal cavity), if the gallbladder bursts, and *empyema* (an accumulation of pus). Both of these complications require urgent surgical treatment. *Cholecystectomy* (removal of the gallbladder) is the usual treatment for chronic cholecystitis.

cholecystography

An X-ray procedure in which a *contrast medium* (a substance that is opaque to X-rays) is used for viewing of the *gallbladder* and common *bile duct*. The technique of cholecystography is usually used for the detection of *gallstones* but has largely been replaced by *ultrasound scanning* of the gallbladder.

cholecystokinin

A *hormone* that is produced in the *duodenum* (the first section of the small intestine) in response to the ingestion of fats and certain other food substances. Cholecystokinin stimulates the *gallbladder* to release bile into the duodenum, and triggers the secretion of digestive enzymes from the *pancreas*, thus aiding the breakdown of foods to release nutrients. Cholecystokinin is also found in the brain, where it has a function as a *neurotransmitter*.

choledochal cyst

A widening of the common bile duct, which carries the digestive juice bile from the liver and gallbladder to the *duodenum*. The disorder is congenital (present at birth), but symptoms may not develop until early adulthood; they consist of abdominal pain and jaundice (yellow coloration of the skin and eyes due to the accumulation of bilirubin, a bile pigment). Surgery is needed to correct the abnormality.

cholelithiasis

See *gallstones*.

cholera

An infection of the small intestine by the bacterium *VIBRIO CHOLERAE*. The dis-

ease causes profuse watery diarrhoea, which can lead to dehydration and death in severe untreated cases.

CAUSE AND INCIDENCE

Infection is acquired by ingesting contaminated food or water. Outbreaks of

the disease occur regularly in northeast India, but worldwide cholera is controlled by sanitation.

SYMPTOMS

Cholera starts suddenly, between one and five days after infection, with diarrhoea that is often accompanied by vomiting. More than 500 ml of fluid may be lost each hour and, if this fluid is not replaced, severe dehydration and then death may occur within hours. The fluid loss is caused by the action of a toxin produced by the cholera bacterium that greatly increases the passage of fluid from the bloodstream into the large and small intestines.

TREATMENT

Treatment is with water containing salts and sugar (see *oral rehydration therapy*) and, in severe cases, by *intravenous infusion*. *Antibiotic drugs* can shorten the period of diarrhoea and infectiousness. After adequate rehydration, affected people usually make a full recovery from the infection.

PREVENTION

Cholera is controlled worldwide by the improvement of sanitation, and in particular by ensuring that sewage is not permitted to contaminate water supplies used for drinking. Vaccination against cholera is not recommended. Travellers planning to visit cholera-infected areas are advised to consume only water that has been boiled, or bottled drinks from reliable sources.

cholestasis

Stagnation of *bile* in the small *bile ducts* within the liver, leading to *jaundice* and liver disease. The obstruction to the flow of bile may be intrahepatic (within the liver) or extrahepatic (in the bile ducts outside the liver).

CAUSES

Intrahepatic cholestasis may develop as a result of viral hepatitis (see *hepatitis, viral*) or as an adverse effect of various drugs. The flow of bile will improve gradually as the inflammation from hepatitis subsides or when a causative drug is discontinued.

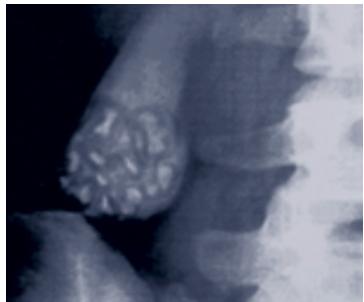

The bile ducts outside the liver can become blocked by abnormalities such as gallstones or tumours (see *bile duct obstruction*). Rarely, the ducts are absent from birth (see *biliary atresia*).

TREATMENT

Bile duct obstruction and biliary atresia are often treated surgically to ensure or restore the free passage of bile from the liver to the duodenum.

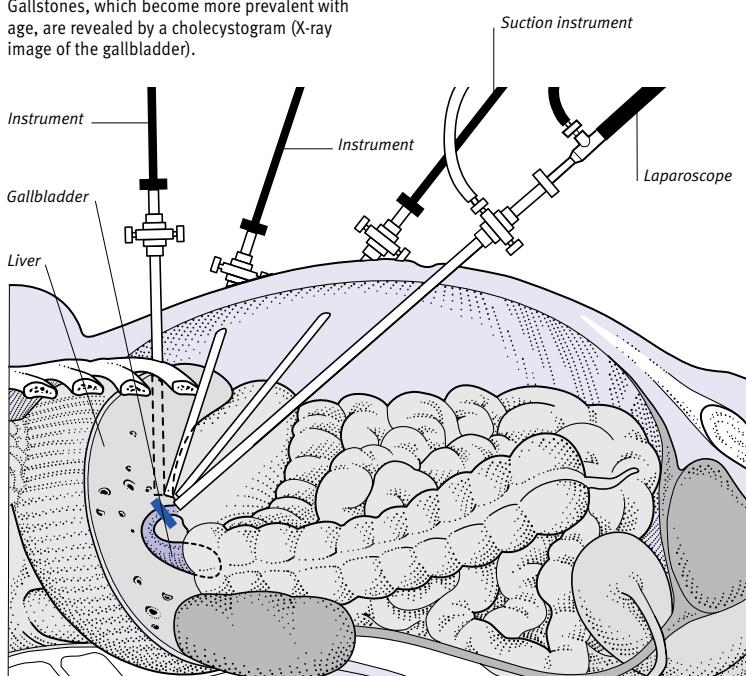

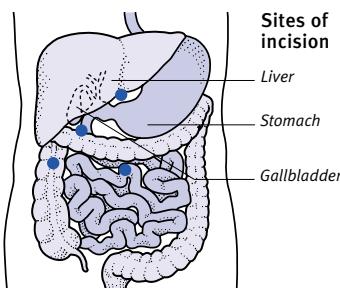

CHOLECYSTECTOMY

Surgery to remove the gallbladder (cholecystectomy) can be performed conventionally or laparoscopically. The procedure is performed under general anaesthesia; it is most often carried out when the gallbladder has been found to contain gallstones.

Cholecystogram of the gallbladder
Gallstones, which become more prevalent with age, are revealed by a cholecystogram (X-ray image of the gallbladder).

Laparoscopic cholecystectomy (pictured here), despite taking twice as long as conventional surgery (about two hours), has the advantage of requiring only small incisions and allowing most patients to make a full recovery in 7 to 10 days.

Procedure for cholecystectomy

The abdominal cavity is inflated with gas to provide a clear view, then a laparoscope fitted with a video camera is introduced through a small incision. Further instruments are passed

through other incisions. While watching the monitor, the surgeon removes the gallbladder, ensuring that there is no leakage from the bile duct or blood vessels.

cholestatic jaundice

Jaundice (yellow discolouration of the skin) that occurs as a result of *cholestasis* (obstruction in the flow of bile to the intestine).

cholesteatoma

A rare but serious condition in which skin cells proliferate and grow inwards from the ear canal into the middle ear. Cholesteatoma usually occurs as a result of long-standing *otitis media* (a middle-ear infection) together with a defect in the eardrum (see *eardrum, perforated*). If left untreated, it may grow and damage the small bones in the middle ear and surrounding structures.

Cholesteatoma needs to be removed surgically through the eardrum or by *mastoidectomy* (removal of the mastoid bone, which is located behind the ear, together with the cholesteatoma).

cholesterol

A fat-like substance that is an important constituent of body cells and also is involved in the formation of *hormones* and bile salts. Cholesterol is made by the liver from various foods, especially those containing saturated fats (see *fats and oils*), although a small amount is absorbed directly from cholesterol-rich foods such as eggs and shellfish.

Both cholesterol and fats (triglycerides) are transported in the blood as lipoproteins. These are particles with a core, which is made of varying proportions of cholesterol and triglycerides, and an outer layer made of proteins.

CHOLESTEROL-RELATED DISEASES

High blood cholesterol levels increase the risk of *atherosclerosis* (accumulation of fatty deposits on the lining of the arteries) and with it the risk of *coronary artery disease* or of *stroke* (damage to part of the brain due to interruption of its blood supply). In general, cholesterol transported in the bloodstream as low-density lipoproteins (LDLs) or as very low-density lipoproteins (VLDLs) is a risk factor for these conditions, while cholesterol in the form of high-density lipoproteins (HDLs) seems to protect against arterial disease.

Levels of cholesterol in the blood are influenced by diet, genetic factors, and metabolic diseases such as *diabetes mellitus*. Cholesterol levels can be measured by blood tests. They are measured in millimoles per litre (mmol/L). The optimum level is less than 5.0. Higher levels may require dietary modification.

Sometimes, however, medication (such as *simvastatin*) may be required to reduce the risk of arterial diseases.

cholesterolosis

Abnormal deposits of *cholesterol* in the lining of the gallbladder that may be associated with the development of *gallstones*. Cholesterolosis is sometimes known as strawberry gallbladder because of the appearance of an affected gallbladder.

cholestyramine

An alternative spelling for the lipid-lowering drug *colestyramine*.

cholic acid

One of the acids contained in *bile*.

cholinergic crisis

A condition that affects people with *myasthenia gravis* who are undergoing treatment with *cholinesterase inhibitors*. The problem is caused by an overdose of cholinesterase inhibitors. During a cholinergic crisis, the muscle weakness that is associated with myasthenia gravis worsens dramatically, and needs emergency medical treatment.

cholinesterase inhibitors**COMMON DRUGS**

- Neostigmine • Pyridostigmine

A group of drugs, also known as anti-cholinesterases, that are used to relieve muscle weakness resulting from myasthenia gravis. In this disease, abnormal activity of the immune system causes the destruction of receptors on muscle cells that bind with acetylcholine, a neurotransmitter that makes the muscles contract. Cholinesterase inhibitors block the action of acetylcholinesterase, the enzyme that normally breaks down acetylcholine, allowing the neurotransmitter more time to act. The drugs are also used to reverse the effects of muscle-relaxant drugs given with general anaesthesia.

chondritis

Inflammation of *cartilage* (connective tissue composed of the gel-like substance collagen). It is usually caused by pressure, stress, or injury.

Costochondritis is inflammation of the cartilage between the ribs and the sternum (breastbone). This condition causes tenderness over the sternum and pain if pressure is exerted on the ribs at

the front of the chest. Chondritis may also affect the cartilage lining the hip and knee joints; this inflammation may eventually lead to *osteoarthritis*.

chondro-

A prefix denoting a relationship to *cartilage*, as in *chondrocyte*, a cell that produces cartilage.

chondrocalcinosis

The presence of calcium pyrophosphate in joint cartilage. The condition, which occurs in *pseudogout* (a form of arthritis), causes pain and swelling.

chondroma

A noncancerous tumour composed of *cartilage*, affecting the bones. Chondromas most often occur in the hands and feet (see *chondromatosis*).

chondromalacia patellae

A painful knee disorder, one cause of anterior knee pain, in which the *cartilage* (connective tissue composed of the gel-like substance collagen) behind the patella (kneecap) is damaged. Adolescents are most commonly affected.

CAUSE

Chondromalacia patellae may result from knee injuries or sporting activities in which the knee is bent for long periods (such as horse-riding). This action may weaken the inner part of the quadriceps muscle (which is at the front of the thigh), causing the patella to tilt when the knee is straightened and rubs against the lower end of the *femur* (thigh bone). The rubbing causes the cartilage that covers both bones to roughen, causing pain and tenderness.

TREATMENT

Treatment of chondromalacia patellae is with *analgesic drugs* (painkillers) and exercises to strengthen the thigh muscles. Rarely, surgery is needed.

chondromatosis

A condition in which multiple non-cancerous tumours, called *chondromas*, arise in the bones, most commonly in the bones of the hands and feet. The tumour cells consist of *cartilage* (connective tissue composed of the gel-like substance collagen). Chondromatosis usually causes no symptoms.

chondrosarcoma

A cancerous growth of *cartilage* (connective tissue composed of the gel-like substance collagen). Chondrosarcoma

occurs within or on the surface of large bones, such as the femur (thigh bone), causing pain and swelling.

The condition usually appears in middle age. The tumour may develop slowly from a noncancerous tumour (see *chondroma*; *dyschondroplasia*) or may grow rapidly from an area of previously normal bone. If a limb is affected, *amputation* of the *bone* above the tumour usually results in a permanent cure. Treatment of sites such as the pelvis or ribs is more difficult.

chordae tendineae

Stringlike strands of fibre that attach the flaps of the mitral and tricuspid *heart valves* to the walls of the ventricles (lower heart chambers). The chordae tendineae, which are popularly known as the heartstrings, prevent the valves from turning inside out.

chordee

Abnormal curvature of the penis, usually downwards. Chordee most often occurs in males with *hypospadias*, a birth defect in which the opening of the urethra lies on the underside of the penis instead of at the tip. It is usually corrected by surgery, between the ages of one and three years.

chorea

A condition that is characterized by irregular, rapid, jerky movements, usually affecting the face, limbs, and trunk. The movements are involuntary and, unlike tics, they are not predictable but occur at random. Chorea disappears during sleep. The disorder is sometimes combined with athetosis (continued writhing movements); this combined condition is known as *choreoathetosis*.

TYPES AND CAUSES

Chorea arises from disease or disturbance of structures lying deep within the brain (in particular, the paired nerve cell groups called the *basal ganglia*). The condition is a feature of *Huntington's disease* and *Sydenham's chorea*. It may also occur in pregnancy, when it is called chorea gravidarum. In addition, chorea may be a side effect of certain drugs, including *oral contraceptives*; certain drugs for psychiatric disorders; and drugs for treating *Parkinson's disease*.

TREATMENT

If the cause of chorea is an underlying disease, the condition may be treated with drugs that inhibit the nerve pathways concerned with movement. If

chorea has occurred as a side effect of a drug, the drug may be withdrawn and a substitute provided.

choreoathetosis

A condition characterized by uncontrollable movements of the limbs, face, and trunk. In this disorder, the jerky, rapid movements typical of *chorea* are combined with the slower, continuous writhing movements of *athetosis*.

Choreoathetosis may occur in children with *cerebral palsy*. It may also be a side effect of certain drugs.

choriocarcinoma

A rare, cancerous *tumour* that develops from placental tissue (see *placenta*) in the uterus. Choriocarcinoma usually occurs as a complication of a *hydatidiform mole* (a noncancerous tumour that arises in placental tissue); however, it sometimes develops after a normal pregnancy, a miscarriage, or an abortion. Occasionally, the tumour may not appear until months or even years after the pregnancy that gave rise to it.

SYMPTOMS

There may be no early symptoms. The tumour may become apparent because of persistent bleeding from the vagina after a miscarriage or abortion, or for more than eight weeks following childbirth. If it is left untreated, the tumour destroys the walls of the uterus; and the cancer may also spread in the bloodstream to the vagina and vulva and then to the liver, lungs, brain, and bones.

DIAGNOSIS AND TREATMENT

Any woman who has been treated for a hydatidiform mole is screened regularly by *ultrasound scanning*. Blood and urine levels of human chorionic gonadotrophin (HCG), a hormone that is normally produced by the placenta, are also measured because high levels of this hormone in the body are associated with choriocarcinoma.

Treatment with *anticancer drugs* is usually very successful. *Hysterectomy* (surgical removal of the uterus) may also be necessary.

chorion

One of the two membranes that surround the *embryo*. The chorion lies outside the *amnion*, has small finger-like projections called the chorionic villi, and develops into the *placenta*.

chorionic gonadotrophin

See *gonadotrophin, human chorionic*.

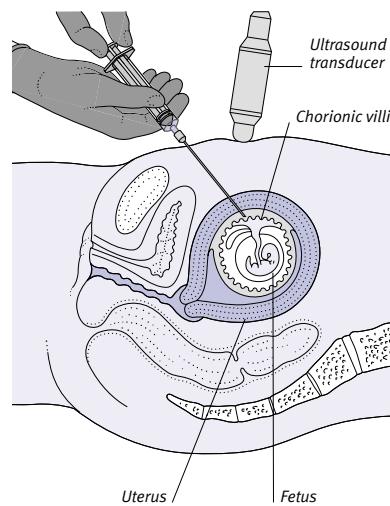

chorionic villi

The short, fingerlike projections that extend from the surface of the *chorion* (the membrane that surrounds a fetus). (See also *chorionic villus sampling*; *villus*.)

chorionic villus sampling (CVS)

A method of diagnosing genetic abnormalities in a *fetus*. The test involves taking a small sample of tissue from the *chorionic villi* at the edge of the *placenta* for laboratory analysis. The cells have the same chromosome makeup as those that form the fetus, so they can be used to detect genetic abnormalities. After removal, the villi cells are transported to a laboratory for *chromosome analysis*.

CVS is offered to women at a higher-than-normal risk of having a child with a genetic disease, such as *thalassaemia*, or a chromosomal abnormality, such as *Down's syndrome*. It is normally performed at around the 10th week of pregnancy and can be carried out via the abdomen (below) or vaginally, depending on the location of the placenta. CVS slightly increases the risk of *miscarriage*.

Sampling via the abdomen

A few chorionic villi are sucked from the placenta through a hollow needle inserted into the abdomen.

choroid

A layer of tissue at the back of the *eye*, beneath the *retina*. The choroid contains a network of blood vessels that supply nutrients and oxygen to the retina and to the surrounding tissues in the eye.

choroiditis

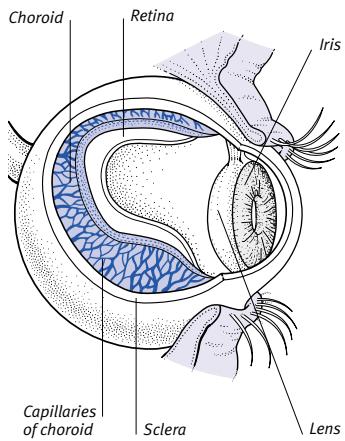

Inflammation of the *choroid* (the blood-rich layer of tissue at the back of the eye). Choroiditis may occur on its own

or as part of a generalized inflammation affecting the whole eye (see *uveitis*). The condition is often the result of infections such as *toxocariasis* or *toxoplasmosis*, and, more rarely, of *sarcoidosis*, *syphilis*, and *histoplasmosis*, although it sometimes has no obvious cause. Chorioditis is painless but causes blurring of vision.

Treatment of chorioditis includes *corticosteroid drugs* to reduce the inflammation and *antibiotic drugs* for any causative infection.

STRUCTURE OF CHOROID

The choroid lines the inside of the eyeball. It thickens around the lens to form the ciliary body. Muscles stretching between the choroid and the lens contract to adjust the shape of the lens in focusing.

choroid plexus

A network of thin-walled blood vessels in the *eye* or *brain*. The choroid plexus of the eye supplies blood to the *retina*. In the brain, the choroid plexus lines the *ventricles* (cavities) and produces *cerebrospinal fluid*.

Christmas disease

A rare genetic bleeding disorder in which there is deficient production of one of the proteins in blood that is needed for blood coagulation (see *blood clotting*).

Christmas disease has similar features to *haemophilia*. However, the deficient proteins are different. In Christmas disease the deficiency is of a protein called factor IX, while in haemophilia the deficiency is of the protein factor VIII.

chromium

A metallic element that plays a vital role in the activities of several *enzymes* (substances that control the rate of chemical reactions) in the body.

Chromium is needed in only minute amounts (see *trace elements*). In excess, it is toxic. It causes inflammation of the skin, and, if inhaled, damages the nose. Chromium fumes may increase the risk of *lung cancer*.

chromosomal abnormalities

Variations from normal in the number or structure of *chromosomes* contained in a person's cells. In most cases, the chromosomal abnormality is present in all of the body's cells. The possible effects range from virtually none to a lethal condition, depending on the particular type of abnormality.

CAUSES

The cause of a chromosomal abnormality is generally a fault in the process of chromosome division, either during the formation of an egg or sperm, or during the first few divisions of a fertilized egg. Occasionally, a parent passes on an abnormal arrangement of his or her own chromosomes.

TYPES

Chromosomal abnormalities are classified according to whether they involve the 44 autosomes (pairs of very similar chromosomes) or the two *sex chromosomes* (X and Y). A whole extra set of chromosomes per cell is called *polyploidy*; this is lethal in early pregnancy.

AUTOSOMAL ABNORMALITIES

These abnormalities cause physical and mental defects of varying severity. Some types of autosomal abnormality, known as *trisomy*, involve the presence of an extra chromosome on one of the 22 pairs of autosomes. The most common trisomy is *Down's syndrome*, which is caused by the presence of three number 21 chromosomes.

Sometimes, part of a chromosome is missing, as in *cri du chat syndrome*. In *translocation*, a part of a chromosome is joined to another, causing no ill effects in the person but a risk of abnormality in his or her children.

SEX CHROMOSOME ABNORMALITIES

Normally, a female has two X chromosomes and a male has an X and a Y. Abnormalities may occur if there are missing or extra sex chromosomes.

In *Turner's syndrome*, a girl is born with only a single X chromosome in her cells instead of the normal comple-

ment of two. The condition causes physical abnormalities, defective sexual development, and infertility.

In boys, one or more extra X chromosomes causes *Klinefelter's syndrome*. This condition results in defective sexual development and infertility.

The presence of an extra X chromosome in women or of an extra Y chromosome in men normally has no physical effect but increases the risk of mild learning difficulties.

DIAGNOSIS

If suspected, chromosomal abnormalities can be diagnosed by *chromosome analysis* in early pregnancy, using *amniocentesis* or *chorionic villus sampling*.

Because chromosomal abnormalities affect every one of a person's cells, no cure is possible. Many disorders caused by autosomal chromosome defects result in early death. Others, such as *Down's syndrome*, are compatible with survival but cause physical and mental disability. Hormonal or surgical treatment, or a combination, can help to correct some of the developmental defects caused by Klinefelter's and Turner's syndromes.

Anyone who has a child or other family member affected by a chromosomal abnormality may wish to consider *genetic counselling* to establish the risk of his or her future children being affected by the condition.

chromosome analysis

Study of the *chromosomes* in cells to find out if a *chromosomal abnormality* is present or to establish its nature.

WHY IT IS DONE

Some pregnancies are associated with a higher-than-average risk of the baby having a chromosomal abnormality. Risk factors include an older mother, the birth of a previous child with a chromosomal defect, or a defect or *translocation* (rearrangement) in the mother's or the father's chromosomes. In many cases, there are no identifiable risk factors, and so all pregnant women are offered a preliminary blood test (see *antenatal screening*) to identify those at high risk of a fetal abnormality. If the fetus is at high risk, a sample of cells is taken for chromosome analysis. If a serious abnormality, such as *Down's syndrome*, is identified, the parents will be offered termination of the pregnancy (see *abortion, induced*) and *genetic counselling* to assess the risk of a subsequent pregnancy being affected.

Chromosome analysis is also carried out when a baby is stillborn without an obvious cause, or when a baby is born with abnormal physical characteristics that suggest a chromosomal defect, such as *Turner's syndrome*.

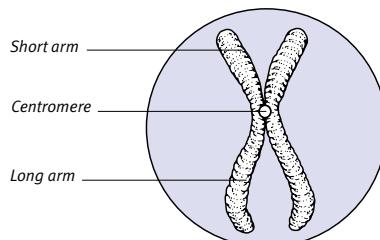

The analysis of the sex chromosomes may be carried out in order to establish the chromosomal sex of a child whose genitals have an ambiguous appearance (see *genitalia, ambiguous*); to confirm or to exclude the diagnosis of *chromosomal abnormalities*; or to investigate *infertility*.

HOW IT IS DONE

Fetal cells for analysis can be obtained by *amniocentesis* or *chorionic villus sampling*. Chromosome analysis in children and adults uses white blood cells taken from a blood sample.

chromosomes

Threadlike structures that exist inside the nuclei (see *nucleus*) of cells and carry inherited information governing all cellular activities and functions. Each chromosome contains around 30,000 *genes* (units of inheritance), which are arranged in single file along a long double filament of *DNA*. The sequence of chemical units, or bases, in the DNA provides the coded instructions for cellular activities. Each cell

Appearance of a dividing chromosome

Just after a chromosome has copied itself, the copies are joined at a constriction (centromere) that divides them into long and short "arms".

contains the chemical machinery for decoding these instructions (see *genetic code; nucleic acids*).

All of an individual's body cells (with the exception of egg or sperm cells) carry the same chromosomal material, which has been copied by a process of *cell division* from the original material in the fertilized egg. Each human cell normally contains 46 chromosomes made up of 23 pairs. Half of each pair of chromosomes comes from the mother and half from the father.

TYPES OF CHROMOSOMES

In each set of chromosomes, 22 pairs are autosomal, which are the same in both sexes, and the remaining pair are the sex chromosomes.

There are two types of sex chromosome, called X and Y. In females, the sex chromosomes are a matched pair of X chromosomes. In males, one is an X and the other is a Y. The mother's egg contributes an X chromosome to every offspring. The father's sperm contributes the other chromosome in the pair: an X in girls or a Y in boys.

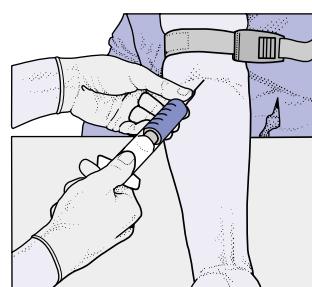

The Y chromosome is thought to provide all of the information required for the development of male sexual characteristics. In the absence of the Y chromosome, the female pattern of development takes place.

CHROMOSOME DIVISION

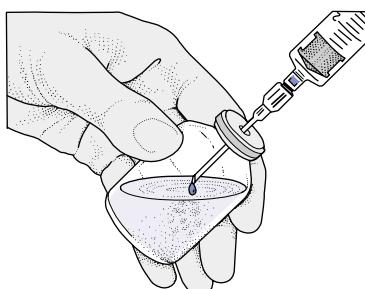

When a cell divides, all of its components, including the chromosomes, are duplicated into the two offspring cells.

The process by which most body cells divide is called *mitosis*. Shortly before cell division, the DNA in each chromosome is copied; if viewed under a microscope, chromosomes at this stage appear as double rods joined at an area called the centromere. As cell division proceeds, the duplicated chromosomes are pulled apart, divided at the centromeres, so that each daughter cell will receive a single copy of each of the usual 46 chromosomes.

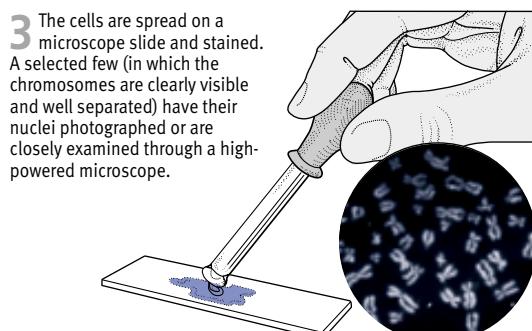

PROCEDURE FOR CHROMOSOME ANALYSIS

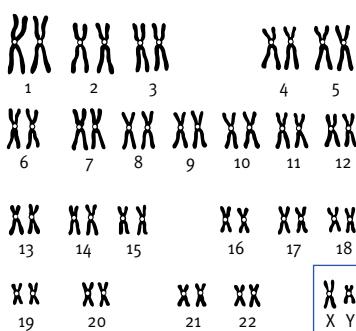

1 In antenatal testing, a collection of fetal cells is obtained by amniocentesis or by chorionic villus sampling. In a test on a baby, child, or adult, white blood cells are obtained from a sample of blood.

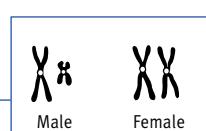

2 The cells are suspended in a medium containing substances that encourage them to divide. Chemicals are then added that stop the cells from dividing at a stage where their chromosome content is most easily visible.

3 The cells are spread on a microscope slide and stained. A selected few (in which the chromosomes are clearly visible and well separated) have their nuclei photographed or are closely examined through a high-powered microscope.

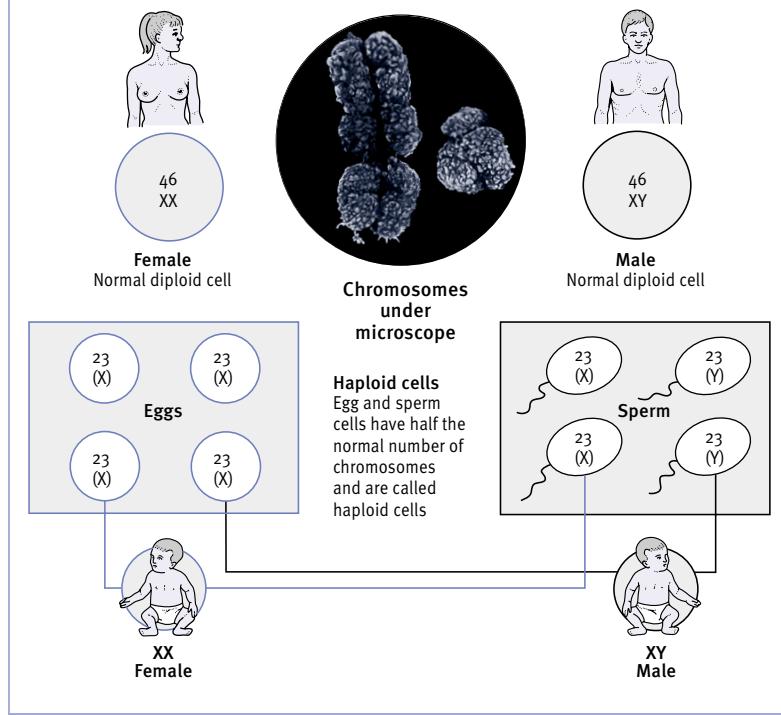

4 The chromosomes are matched up and arranged into the 22 pairs of autosomes and the sex chromosomes. A study of the complete set will reveal any abnormalities.

CHROMOSOMES: EGG AND SPERM CELLS

These differ from other body cells in that they contain only 23 chromosomes – one from each of the 22 autosome pairs plus an X chromosome (in the case of an egg) and either an X or a Y (in the case of a sperm). Because they have only half the normal complement, they are called haploid, while other cells are diploid.

When egg or sperm cells are formed, by a process called *meiosis*, there are two important departures from the normal process of chromosome division. First, after the DNA has been copied (before division takes place), some sections of chromosomal material are exchanged between the two members of each chromosome pair. This helps to ensure that each of a person's eggs or sperm contains a different combination of chromosomal material, and this is the reason why siblings (with the exception of identical twins) have a unique appearance. Next, the cells undergo two consecutive divisions. Therefore, the original parent cell gives rise to four separate egg or sperm cells, each of which has only 23 chromosomes.

DISORDERS

Defective chromosome division during the formation of eggs and sperm (or, more rarely, during the first few divisions of a fertilized egg) can lead to various *chromosomal abnormalities*. The

precise nature of the abnormality can be investigated by detailed *chromosome analysis*. (See also *genetic disorders*.)

chronic

A term that is used to describe a disorder or a set of symptoms that has persisted over a long time. The term "chronic illness" implies a continuing disease process with progressive deterioration (sometimes despite treatment). Chronic disorders are usually contrasted with *acute* disorders, which are of sudden onset and are short in duration.

A chronic illness produces little change in symptoms from day to day, and an affected person may be able to carry out normal activities. The term "acute", in contrast, suggests rapid onset of severe symptoms such as high fever, intense pain, or breathlessness, with a rapid change in the person's condition from one day to the next.

A person with a chronic disease may suffer an acute exacerbation (flare-up) of symptoms. On the other hand, peo-

ple who have had a *stroke* or some other acute illness may be left with permanent disabilities, but their condition is not chronic.

chronic bronchitis

See *pulmonary disease, chronic obstructive*.

chronic fatigue syndrome

A condition that causes extreme fatigue over a prolonged period, often for several years. It is most common in women aged between 25 and 45.

CAUSES

The cause is unclear. In some cases, the condition develops after a viral infection or after a stressful event such as bereavement. In other cases, there is no such preceding illness or event.

SYMPTOMS

The main symptom of chronic fatigue syndrome is persistent tiredness. Other symptoms vary, but commonly include impairment of short-term memory or concentration, sore throat, tender *lymph nodes*, muscle and joint pain, muscle fatigue, unrefreshing sleep, and headaches. The disorder is often associated with *depression* or *anxiety*.

DIAGNOSIS

There is no diagnostic test for chronic fatigue syndrome, and investigations of the condition are usually aimed at excluding other possible causes of the symptoms, such as *anaemia*. A physical examination, blood tests, and a psychological assessment may be carried out. If no cause can be found, a diagnosis of chronic fatigue syndrome can be made from the symptoms.

TREATMENT

Analgesic drugs (painkillers) or *antidepressant drugs* may help to relieve the symptoms. *Physiotherapy* or *psychotherapy* may also be helpful. Chronic fatigue syndrome is a long-term disorder, but the symptoms clear up after several years in some people.

chronic glaucoma

See *glaucoma*.

chronic heart failure

See *heart failure*.

chronic obstructive lung disease

See *pulmonary disease, chronic obstructive*.

chronic obstructive pulmonary disease

See *pulmonary disease, chronic obstructive*.

chronological age

The most common measurement of an individual's *age*.

Churg–Strauss syndrome

A condition characterized by vasculitis (inflammation in the walls of small blood vessels), which mainly affects adults in their thirties who have *asthma*. It is thought to be due to an allergy of unknown cause.

The vasculitis can cause a variety of symptoms, depending on the parts of the body that are affected. Common problems include abdominal pain, if the bowel is involved, and skin rashes. The disease may be severe or even life-threatening, although in most cases it responds well to treatment with oral *corticosteroid drugs*. The drug treatment may need to be continued, at a low dose, for some time to prevent a recurrence of the condition.

chylomicron

A globule of fat (see *fats and oils*) that is carried into the bloodstream from the intestine following the digestion of a meal containing fat.

Cicatrin

The brand name for an *antibacterial* skin preparation.

ciclosporin

An *immunosuppressant drug* that is used following *transplant surgery*. The drug reduces the risk of tissue rejection and the need for large doses of *corticosteroid drugs*. Ciclosporin may need to be taken indefinitely after a transplant. It is also used to treat *rheumatoid arthritis* and other *autoimmune disorders*.

Because ciclosporin suppresses the *immune system*, it increases the susceptibility of the body to various infections. Swelling of the gums and increased hair growth are fairly common side effects. The drug may also cause kidney damage, so it is necessary for anyone who is taking it to undergo regular monitoring of kidney function.

Cilest

The brand name for a combined *oral contraceptive*.

cilia

Hairlike, mobile filaments that exist on the surface of some epithelial cells (see *epithelium*). Cilia are found in particularly abundant amounts in the

linings of the respiratory tract, where they move rhythmically to propel dust and mucus out of the airways.

ciliary body

A structure in the *eye* containing muscles that alter the shape of the *lens* to adjust focus. (See also *accommodation*.)

cimetidine

An *H₂-receptor antagonist*, which is a type of *ulcer-healing drug*. Cimetidine can be taken in tablet or liquid form, or it may be injected. The drug promotes healing of gastric and duodenal ulcers (see *peptic ulcer*) and reduces the symptoms of *oesophagitis* (inflammation of the gullet).

Side effects include fatigue, dizziness, and skin rashes. Rarely, the drug may cause impotence and *gynaecomastia* (breast enlargement in men).

CIN

The abbreviation for *cervical intraepithelial neoplasia*.

cinnarizine

An *antihistamine drug* used to control nausea and vomiting due to travel sickness, or to reduce nausea and vertigo in disorders of the inner ear such as *labyrinthitis* and *Ménière's disease*. High doses of the drug are sometimes used to improve circulation in people with *peripheral vascular disease* and *Raynaud's disease*. Side effects of cinnarizine may include drowsiness, lethargy, a dry mouth, and blurred vision.

Cipramil

A brand name for citalopram, an *antidepressant drug*.

ciprofloxacin

An *antibiotic drug* that is used to treat infections of the respiratory, gastrointestinal, and urinary tracts. Ciprofloxacin may also be used as an initial treatment for *anthrax*.

Ciproxin

A brand name for ciprofloxacin, an *antibiotic drug*.

circadian rhythms

Any pattern of physiological functions that is based on a cycle approximately 24 hours long (also called a diurnal rhythm). One example of this pattern is the daily cycle of sleeping and wakefulness. (See also *biorhythms*.)

circulation, disorders of

Conditions affecting the flow of blood around the body. (See *arteries, disorders of; veins, disorders of*.)

circulatory collapse

A life-threatening condition in which the circulatory system is unable to maintain an adequate blood flow to the organs and tissues of the body (see *shock*). Circulatory collapse can occur when the heart stops beating (see *cardiac arrest*), or be due to loss of blood or problems with the blood vessels.

circulatory system

The *heart* and *blood vessels*, which together are responsible for the maintenance of a continuous flow of blood through the body. Also known as the *cardiovascular system*, the circulatory system provides the body tissues with a supply of oxygen and nutrients, and carries away carbon dioxide and other waste products.

STRUCTURE AND FUNCTION

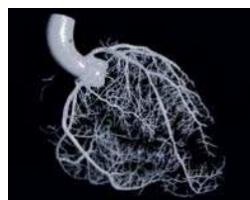

The circulatory system has two main parts: the *systemic circulation*, which supplies blood to the whole body apart from the lungs; and the *pulmonary circulation* to the lungs, which supplies the blood with fresh oxygen (see *circulatory system* box, overleaf).

Oxygen-rich blood from the pulmonary circulation enters the systemic circulation via the left *ventricle* of the heart. The ventricle pumps it under high pressure into the *aorta* (the body's main artery), from where it travels through arteries and smaller arterioles to all parts of the body. Within the body tissues, the arterioles branch into networks of fine blood vessels known as *capillaries*. Oxygen and other nutrients pass from the blood through the thin capillary walls and into the tissues; carbon dioxide and other waste products pass in the opposite direction. Deoxygenated blood is returned to the heart via venules (small veins), veins, and the *venae cavae* (the two principal veins in the body).

Within the systemic circulation, there is also a bypass (the *portal circulation*) that carries nutrient-rich blood from the stomach, intestine, and other digestive organs via the *portal vein* to the *liver*. Nutrients and other substances pass into the liver cells for processing, storage, breakdown, or re-entry into the general circulation. Blood passes out of the liver through

CIRCULATORY SYSTEM

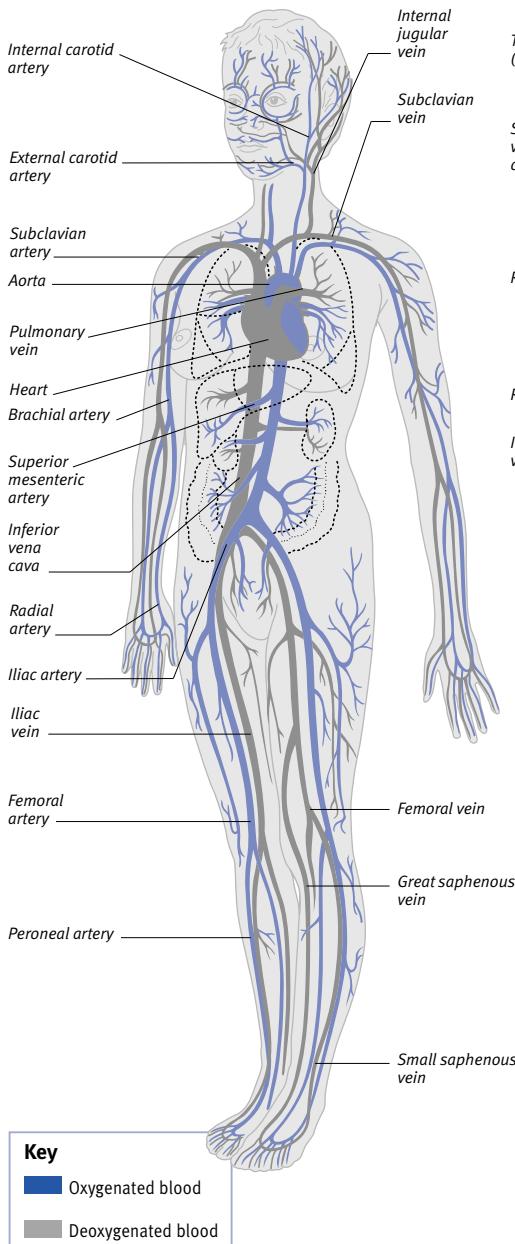

The heart and blood vessels create a continuous flow of blood around the body to provide tissues with oxygen and nutrients. The circulatory system also removes waste products. The systemic circulation deals with the supply of blood to all parts except the lungs; the pulmonary (lung) circulation reoxygenates the blood.

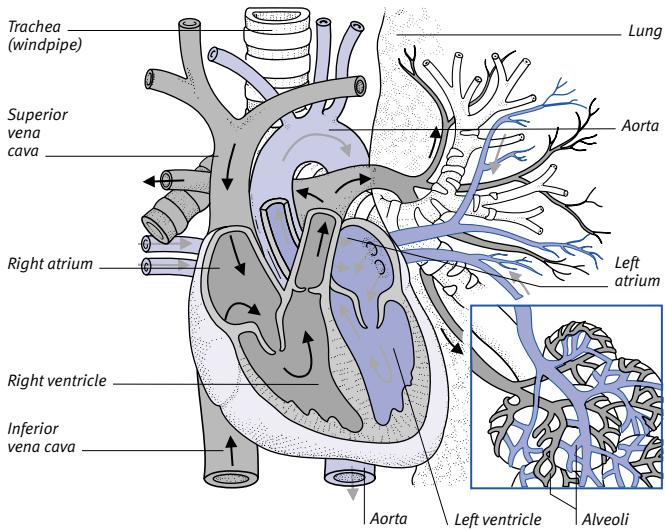

Resin cast of coronary arteries

The photograph on the left shows a resin cast of the arteries that supply oxygenated blood to all parts of the heart muscle. The larger vessels are called the coronary arteries. They branch off the root of the aorta, the largest artery in the body, which receives oxygenated blood directly from the heart.

SYSTEMIC CIRCULATION

PULMONARY CIRCULATION

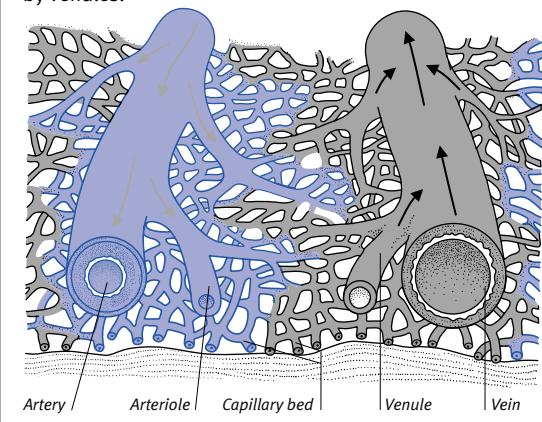

Blood circulation

The right side of the heart receives deoxygenated blood from the systemic ("body") circulation via the venae cavae. The heart pumps this blood to the lungs, where it is oxygenated and returns to the left side of the heart (pulmonary circulation). It is then pumped via arteries to the tissues, where the blood releases oxygen. Deoxygenated blood then returns to the heart.

CAPILLARY NETWORK

All tissues contain a network of tiny capillaries. Blood enters these vessels from the arterioles and is drained by venules.

the hepatic vein and rejoins the main systemic circulation via the inferior (lower) vena cava.

Venous blood returns to the right atrium of the heart to enter the pulmonary circulation. It is pumped from the right ventricle through the pulmonary artery to the lungs, where carbon dioxide is exchanged for oxygen. The reoxygenated blood then returns via the pulmonary veins to the heart and re-enters the systemic circulation.

On its journey from the heart to the body tissues, blood is forced along the arteries at high pressure. In contrast, blood flowing through the veins and back to the heart is at low pressure. It is kept moving by muscles in the limbs, which compress the veins and thus squeeze blood through them, and by valves in the veins that prevent the blood from flowing backwards. (See also *lymphatic system; respiration*).

circumcision

Surgical removal of the foreskin of the *penis*. Circumcision is usually performed on newborn babies for religious or hygienic reasons. In some cases, it may be medically required to treat *phimosis* (a tight foreskin that causes ballooning on urination), recurrent attacks of *balanitis* (infection under the foreskin due to retained secretions), or *paraphimosis* (painful compression of the shaft of the penis by a retracted foreskin).

circumcision, female

Removal of all or some parts of the female external genitalia: the *clitoris*, labia majora, and labia minora (see *labia*). Female circumcision is sometimes combined with narrowing of the entrance to the *vagina*.

Female circumcision is common in certain parts of Africa but has no valid medical purpose. It can cause retention of urine and injuries during sexual intercourse and childbirth.

cirrhosis

A condition of the *liver* that results from long-term damage to liver cells. In cirrhosis, bands of fibrosis (internal scarring) develop, leaving *nodules* of regenerating cells that are inadequately supplied with blood. Liver function is gradually impaired; the liver no longer effectively removes toxic substances from the blood (see *liver failure*). The distortion and fibrosis also lead to *portal hypertension* (abnormally high blood pressure in the veins leading from the intestines and spleen to the liver).

CAUSES

The most common cause of cirrhosis is excessive *alcohol* consumption. Another possible cause is one of the forms of chronic *hepatitis* (inflammation of the liver). Other causes, which are rare, include disorders of the *bile ducts*; *haemochromatosis*, in which increased iron absorption occurs; *Wilson's disease* (an increase in copper absorption); *cystic fibrosis*, which causes obstruction of the bile ducts with mucus; and *heart failure*.

SYMPOTMS AND COMPLICATIONS

Cirrhosis may go unrecognized until symptoms such as mild *jaundice*, *oedema* (an accumulation of fluid in body tissues) and vomiting of blood develop. There may be enlargement of the liver and spleen. Men may experience loss of body hair and enlargement of the breasts due to an imbalance in sex hormones caused by liver failure.

Complications of cirrhosis include *ascites* (an accumulation of fluid in the abdominal cavity), *oesophageal varices* (enlarged veins within the oesophagus wall), and *hepatoma* (liver cancer). Cirrhosis may also cause toxins to build up in the brain, producing symptoms such as confusion and coma (see *hepatic encephalopathy*).

TREATMENT

Treatment is focused on slowing the rate at which liver cells are being damaged, if possible by treating the cause. Any complications will also be treated. In some cases, however, the cirrhosis progresses and a *liver transplant* may need to be considered.

cisplatin

An *anticancer drug* used to treat some cancers of the *testis* and the *ovary*.

citalopram

An *antidepressant drug* belonging to a group called selective serotonin re-uptake inhibitors (SSRIs). Citalopram takes up to four weeks to reach its full effect; it gradually improves the user's mood, energy levels, and level of interest in everyday activities.

The drug may cause gastrointestinal problems such as nausea, vomiting, or diarrhoea, but these usually diminish with continued use. Citalopram may also cause drowsiness and, for this reason, people taking the drug should avoid alcohol, and should not carry out

activities such as driving vehicles until they have learned how strongly citalopram affects them.

CJD

The abbreviation for *Creutzfeldt-Jakob disease*.

CK

The abbreviation for *creatinine kinase*.

clamp

An instrument that is used during surgical procedures to compress the cut end of an organ or blood vessel temporarily, in order to prevent leakage of blood or other fluids.

clap

A slang term for *gonorrhoea*.

clarithromycin

An *antibiotic drug* that belongs to the macrolide group. Clarithromycin is used to treat infections of the skin and the respiratory tract.

classic migraine

A type of *migraine* attack accompanied by an aura (neurological disturbances), nausea, and vomiting.

claudication

A cramplike pain in a muscle, most often in the legs, due to inadequate blood supply. Claudication in the legs is usually caused by blockage or narrowing of arteries due to *atherosclerosis* (see *peripheral vascular disease*). In intermittent claudication, pain is felt in the calves after walking a certain distance and is relieved by rest.

A rarer cause is spinal *stenosis* (narrowing of the canal carrying the spinal cord), causing pressure on the nerve roots that pass into either leg.

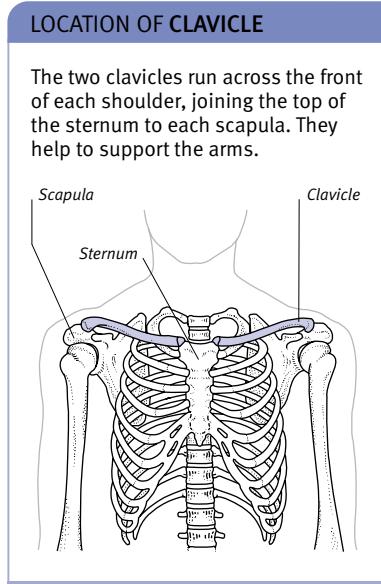

claustrophobia

An intense fear of being in enclosed spaces, such as lifts or tunnels, or of being in crowded areas. The usual treatment is *behaviour therapy* involving techniques that gradually lessen the patient's anxiety. (See also *phobia*.)

clavicle

The collarbone. The two clavicles, one on each side, form joints with the top of the sternum (breastbone) and the scapula (shoulderblade). The clavicles support the arms and transmit forces from the arms to the central skeleton.

Most fractures of the clavicle occur as a result of a fall on to the shoulder or on to an outstretched arm. When the clavicle is broken, the arm must be supported in a sling and a figure-of-eight bandage must be used to keep the fractured bone ends together. Healing takes about three weeks.

clavulanic acid

A substance that is combined with the penicillin drug *amoxicillin* to produce the antibiotic drug *co-amoxiclav*.

claw-foot

A deformity of the foot in which the arch of the foot is exaggerated and the tips of the toes turn under. Claw-foot may be present from birth, or it may result from damage or disruption to the nerve or blood supply to the muscles of the foot. Surgery may improve the condition.

claw-hand

A deformity in which the fingers are permanently curled. It is caused by injury to the *ulnar nerve*, which controls the muscles of the thumb and fingers. Treatment includes repairing the nerve by using splints to hold the fingers straight, or cutting a tendon in the wrist to allow the fingers to straighten.

claw-toe

A deformity of unknown cause in which the end of one or more affected toes bends downwards so that the toe

curls under. A painful *corn* may form on the tip of the toe or on the top of the bent joint. Protective pads can relieve pressure from footwear. In severe cases, surgery may be required.

clear liquid diet

A diet consisting solely of clear or strained fluids, such as broth, ginger ale, or fruit juices. A clear liquid diet provides little nourishment. It is mainly used for very short periods, such as during the first 24 hours following surgery or in the initial stages of an episode of diarrhoea and vomiting.

cleft lip and palate

A split in the upper lip and/or palate that is present at birth. Cleft lip is a vertical, usually off-centre split in the upper lip; it may be a small notch, or may extend to the nose. The gum may also be cleft, and the nose may be crooked. The term "harelip" refers only to a midline cleft lip, which is rare. Cleft palate is a gap that may extend from the back of the palate to behind the teeth and be open to the nasal cavity. The condition is often accompanied by other problems such as partial deafness and possibly other *birth defects*.

TREATMENT

Surgery to repair a cleft lip may be undertaken in the first few days after birth or when the baby is about three months of age. Surgery improves the child's appearance; after repair, speech defects are rare. A cleft palate is usually repaired at about 12 months, but further surgery, *orthodontic* treatment, and *speech therapy* may be required.

cleidocranial dysplasia

Also called cleidocranial dysostosis, a rare, autosomal dominant *genetic disorder* causing malformation of the bones, particularly those in the skull and shoulders. An affected person typically has absent or underdeveloped *clavicles* (collarbones), and can move the shoulders forwards so that they almost touch. The sutures (fixed joints) of the *skull* bones take longer than normal to fuse together. There may also be abnormalities in the structure of the pelvis, fingers, teeth, and *vertebrae* (bones of the spinal column).

clemastine

An *antihistamine drug* that is used to relieve the symptoms of allergic conditions such as *urticaria* (nettle rash) and

allergic *rhinitis* (hay fever). Clemastine can cause drowsiness so driving and hazardous work should be avoided.

clergyman's knee

Inflammation of the *bursa* (the fluid-filled sac) that cushions the pressure point above the tibial tubercle (the bony prominence just below the knee). The condition is caused by prolonged kneeling. (See also *bursitis*.)

climacteric

See *menopause*.

clindamycin

An *antibiotic drug* that may be prescribed as a skin preparation to treat severe *acne* or in creams to treat bacterial vaginal infections. Sometimes, it is also given as tablets or by injection.

Clindamycin can have serious side effects. In particular, it may cause a potentially life-threatening form of bowel inflammation called antibiotic-associated colitis. For this reason, the drug is prescribed only when other types of antibiotic cannot be used.

clinic

A hospital department or health-care institution for the treatment of particular diseases (such as conditions that are specific to women or to men, or sexually transmitted infections).

clinical diagnosis

A procedure in which a doctor determines the nature of a disorder on the basis of an individual's description of his or her symptoms and a physical examination. Unlike *pathological diagnosis*, a clinical diagnosis does not depend on the analysis of tissue specimens taken from the body.

clinical pharmacology

The branch of *pharmacology* (the science concerned with the nature and action of drugs) that deals with the use of drugs in patients, in hospitals and in the community. Clinical pharmacologists are concerned with drug doses; when and when not to give specific drugs (indications and contraindications); administration; and side effects.

clinical psychology

The branch of *psychology* (the scientific study of mental processes) concerned with the diagnosis and treatment of emotional and behavioural problems.

clinical trial

See *trial, clinical*.

Clinistix

A brand-named product that detects *glucose* (sugar) in urine and which can be used by people with *diabetes mellitus* to monitor their condition. Clinistix consists of test strips impregnated with a chemical that reacts with glucose.

Clinitest

The brand name of a product that detects *glucose* (sugar) in urine, which some people with *diabetes mellitus* use to monitor their condition. Clinitest consists of tablets containing a chemical that reacts with glucose.

clioquinol

An *antibacterial drug* and *antifungal drug* used as ear drops to treat infections of the outer ear. Clioquinol is also included in some skin preparations.

clip

A small metal device used by surgeons to hold a wound closed or to prevent leakage from a blood vessel. Specialized plastic clips are used in female sterilization operations (see *sterilization, female*) to seal the fallopian tubes.

clitoridectomy

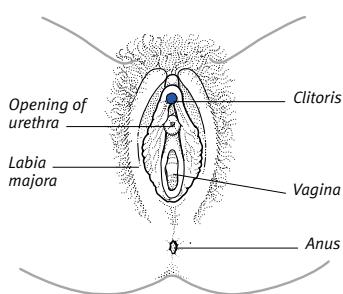

An operation to remove the *clitoris* (see *circumcision, female*).

clitoris

A small, sensitive, erectile organ that is part of the female genitalia. It is partly enclosed in the *labia* and covered by a

LOCATION OF CLITORIS

The clitoris is a part of the external genitals in females. It is located just below the pubic bone, and is partly enclosed within the labia.

fold of skin called the *prepuce*, or hood. The clitoris swells and becomes more sensitive during sexual stimulation.

clobazam

A type of *benzodiazepine* drug used in the treatment of *anxiety* and *epilepsy*.

clobetasone

A *corticosteroid drug*, used as a cream or an ointment to treat inflammatory skin conditions, such as *eczema*.

clofibrate

A *lipid-lowering drug* that helps to reduce levels of *cholesterol* and *triglycerides* in the blood. Clofibrate is prescribed as a treatment for some types of *hyperlipidaemia*.

Clomid

A brand name for *clomifene*, a drug that is used to treat female infertility.

clomifene

A drug used to treat female *infertility* caused by failure to ovulate. Minor side effects may include hot flushes, headache, nausea, breast tenderness, and blurred vision. More seriously, *ovarian cysts* occasionally develop, but they shrink when the dose is reduced. The drug may also cause multiple births.

clomipramine

A *tricyclic antidepressant drug*, which is used as a treatment for *depression*. Side effects include dry mouth, blurred vision, and constipation.

clonazepam

A *benzodiazepine drug* used mainly as an *anticonvulsant drug* to prevent and treat epileptic fits (see *epilepsy*). It also prevents *petit mal* attacks in children. Side effects include drowsiness, dizziness, fatigue, and irritability.

clone

An exact copy. In medicine, the term "clone" usually refers to duplicates of cells, genes, or organisms.

Clones of cells are all descended from one original cell. In many types of cancer, cells are thought to be derived from one abnormal cell. Clones of genes are copies of a single gene. In research, several clones of a gene can be made so the gene can be studied in detail. Clones of organisms are produced by removing the nuclei from cells of a donor individual and trans-

planting them into the egg cells of another individual. The eggs mature into living plants or animals that are all identical to the donor.

clonic

Relating to the abnormal muscle contractions known as *clonus*, which are sometimes a sign of a brain or spinal cord disorder.

clonic convulsion

A form of *seizure* in which there are uncontrolled, jerking movements of the limbs and body (see *clonus*). Clonic convulsions are a feature of some types of *epilepsy*.

clonidine

An *antihypertensive drug* that controls hypertension (high blood pressure) by acting on the part of the brain that regulates the size of blood vessels. Clonidine is also used to control hot flushes in menopausal women and to treat some cases of migraine. Possible side effects of the drug include constipation, drowsiness, dry mouth, and dizziness. Caution should be taken if high doses of the drug are suddenly stopped because this can cause a dangerous rise in blood pressure.

clonus

A series of rapid, abnormal *muscle contractions*. Clonus is a sign of damage to nerve fibres that carry impulses from the motor cortex in the *cerebrum* of the brain to a particular muscle. It may occur in the wrist, knee, ankle, or toe in response to stretching of the muscles in that area. It may also be a feature of seizures (see *clonic convulsion*).

clopidogrel

An *antiplatelet drug* that is used to prevent the formation of unwanted blood clots in individuals who are suffering from *atherosclerosis*.

Clopixol

The brand name of zuclopentixol, an *antipsychotic drug*.

closed-angle glaucoma

An alternative term for acute *glaucoma*.

closed fracture

A type of *fracture*, also known as a simple fracture, in which the broken bone ends do not penetrate the overlying skin.

Clostridium

Any of a group of rod-shaped *bacteria*. Clostridia are found in soil and in the gastrointestinal tracts of humans and animals. They produce powerful toxins and are responsible for potentially life-threatening diseases such as *botulism*, *tetanus*, and *gangrene*.

clot

See *blood clotting*.

clotrimazole

An *antifungal drug* that is used to treat yeast and fungal infections, especially *candidiasis*.

clotting factor

A circulating protein that is activated during the *blood clotting* process. There are a number of clotting factors, which are involved in a complex series of chemical reactions leading to the formation of a blood clot.

clotting time

The time taken for blood to coagulate, which is measured in tests by the observation of a blood sample under laboratory conditions. (See also *blood-clotting tests*.)

cloudy urine

An abnormality in the appearance of *urine*, which may be caused by a *urinary tract infection* or the presence of salts. (See also *urine, abnormal*.)

clove oil

An oil distilled from the dried flower-buds of *EUGENIA CARYOPHYLLATA* that is used mainly as a flavouring in pharmaceuticals. Clove oil is sometimes used to relieve abdominal pain due to *flatulence* and as a remedy for toothache.

cloxacillin

A penicillin-type antibiotic drug used to treat infections with staphylococcal bacteria (see *penicillin drugs*).

clozapine

A type of *antipsychotic drug*. Clozapine is used to treat *schizophrenia* in patients who have not responded well to other forms of treatment, or in those who have experienced severe side effects from more conventional drugs. A person taking clozapine needs to have regular blood tests because the drug may cause a serious decrease in the number of *white blood cells*.

Clozaril

A brand name for *clozapine*.

clubbing

Thickening and broadening of the fingertip and ends of the toes, which is usually accompanied by increased curving of the nails. Clubbing is associated with certain chronic lung diseases, such as *lung cancer*, *bronchiectasis*, and fibrosing *alveolitis*; with some heart abnormalities; and, rarely, with the inflammatory bowel diseases *Crohn's disease* and *ulcerative colitis*.

club-foot

A deformity of the foot that is present from birth (see *talipes*).

clumping

The common name for agglutination, a process in which tiny particles that the body identifies as foreign (see *antigen*), such as the proteins on the surfaces of bacteria or foreign red blood cells, stick together to form visible masses. This process is an immune system reaction caused by antibodies (proteins manufactured by the immune system; see *antibody*) called agglutinins. Particles of a particular antigen will only clump together in the presence of the specific agglutinin to that antigen.

Looking for clumping can be used as a means of determining people's blood groups. In blood typing, samples of a person's blood are mixed with antibodies against the blood types A and B to see if clumping occurs with either of these antibodies, neither, or both (see *blood groups*). In *cross-matching*, a sample of a person's blood is mixed with a sample of blood from a possible donor; if the red blood cells clump together, it shows that the two samples of blood are of incompatible types. In addition, bacteria can be identified using samples that contain agglutinins to specific bacteria (as, for example, in the *latex agglutination test*).

cluster headaches

Brief but severe headaches that recur up to several times a day over a period of a few days or weeks. Cluster headaches tend to affect one side of the head or face, often in a characteristic pattern, and may also cause pain and watering of the eye. The cause is uncertain, but they may be due to dilation of blood vessels in the brain, as in *migraine*. *Beta-blocker drugs* may be given in order to

lessen the dilation of the blood vessels and reduce the severity and frequency of cluster headaches.

CMV

The abbreviation for *cytomegalovirus*, which is a type of *herpes* virus.

CNS

The abbreviation for *central nervous system* (the brain and spinal cord).

CNS stimulants

Drugs that increase mental alertness (see *stimulant drugs*).

coagulation, blood

The main mechanism by which blood clots are formed. Coagulation involves a complex series of reactions in the blood *plasma* (see *blood clotting*).

coal tar

A thick, black, sticky substance that is distilled from coal. Coal tar is a common ingredient in many ointments and medicinal shampoos that are prescribed for certain skin and scalp disorders, such as *psoriasis* and some types of *dermatitis* and *eczema*.

co-amilofruse

A combined preparation that contains the diuretic drugs *amiloride* and *furosemide* (frusemide).

co-amoxiclav

A *penicillin drug* containing a mixture of *amoxicillin* and *clavulanic acid*. It is a more powerful antibiotic than amoxicillin alone, so it is used to treat infections caused by strains of bacteria that are resistant to amoxicillin.

coarctation of the aorta

A *congenital* heart defect of unknown cause, in which there is narrowing in a section of the *aorta* that supplies blood to the lower body and legs. To compensate for this problem the heart has to work harder than normal, thereby causing *hypertension* (high blood pressure) in the upper part of the body.

SYMPTOMS

Symptoms of coarctation of the aorta usually appear in early childhood. They include headache, weakness after exercise, cold legs, and, rarely, breathing difficulty and swelling of the legs due to *heart failure*. Associated abnormalities include a heart *murmur*, weak or absent pulse in the groin, lack of synchronization

tion between the groin and wrist pulses, and blood pressure that is higher in the arms than in the legs.

DIAGNOSIS AND TREATMENT

X-rays confirm the diagnosis. Surgery to correct the defect is usually performed before four years of age.

Coat's disease

A disease that causes a progressive deterioration in vision. It is congenital (present at birth) but usually begins in childhood, and affects boys more than girls. The cause is unknown.

In Coat's disease, the capillaries (tiny blood vessels) supplying the retina become damaged and leak fluid (a process called exudation). As a result, the retina does not function properly. Usually, only one eye is affected. Vision may be impaired in the centre of the visual field or around the edges. In some cases, a squint develops. There is also a risk of retinal detachment.

Diagnosis involves viewing the retina through an ophthalmoscope, and by imaging the blood vessels using *fluorescein* dye. Treatment may involve sealing the capillaries by phototherapy (treatment with light rays) or cryotherapy (treatment with cold). If given early enough, it may stabilize the disease and may even improve vision. In some cases, the disease stabilizes by itself.

cobalamin

A complex molecule that contains *cobalt* and is part of *vitamin B₁₂*.

cobalt

A metallic element. Cobalt is found in foods as a constituent of *vitamin B₁₂*. A radioactive form is used in *radiotherapy*.

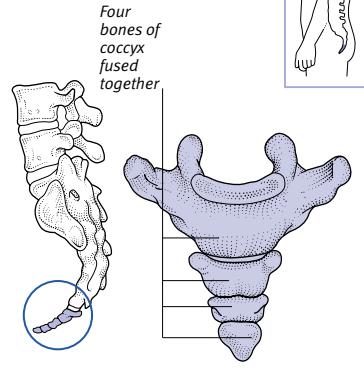

Cobb syndrome

A very rare disorder in which spinal cord *angiomas* (noncancerous tumours of the blood or lymph vessels) occur together with arteriovenous malformations (abnormal connections between arteries and veins) in the overlying skin. It is *congenital* (present from birth) but is almost never inherited.

The symptoms usually appear in childhood or adolescence; they include weakness, paralysis, loss of sensation, and loss of bowel and bladder control. Treatment includes surgery to block the blood flow to the abnormal vessels (see *embolization*) and to relieve pressure on the spinal cord (see *decompression*, *spinal canal*).

ANATOMY OF COCCYX

The coccyx consists of four fused bones at the base of the spine. With the sacrum, it forms the back of the pelvis.

co-beneldopa

A preparation containing the drugs benserazide and *levodopa*; co-beneldopa is used in the treatment of *Parkinson's disease*.

cocaine

A drug obtained from the leaves of the coca plant *ERYTHROXYLON COCA*. In the past, cocaine was used as a local anaesthetic (see *anaesthesia, local*) for minor surgical procedures, but it has largely been replaced by other anaesthetics due to its potential for abuse.

Cocaine affects the brain, producing euphoria and increased energy. These effects have led to its illicit use (see *drug abuse*). Regular inhalation of the drug can damage the lining of the nose and may eventually cause perforation of the septum (the tissue separating the two sides of the nose). Continued use of the drug can cause dependence (see *drug dependence*), and, if high doses are taken, may result in *psychosis*, which can cause users to become violent. Overdose of cocaine can cause seizures and *cardiac arrest*.

Crack, which is a purified form of cocaine, produces a more rapid and intense reaction; and deaths have occurred as a result of the drug's adverse effects on the heart.

cocci

Spherical *bacteria*, some of which cause infections in humans (see *staphylococcal infections*; *streptococcal infections*).

coccus

The singular of *cocci*.

coccydynia

A pain in the region of the *coccyx*. Coccydynia may result from a blow to the base of the spine in a fall, prolonged pressure due to poor posture when sitting, or the use of the lithotomy position (lying on the back with hips and knees bent) during childbirth. The pain usually eases in time. Treatment may include heat, injections of a local anaesthetic, and *manipulation*.

coccyx

A small, triangular bone, commonly called the tailbone, made up of four tiny bones fused together at the base of the *spine*. Together with a larger bone called the *sacrum*, situated just above it, the coccyx forms the back section of the *pelvis*. There is very little movement between the coccyx and sacrum, and later in life the two structures commonly become fused together.

cochlea

The spiral-shaped organ situated in the *labyrinth* of the inner ear that enables *hearing*. A structure known as the *organ of Corti*, inside the cochlea, can detect sound vibrations of different frequencies and converts them into electrical impulses. These electrical impulses are then transmitted to the brain via the *vestibulocochlear nerve*. Sound waves of different frequencies stimulate different areas inside the cochlea, enabling us to hear and differentiate between a wide variety of sounds.

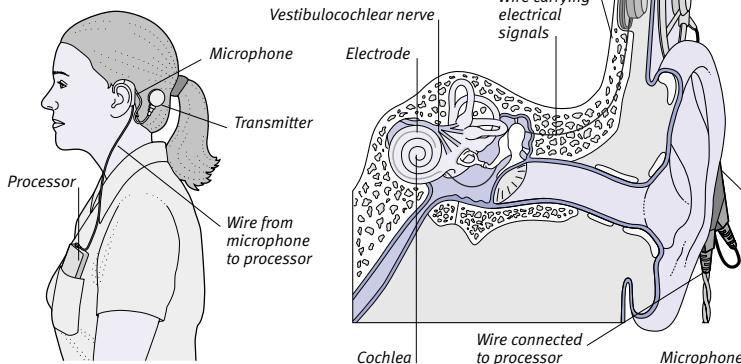

cochlear implant

A device that is used to treat profoundly deaf people who are not helped by hearing aids. Unlike a hearing aid, which amplifies sounds, a cochlear implant converts sounds into electrical signals that are relayed to the cochlear nerve deep in the inner ear (see *cochlear implant box*, overleaf).

The implant consists of tiny electrodes that are surgically implanted in the cochlea, and a receiver that is embedded in the skull just behind and above the ear. A microphone, sound processor, and transmitter are worn externally. A cochlear implant does not restore normal hearing, but it enables patterns of sound to be detected. Combined with lip-reading, it may enable speech to be understood.

COCHLEAR IMPLANT

Sounds picked up by the microphone are converted into electronic signals by the sound processor and relayed to the external transmitter, which sends them through the skin to the receiver. The waves then travel along the wire to the electrodes in the cochlea, where sound is normally received.

Cockayne's syndrome

An autosomal recessive *genetic disorder* that causes premature aging and deterioration of the nervous system. The syndrome causes dwarfism (see *short stature*) and abnormally rapid aging (see *progeria*). Affected people also have very thin skin that is extremely sensitive to the effects of sunlight. In addition, there may be visual problems due to degeneration of the retina (see *retinitis pigmentosa*) or atrophy (wasting away) of the *optic nerve*; *deafness*; and *learning difficulties*. The age at which symptoms appear and the course of the disease vary from one individual to another.

There is no cure for the aging or the neurological symptoms, but an affected person can protect his or her skin from sun damage by avoiding exposure to ultraviolet light, or by applying a sun-block to protect areas of exposed skin when outdoors in sunlight.

co-codamol

A compound *analgesic drug* containing *paracetamol* and *codeine*.

codeine

An *opioid analgesic drug* derived from the opium poppy plant. Codeine is useful for mild to moderate pain and may be combined with other analgesics in painkilling preparations. It is also used as a *cough remedy* and as an *anti-diarrhoeal drug*.

It may cause dizziness and drowsiness, especially if taken with alcohol. If used for long periods, it may cause constipation and be habit-forming.

cod-liver oil

A pale yellow oil obtained from the liver of fresh cod, which is a valuable source of *vitamin A* and *vitamin D*.

co-dydramol

A compound *analgesic drug* (painkiller) that contains *paracetamol* and dihydrocodeine.

coeliac disease

A condition, sometimes called gluten-sensitive enteropathy, that results from *hypersensitivity* to *gluten*, a protein found in wheat, rye, and some other cereals. Exposure to foods containing gluten causes an abnormal immune response in which the lining of the small intestine is damaged. The condition leads to *malabsorption* and results in vitamin and mineral deficiencies.

CAUSES AND SYMPTOMS

Coeliac disease tends to run in families, and varies in severity. The disorder may first appear during infancy, or may not develop until adulthood.

In babies, symptoms usually develop within six months of the introduction of gluten into the diet. The baby may become listless and irritable, develop vomiting and diarrhoea, and become dehydrated and seriously ill. Babies

and children may also fail to grow or to gain weight, and may suffer from muscle wasting, especially around the buttocks. In adults, symptoms that include tiredness, breathlessness, abdominal pain, diarrhoea, vomiting, and swelling of the legs may develop over several months. In addition, a chronic, distinctive rash called *dermatitis herpetiformis* may occur.

Damage to the intestinal lining and malabsorption cause weight loss and result in faeces that are bulky and foul-smelling. The resulting vitamin and mineral deficiencies can result in *anaemia* as well as skin problems. Some affected people suffer damage to the intestinal lining but never develop symptoms of the disease.

DIAGNOSIS AND TREATMENT

Diagnosis may be made by blood tests but in most cases *jejunal biopsies*, in which tissue samples from the lining of the jejunum (the central part of the small intestine) are taken for examination, are also performed.

Coeliac disease is treated by a life-long gluten-free diet, which can relieve symptoms within weeks of its introduction. Specially manufactured foods, such as gluten-free flour and pasta, are available. Without such treatment, there may be a long-term risk of cancers developing in the small intestine.

coenzyme

A nonprotein chemical, occurring naturally in the body, that plays a role in assisting the proper functioning of some types of *enzyme* (proteins that regulate chemical reactions in the body). (See also NAD.)

Coffin–Siris syndrome

An autosomal *genetic disorder* characterized by absence or underdevelopment of the tips of the little finger and little toe. Other features include *hirsutism* (excessive hair), *hypotonia* (lack of muscle tone) and weak joints, and *learning difficulties*.

cognition

Mental processes by which knowledge is acquired. Such cognitive processes include perception, problem-solving, and reasoning.

cognitive–behavioural therapy

A method of treating psychological disorders such as *anxiety* and *depression*, based on the idea that problems arise

from a person's faulty cognitions (erroneous ways of perceiving the world and oneself). In cognitive-behavioural therapy, the patient is helped to identify negative or false cognitions and then encouraged to try out new thought strategies. For example, a patient may be asked to keep a diary of his or her thoughts and feelings, in order to identify triggers for distress, and may be taught techniques for responding differently to upsetting thoughts.

cognitive dissonance

A state of mental or emotional tension caused by inconsistency and disagreement among different aspects of a person's thoughts, beliefs, values, and behaviour. (For example, a person may buy a well-made pair of shoes but find that they are actually very uncomfortable.) People may try to reduce such tension by reinterpreting or rationalizing the situation. (For example, the person with the uncomfortable shoes may persuade himself or herself that the comfort of the shoes will improve with continued wear.)

cogwheel rigidity

A term that is sometimes used for a characteristic muscle stiffness seen in people with *Parkinson's disease*. When the limbs of an affected person are passively moved, the muscles stretch in a series of small jerks.

coil

The common name for any of the various types of intrauterine contraceptive device (see *IUD; Mirena*).

coitus

Another term for *sexual intercourse*.

coitus interruptus

A method of contraception (see *contraception, withdrawal method of*) in which the man withdraws his penis from the woman's vagina before *ejaculation* (the discharge of semen) occurs. Coitus interruptus is unreliable because sperm can be released before orgasm occurs, and it may cause *psychosexual dysfunction* in men and women.

colchicine

A drug extracted from the autumn crocus (*COLCHICUM AUTUMNALE*). Colchicine is used to treat acute attacks of *gout* and to reduce their frequency. Side effects include vomiting and diarrhoea.

cold abscess

An *abscess* caused by infection with the *tuberculosis* bacterium. A cold abscess does not usually produce redness and heat, hence its name.

cold, common

A common viral infection that causes inflammation of the mucous membranes lining the nose and throat.

CAUSES

There are at least 200 highly contagious viruses that are known to cause the common cold. These organisms are easily transmitted in minute airborne droplets sprayed from the coughs or sneezes of infected people. In many cases, cold viruses are also spread to the nose and throat by hand-to-hand contact with an infected person, or by handling objects that have become contaminated with the virus.

SYMPOTMS AND TREATMENT

The symptoms of a cold typically include a stuffy or runny nose, sore throat, headache, and cough. They usually intensify over 24–48 hours (unlike the symptoms of *influenza*, which tend to worsen rapidly over a few hours).

Most colds clear up by themselves within a week. Affected people can take simple measures to cope with symptoms; for example, mild *analgesic drugs* or *cold remedies* may help to relieve aches and pains, and *cough remedies* can soothe a cough. Sometimes, however, infection spreads and may cause *laryngitis*, *tracheitis*, acute *bronchitis*, *sinusitis*, or *otitis media*. In these cases, a bacterial infection may develop on top of the viral infection, and *antibiotic drugs* may be needed to treat it. (Antibiotics are ineffective against viruses, so they will not cure colds.)

cold injury

Localized tissue damage caused by chilling of part of the body. Cold injury is distinct from *hypothermia*, which refers to chilling of the whole body.

The most serious form of cold injury is *frostbite*. In this condition, an area of skin and flesh becomes frozen, hard, and white as a result of exposure to very cold, dry air. Sometimes there is restriction of the blood supply to the affected area. Another type of injury, *immersion foot*, occurs when the legs and feet are kept cold and damp for hours or days. The main risk of both conditions is that the blood flow will be slowed so much that the tissues die

and, as a result, develop *gangrene*. Less serious forms of cold injury include *chilblains* and *chapped skin*.

cold remedies

Preparations used to relieve symptoms of colds (see *cold, common*). The main ingredient of cold remedies is usually a mild *analgesic drug*, such as *paracetamol* or *aspirin*, which helps to relieve aches and pains. Other common ingredients include *antihistamine drugs* and *decongestant drugs*, designed to reduce nasal congestion; *caffeine*, which acts as a mild stimulant; and *vitamin C*.

cold sore

A small skin blister, usually around the mouth, commonly caused by a strain of the *herpes simplex* virus called HSV1 (herpes simplex virus type 1).

CAUSES AND SYMPTOMS

The first attack of the virus may be symptomless; alternatively, it may cause a flulike illness with painful mouth and lip ulcers, called *gingivostomatitis*. The virus then lies dormant within nerve cells, but may occasionally be reactivated and cause cold sores.

Reactivation of the virus may occur after exposure to hot sunshine or a cold wind, during a common cold or other infection, or in women around the time of their *menstrual periods*. Prolonged attacks may occur in people whose immunity to infection has been reduced due to illness or treatment with *immunosuppressant drugs*.

In many cases, an outbreak of cold sores is preceded by tingling in the lips, followed by the formation of small blisters that enlarge, causing itching and soreness. Within a few days the blisters burst and become encrusted. Most disappear within a week.

TREATMENT

The antiviral drug *acyclovir*, applied as a cream, may prevent cold sores if used at the first sign of tingling.

colecalciferol

An alternative name for vitamin D₃ (see *vitamin D*).

colectomy

The surgical removal of part or all of the *colon* (the major part of the large intestine, which produces faeces).

WHY IT IS DONE

Partial colectomy is usually carried out to remove damaged or distorted sections of colon. It may be performed to

treat severe cases of *diverticular disease* (in which abnormal pouches form in the colon wall); to cut out a cancerous tumour (see *colon, cancer of*); or to remove a narrowed part of the intestine that is causing a blockage to the passage of faeces.

Total colectomy is performed to treat severe cases of *ulcerative colitis*, when the condition cannot be controlled by drugs. It may also be performed on individuals with familial polyposis (see *polyposis, familial*), an inherited condition in which large numbers of growths develop in the colon.

HOW IT IS DONE

In a partial colectomy, the diseased section of the colon is removed, and the ends of the severed colon are joined. A temporary *colostomy* (which allows the discharge of faeces from the large intestine through an artificial opening in the abdominal wall) may be needed until the rejoined colon has healed.

In a total colectomy, the whole of the large intestine is removed, either with or without the *rectum*. If the rectum is removed, an *ileostomy* (similar to a colostomy, but using the small intestine) may be performed.

RECOVERY

The colon usually functions normally after a partial colectomy. But in a total colectomy, the large intestine's ability to absorb water from faeces is reduced; this can result in diarrhoea. *Antidiarrhoeal drugs* may therefore be required.

colestyramine

A *lipid-lowering drug* used to treat some types of *hyperlipidaemia* (very high levels of fats in the blood). It is also used to treat diarrhoea in disorders such as *Crohn's disease*.

colic

A term that means "pertaining to the colon". The term "colic" also refers to a severe, spasmodic form of abdominal pain that occurs in waves of increasing intensity. (See also *biliary colic*; *colic, infantile*; *renal colic*; *colic, uterine*.)

colic, biliary

See *biliary colic*.

colic, gallstone

Another term for *biliary colic*.

colic, infantile

Episodes of irritability and excessive crying in otherwise healthy infants. The

condition is thought to be due to muscle spasms in the intestines.

A baby that suffers an attack of colic cries or screams incessantly, draws up his or her legs towards the stomach, and may become red in the face and possibly also pass wind. The baby will not respond to normal methods of comforting, such as feeding or cuddling. Colic often tends to be worse in the evenings; the symptoms may also be made worse by tiredness or stress.

Colic can be very distressing, but it is harmless. Usually, The condition first appears at the age of three to four weeks, and it clears up without treatment by the age of 12 weeks. Carers should seek medical help, however, if additional symptoms, such as fever, develop, or if they are finding it difficult to cope with the baby.

colic, renal

See *renal colic*.

colic, uterine

Cramping abdominal pains that are usually associated with menstruation. (See also *dysmenorrhoea*.)

coliform bacteria

A group of rod-shaped *bacteria* that inhabit the intestine. Coliform bacteria include *ESCHERICHIA* and other genera that are sometimes associated with gastrointestinal illnesses.

colistin

One of the *polymyxin* group of *antibiotic drugs*. Colistin is used in *topical* preparations for eye and skin conditions. It may also be given orally to destroy bacteria in the large intestine, in people who are particularly susceptible to infection. In addition, colistin may be used in a *nebulizer* in order to treat lung infections. The drug is used only to treat infections that are resistant to other antibiotic drugs because it is toxic and may cause damage to kidney and nerve tissue.

colitis

Inflammation of the *colon*. Colitis causes diarrhoea, usually containing blood and mucus. Other symptoms may include abdominal pain and fever.

CAUSES

Colitis is a feature of the inflammatory bowel disorders *ulcerative colitis* and *Crohn's disease*. It may also be associated with other conditions that cause

inflammation in the colon or rectum, such as *diverticular disease* or *proctitis*, or with cancer (see *colon, cancer of*). In addition, it may result from infection with various types of microorganism, such as *campylobacter* and *shigella* bacteria, viruses, or *amoebae*. One form of colitis may be provoked by *antibiotic drugs*; the drugs destroy bacteria that normally live in the intestine and allow *CLOSTRIDIUM DIFFICILE*, a bacterium that causes irritation, to proliferate.

DIAGNOSIS

Investigations into colitis may include examination of a sample of faeces for micro-organisms or for obvious or hidden blood (see *faecal occult blood test*); *sigmoidoscopy* or *colonoscopy* (viewing of the inside of the colon); *biopsy* (tissue sampling) of the inflamed areas or ulcers; and a barium enema (see *barium X-ray examinations*).

TREATMENT

If the cause is an infection, antibiotics may be needed. Crohn's disease and ulcerative colitis are treated with *corticosteroid* and *immunosuppressant drugs*, together with a special diet.

collagen

A tough, fibrous *protein*. Collagen is the body's major structural protein, forming an important part of *tendons*, *bones*, and *connective tissue*.

collagen diseases

See *connective tissue diseases*.

collapse

A nonmedical term for a state of prostration or extreme exhaustion. The word "collapse" may also be used to describe a fainting fit or loss of consciousness. The medical term *circulatory collapse* refers to a life-threatening condition in which the blood no longer circulates effectively.

collarbone

The common name for the *clavicle*.

collar, orthopaedic

A soft foam or stiffened device that is worn around the neck to relieve pain or give additional support.

Colles' fracture

A break in the *radius* (one of the bones of the forearm) just above the wrist, in which the wrist and hand are displaced backwards, restricting movement and causing swelling and severe pain. The

fracture is usually the result of putting out a hand to lessen the impact of a fall. It is more common in elderly people, due to weakening of the bones by ageing or *osteoporosis*.

The broken bones are manipulated back into place and set in a *cast*. Healing of the bones takes up to six weeks. Hand and wrist movements usually return to normal, but there may be minor wrist deformity.

Collet–Sicard syndrome

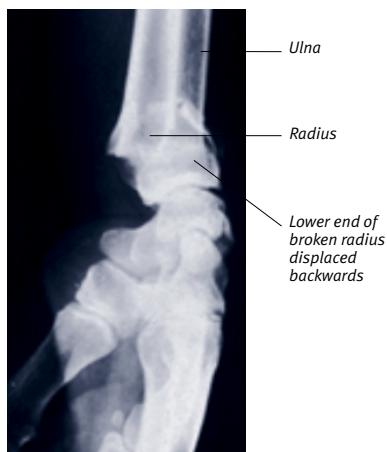

A condition resulting from damage to the *cranial nerves* that control muscles in the tongue and throat. It is usually due to a *head injury* or to compression of the nerves by a tumour. The syndrome causes paralysis of muscles in the tongue, palate, throat, larynx (voice-box), and neck on one side. There is no cure, but the cause is treated if possible.

collodion

A syrupy mixture of *ether*, *alcohol*, and pyroxylin used in skin preparations for minor cuts and abrasions. Collodion acts by evaporating rapidly to leave a protective film over the area.

colloid

A form of fluid that is similar to a suspension (a fluid consisting of insoluble particles of a substance suspended in a liquid). Particles in a suspension are large and heavy enough to be separated from the liquid in a *centrifuge*. A colloid has smaller, lighter particles that can only be separated out of the liquid by

X-ray of Colles' fracture

This X-ray clearly shows that the lower end of the broken radius has been pushed back. This gives a classic "dinner fork" appearance when the wrist is viewed from the side.

spinning at a very high speed. In medicine, *plasma proteins* are separated from blood and sometimes used in colloid preparations to treat *shock*.

The term "colloid" also refers to a material that contains protein and is found in the *thyroid gland*.

coloboma

A rare *birth defect* in which a gap exists in the tissues of the eye. The gap may be in the eyelid or in part of the eyeball, such as the *iris*, *retina*, or *choroid*. A coloboma in the iris will be visible as a black notch, or as a gap stretching from the pupil to the edge of the iris.

The condition results from incomplete development of the eyes while the baby is still an *embryo*; this problem may, in turn, be linked to certain *chromosomal abnormalities*. Coloboma may range from minor to severe. In some cases, it may cause *blurred vision* or decreased *visual acuity*.

colon

The major part of the large *intestine*.

STRUCTURE

The colon is a segmented tube, about 1.3 m long and 6.5 cm wide, that forms a large loop in the abdomen. It consists of four sections: the ascending, transverse, and descending colons, and the S-shaped sigmoid colon, which connects with the rectum.

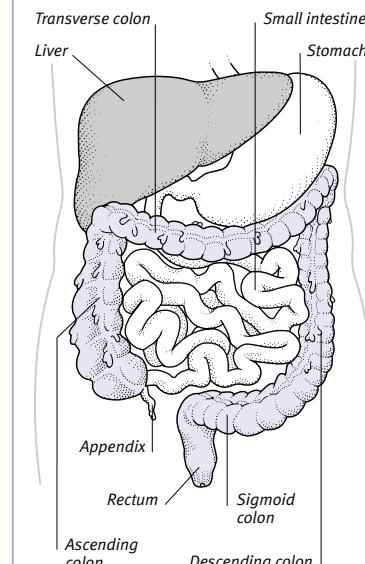

The colon consists of four layers. It has a tough outer membrane that protects it from damage. The next layer comprises muscles that contract and relax rhythmically to move the intestinal contents along (see *peristalsis*). Inside the muscular layer is a submucous coat containing blood vessels and lymph vessels (see *lymphatic system*). The innermost layer produces mucus, which helps to lubricate the passage of waste material.

FUNCTIONS

The main functions of the colon are to absorb water and mineral salts from food residue and to concentrate the remaining waste products. The material that remains after digestion enters the colon from the small intestine. As this substance passes through the colon, the water and salts that it contains are absorbed into the blood vessels in the submucous coat. The waste material becomes increasingly concentrated and is finally expelled from the rectum in the form of *faeces*. (See also *digestive system*; *intestine, disorders of*.)

LOCATION OF COLON

The colon is a segmented tube. It runs from the caecum (where the large and small intestines meet) to the rectum, forming an M-shaped loop within the abdomen.

colon, cancer of

A *malignant* tumour of the *colon* (the major part of the large intestine). Cancers of the colon or of the rectum (the lower part of the colon), which are generally referred to as *colorectal cancer*, are among the most common forms of cancer. They most often occur in people over the age of 60.

CAUSES

A genetic basis has been found for some types of colon cancer. Up to one in three cases are associated with a family history of colon disease. In particular, an inherited disorder called *familial adenomatous polyposis* (in which large numbers of polyps develop in the colon) greatly increases the risk. In the majority of cases, however, the precise cause is not known. Contributory factors include diet: eating a lot of meat and fatty foods and not enough fibre may increase the risk. The disease also sometimes occurs in association with *ulcerative colitis*.

SYMPOTMS

The first symptoms of colon cancer include an inexplicable change in

bowel movements (either constipation or diarrhoea), blood mixed in with the faeces, and pain in the lower abdomen. Sometimes, however, there are no symptoms until the tumour has grown large enough to cause an obstruction in the intestine (see *intestine, obstruction of*) or perforate it (see *perforation*).

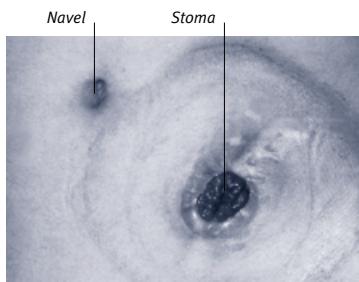

DIAGNOSIS AND TREATMENT

Successful treatment of cancer of the colon depends, crucially, on an early diagnosis. Screening may be carried out to detect early signs. This procedure includes a test to detect blood hidden in the faeces (see *faecal occult blood test*). If the test is positive, doctors may perform *sigmoidoscopy* and *colonoscopy* to view the inside of the colon. A *biopsy* may be performed at the same time.

In most cases, a partial *colectomy* is carried out. In this procedure, the diseased part of the colon is removed, together with a surrounding area of healthy tissue, then the cut ends of the colon are rejoined. Surgery may be combined with *radiotherapy* or possibly with *chemotherapy*. The chance of survival depends on how far the tumour has spread, but colon cancer in its early stages can be cured.

PROCEDURE FOR COLOSTOMY

An incision is made in the abdominal wall and part of the colon is pulled through. In a temporary colostomy, a small loop is exposed, and an opening is made in it large enough for faeces to pass through. If the rectum and anus have been removed, the cut end of the colon is brought to the skin surface. The edges of the opening or severed end are stitched to the skin at the edges of the abdominal incision to create a stoma (artificial opening) through which faeces will be expelled.

Position of the stoma

A colostomy bag is attached over the stoma to collect faeces. After a bowel movement, it is either replaced or emptied.

colon, disorders of

See *intestine, disorders of*.

colon, irritable

See *irritable bowel syndrome*.

colonization

The multiplication of foreign organisms, such as *bacteria*, in a host body. (This process is not necessarily harmful.) The term "colonization" is also used to refer to the development of *cancer* cells in an area to which they have spread that is separate from the primary tumour.

colonoscopy

The viewing of the inside of the *colon* using a flexible endoscope (fibre-optic instrument) known as a colonoscope, which is introduced through the *anus* and guided along the colon. Colonoscopy is used to investigate symptoms such as bleeding from the anus and to detect physical abnormalities such as inflammation (see *colitis*), growths (see *polyps*), and *cancer*. Instruments may be passed through the colonoscope to take *biopsy* specimens or remove polyps. (See also *endoscopy*.)

colon, spastic

See *irritable bowel syndrome*.

Colorado tick fever

A viral illness transmitted by the bites of infected ticks. It occurs in the mountain areas of the western United States, usually in early summer. Symptoms appear 3–6 days after a tick bite; they include flulike chills and fever, severe headache, nausea, and sometimes a red, raised rash. The illness usually lasts for a few days, subsides, then returns for a further few days. The virus can, however, remain in the blood for several months.

Treatment involves removal of the tick as soon as possible and taking *analgesic drugs* (painkillers) if necessary. Tick bites can be prevented by wearing clothing that covers the arms and legs and tucking trouser legs into socks. (See also *ticks and disease*.)

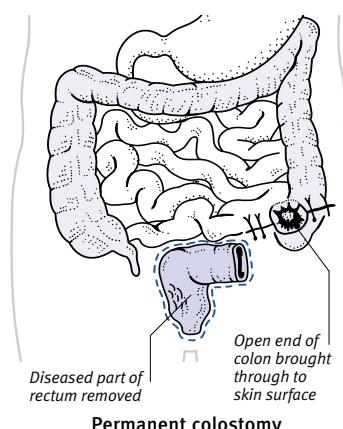

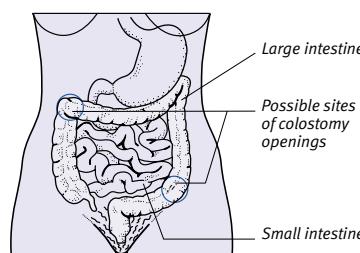

colorectal cancer

A general term referring to cancer of the colon (see *colon, cancer of*) and/or of the rectum (see *rectum, cancer of*).

colostomy

An operation in which part of the *colon* is brought to the surface of the skin through an incision in the abdominal wall. The exposed part is formed into a *stoma*, an artificial opening through which *faeces* are discharged into a bag attached to the skin. A colostomy may be either temporary or permanent.

A temporary colostomy may be performed at the same time as a partial *colectomy* (removal of part of the colon) to allow the remainder of the colon to heal without faeces passing through and contaminating it. The colostomy is closed when the rejoined colon has healed. A permanent colostomy is needed if the rectum or anus has been removed (for example, to treat colon cancer) and normal defaecation is therefore impossible.

colostrum

A thick, yellowish fluid that is produced by the breasts during the first few days after childbirth, before being replaced by breast milk. Colostrum contains less fat and sugar, but more minerals and protein, than breast milk. It also has a high content of *lymphocytes* (white blood cells) and *immunoglobulins*, which help to protect the baby against infections.

colour blindness

See *colour vision deficiency*.

colour vision

The ability to see and distinguish the different parts of the colour spectrum, which consists of electromagnetic radiation (energy waves) with a range of wavelengths between about 400 and 700 nanometres (millionths of a milli-

metre). Different wavelengths trigger nerve signals in the *retina* (the light-sensitive layer of cells at the back of the eye); these signals pass to the brain and are interpreted as violet, indigo, blue, green, yellow, orange, and red.

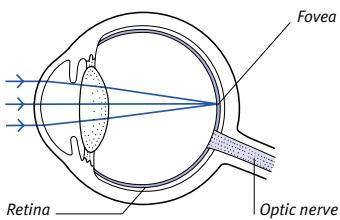

RETINAL FUNCTION

As light falls on the retina, it strikes light-sensitive cells called rods and cones. The rods can detect all visible

light, but only the cones can distinguish colour. There are three types of cone: red-sensitive, blue-sensitive, and green-sensitive. Each of these types of cone responds more strongly to a particular part of the light spectrum. The cones are most concentrated in a central area of the retina called the *fovea*; for this reason, colour vision is most accurate for objects that are viewed

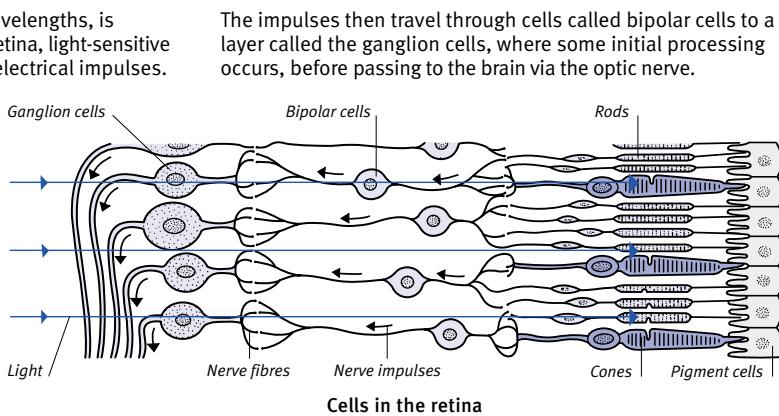

COLOUR VISION

Light, consisting of radiation of various wavelengths, is focused on the retina. At the back of the retina, light-sensitive rod and cone cells are stimulated to emit electrical impulses.

Location of colour-sensitive cells

The rods and cones are located at the back of the retina. Behind them is a darkly pigmented layer of cells, which reduces light scattering. Colour vision depends on the cones, which are concentrated in an area called the fovea.

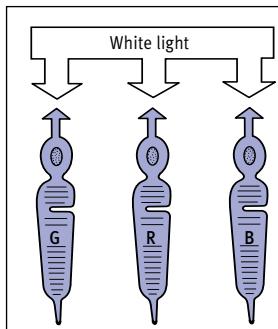

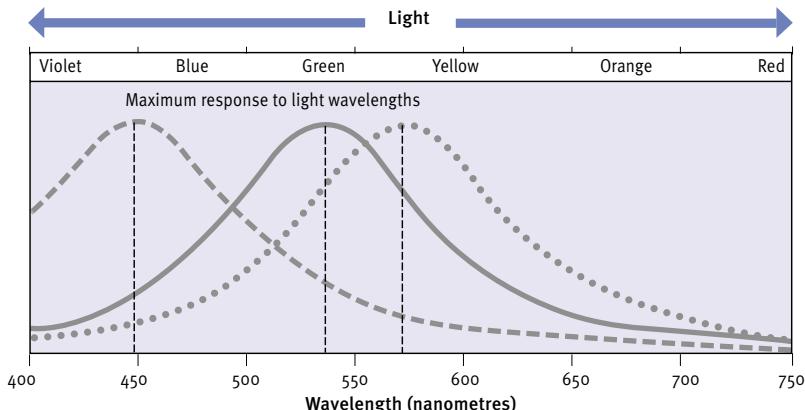

Key

- Blue-sensitive cones
- Green-sensitive cones
- Red-sensitive cones

Colour response of cones (right)

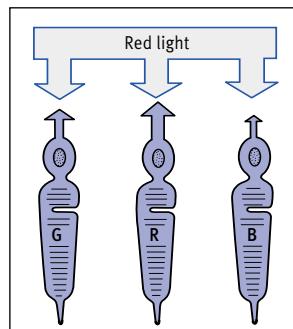

There are three classes of cone. One of these (red-sensitive) responds best to light of long wavelengths; another (blue-sensitive) to light of short wavelengths; and the third (green-sensitive) to intermediate wavelengths.

Response to white light
White light consists of a mixture of all wavelengths (colours), and it therefore stimulates all three classes of cone to signal equally. This pattern of response is interpreted as whiteness by the brain.

Key

- G Green-sensitive
- R Red-sensitive
- B Blue-sensitive

Response to red light
Light with a long wavelength (red light) produces a strong response from red-sensitive cones, a weak response from blue-sensitive cones, and an intermediate response from green-sensitive cones. This pattern of signalling is interpreted as the colour red by the brain.

directly. Colour vision is, therefore, poor at the periphery of vision.

When light hits a cone, it causes a structural change in the pigment within the cone, which in turn causes the cone to emit an electrical signal. This signal passes to the brain via the *optic nerve*. Colour perception requires a minimum level of light; below this level, everything is perceived only by the rods and is seen as various shades of grey. (See also *colour vision deficiency; eye; perception; vision*.)

colour vision deficiency

Any abnormality in *colour vision* that causes a person to have difficulty in distinguishing between certain colours.

TYPES

The most common type of colour vision deficiency is the reduced ability to discriminate between red and green. Most cases of red–green colour vision deficiency are the result of defects in the light-sensitive cells in the *retina*. These defects are usually inherited, and tend to be sex-linked (see *genetic disorders*); the majority of sufferers are male, while females are unaffected, but they can pass on the disorder to their children. Occasionally, defects may be acquired as a result of diseases of the retina or the optic nerve, or they are caused by injury. There are two forms of red–green deficiency. A person with a severe green deficiency has difficulty in distinguishing between oranges, greens, browns, and pale reds. A severe red deficiency causes all shades of red to appear dull.

A much rarer colour vision deficiency exists in which blue cannot be distinguished. This condition may be inherited, or it may be due to degeneration of the retina or the optic nerve. Monochromatism (the total absence of colour vision) also exists, but this deficiency is very rare.

Colpermin

A brand name for peppermint oil. This preparation is used to relieve the pain that results from muscle spasms in *irritable bowel syndrome* and *diverticular disease*.

colposcopy

Viewing of the *cervix* (the neck of the uterus) and *vagina* using a magnifying instrument called a colposcope. Colposcopy is carried out to detect areas of precancerous tissue (see *dysplasia*) or

of early cervical cancer (see *cervix, cancer of*). Removal of tissue samples (see *biopsy*) or treatment to remove any abnormal areas can be performed during colposcopy, and this is usually done under local anaesthetic.

coma

A state of unconsciousness and unresponsiveness to external stimuli (for example, pinching) or internal stimuli (such as a full bladder).

CAUSES

Coma results from disturbance or damage to areas of the *brain* involved in conscious activity or maintenance of consciousness – in particular, parts of the *cerebrum*, upper parts of the *brain-stem*, and central regions of the brain, especially the *limbic system*.

Conditions that can produce coma include severe *head injury*; disorders such as *stroke* or *cardiac arrest*, in which part or all of the brain tissue is deprived of blood; or infectious disorders that affect the brain, such as *meningitis* and *encephalitis*. In addition, excessively high or low blood levels of certain substances may result in coma; for example, a person with *diabetes mellitus* may become comatose if his or her blood level of glucose (sugar) rises or falls to an abnormal degree.

SYMPTOMS

There are varying depths of coma. In less severe forms, the affected person may make small movements and respond to certain stimuli. In a deep coma, the person does not make any movements or respond to any stimulus. However, even people in deep comas may show some automatic responses, for example breathing unaided and blinking. If the lower brainstem is damaged, however, vital functions are impaired, and artificial ventilation and maintenance of the circulation are required.

OUTLOOK

If brain damage is minor and reversible, the person may make a full recovery, but deep coma due to severe trauma may result in long-term neurological problems such as muscle weakness or changes in behaviour. A person in a deep coma (a *persistent vegetative state*) may be kept alive for years provided the brainstem is still functioning. Complete and irreversible loss of brainstem function leads to *brain death* (the permanent cessation of all brain functions).

combination drug

A preparation containing more than one active substance.

comedo

Another name for a *blackhead*.

commensal

A *bacterium* or other organism that normally lives in or on the body without either harming or benefiting its host.

comminuted fracture

A type of *fracture* in which the bone shatters into more than two pieces. A severe blow, such as an impact occurring in a car accident, may result in a comminuted fracture.

commode

A portable chair that contains a removable toilet bowl in its seat.

common cold

See *cold, common*.

communicable disease

Any disease due to a microorganism or parasite that can be transmitted from one person to another. (See also *contagious; infectious disease*.)

compartment syndrome

A painful *cramp* due to compression of a group of muscles within a confined space. It may occur when muscles are enlarged due to intensive sports training or to an injury such as *shin splints*. Cramps induced by exercise usually disappear when the exercise is stopped. Severe cases may require *fasciotomy* to improve blood flow and prevent development of a permanent *contracture*.

compensation

The adjustment made by an organ to make up for changes in body function or structure. An example of compensation is the increased size of one kidney when the other has been removed.

complement

A collection of *proteins* in the *plasma* (the fluid part of *blood*) that helps to destroy foreign cells and is an important part of the *immune system*.

complementary medicine

A group of therapies, often described as “alternative”, that are now increasingly used to complement or to act as an alternative to conventional medicine.

Such treatments fall into three broad categories: touch and movement (as in *acupuncture*, *massage*, and *reflexology*); medicinal (as in *naturopathy*, *Chinese medicine*, and *homeopathy*); and psychological (as in *biofeedback*, *hypnotherapy*, and *meditation*).

complete abortion

The expulsion from the uterus of an embryo or a fetus together with its membranes and placenta (see *abortion*).

complete heart block

See *heart block*.

complex

A term used in medicine to mean a group or combination of related signs and symptoms that form a syndrome (as in *Eisenmenger complex*), or a collection of substances of similar structure or function (as in *vitamin B complex*). In psychology, a complex (for example, the *Oedipus complex*) denotes a group of unconscious ideas and memories that have emotional importance.

compliance

The degree to which patients follow medical advice.

complication

A condition resulting from a preceding disorder or from its treatment.

compos mentis

Latin for "of sound mind".

compound

A term used in chemistry to describe a substance that contains two or more chemically combined elements. In *pharmacy*, a compound is a preparation that contains a number of ingredients.

compound fracture

A type of *fracture*, also known as an open fracture, in which a broken bone breaks through the overlying skin. In this type of fracture, there is a high risk of infection.

compress

A pad of lint or linen applied, under pressure, to an area of skin. Cold compresses soaked in ice-cold water or wrapped around ice help to reduce pain, swelling, and bleeding under the skin after an injury (see *ice pack*). Hot compresses increase the circulation and help to bring *boils* to a head. A dry

compress may be used to stop bleeding from a wound or may be coated with medication to help treat infection.

compression syndrome

A collection of localized neurological symptoms, such as numbness, tingling, discomfort, and muscle weakness, that is caused by pressure on a *nerve*.

compulsive behaviour

See *obsessive-compulsive disorder*.

computed tomography

Another name for *CT scanning*.

computer-aided diagnosis

The use of computer technology in certain diagnostic tests and procedures. It involves the use of probability-based computer systems that store information on thousands of cases of different disorders, detailing the type, location, duration, symptoms, medical history, and diagnosis. A patient's symptoms and medical history can be entered into a computer, which then compares the details with existing data and produces a list of the most likely diagnoses.

Such technology is not currently in common use in hospitals, but is of value for people who are isolated from medical services, such as oil-rig crews. Computers programmed to interpret visual data, such as abnormal cells, have potential use in certain types of blood test and *cervical smear tests*. Computers are also used in investigative procedures such as *CT scanning* and *MRI*.

concealed haemorrhage

Internal loss of blood (see *bleeding*).

conception

The *fertilization* of a woman's *ovum* (egg) by a man's *sperm*, followed by implantation of the resulting *blastocyst* (the growing mass of fertilized cells) in the lining of the *uterus*. This process marks the beginning of *pregnancy*. (See also *contraception*; *infertility*.)

concussion

Brief *unconsciousness*, usually following a violent blow to the head. The loss of consciousness is due to a brief disturbance of the electrical activity in the brain. Common symptoms following concussion include confusion, inability to remember events that occurred just prior to the injury, dizziness, blurred vision, and vomiting.

Anyone who has been concussed, however briefly, should see a doctor as soon as possible. Persistent symptoms, or new ones such as drowsiness, difficulty in breathing, repeated vomiting, or visual disturbances, could signify brain damage or an *extradural haemorrhage*, and medical advice should be sought without delay. Repeated concussion can cause *punch-drunk syndrome*. (See also *head injury*.)

conditioning

The formation of a specific physical or behavioural response to a particular *stimulus* in the environment.

CLASSICAL CONDITIONING

In classical conditioning, a stimulus that consistently evokes a particular response is paired repeatedly with a second stimulus that would not normally produce the response. Eventually, the second stimulus begins to produce the response whether or not the first stimulus is present. This phenomenon was shown by the physiologist Ivan Pavlov. He observed that dogs salivated in anticipation of food (an unconditioned response to a stimulus). He then devised a procedure in which a bell was rung every time a dog was given food; once the procedure had been repeated several times, the dog began to salivate every time it heard the bell (a conditioned response to a stimulus) even if no food was presented.

OPERANT CONDITIONING

In operant conditioning, attempts are made to modify behaviour by rewarding or punishing a subject (animal or human) every time the subject shows a particular response to a specific stimulus. A response that is rewarded will be reinforced and become more frequent, while one that is punished will be inhibited and become less frequent.

USE IN MEDICINE

Behavioural psychology (see *behaviour therapy*) is based on the idea that inappropriate behaviour patterns in some psychological disorders are learned through conditioning. It is thought that these patterns can be modified by the same process of conditioning.

condom

A barrier method of *contraception* in the form of a thin latex rubber or plastic sheath, which is placed over a man's *penis* before sexual *intercourse*. Condoms also provide some protection against *sexually transmitted infections*.

condom, female

A barrier method of *contraception* in the form of a sheath that is inserted into a woman's *vagina* before sexual *intercourse*. Female condoms also offer some protection against *sexually transmitted infections*.

conduct disorders

Repetitive and persistent patterns of aggressive and/or antisocial behaviour, such as vandalism, substance abuse, and persistent lying, in children or adolescents. (See also *behavioural problems in children; adolescence*.)

conduction

The movement of particular forms of energy, such as nerve impulses and sound waves, through a system.

conductive deafness

Deafness caused by faulty *conduction* of sound from the outer to the inner *ear*. Causes include excess earwax or fluid in the middle ear (see *glue ear*).

conduit

A channel or tube that conveys fluid. Conduits may be created surgically to redirect the flow of body fluids. The most common form of artificially constructed conduit is an ileal conduit, which is created from part of the small intestine to divert urine out of the body when the bladder has had to be removed (see *cystectomy*).

condyle

A round projection on the end of a *bone* that fits into a hollow on another bone to form a joint; an example of a condyle is the elbow.

condyloma

A warty skin growth that usually occurring in moist areas of the body, for example the genitals. The most common type of condyloma is caused by the human papillomavirus (see *genital warts*). Condylomata are highly infectious flattened growths that may develop around the genitals in the secondary stage of *syphilis*.

condyloma acuminatum

See *warts, genital*.

cone

A type of light-sensitive cell located in the *retina* of the eye. Cones play a major role in *colour vision*.

cone biopsy

A surgical procedure in which a conical or cylindrical section of tissue from the lower part of the *cervix* (neck of the uterus) is removed (see *biopsy of the cervix* box on p.159). A cone biopsy is performed following an abnormal result of a *cervical smear test* if the extent of the precancerous or cancerous area cannot be seen by *colposcopy* (inspection of the cervix with a viewing instrument). (See also *cervix, cancer of*.)

confabulation

The use of a fictional story to make up for gaps in memory. The phenomenon occurs most commonly in chronic alcoholics who suffer from *Wernicke-Korsakoff syndrome*. It may also occur in people with *head injuries*.

confidentiality

The ethical principle that a doctor does not disclose any information given in confidence by a patient.

The patient's *consent* is necessary before a doctor supplies confidential information to an insurance company, an employer, or a lawyer. Doctors must, however, disclose information about patients when required to do so by law, or when they are faced with injuries or disorders that indicate a serious crime. Doctors are also required to notify health authorities about patients with specified infectious diseases.

Treatment of young children is usually discussed with the parents, but an older child's request for confidentiality is generally respected if the doctor feels that he or she is competent enough to understand the issues involved.

confluent

A term meaning "merging or running together". It is used, for example, in relation to individual skin blemishes that merge to form one abnormal area.

confusion

An acute or chronic disorganized mental state in which thought, memory, and reasoning are impaired.

CAUSES AND SYMPTOMS

Acute confusion can arise as a symptom of *delirium*, in which brain activity is affected by fever, drugs, poisons, or injury. People with acute confusion may also have *hallucinations* and behave in a violent manner. Chronic confusion is often associated with *alcohol dependence*, the long-term use of *antianxiety*

drugs, and certain physically based mental disorders. Many of the conditions that cause chronic confusion (for example, *dementia*) are progressive. Features of such conditions include absent-mindedness, poor short-term memory, and a tendency to be repetitive.

TREATMENT

If the underlying cause of confusion can be treated, there may be marked improvement. *Sedative drugs* can be of benefit in acute confusion.

congenital

A term meaning "present at birth". Congenital abnormalities (sometimes called *birth defects*) may be inherited. Alternatively, they may result from damage or infection occurring either in the *uterus* or at the time of birth.

congenital adrenal hyperplasia

See *adrenal hyperplasia, congenital*.

congenital amputation

See *amputation, congenital*.

congestion

A term that usually refers to the accumulation of excess *blood*, *tissue fluid*, or *lymph* in part of the body.

A major cause of congestion is an increased blood flow to an area due to inflammation. Another possible cause is reduced drainage of blood from an affected area, as can occur in *heart failure*, in venous disorders such as *varicose veins*, and in *lymphatic disorders*. (See also *nasal congestion*.)

congestive heart failure

See *heart failure*.

conjoined twins

See *twins, conjoined*.

conjunctiva

The transparent membrane covering the *sclera* (white of the eye) and lining the inside of the eyelids. Cells in the conjunctiva produce a fluid that lubricates the lids and the *cornea*.

conjunctival haemorrhage

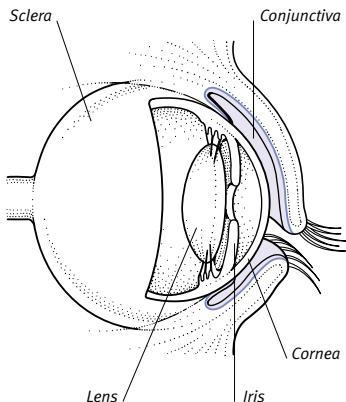

An alternative term for *subconjunctival haemorrhage* (bleeding in the white of the eye).

conjunctivitis

Inflammation of the *conjunctiva*, causing redness, discomfort, and discharge from the affected eye.

LOCATION OF CONJUNCTIVA

This transparent membrane covers the sclera (white of the eye) and lines the inside of the eyelids.

TYPES AND SYMPTOMS

There are two common types: infective conjunctivitis, caused by bacteria or viruses; and allergic conjunctivitis, an allergic response to substances such as cosmetics and pollen. Both types may have similar symptoms. In infective conjunctivitis, the discharge contains pus and may result in the eyelids being stuck together on waking in the mornings. In allergic conjunctivitis, the discharge is clear and the eyelids are often swollen and itchy.

Other forms of conjunctivitis that occur less commonly include *neonatal ophthalmia* (infective eye disease in newborns), *keratoconjunctivitis* (inflammation of both the conjunctiva and the cornea), and *trachoma* (a serious form of chlamydial infection).

TREATMENT

Bacterial infections are treated with eyedrops or ointment containing an *antibiotic drug*. Viral conjunctivitis often disappears without the need for treatment. Allergic conjunctivitis may be treated with eyedrops that contain cromoglicate, an *antihistamine*, or a *corticosteroid drug*.

connective tissue

The material that supports, binds, or separates the various structures of the body. *Tendons* and *cartilage* are made up of connective tissue. This type of tissue also forms the matrix (basic substance) of *bone* and the nonmuscular structures of *arteries* and *veins*.

connective tissue diseases

Certain *autoimmune disorders* (disorders in which the immune system attacks the body's own tissues) that often affect blood vessels and produce secondary damage to *connective tissue*. Connective tissue diseases include *rheumatoid arthritis*, *polyarteritis nodosa*, *systemic lupus erythematosus*, *systemic sclerosis*, and *dermatomyositis*.

Conn's syndrome

A disorder caused by the secretion of excessive amounts of the hormone *aldosterone*. The overproduction of this hormone is caused by a noncancerous tumour of one of the *adrenal glands*. (See also *aldosteronism*.)

consciousness

A state of alertness in which a person is fully aware of his or her thoughts, surroundings, and intentions.

consent

Also sometimes referred to as informed consent, the legal term describing a patient's agreement to a doctor performing an operation, arranging drug treatment, or carrying out a diagnostic test. The patient's consent is also needed before a doctor supplies confidential information to an insurance company, an employer, or a lawyer.

Consent is valid only if the patient has been fully informed about the purpose of that particular procedure, the likely outcome, and any complications and side effects. Consent cannot be given by young children or by people who are not considered to be competent, but a relative may give or withhold consent on their behalf.

constipation

The infrequent or difficult passing of hard, dry *faeces*. Constipation may be uncomfortable but in the short term is usually harmless.

CAUSES

The most common cause of constipation is insufficient fibre in the diet (see *fibre, dietary*), because fibre assists the propulsion of waste matter through the *colon*. Other common causes include lack of regular bowel movements due to poor toilet-training in childhood or repeatedly ignoring the urge to move the bowels. Constipation in elderly people may be due to immobility or to weakness of the muscles of the abdomen and the pelvic floor.

Occasionally, constipation is a symptom of an underlying disorder. This is especially likely if it is part of a persistent change in bowel habits in someone over the age of 40, or if it is accompanied by other symptoms such as blood in the faeces, pain on moving the bowels, or weight loss. Conditions that may cause constipation include *haemorrhoids*, *anal fissure*, *irritable bowel syndrome*, and narrowing of the colon due to disorders such as *diverticular disease* or cancer (see *colon, cancer of*).

TREATMENT

Self-help measures such as establishing a regular bowel routine, increasing the amount of fibre in the diet, and drinking more fluids are usually beneficial. Prolonged use of *laxative drugs* should be avoided, because this can impair the normal functioning of the colon.

constriction

A narrowed area in the body, or the process of narrowing.

consultant

In the UK, a doctor, usually attached to a certain hospital, who is a specialist in a particular branch of medicine and who takes full responsibility for the patients in his or her care.

contact dermatitis, allergic

A type of *dermatitis* caused by an allergic skin reaction to a substance that is harmless for most people. Common causes include nickel and rubber. (See also *irritant dermatitis*.)

contact lenses

Thin, shell-like, transparent discs fitted over the *cornea* of the eye that are used to correct defective vision. Contact lenses are most commonly used for the correction of *myopia* (shortsightedness) and *hypermetropia* (longsightedness). In addition, noncorrective lenses are available for cosmetic use, for example to change eye colour.

TYPES

There are several types. Hard plastic lenses give good vision; they are also long-lasting and durable, inexpensive, and easy to maintain. Sometimes, however, these lenses are difficult for the wearers to tolerate and may fall out. Hard gas-permeable lenses are more comfortable because they allow oxygen to pass through to the eye, but are less durable. Soft lenses are the most comfortable because of their high water

content. Disposable soft lenses are for single use only; extended-wear lenses are worn for up to a month.

Other types of contact lenses include rigid scleral lenses, which cover the whole of the front of the eye and are used to disguise disfigurement; bifocal contact lenses; and toric contact lenses, which have an uneven surface curvature and can correct *astigmatism*.

PROBLEMS

Hard plastic lenses may cause abrasion of the cornea if worn for too long. Soft lens wearers sometimes develop sensitivity of the eyes and lids. Any type of contact lens may cause redness of the eye. The most serious complication of using lenses is infection, which can occasionally cause permanent damage to the cornea and affect vision; meticulous hygiene lowers the risk.

contact tracing

A service provided by clinics treating *sexually transmitted infections*, in which all contacts of a person diagnosed as having a sexually transmitted infection are traced and then encouraged to be examined and treated. Contact tracing is also used in cases of other infections, especially *tuberculosis*, *meningitis*, and imported *tropical diseases*.

contagious

A term used to describe a disease that can be transferred from person to person by ordinary social contact. All contagious diseases, such as the common cold or chickenpox, are *infectious*. The term “contagious” does not apply to the many *infectious diseases*, such as typhoid, syphilis, or AIDS, which are spread by other means.

continuous positive airway pressure (CPAP)

A method of *ventilation* (mechanically assisted breathing) in which the air pressure inside a patient's airways is kept above atmospheric pressure.

continuous positive pressure ventilation (CPPV)

A rarely used method of *ventilation* (mechanically assisted breathing) in which positive pressure is applied to the airways to produce each inhalation.

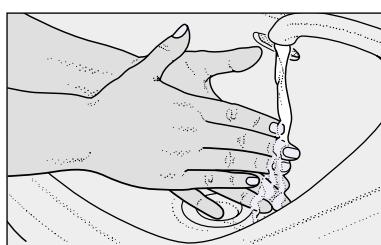

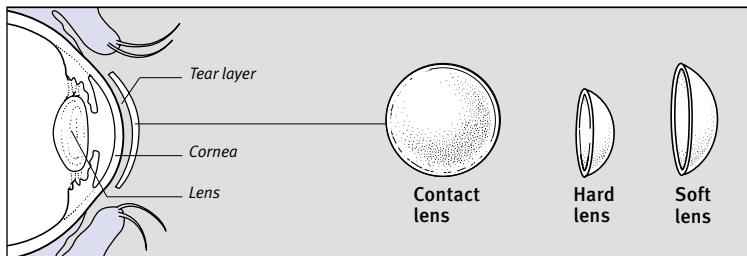

contraception

The control of fertility to prevent *pregnancy*. Contraception can be achieved by a variety of methods. Some forms

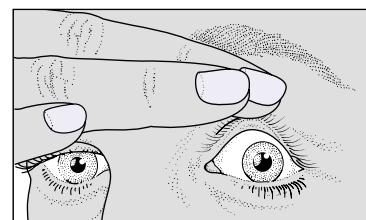

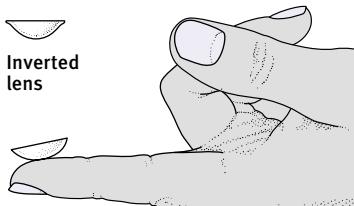

CARE AND INSERTION OF CONTACT LENSES

The care of hard contact lenses may require the use of several chemical solutions. A cleaning solution is used to remove deposits of mucus and protein from the lenses. A wetting solution is used before inserting a lens in the eye. A further solution may also be used for storage; if used, a storage solution must be washed off before a contact lens is inserted.

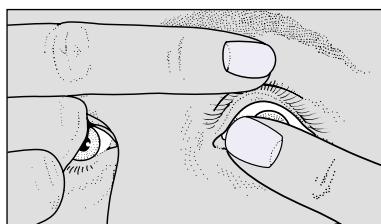

Soft contact lenses absorb any chemicals with which they come into contact, so the solutions used must be weaker. Disinfection with a chemical or heating system is needed to prevent contamination and eye infection. Two or three solutions may be necessary, but intermittent cleaning with a third system, such as an enzyme tablet or an oxidizing agent, may also be required.

- 1 Before touching lenses, wash your hands thoroughly under running water and take care to rinse off all traces of soap. Remove the lens from its container; for a hard lens, you may prefer to do this with a rubber sucker. Rinse the lens thoroughly in the wetting solution. Do not use tapwater.

- 2 Place the contact lens on the tip of your index finger. If it is a soft lens, make sure that it has not turned inside out. If it has, you will see an out-turned rim.

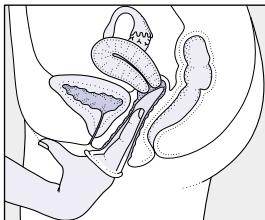

- 3 Keep both eyes open. Hold the upper lid of one eye open, and look straight ahead or at the lens as you bring it up to your eye.

- 4 Place the contact lens on your eye, over the iris and pupil. Look downwards and then release the lid. If necessary, the lens may be centred by gently massaging the eyelid. The photograph on the right shows a hard lens correctly positioned.

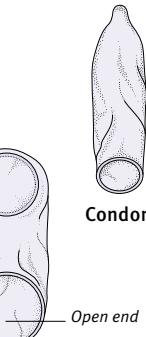

METHODS OF CONTRACEPTION

Forms of contraception include natural, barrier, hormonal, and postcoital methods. Most are for use by women. Another option is sterilization, surgery that disrupts part of the male or female reproductive system to render a person permanently infertile.

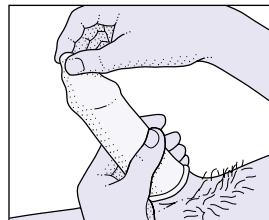

Female condom

The female condom is placed in the vagina with the open end extending just beyond the vaginal opening.

Female condom

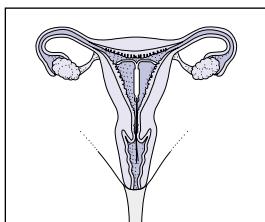

Male condom

Condoms should be checked for holes and air squeezed from the tip to prevent bursting. They may be used with a spermicide. On withdrawal, the rim should be held to stop the condom slipping off.

Hormone injection

A progestogen is injected by a doctor or nurse into a muscle in the woman's arm or buttock. The hormone is released into her body over a period of 8 to 12 weeks, after which time the procedure is repeated.

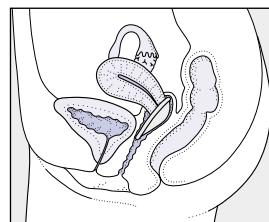

IUD in position

An IUD is a small piece of moulded plastic with strings attached. Some contain copper or a progestogen. The IUD is fitted in the uterus to stop fertilized eggs implanting.

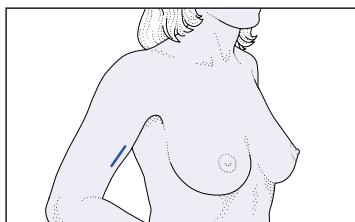

Diaphragm plus spermicide

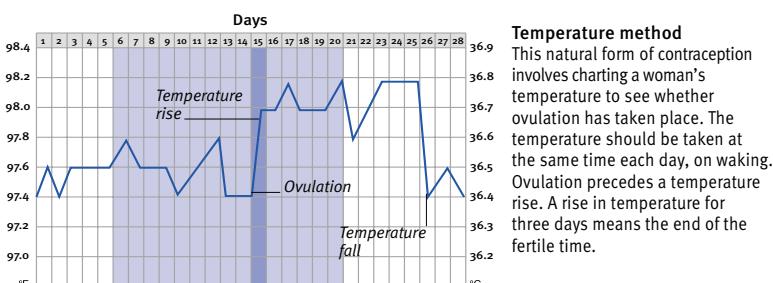

Diaphragm in position

A diaphragm is a rubber dome held in place over the cervix by means of a coiled metal spring in its rim. It physically prevents sperm from reaching the cervix.

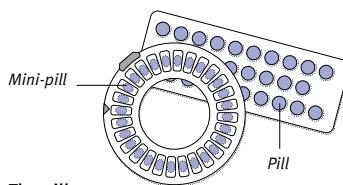

Hormonal implant

A flexible rod containing a progestogen hormone is inserted into the woman's arm, under the skin, where it releases progestogen into the blood.

Temperature method

This natural form of contraception involves charting a woman's temperature to see whether ovulation has taken place. The temperature should be taken at the same time each day, on waking. Ovulation precedes a temperature rise. A rise in temperature for three days means the end of the fertile time.

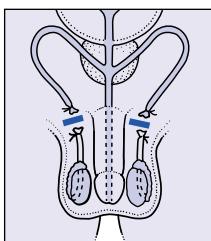

The pill

Contraceptive pills contain oestrogen to prevent ovulation, and/or a progestogen, which changes the cervical mucus to prevent sperm penetration, or alters the uterine lining to prevent implantation.

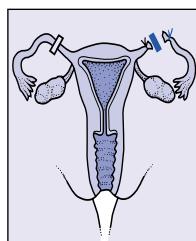

STERILIZATION

This procedure offers an almost completely safe and reliable form of birth control; it is usually irreversible. It does not affect sex hormones, so a man produces sperm-free semen and a woman produces normal eggs that do not reach the uterus.

Male sterilization (vasectomy)

The vas deferens (tube from a testis to the urethra) on each side is cut so sperm cannot enter the urethra.

Female sterilization

A laparoscope (viewing tube) is inserted, under anaesthetic, through the abdominal wall. An instrument is passed through it to cut or seal the fallopian tubes.

prevent *ovulation* in the woman; others stop *sperm* from meeting an *ovum* in the *fallopian tube* (preventing *fertilization*), or prevent a fertilized ovum from implanting in the *uterus*.

Some contraceptive methods involve changes in sexual activity; such methods include total or periodic abstinence from intercourse (see *contraception, natural methods of*) and *coitus interruptus*, in which sexual intercourse is stopped before ejaculation occurs. Other methods, known as barrier methods (see *contraception, barrier methods of*), involve the use of condoms to prevent sperm from coming into contact with eggs. Hormonal methods, including the use of *oral contraceptives*, implants, and injections (see *contraceptives, injectable*), prevent conception by altering the hormone balance in a woman's body. Further forms of contraception include the use of intrauterine devices (see *IUDs*); postcoital methods (see *contraception, emergency*); or sterilization of the male (see *vasectomy*) or female (see *sterilization, female*).

contraception, barrier methods of

The use of a device and/or a chemical that will physically stop *sperm* from reaching an *ovum*, thus preventing *fertilization* and pregnancy. Barrier methods and *spermicides* (preparations that kill sperm), when used together correctly, can be highly effective in preventing conception. Barrier methods of contraception also help to prevent the sexual transmission of diseases such as *HIV*, genital herpes (see *herpes, genital*), and viral hepatitis (see *hepatitis, viral*).

The male *condom*, a latex sheath that covers the penis, is one of the most widely used barrier contraceptives. The female condom (see *condom, female*), which lines the vagina, is similar to the male condom but is larger.

Other barrier methods that are used by women include the diaphragm and the cap. The diaphragm (see *diaphragm, contraceptive*) is a hemispherical dome of thin rubber with a metal spring in the rim to hold it in place against the vaginal wall, blocking the entrance to the *cervix*. It is used with a spermicide. A cervical cap (see *cap, cervical*) is an alternative to the diaphragm.

Spermicides, in the form of aerosol foams, creams, gels, and pessaries, are placed in the vagina as close as possible to the cervix shortly before sexual intercourse. Although some condoms are precoated with spermicide, not all

types of spermicide should be used with rubber barrier devices. (See also the illustrated box on previous page.)

contraception, emergency

Measures to avoid *pregnancy* following unprotected *sexual intercourse*. There are two main methods: hormonal and physical. In the first, *oral contraceptives* (the "morning after" pill) should be taken in a high dose as soon as possible after unprotected sexual intercourse: preferably within 12 hours, but no later than 72 hours afterwards. The pills contain a high dose of the hormone *progesterone*. In the physical method, an *IUD* is inserted by a doctor within five days of unprotected sex. Both methods are thought to work by preventing a fertilized egg from implanting in the uterus. (See also the illustrated box on previous page.)

contraception, hormonal methods of

The use by women of synthetic *progesterone drugs*, often combined with synthetic *oestrogens*, to prevent conception. The combined pill (see *oral contraceptives*), the best-known form of hormonal contraception, contains both an oestrogen and a progestogen; it acts by suppressing *ovulation* (the release of an egg from an ovary). Progestogen drugs make cervical mucus thick and impenetrable to sperm. They also cause thinning of the *endometrium* (lining of the uterus), which reduces the chance of a fertilized egg implanting successfully. Progestogens can be given as pills, as *contraceptive implants* under the skin, or by injection (see *contraceptives, injectable*), or they can be released into the uterus by some *IUDs*. (See also the illustrated box on previous page.)

contraception, natural methods of

Methods of avoiding conception that do not involve the use of any contraceptive hormones or devices. These methods are based on attempts to pinpoint a woman's fertile period around the time of *ovulation*, so that sexual *intercourse* can be avoided at this time.

The *calendar method* is based on the assumption that ovulation takes place around 14 days before menstruation. Due to its high failure rate, it has been largely superseded by other methods.

The *temperature method* is based on the normal rise of a woman's body temperature in the second half of the menstrual cycle, after ovulation has

occurred. The woman takes her temperature each day using an ovulation thermometer. Sex is considered to be safe only after there has been a rise in temperature lasting at least three days.

The *cervical mucus method* involves attempting to pinpoint the fertile period by charting the appearance and amount of cervical mucus during the menstrual cycle. Certain recognized changes in the mucus occur before and often at ovulation. The *sympothermal method* is a combination of the temperature and mucus methods. (See also the illustrated box on previous page.)

contraception, postcoital

See *contraception, emergency*.

contraception, withdrawal method of

See *coitus interruptus*.

contraceptive

Any agent that reduces the likelihood of *conception*. (See also *contraction*.)

contraceptive implant

A hormonal method of *contraception* in which a long-acting *progesterone drug* is inserted under the skin inside the upper arm. An implant consists of a small, flexible rod that steadily releases the drug into the bloodstream. It functions continually for several years.

contraceptives, injectable

A hormonal method of *contraception* in which long-acting *progesterone drugs* are injected every two to three months. Injectable contraceptives are very effective, but they may cause menstrual disturbances, weight gain, headaches, and nausea, especially in the first few months.

contractions, uterine

Rhythmic, squeezing muscular spasms that occur in the walls of the *uterus* before and during *childbirth* in order to expel the baby from the uterus. Regular contractions indicate the start of *labour* and increase in strength and frequency throughout the first stage. (See also *Braxton Hicks' contractions*.)

contracture

A deformity that is caused by shrinkage of tissue in an area of skin, muscle, or a tendon and that may restrict the movement of a joint. Skin contractures commonly occur as a result of scarring following extensive burns or other

injuries. Other types of contracture are caused by inflammation and shrinkage of *connective tissues*; examples of these include *Dupuytren's contracture* and *Volkman's contracture*.

contraindication

Factors in a patient's condition that would make it unwise to pursue a certain line of treatment.

contrast enema

A *contrast medium* (opaque substance), which is introduced through the anus, that enables the colon and rectum to be seen in outline on an X-ray. (See also *barium X-ray examinations*.)

contrast medium

A substance that is opaque to *X-rays* and is introduced into hollow or fluid-filled parts of the body to render them visible on X-ray film. Barium is one of the most commonly used contrast media (see *barium X-ray examinations*).

controlled drug

One of a number of drugs that are subject to restricted use because of their potential for abuse. Controlled drugs include opiates such as *cocaine* and *morphine*, *amphetamine drugs*, and *barbiturate drugs*.

controlled trial

A scientific method of testing the effectiveness of new treatments or of comparing different treatments.

In a typical controlled drug trial, two comparable groups of patients with the same illness are given courses of apparently identical treatment. Only one group, however, actually receives the new treatment; the second group (known as the control group) is given a *placebo* (a harmless substance containing no active ingredients). Alternatively, the control group may be given an established drug that is already known to be effective. After a predetermined period, the two groups are assessed medically. If the patients on the new treatment show a greater improvement than those on the placebo (or those on an existing treatment), this result proves that the drug has a beneficial effect.

Controlled trials must be conducted "blind" (meaning that the patients do not know which treatment they are receiving). In a "double-blind" trial, neither the patients nor the doctors who assess them know who is receiving which treatment.

contusion

Bruising to the skin and underlying tissues from a "blunt" injury such as an abrasion (graze) or an impact.

convalescence

The period of recovery following an illness or a surgical operation during which the patient gradually regains strength before returning to their normal activities.

convergent squint

A type of *squint* in which the abnormal eye is directed too far inwards towards the other eye.

conversion disorder

A psychological disorder, formerly called hysteria, in which repressed emotions appear to be unconsciously converted into physical symptoms such as blindness, loss of speech, or paralysis. Conversion disorder is generally treated by *psychotherapy*.

convulsion

See *seizure*.

convulsion, febrile

Twitching or jerking of the limbs with loss of consciousness that occurs in a child after a rapid rise in body temperature. Febrile convulsions are common and usually affect children between the ages of six months and five years.

CAUSES

The convulsions are due to immaturity of the temperature-lowering mechanism in the brain; the mechanism allows the child's body temperature to rise too rapidly in response to infections such as *measles* or *influenza*.

TREATMENT AND PREVENTION

Treatment involves lowering the temperature by sponging the child's face and body with tepid water and using a fan. Seizures can often be prevented in susceptible children by giving *paracetamol* at the first signs of fever.

OUTLOOK

Most children who have one or more febrile convulsions suffer no long-term effects. However, there is a very small risk of developing *epilepsy*, which is increased in children with a pre-existing abnormality of the brain or nervous system, or children with a family history of epilepsy.

Cooley's anaemia

See *thalassaemia*.

COPD

The abbreviation for chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*).

copper

A metallic element that is an essential part of several *enzymes* (substances that regulate chemical reactions in the body). Copper is required by the body in only minute amounts (see *trace elements*). An excess in the body may occur as a result of the rare inherited disorder *Wilson's disease*.

co-proxamol

An *analgesic drug* (painkiller) containing *paracetamol* and the weak *opioid* analgesic drug dextropropoxyphene. Co-proxamol is used to relieve mild to moderate pain that has not responded to paracetamol or other nonopiod analgesics alone. Side effects include dizziness, drowsiness, constipation, and nausea. The drug may be habit-forming if taken over a long period.

cordotomy

A surgical procedure in which certain bundles of nerve fibres within the *spinal cord* are severed. Cordotomy is carried out to relieve persistent, severe pain that has not responded to other treatment. It is most frequently performed to treat pain occurring in the lower trunk and legs, especially in people who have cancer.

cord, spermatic

See *spermatic cord*.

cord, testicular

See *spermatic cord*.

cord, umbilical

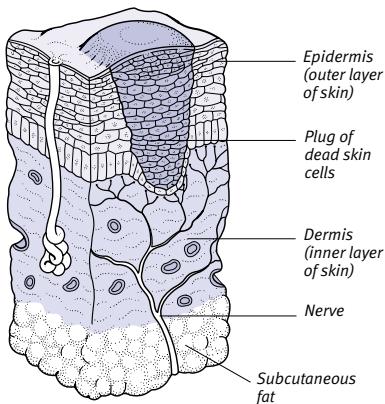

See *umbilical cord*.

cord, vocal

See *vocal cords*.

corn

A small area of thickened skin on a toe or other part of the foot. A corn is caused by the pressure of a tight-fitting shoe. The dead skin cells form a hard plug that extends down into the skin tissues. Pressure on this plug can cause pain. If a corn is painful, a spongy ring or corn pad can be placed over it to relieve the pressure. If the corn persists, the area of thickened skin can be removed by a chiropodist.

**Cross-section of a corn**

A plug of dead skin cells extends through the epidermis into the dermis, which has a nerve supply. Pressure on the plug can cause pain.

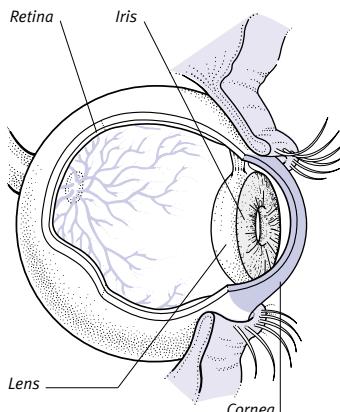

cornea

The transparent, thin-walled surface that forms the front of the eyeball. The cornea has two main functions. It helps to focus light rays on to the *retina* at the back of the eye, and protects the front of the eye from debris and injury.

The cornea is joined at its circumference to the *sclera* (white of the eye); the black *pupil* and the coloured *iris* are visible beneath it. There are five layers. The outermost layer (the epithelium) protects the eye and absorbs oxygen and nutrients from tears. The central layer (the stroma) is by far the thickest and gives the cornea its form. The inner layer (the endothelium) expels excess

LOCATION OF CORNEA

The cornea is a transparent, thin-walled dome forming the front of the eyeball, over the iris. It consists of five layers of differing thickness.

fluid from the cornea, thus keeping the tissues transparent.

For the cornea to stay healthy, it must be kept moist and clean. It is kept moist by a film of *tears*, which are produced by the *lacrimal gland* and by the mucus- and fluid-secreting cells in the eyelids and *conjunctiva*. Further protection is provided by the eyelids, which blink or close to keep out debris. In addition, the cornea is very sensitive, and immediately registers the presence of any injury or foreign body.

corneal abrasion

A scratch or defect in the *epithelium* (outer layer) of the *cornea* caused by a small, sharp particle in the eye (see *eye, foreign body in*) or by an injury. Corneal abrasions usually heal quickly but may cause severe pain and *photophobia*.

Treatment of a corneal abrasion includes covering the eye with a patch and *analgesics* to relieve pain. If the ciliary muscles go into spasm, eyedrops containing cycloplegic drugs may be used to paralyse the ciliary muscle. *Antibiotic* eyedrops are usually given to prevent bacterial infection (which can lead to a *corneal ulcer*).

corneal graft

The surgical transplantation of donor corneal tissue to replace a damaged *cornea*. In most grafts, tissue is taken from a human *donor* after death. The success rate of corneal grafts is generally high, because the cornea has no blood vessels; this reduces access for white blood cells, which could otherwise cause *rejection* of the donor tissue.

corneal transplant

See *corneal graft*.

corneal ulcer

A break, erosion, or open sore in the *cornea*. It usually affects the outer layer of the cornea, but in some cases may penetrate down to the middle layer.

Corneal ulcers are commonly caused by a *corneal abrasion*. They may also be due to chemical damage, or infection with *bacteria*, *fungi*, or *viruses* (particularly *herpes virus*). Eye conditions such as *keratoconjunctivitis sicca* and eyelid deformities such as *entropion* or *ectropion* increase the risk of an ulcer.

Ulcers are revealed by introducing *fluorescein* dye into the eye. Infections and predisposing eye conditions are

DISORDERS OF THE CORNEA

Various injuries or conditions can affect the sensitive cornea.

Injury

A *corneal abrasion* (scratch) can become infected and progress to a *corneal ulcer*. Penetrating corneal injuries can cause scarring, which may lead to impairment of vision. Chemical injuries can result from contact with a corrosive substance such as an acid or alkali.

In *actinic keratopathy*, the outer layer of the cornea is damaged by ultraviolet light. In *exposure keratopathy*, damage occurs as a result of reduced protection from the tear film and blink reflex.

Infection

The cornea can be infected by viruses, bacteria, or fungi. Some infections can cause ulceration, the *herpes simplex* virus being especially dangerous.

Inflammation

True inflammation of the cornea (called *keratitis*) is uncommon because the cornea contains no blood vessels.

Congenital defects

Rare congenital defects include *microcornea* (a cornea that is smaller than normal) or *megalocornea* (one that is bigger than normal) and *bupthalmos*, or "ox-eye", in which the entire eyeball is distended as a result of *glaucoma* (raised fluid pressure in the eyeball).

Degeneration

Degenerative conditions of the cornea include calcium deposition, thinning, and spontaneous ulceration. Such conditions occur mainly in elderly people, and are more common in previously damaged eyes.

Other disorders

Other disorders include: *keratomalacia*, which may result from vitamin A deficiency; *keratoconjunctivitis sicca* (dry eye); corneal dystrophies, such as *keratoconus*, in which the cornea becomes thinner and cone-shaped; and *oedema*, in which fluid builds up inside the cornea and impairs vision.

treated according to their cause. A superficial, noninfectious ulcer usually heals quickly; if it fails to do so, it may be treated with a "bandage" contact lens or with *tarsorrhaphy* (temporary sealing of the eyelids).

coronary

Any structure that encircles another like a crown. The term is usually used to refer to the *coronary arteries*, which surround the heart and supply it with blood. It is also sometimes used as a nonmedical term for a heart attack (see *myocardial infarction*).

coronary artery

Either of the two main *arteries* that supply the heart tissues with oxygen-rich blood. These vessels, known as the left and right main coronary arteries, arise directly from the *aorta* (the main artery in the body). The term "coronary artery" is also applied to any of the arteries that branch off from the main coronary arteries, such as the left circumflex artery and the left anterior descending artery. Blockage of a coronary artery as a result of *atherosclerosis* (an accumulation of fatty deposits in the artery) can lead to *myocardial infarction*. (See also *coronary artery disease*.)

coronary artery bypass

A major heart operation that is carried out in order to bypass *coronary arteries* that have become narrowed or blocked (usually as a result of *atherosclerosis*). The procedure involves using additional blood vessels (such as a mammary artery or a vein from the leg) to improve blood flow to the heart muscle. A coronary artery bypass is performed if symptoms of coronary artery disease have not been relieved by drugs, or if balloon *angioplasty* (a surgical procedure used to widen blocked arteries) is inappropriate or has failed.

Before surgery, sites of blockage are identified using an imaging procedure called *angiography*. Usually, a *heart-lung machine* is needed to maintain the circulation during the operation, although sometimes *minimally invasive surgery* may be used to bypass the artery, thereby avoiding the need to stop the heart.

The long-term outlook is good following a coronary artery bypass. However, the grafted vessels may also eventually become blocked by *atherosclerosis*. (See also *Coronary artery bypass* box, overleaf.)

coronary artery disease

Narrowing of the coronary arteries, which supply blood to the heart, leading to damage or malfunction of the heart. The most common heart disorders due to coronary artery disease are *angina pectoris* (chest pain due to insufficient oxygen reaching the heart) and *myocardial infarction* (heart attack).

CAUSES

The usual cause is *atherosclerosis*, in which fatty plaques develop on artery linings. An affected vessel can become totally blocked if a blood clot forms or lodges in the narrowed area.

Atherosclerosis has many interrelated causes, including smoking, a high-fat diet, lack of exercise, being overweight, and raised blood cholesterol levels. Other risk factors include a genetic predisposition and diseases such as *diabetes mellitus* and *hypertension*.

SYMPOTMS

In its early stages, coronary artery disease often produces no symptoms. The first sign is frequently the chest pain of angina, or an actual heart attack.

The disease may also cause arrhythmias (abnormalities in the heartbeat); in severe cases, arrhythmia can cause *cardiac arrest* (in which the heart stops beating). In elderly people, it may lead to *heart failure*, in which the heart gradually becomes less and less efficient.

TREATMENT

Drugs are given to help the heart to function more efficiently and to relieve symptoms. These include glyceryl trinitrate and other *nitrate drugs*; *calcium channel blockers*; *beta-blockers*; *potassium channel activators*; and *vasodilator drugs*.

If drug treatment fails to relieve the symptoms of coronary artery disease, or if there is extensive narrowing of the coronary arteries, blood flow may be improved by balloon *angioplasty* or *coronary artery bypass* surgery.

coronary care unit

A specialist ward for the care of acutely ill patients who may have suffered a *myocardial infarction* (heart attack) or another serious cardiovascular disorder.

coronary heart disease

An alternative name for *coronary artery disease*.

coronary thrombosis

A condition in which a *thrombus* (blood clot) narrows or blocks one of the *coronary arteries*, thereby prevent-

ing sufficient oxygen from reaching a section of the heart muscle. In most cases, the thrombus forms in a blood vessel that has already been narrowed by *atherosclerosis*. Sudden blockage of a coronary artery will cause a *myocardial infarction* (heart attack).

coroner

A public officer appointed to inquire into a cause of death when it is unknown or when unnatural causes are suspected.

cor pulmonale

Enlargement of, and strain upon, the right side of the *heart*, that is caused by one of several chronic lung diseases. Damage to the lungs leads to *pulmonary hypertension* (abnormally high blood pressure in the arteries that supply the lungs). The resulting "back pressure" of blood puts strain on the heart, and may eventually cause right-sided *heart failure* with *oedema*.

corpus callosum

The band of nerve fibres that forms a connection between the two hemispheres of the *brain*.

corpus cavernosum

One of two cylindrical bodies of erectile tissue that is found in both the *clitoris* and the *penis*. The spongy structure of the corpus cavernosum allows the tissue to become rigid when it becomes filled with blood.

corpuscle

Any minute body or cell, particularly red and white blood cells or certain types of *nerve ending*.

corpus luteum

A small tissue mass in the *ovary* that develops from a ruptured egg *follicle* after *ovulation* (the release of an egg). The corpus luteum secretes the female sex hormone *progesterone*, which causes the lining of the uterus to thicken in preparation for implantation of a fertilized egg. If fertilization does not occur, the corpus luteum shrinks and dies.

corrosive oesophagitis

A type of *oesophagitis* that is caused by swallowing caustic chemicals.

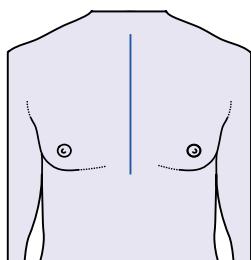

corset

A device that is worn around the trunk to relieve *back pain* and treat spinal injuries or deformities.

CORONARY ARTERY BYPASS

This procedure is now the most common and successful major heart operation in the Western world. Each year some 10,000 people in the UK undergo the operation, which can relieve them from dependence on drug treatment for heart disease and restore them to active life.

Site of incision

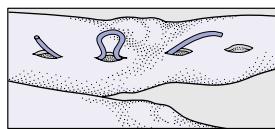

HOW IT IS DONE

Coronary artery bypass is a major procedure, requiring two surgeons and lasting up to five hours.

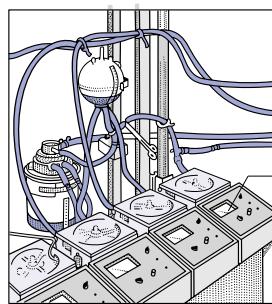

1 The first surgeon makes an incision down the centre of the patient's chest. The heart is then exposed by opening the pericardium.

First surgeon prepares heart for bypass

2 Simultaneously, several incisions are made in the leg, and a length of vein removed.

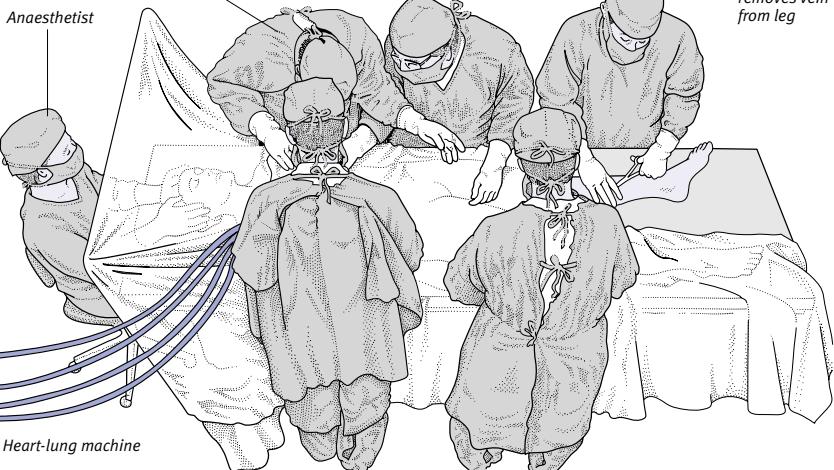

3 Before any incisions are made in the coronary arteries, the patient is connected to a heart-lung machine. This takes over the function of the heart and lungs while the surgeon repairs the heart.

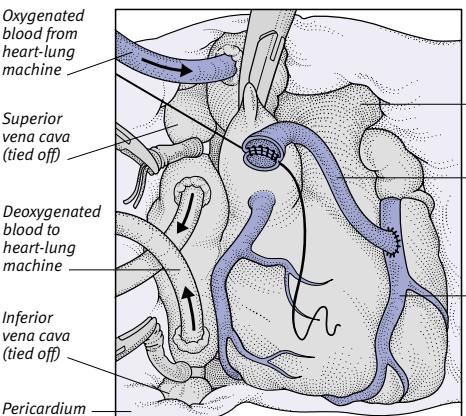

Anaesthetist

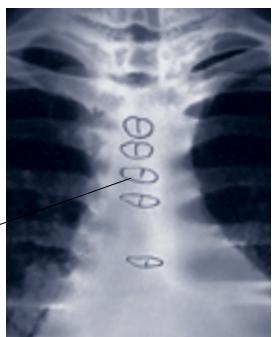

Second surgeon removes vein from leg

4 The section of the vein taken from the leg is then sewn to the aorta and to a point below the blockage. If several arteries are blocked, they can be bypassed by using other sections from the same leg vein, or an arterial graft may be taken from the chest.

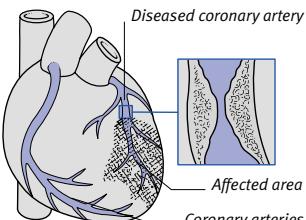

5 The heart-lung machine is disconnected, allowing the blood to flow back into the coronary arteries.

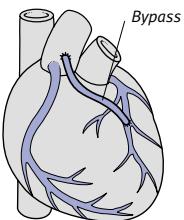

WHY IT IS DONE

Narrowed coronary arteries are unable to supply the heart muscle with a sufficient amount of blood, and, as a result, the heart muscle becomes starved of oxygen. This may cause angina (chest pain) or damage to the heart tissue. By joining lengths of a vein (taken from the leg during the operation) to the aorta and to a point below the blockages, the narrowed or blocked sections of coronary artery can be bypassed.

Before the operation

After the operation

6 Finally, the breastbone is wired together, and the pericardium and chest are sewn up.

cortex

The outer layer of certain organs, such as the brain or kidneys.

corticosteroid drugs

COMMON DRUGS

- Beclometasone • Cortisone
- Dexamethasone • Fludrocortisone
- Hydrocortisone • Prednisolone
- Prednisone • Triamcinolone

A group of drugs that are chemically similar to *corticosteroid hormones*, which are produced by the *adrenal glands*.

WHY THEY ARE USED

Corticosteroid drugs are used as hormone replacement therapy in *Addison's disease* and when the *adrenal glands* or *pituitary gland* have been destroyed by disease or have been removed. They are also used to treat inflammatory intestinal disorders, such as *ulcerative colitis* and *Crohn's disease*, and as an urgent treatment for the inflammation in the artery supplying the retina that occurs in *temporal arteritis*. Other uses of corticosteroid drugs include the treatment of *autoimmune diseases* such as systemic *lupus erythematosus* and *rheumatoid arthritis*, and the treatment of *asthma*, *eczema*, and *allergic rhinitis*.

Corticosteroid drugs are also used to prevent organ rejection following *transplant surgery* and in the treatment of some types of cancer, such as *lymphoma* or *leukaemia*. In addition, injections of corticosteroids may be administered to relieve pain in disorders such as *tennis elbow* and *arthritis*.

POSSIBLE ADVERSE EFFECTS

Side effects are uncommon when corticosteroid drugs are used in the form of cream or taken by inhaler. However, tablets taken in high doses for long periods may cause *diabetes mellitus*, *hypertension*, *osteoporosis*, *oedema*, *peptic ulcer*, *Cushing's syndrome*, inhibited growth in children, and, in rare cases, *cataract* or *psychosis*. High doses of the drugs also impair the *immune system*, increasing the risk of serious infections such as *septicaemia* and *tuberculosis*; and *chickenpox* can be life-threatening in people taking corticosteroids.

Long-term treatment suppresses production of corticosteroid hormones by the adrenal glands, and sudden withdrawal may lead to *adrenal failure*, which can be life-threatening. For this reason, anyone who is taking corticosteroids, or who has recently taken them, should always carry a steroid

treatment card and inform a doctor of the fact before undergoing any other form of medical treatment.

corticosteroid hormone

Any of a variety of hormones that is produced by the cortex of the *adrenal glands*. There are two main groups of corticosteroid hormone: *glucocorticoids* (such as *hydrocortisone*, *cortisone*, and *corticosterone*) and *mineralocorticoids* (such as *aldosterone*). (See also *corticosteroid drugs*; *steroid hormones*.)

corticotropin

An alternative name for *ACTH* (adrenocorticotrophic hormone).

Corti, organ of

See *organ of Corti*.

cortisol

An alternative name for *hydrocortisone*, a corticosteroid hormone that is produced by the *adrenal glands*.

cortisone

A *corticosteroid hormone* that is produced synthetically. Cortisone is used as a replacement hormone in the treatment of *Addison's disease*. Side effects of the hormone include *peptic ulcer* and bleeding in the stomach.

Corynebacterium

A genus of gram-positive (see *Gram's stain*), rod-shaped bacteria. *Corynebacteria* cause disease, including *diphtheria* in humans and various types of infection in domestic animals and birds.

coryza

A term for the nasal symptoms of the common cold (see *cold, common*).

COSHH Regulations

The abbreviation for the Control of Substances Hazardous to Health Regulations, which is one of the major legal provisions in the UK regarding the use of dangerous chemicals in the workplace.

cosmesis

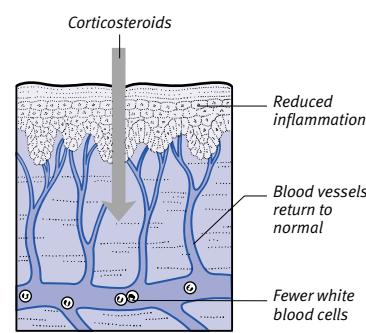

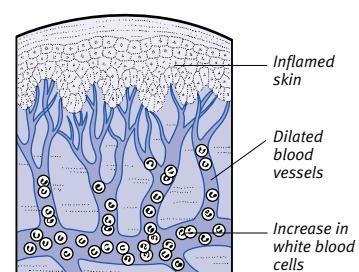

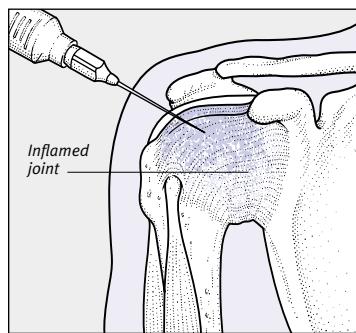

A term used for any procedures that are carried out to improve a person's appearance or to correct a disfiguring physical defect, such as *cosmetic surgery*, *cosmetic dentistry*, or the use of make-up to cover physical flaws.

cosmetic dentistry

Procedures to improve the appearance of the *teeth* or prevent further damage to the teeth and/or *gums*. Cosmetic dentistry procedures include: fitting an *orthodontic appliance* to correct teeth

HOW CORTICOSTEROIDS WORK

When given as hormone replacement therapy (such as in *Addison's disease*), corticosteroids supplement or replace natural hormones. Large doses have an anti-inflammatory effect (right) because they reduce the body's production of prostaglandin (natural chemicals that cause inflammation in damaged tissues such as an arthritic joint). They also suppress the immune system by reducing release and activity of white cells.

that are out of alignment or an incorrect bite (see *malocclusion*); fitting a *crown*; *bonding* to treat chipped or stained teeth; and *bleaching* of discoloured teeth.

cosmetic surgery

Any operation performed to improve appearance rather than to cure or treat disease. Cosmetic surgery techniques include the removal of skin blemishes or *dermabrasion*; *rhinoplasty* to alter the shape or size of the nose; *face-lifts*; *mammoplasty* to reduce or enlarge the breasts; *body contour surgery* to remove excess body fat and tissue; *hair transplants*; *blepharoplasty* to remove excess skin on the eyelids; and *mentoplasty* to alter the size or shape of the chin.

As with any surgical procedure, all forms of cosmetic surgery carry the risk of side effects from the anaesthetic, and of complications arising from the operation itself.

costal

A term meaning "relating to the ribs".

costalgia

Pain that occurs around the chest as a result of damage to a *rib* or to one of the *intercostal nerves* beneath the ribs. Damage to an intercostal nerve most commonly results from an attack of the viral infection *herpes zoster* (shingles). The pain is difficult to treat and has a tendency to persist.

Costen's syndrome

A term that is sometimes used to describe facial pain due to *temporomandibular joint* disorders.

costosternal

A combined term sometimes used to describe the junction of the *ribs* and the *sternum* (breastbone).

cot death

See *sudden infant death syndrome*.

co-trimoxazole

An *antibacterial drug* that is a combination of trimethoprim and sulfamethoxazole. Because of rare but potentially serious side effects, co-trimoxazole is now used to treat certain infections only in circumstances in which they cannot be treated with other drugs. Its main use is for the prevention and treatment of *pneumocystis pneumonia* in people with *AIDS*.

cough

A *reflex* action that helps to clear the airways of sputum, a foreign body, or any other irritant or blockage. A cough is described as "productive" when it brings up mucus or sputum and "unproductive" or "dry" when it does not.

CAUSES

Many coughs are due to irritation of the airways by dust, smoke (see *cough, smoker's*), or a viral infection of the upper respiratory tract (see *cold, common; laryngitis; pharyngitis; tracheitis*). Coughing is also a feature of *bronchitis, asthma, pneumonia*, and *lung cancer*.

TREATMENT

Over-the-counter *cough remedies* are available, but, in general, they just ease symptoms. More specific treatment is directed at the underlying disorder.

coughing up blood

A symptom, also called haemoptysis, caused by the rupture of a blood vessel in the airway, lung, nose, or throat.

The coughed-up blood may appear as bright-red or rusty-brown streaks, clots in the sputum, a pinkish froth, or, more rarely, blood alone. In all cases, medical assessment is needed.

CAUSES

Many disorders can cause haemoptysis. The most common are infections, such as *pneumonia* or *bronchitis*; and *congestion* and rupture of blood vessels in the lungs due to *heart failure, mitral stenosis*, or *pulmonary embolism*. A cancerous tumour can also produce haemoptysis by eroding the wall of a blood vessel.

DIAGNOSIS AND TREATMENT

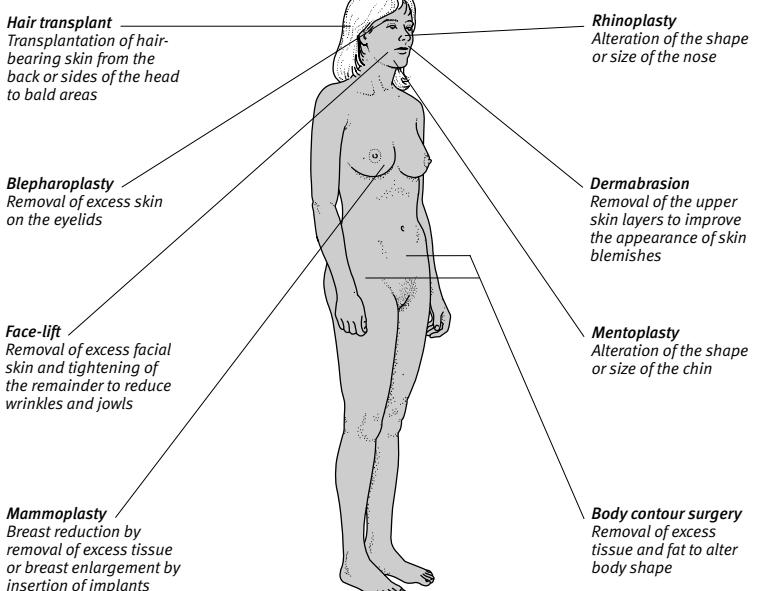

Investigations into coughing up blood include *chest X-ray*, and, in some cases, *bronchoscopy*. In about a third of cases, no underlying cause is found. Treatment depends on the cause.

cough remedies

Over-the-counter medications used for treating a *cough*. There are various preparations, but the effectiveness of most is unproven. *Expectorant* cough remedies are purported to encourage expulsion of sputum by making it less viscous (sticky). Cough suppressants, which control the coughing reflex, include some *antihistamine drugs* and *codeine*. They may be helpful in controlling coughing at night that prevents sleep; however, they cause drowsiness and often cause constipation as well.

TYPES OF COSMETIC SURGERY

There is a range of cosmetic surgery procedures for various parts of the body. The sites of some of the more commonly performed operations are shown below. The procedures vary in the permanency of their results and in the likelihood of achieving a satisfactory appearance.

cough, smoker's

A recurrent cough that is due to *smoking*. The cough is usually triggered by the accumulation of thick sputum in the airways as a result of inflammation caused by tobacco smoke. Giving up smoking will usually stop the cough, but it may take time. In general, the longer a person has been smoking, the longer it takes for the cough to clear. Smokers who have a persistent cough should seek medical advice, particularly if the cough changes, because smoking is associated with *lung cancer*.

counselling

Advice and psychological support from health professionals to help people to deal with personal difficulties. Counselling is used to address problems at school, work, or in the family; provide advice on medical problems and sexual and marital problems; help people to deal with addictions; and give support during life crises. Types of counselling include *genetic counselling*, trauma counselling, and *sex therapy*.

In most cases counselling is a one-to-one activity, but it may also be carried out in small groups. (See also *child guidance*; *family therapy*; *marriage guidance*; *psychotherapy*.)

Cowden's disease

An autosomal dominant *genetic disorder*, also called multiple hamartoma syndrome, in which non-cancerous growths develop in tissues, including the skin, mouth, and intestines. Skin growths may include flat-topped, flesh-coloured lesions on the face. Multiple polyps may grow in the intestines.

People with Cowden's disease are also at increased risk of developing certain cancers, particularly thyroid cancer, colorectal cancer, and, in women, breast and ovarian cancer. There is no specific treatment for the condition, but affected individuals are carefully monitored in order that early signs of these cancers can be detected.

cowpox

An infection caused by the vaccinia virus, which usually affects cows. This virus was used in the past to confer immunity against *smallpox*.

coxa vara

A deformity of the *hip* in which the angle between the neck and head of the *femur* (thigh-bone) and the shaft of the

femur is reduced, resulting in shortening of the leg, pain and stiffness in the hip, and a limp. The most common cause is a fracture to the neck of the femur or, during adolescence, injury to the developing part of the head of the femur. Coxa vara can also occur if the bone tissue in the neck of the femur is soft, a condition that may be *congenital* or the result of a bone disorder such as *rickets* or *Paget's disease*. Treatment may include surgery (see *osteotomy*).

COX-2 inhibitor drugs

A group of *nonsteroidal anti-inflammatory drugs* (NSAIDs) that are less likely to cause stomach irritation than the other NSAIDs. One example of a COX-2 inhibitor drug is *celecoxib*.

coxsackievirus

One of a group of *viruses* responsible for a broad range of diseases. There are two main types of coxsackievirus: A and B. The best known of the type A infections is *hand, foot, and mouth disease*, which is a common childhood disorder characterized by blistering of skin around the mouth, hands, and feet. Type B viruses can cause serious illnesses such as *meningitis*, *pericarditis*, and *pneumonia*.

CPAP

The abbreviation for *continuous positive airway pressure*.

CPPV

The abbreviation for *continuous positive pressure ventilation*.

crab lice

See *pubic lice*.

crack

A popular term for a highly potent, fast-acting form of *cocaine*.

cracked heel

See *heel, cracked*.

cradle cap

A skin condition, common in babies and most prevalent between the age of 3 and 9 months, in which thick, yellow scales occur in patches over the scalp. Cradle cap, which is a form of *seborrhoeic dermatitis*, may also occur on the face, neck, behind the ears, and in the nappy area. The reason why cradle cap occurs is not clear, but the condition is not due to poor hygiene.

Cradle cap is harmless as long as the skin does not become infected. It can be treated by daily use of a simple shampoo. Alternatively, warm olive oil may be rubbed into the baby's scalp and left on overnight to loosen and soften the scales, which can be washed off the following day. A mild ointment that contains an *antifungal drug* and a *corticosteroid drug* may be prescribed if the skin becomes inflamed.

Appearance of cradle cap

Thick, yellow, scaly patches occur on the scalp of babies, most commonly between the age of 3 and 9 months. It is not clear why cradle cap occurs.

cramp

A painful spasm in a *muscle* that is caused by excessive and prolonged contraction of the muscle fibres. The affected muscle may feel hard and tender. Cramps often occur as a result of increased muscular activity, which causes a build-up of *lactic acid* and other chemicals in the muscles, and leads to small areas of muscle-fibre damage. Repetitive movements, such as writing (see *cramp, writer's*) or sitting or lying in an awkward position may also result in cramps. In addition, cramps may follow profuse sweating because loss of sodium salts disrupts muscle cell activity.

Massaging or stretching the muscles involved may bring relief. A drug containing *calcium* or *quinine* may be given for recurrent night cramps. Recurrent, sudden pain in a muscle not associated with hardness of the muscle may be caused by *peripheral vascular disease*.

cramp, writer's

Painful spasm in the hand muscles following repetitive movements, which makes writing or typing impossible.

Crandall's syndrome

A rare *congenital* disorder that runs in families and is characterized by twisted, brittle hairs, sensorineural *deafness*, and *hypogonadism* (underdevelopment

of the *ovaries* or *testes*). The condition is associated with deficiencies of *luteinizing hormone* and *growth hormone*.

cranial nerves

Twelve pairs of *nerves* that emerge from the underside of the *brain*. Each of the cranial nerves has a number as well as a name; the numbers are used to indicate the sequence in which the nerves emerge from the brain.

Certain cranial nerves primarily send sensory information from the ears, nose, and eyes to the brain. These nerves are the *vestibulocochlear nerve* (hearing and balance), *olfactory nerve* (smell), and *optic nerve* (vision). Other cranial nerves carry impulses that move the muscles in the head and neck. They are the *oculomotor nerve*, the *trochlear nerve*, and the *abducent nerve* (producing eye movements), the *spinal accessory*

nerve (producing head and shoulder movements), and *hypoglossal nerve* (producing tongue movements).

Some cranial nerves have both sensory and motor functions. They are the *facial nerve* (facial expressions, taste, and the secretion of saliva and tears), the *trigeminal nerve* (facial sensation and jaw movements), and the *glossopharyngeal nerve* (taste and swallowing). The *vagus nerve* has branches to all the main digestive organs, as well as to the heart and the lungs. It is a major component of the *parasympathetic nervous system*, which is concerned with maintaining automatic body functions such as breathing, the heartbeat, and digestion.

craniopharyngioma

A rare, non-hormone-secreting tumour of the *pituitary gland*. Symptoms of a craniopharyngioma may include head-

aches, vomiting, and defective vision. If the tumour develops in childhood, the child's growth may be stunted and sexual development may not occur.

Craniopharyngiomas are usually surgically removed. If left untreated, they may cause permanent brain damage.

craniosynostosis

The premature closure of one or more of the joints (sutures) between the *skull bones* in infants. If all of the joints are involved, the growing *brain* may be compressed and there is a risk of brain damage due to the increased pressure inside the skull. If the abnormality is localized, the head may be deformed.

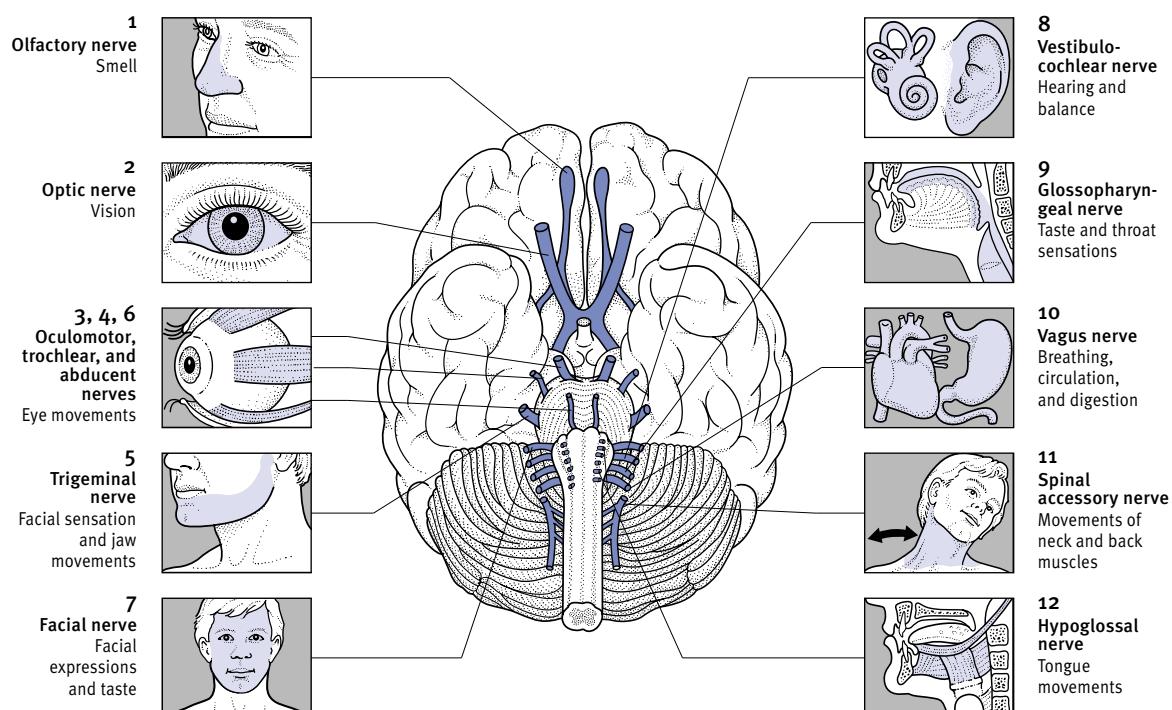

Craniosynostosis may occur before birth and may be associated with other *birth defects*. It may also occur in an otherwise healthy baby, or in a baby with a disorder such as *rickets*.

CRANIAL NERVES

All but two of the cranial nerve pairs connect with nuclei in the brainstem. The olfactory and optic nerves, in contrast, link directly with parts of the cerebrum. The nerves emerge through openings in the cranium (skull); many then divide into branches.

Certain cranial nerves are principally concerned with transmitting sensory information from organs such as the

ears, nose, and eyes to the brain. Others carry impulses that move the tongue, eyes, and facial (and other) muscles, or stimulate glands such as the salivary glands. A few nerves have both sensory and motor functions. The 10th, or *vagus nerve*, is one of the most important parts of the *parasympathetic nervous system*, and has branches to the main digestive organs, the heart, and the lungs.

If the brain has been compressed, an operation may be performed to separate the fused skull bones.

craniotomy

The temporary removal of a section of the skull to enable doctors to perform an operation on the *brain*. A craniotomy may be carried out to take a sample of tissue for analysis, remove a *tumour*, or drain an *abscess* or blood clot.

cranium

The part of the *skull* around the *brain*.

C-reactive protein

A protein produced by the body in response to inflammation. The blood level of this protein is measured to evaluate treatment of inflammatory conditions.

cream

A thick, semi-solid preparation with moisturizing properties, used to apply medications to the skin.

creatine kinase

An *enzyme* (a protein that alters the rate of a chemical reaction in the body) found in muscle. After damage to muscle cells, including those of the heart muscle, creatine kinase leaks into the blood. Increased levels of the enzyme can be detected by diagnostic tests (see *muscle enzymes*). Different types of creatine kinase exist in different types of muscle. If blood tests show a raised level of the form found in heart muscle, this may indicate that a *myocardial infarction* (heart attack) has occurred. Raised levels of the form found in skeletal muscles may indicate a range of disorders, from muscle injury to diseases such as *muscular dystrophy*.

creatinine

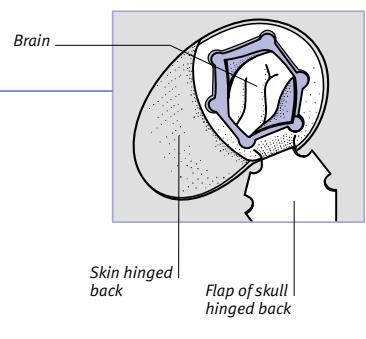

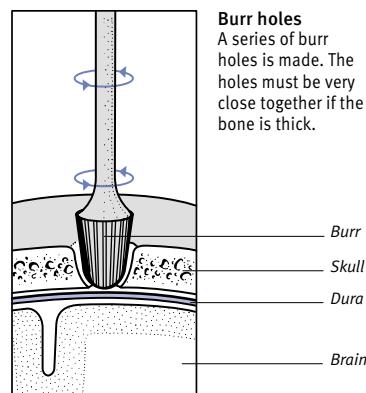

A waste product from chemical processes in the muscles. The kidneys filter it from the blood for excretion in *urine*.

creatinine clearance

A type of *kidney function test* in which the level of *creatinine* in the blood and the urine is measured. The blood level is measured, then the urine is collected and tested over 24 hours to measure the level of creatinine being excreted. The two levels are compared; if there is a high level of creatinine in the blood but a low level in the urine, it shows that the kidneys are not effectively clearing creatinine from the body.

PROCEDURE FOR CRANIOTOMY

Before the operation, all or part of the patient's scalp is shaved. After a general anaesthetic has been given, layers of skin, muscle, and membrane are cut away from the skull at the planned operation site and the bone is cut with a saw (see below). The "lid" of bone is then either folded back on a "hinge" of muscle or removed completely. The dura (the outermost of the three membranes that surround the brain) is then opened to reveal the inner membranes and the brain.

Gigli's saw
The bone between the burr holes is cut using Gigli's saw, which is passed between the burr holes using a malleable saw guide.

crepitus

A crackling sound in the lungs (heard through a *stethoscope*) due to a buildup of fluid. (See also *auscultation*.)

crepitus

A grating sound or sensation caused by rough surfaces inside the body rubbing together. Crepitus may be felt or heard when the ends of a broken bone rub against each other, or when *cartilage* on the surfaces of a joint has worn away due to *osteoarthritis*. Faint crepitus may be heard in the lung due to abnormalities such as inflammation in *pneumonia*.

The term also describes the crackling sound made when an air pocket under the skin (see *emphysema, surgical*), or an area of *gas gangrene*, is pressed.

cretinism

A *congenital* condition in infants that is characterized by stunted growth, failure of normal development, *learning*

difficulties, and coarse facial features. Cretinism occurs when the *thyroid gland* produces insufficient amounts of, or fails to produce any, of the thyroid hormone *thyroxine* at birth. However, provided that the condition is recognized early, replacement therapy with thyroxine can effect a cure. (See also *hypothyroidism*.)

Creutzfeldt–Jakob disease

A rare, progressive degenerative disease of the *brain*. Creutzfeldt–Jakob disease (CJD) is thought to be caused by infection with a *prion* (a type of infectious protein). A similar agent causes scrapie in sheep and *bovine spongiform encephalopathy* (BSE) in cattle.

TYPES

One form of CJD largely affects middle-aged or elderly people, and appears to have no obvious cause. A second form occurs in younger people, and this is associated with contamination during

brain surgery or transplants from infected people, or with treatment using infected human growth hormone or *gonadotrophins*.

A third form, new variant (nv) CJD, was first identified in 1995 and affects people in their teens and 20s. It is thought to be acquired by eating beef infected with BSE. This form causes pathological changes in the brain that are similar to the changes found in cattle suffering from BSE.

SYMPTOMS

Symptoms are broadly similar for all forms of the disease. Slowly progressive *dementia* (deterioration in brain function) and *myoclonus* (sudden muscular contractions) occur; coordination diminishes; the intellect and personality deteriorate; and blindness may develop. As the disease progresses, speech is lost and the body becomes rigid.

OUTLOOK

There is no treatment, and death usually occurs within two to three years.

cri du chat syndrome

A rare *congenital* condition that causes severe *learning difficulties*, abnormal facial appearance, low birth weight, and short stature. It is characterized by a cat-like cry in infancy. Cri du chat syndrome is caused by a *chromosomal abnormality*. There is no treatment. (See also *genetic counselling*.)

Crigler–Najjar syndrome

A rare *genetic disorder* in which there is an absence or lack of the liver enzyme that breaks down *bilirubin* (the yellowish pigment in the digestive juice *bile*) for excretion. The condition appears in early childhood.

Children with Crigler–Najjar syndrome have jaundice (yellowing of the skin and whites of the eyes, due to a buildup of bilirubin in the blood). In some children, the liver enzyme is completely absent, and the condition is fatal by about two years of age. Some other children may just have insufficient amounts of the enzyme, and may live into adulthood. A *liver transplant* may be the only effective treatment for the syndrome.

crisis

A term for a turning point in the course of a disease (either the onset of recovery or deterioration). The word is also used to describe a distressing and difficult episode in life.

crisis intervention

The provision of immediate advice or help, by agencies such as social services departments, to people with acute personal or sociomedical problems.

critical

A term used to mean "seriously ill" or to describe a crucial state of illness from which a patient may not recover.

Crohn's disease

A chronic inflammatory disease that can affect any part of the gastrointestinal tract from the mouth to the anus. Crohn's disease can occur at any age, but people in their mid-twenties are most likely to be affected.

The most common site of inflammation is the terminal ileum (the end of the small intestine where it joins the large intestine). The wall of the intestine becomes extremely thick due to continued chronic inflammation, and deep, penetrating ulcers may form. The disease tends to be patchy; areas of the intestine that lie between the diseased parts may appear to be normal, but are usually mildly affected.

CAUSES

The cause is unknown, but genetic and environmental factors seem to be involved. It is possible that the disease is caused by an abnormal immune response to an *antigen* (foreign protein). Smoking increases the risk, and worsens the condition once developed.

The risk of developing Crohn's disease is higher in people who have a close relative with the disorder.

SYMPTOMS

In young people, the ileum is usually involved. The disease causes spasms of abdominal pain, diarrhoea and chronic sickness, loss of appetite, anaemia, and weight loss. The ability of the small intestine to absorb nutrients from food is reduced. In elderly people, it is more common for the disease to affect the rectum and cause rectal bleeding.

Crohn's disease can also affect the colon (the major part of the large intestine), causing bloody diarrhoea. In rare cases, it also affects the mouth, oesophagus, stomach, and duodenum (the upper part of the small intestine).

Complications may affect the intestines or may develop elsewhere in the body. The thickening of the intestinal wall may narrow the inside of the intestine so much that an obstruction occurs (see *intestine, obstruction of*).

About three in ten affected people develop a fistula (abnormal passage-way). Internal fistulas may form between loops of intestine. External fistulas, from the intestine to the skin of the abdomen or around the anus, may cause leakage of faeces (see *faecal fistula*).

Abcesses (pus-filled pockets of infection) form in about one in five people. Many abcesses occur around the anus, but some occur within the abdomen.

Complications in other parts of the body may include inflammation of various parts of the eye, severe arthritis affecting various joints of the body, *ankylosing spondylitis* (an inflammation of the spine), skin disorders, liver disease, and *gallstones*.

DIAGNOSIS

A physical examination may reveal tender abdominal swellings that indicate thickening of the intestinal walls. *Sigmoidoscopy* (examination of the lower, or sigmoid, colon and the rectum with a viewing instrument) may confirm the diagnosis. X-rays using barium follow-through or barium enemas (see *barium X-ray examinations*) will show thickened loops of intestine with deep fissures.

It may be difficult to differentiate between Crohn's disease when it is affecting the colon and *ulcerative colitis*, an inflammatory bowel disease limited to the large intestine. However, *colonoscopy* (examination of the colon using a flexible viewing instrument) and *biopsy* (the removal of a sample of tissue for microscopic examination) can confirm the diagnosis.

TREATMENT

The aim of treatment is to bring about long-term remission of the disease. It may involve high doses of *corticosteroid drugs*, which are given either orally or intravenously; the *immunosuppressant drugs* azathioprine or mercaptopurine; metronidazole; and also *enteral feeding*, in which easily digestible food in liquid form is given through a tube directly into the intestines. Once the disease is in remission, normal feeding can be resumed and the dose of corticosteroids reduced. Aminosalicylate drugs, such as *sulfasalazine* or *mesalazine*, may be given.

Surgical treatment to remove damaged sections of the intestine is avoided whenever possible because the disease may recur in other parts. Many patients do need surgery at some stage, however, to treat problems including perforation or blockage of the intestine.

OUTLOOK

Some people in whom the disease is localized remain in normal health indefinitely and seem to be cured.

cromoglicate

See *sodium cromoglicate*.

crossbite

A type of *malocclusion* (an abnormal relationship between the upper and lower teeth) in which some or all of the lower front teeth overlap the upper front teeth. A molar crossbite, in which the upper and lower back teeth overlap, can also occur.

cross-eye

A type of *strabismus* (squint) in which one of the eyes turns inwards relative to the other, or in which both eyes turn inwards towards each other.

cross-matching

A procedure to determine compatibility between the blood of a person who requires a *blood transfusion* and that of a *donor*. Red blood cells from one person are combined with *serum* (the clear fluid that separates from blood when it clots) from the other. Clumping of red blood cells indicates the presence of *antibodies*, showing that the blood is not compatible.

croup

A common disorder in infants and young children, in which narrowing and inflammation of the airways causes hoarseness, stridor (a grunting noise during breathing), and a barking cough.

Croup may be caused by a viral or bacterial infection affecting the *larynx*, *epiglottis*, or *trachea*. Most cases are due to a viral infection and are generally mild. Other causes include *diphtheria*, *allergy*, spasm due to insufficient *calcium* levels in the blood, and inhalation of a *foreign body*.

Humidifying the air can help to ease breathing. In some cases, *corticosteroid drugs* administered through a *nebulizer*, and oxygen, may be prescribed. If the infection is bacterial, it is treated with *antibiotic drugs*.

Crouzon's syndrome

An autosomal dominant *genetic disorder* that causes facial deformities. Affected people have these features: eyes that protrude (see *exophthalmos*) and are spaced widely apart; a *squint*; an abnormally tall skull; a large, beaked nose; and an underdeveloped upper jaw, which makes the lower jaw look as if it is protruding.

crowding, dental

See *overcrowding, dental*.

crown

The name for the top of the head. The word is also used of the visible part of a tooth. (See also *crown, dental; crowning*.)

crown, dental

An artificial replacement for the crown of a decayed, discoloured, or broken tooth. A crown made from porcelain is usually used on front teeth, but back teeth need the greater strength of a crown made from gold or porcelain fused to metal.

A crown may be fitted by filing the tooth to form a peg and cementing the crown over the top of it. For a badly decayed or weakened tooth, it may be necessary to remove the natural crown, perform *root-canal treatment*, then fit the artificial crown on to a post that is cemented in the root canal. For details on how crowns are fitted, see the illustrated box below.

crown-heel length

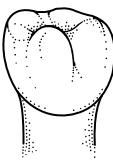

A routine measurement of the length of a newborn baby, taken from the *crown* of the head to the heels.

crowning

The popular name given to the phase in the second stage of labour (see *childbirth*) when the baby's head first appears at the mother's vaginal opening.

HOW CROWNS ARE FITTED

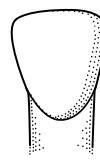

The tooth is filed down to form a peg over which the replacement is fitted. An impression of the peg and the natural tooth is taken and a replica is made. Using this replica as a model, the artificial crown is constructed.

Cast full crown

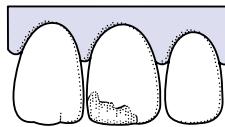

Porcelain fused to metal crown

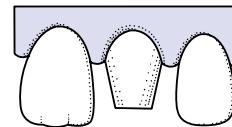

Porcelain jacket crown

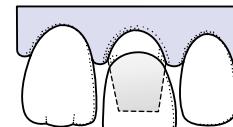

Three-quarter crown

1 A cracked or broken tooth, or one that has been heavily filled, can be replaced by a crown.

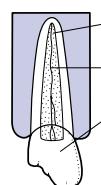

2 The damaged area of the tooth is removed and the remaining part is shaped to receive the crown.

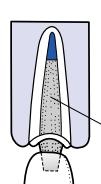

3 The artificial crown, a hollow shell, is fitted over the shaped tooth and then cemented in place.

POST CROWNS

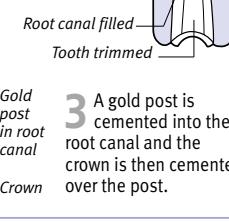

If the natural tooth is badly decayed or has been weakened, its crown is removed and a post crown is fitted.

1 This tooth is so decayed that a retaining peg cannot be fashioned.

2 The tooth's natural crown is completely removed.

3 A gold post is cemented into the root canal and the crown is then cemented over the post.

cruciate ligament

One of the two *ligaments* in the knee that pass over each other to form a cross. The ligaments form connections between the *femur* and *tibia* inside the knee joint and prevent overbending and overstraightening at the knee.

crush syndrome

Damage to a large amount of *muscle* (usually as a result of a serious accident), which causes *kidney failure*. The damaged muscles release proteins into the bloodstream, temporarily impairing kidney function. As a result, some substances normally excreted in the urine build up to toxic levels in the blood. If left untreated, crush syndrome may be fatal, but *dialysis* allows the kidneys time to recover.

crutch palsy

Weakness or *paralysis* of muscles in the wrist, fingers, and thumb in people who walk with a crutch under the armpit. Crutch palsy is due to pressure on the *nerves* supplying these muscles. It does not occur if elbow crutches are used.

crying in infants

A normal response in babies to needs or discomforts, such as hunger or thirst. Most healthy babies stop crying when their needs are attended to. In a few cases, persistent crying may be due to a physical cause such as intolerance of cow's milk or an illness (such as an ear or throat infection, or a viral fever).

cryo-

A prefix meaning "ice cold". It is used of medical procedures that involve the use of freezing or low temperatures.

cryopreservation

The preservation of living cells or tissue samples by freezing. The technique is used to store human eggs for *in vitro fertilization*, sperm for *artificial insemination*, or *plasma* and blood obtained from people with rare blood groups.

cryosurgery

The use of temperatures below freezing to destroy tissue, or the use of cold during surgical procedures to produce *adhesion* between an instrument and an area of body tissue.

Cryosurgery causes only minimal scarring. It is used to treat cancerous tumours in sites where heavy scarring can block vital openings, such as in the

cervix, the liver, and the intestines. It may be used in eye operations, for example in *cataract surgery* and treatment for *retinal detachment*. It is also commonly used for removing *warts*, *skin tags*, some *birthmarks*, and some skin cancers, and to treat *haemorrhoids*.

cryotherapy

The use of cold or freezing temperatures or substances in treatment. (See also *cryosurgery*.)

cryptococcosis

A rare infectious disorder caused by inhaling the fungus *CRYPTOCOCCUS NEOFORMANS*, which is found especially in soil contaminated with pigeon faeces. The most serious form of the infection can take is *meningitis*. Another form of infection causes growths in the lungs, resulting in chest pain and a cough, or on the skin, causing a rash of ulcers. Most cases of cryptococcosis occur in people with reduced immunity, such as those with *AIDS*.

Cryptococcal meningitis is diagnosed from a sample of spinal fluid. A combination of the antifungal drugs *amphotericin B* and flucytosine is usually prescribed to treat the infection. Most cases in which only the lungs are infected need no treatment.

cryptophthalmus

A *birth defect* in which the opening between the upper and lower eyelids is absent. (See also *Fraser's syndrome*.)

cryptorchidism

A developmental disorder of male infants in which the testes fail to descend normally into the scrotum (see *testis, undescended*).

cryptosporidiosis

A type of diarrhoeal infection caused by *protozoa*, which may be spread from person to person or be transmitted from domestic animals to people. The disease causes watery diarrhoea and sometimes fever and abdominal pain. It is most common in children but also occurs in people with AIDS.

In most cases, *rehydration therapy* is the only treatment needed. In people whose *immune system* is suppressed, however, the infection may be much more severe. Such people may need to be admitted to hospital for treatment with intravenous fluids and *antidiarrhoeal drugs*.

CSF

The abbreviation for *cerebrospinal fluid*.

CS spray

A noxious powder, also known as CS gas or tear gas, that is used in aerosol form as a means of riot control. CS spray causes severe irritation of the eyes, airways, and skin, and sometimes nausea and vomiting. Its effects are short-lived, usually lasting for only a few minutes.

CT scanning

A diagnostic technique in which the combined use of a computer and a machine emitting *X-rays* produces cross-sectional images of the body tissues.

A CT (computed tomography) scanner is a machine that is shaped like a doughnut that rotates around the patient's body. The machine contains one or more X-ray sources and, on the opposite side, some X-ray detectors. Unlike a conventional X-ray image, which shows only a few levels of tissue density, the X-ray detector can register hundreds of levels of density. It sends this information to a computer, which processes the data and shows the results as an image on a monitor. CT images usually show the body as "slices", in which the different tissues can be seen in detail. In some machines, this information can be used to produce a three-dimensional reconstruction of the area scanned.

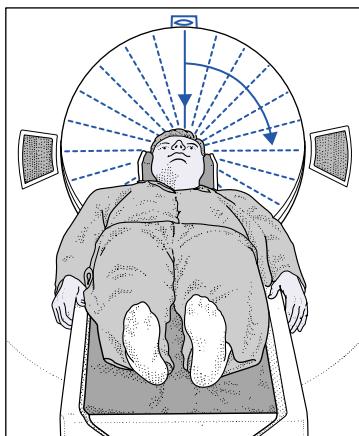

CT scanning has revolutionized the diagnosis and treatment of *tumours*, *abscesses*, and haemorrhages in the brain, as well as *head injuries* and *strokes*. The procedure is also used to locate and show tumours, to investigate a wide range of diseases, and to aid needle *biopsy* in organs of the trunk.

Newer types of CT scanners use a spiral technique: the scanner rotates around the body as the patient is moved slowly forwards on a bed, causing the X-ray beams to follow a spiral course. Images can be made of hollow organs such as the colon (a procedure known as "virtual colonoscopy"). For some procedures, injected or swallowed contrast media (chemicals that are opaque to X-rays) may be used to make certain tissues more easily visible.

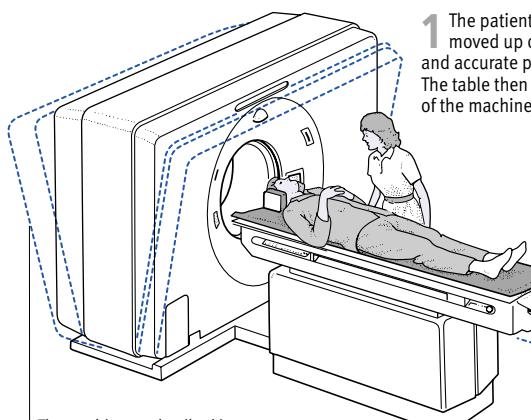

The images produced during CT scanning can be stored digitally or on conventional X-ray film. (For details of the procedure, see *Performing a CT scan* box, opposite.)

PERFORMING A CT SCAN

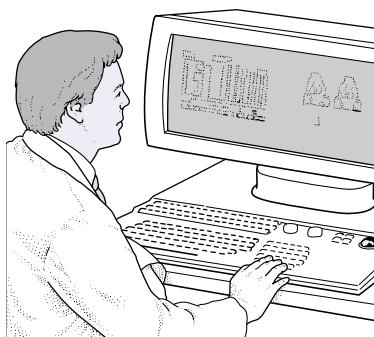

CT scanning combines the use of a computer and X-rays emitted by a rotating machine to produce cross-sectional images. Before the scan is carried out, a contrast medium may be injected to make blood vessels, organs, or abnormalities show up more clearly; for scans of the intestines, a drink of contrast medium may be given to highlight loops of intestine.

2 The scanner rotates around the patient. As it does so, it sends a great number of X-ray beams, each of low dosage and lasting only a fraction of a second, through the patient's body at different angles.

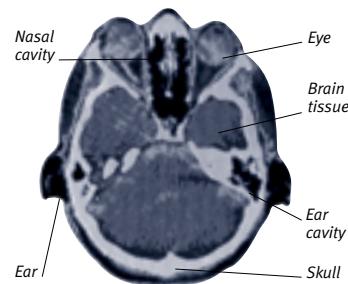

The machine can be tilted in any direction to allow precise areas to be X-rayed

1 The patient lies on a table that can be moved up or down to allow easy transfer and accurate positioning within the machine. The table then slides the patient into the centre of the machine.

A central sliding cradle in the table moves the patient, at a controllable rate, into the machine

3 Detectors in the scanner record the amount of X-rays absorbed by different tissues. This information is sent to a computer, which converts it into an image (such as the section through the head, above) for a radiologist to interpret.

cuff

A body structure that consists of muscle and tendon fibres and encircles a *joint*. (See also *rotator cuff*.)

culture

A growth of bacteria or other microorganisms, cells, or tissues cultivated artificially in the laboratory.

Microorganisms are collected from the site of an infection and cultured in order to produce adequate amounts so that tests to identify them can be performed. Cells from a fetus may be cultured to diagnose disorders prenatally. Healthy cells may be cultured for the study of chromosomes (see *chromosome analysis*). Some types of tissue, such as skin, may be cultured to produce larger amounts that can then be used for grafting. Other tissues are cultivated to provide a medium in which viruses can be grown and identified in the laboratory; viruses will only multiply within living cells.

cupping

An ancient procedure in which the practitioner draws blood to the skin surface by applying a heated vessel to the skin. It produces an inflammatory response thought to relieve *bronchitis*, *asthma*, and musculoskeletal pains.

curare

An extract from the bark and juices of various trees that has been used for centuries by South American Indians as an arrow poison. Curare kills by producing muscle *paralysis*. Synthetic compounds that are related to curare are sometimes used to produce paralysis during surgery.

cure

The process of restoration to normal health after an illness. The word "cure" usually means the disappearance of a disease rather than simply a halt in its progress. A treatment that ends an illness may also be called a cure.

curettage

The use of a surgical instrument called a *curette* to scrape abnormal tissue, or samples for analysis, from the lining of a body cavity or from the skin.

curettage, dental

The scraping of a cavity or other dental surface with a *curette* (a narrow, spoon-shaped instrument). Dental curettage is one method used to remove the lining of periodontal pockets and diseased tissue from root surfaces in *periodontitis*. This enables the healthy underlying tissue to reattach itself to the root surface.

curette

A spoon-shaped surgical instrument used for scraping away material or tissue from an organ, cavity, or surface.

Curling's ulcer

A type of *stress ulcer* that occurs specifically in people who have suffered extensive skin burns.

Cushing's syndrome

A hormonal disorder caused by an abnormally high level of *corticosteroid hormones* in the blood. Cushing's syndrome is characterized by a reddened, moon-shaped face, wasting of the limbs, thickening of the trunk, and a humped upper back. Other symptoms include *acne*; stretch marks on the skin; bruising; *osteoporosis* (loss of bone density); susceptibility to infection and *peptic ulcers*; and, in women, increased hairiness. Mental changes frequently also occur, causing *depression*, *insomnia*, *paranoia*, or, *euphoria*. *Oedema*, *hypertension*, and *diabetes mellitus* may develop. In children, growth may be suppressed.

The excess of hormones is most commonly due to prolonged treatment with *corticosteroid drugs*. Such cases of Cushing's syndrome are usually mild. In other cases, high hormone levels are due to overactivity of the *adrenal glands* because of an *adrenal tumour*, or due to a *pituitary tumour* affecting production of *ACTH* (adrenocorticotrophic hormone), which in turn stimulates the adrenal glands.

Cushing's syndrome due to corticosteroid drugs usually disappears when the dose of the drug is gradually reduced. In cases of Cushing's syndrome that are caused by an adrenal gland tumour, the tumour will be removed surgically. If the cause of the disease is a pituitary tumour, it may be removed surgically or shrunk by irradiation and drug treatment. In both of these cases, surgery is followed by *hormone replacement therapy*.

cushion

Any soft body structure resembling a pad or cushion, such as a *bursa*.

cusp

A tapering point, such as on a tooth. The term also refers to the flaps of the *heart valves*.

cusp, dental

One of the protrusions found on the grinding surface of a *tooth*.

cutaneous

Relating to the skin.

cutaneous anthrax

See *anthrax*.

cutaneous horn

See *horn, cutaneous*.

cutdown

Creation of a small skin incision in order to gain access to a *vein*, to take blood or to give intravenous fluid. This procedure is sometimes needed when a vein cannot be identified through the skin, in conditions such as *shock*.

cuticle

The outermost layer of skin. The term commonly refers to the thin flap of skin at the base of a nail, and also to the outer layer of a hair shaft.

CVA

The abbreviation for *cerebrovascular accident*.

CVP

The abbreviation for *central venous pressure* (the pressure within the right atrium of the heart).

CVS

The abbreviation for *chorionic villus sampling*, and for *cardiovascular system*.

cyanide

Any of a group of salts of hydrocyanic acid. Most of these substances are extremely poisonous, and their inhalation or ingestion can rapidly lead to breathlessness and *paralysis*, followed by unconsciousness and death. Certain cyanides are eye irritants and are used in tear gases.

cyanocobalamin

An alternative name for *vitamin B₁₂*.

cyanosis

A bluish coloration of the skin or mucous membranes caused by an abnormally high level of deoxygenated *haemoglobin* in the blood. Cyanosis confined to the hands and feet is not serious; it is usually due to slow blood flow, often as a result of exposure to cold. A blue tinge to the lips and tongue, however, could be caused by a serious heart or lung disorder such as chronic obstructive *pulmonary disease* or *heart failure*.

cyclopentthiazide

A *thiazide diuretic* drug used to reduce *oedema* associated with *heart failure*, kidney disorders, *cirrhosis* of the liver, and to treat *hypertension*. Side effects of this drug include lethargy, loss of appetite, leg cramps, dizziness, rash, and impotence.

cyclophosphamide

An *anticancer drug* used in the treatment of *Hodgkin's disease* and *leukaemia*. It is also used as an *immunosuppressant* and to treat connective tissue diseases.

cycloplegia

Paralysis of the ciliary muscle of the eye, which makes *accommodation* difficult. In some circumstances, cycloplegia may be induced by cycloplegic drugs to facilitate eye examinations.

cyclosporin

An alternative spelling for *ciclosporin*.

cyclothymia

A personality characteristic typified by marked changes of mood from cheerful, energetic, and sociable to gloomy, listless, and withdrawn. Mood swings may last for days or months and may follow a regular pattern.

Cymalon

A brand name for an over-the-counter preparation containing sodium bicarbonate, sodium carbonate, citric acid, and sodium citrate. This preparation is commonly used to relieve the symptoms of *cystitis*.

ciproterone acetate

A drug that blocks the action of *androgen hormones*. It is used to treat prostate cancer (see *prostate, cancer of*) and occasionally to reduce male sex drive. Side effects include weight gain and an increased risk of blood clots.

cyst

An abnormal but usually harmless lump or swelling filled with fluid or semi-solid material. Cysts occur in body organs or tissues. There are various types, including *sebaceous cysts*, *dermoid cysts*, *ovarian cysts*, *breast cysts*, *Baker's cysts*, and cysts that form around parasites in diseases such as hydatid disease or amoebiasis. Cysts may need to be removed surgically if they disrupt the function of body tissues.

cyst-/cysto-

Relating to the *bladder*, as in *cystitis* (inflammation of the bladder).

cystectomy

The surgical removal of part or all of the *bladder*. The procedure is used for treating bladder cancer (see *bladder tumours*). Radical cystectomy (in which

all of the bladder is removed) is followed by the construction of an alternative channel for *urine*, usually ending in a *stoma* in the lower abdomen (see *urinary diversion*). In men, the *prostate gland* and *seminal vesicles* are also removed, usually resulting in *impotence*. In women, the *uterus*, *ovaries*, and *fallopian tubes* are removed. After radical cystectomy, the patient has to wear an external pouch to collect urine.

cysticercosis

An infection, which is rare in developed countries, caused by the larvae of the pork *tapeworm*. The disease is characterized by the presence of *cysts* in the muscles and brain, which are formed by the worms during their larval stage.

cystic fibrosis

A serious and potentially fatal *genetic disorder*, characterized by a tendency to develop chronic lung infections combined with an inability to absorb fats and other nutrients from food. The main characteristic feature of cystic fibrosis (CF) is the secretion of sticky, viscous mucus in the nose, throat, airways, and intestines.

CAUSES

CF is caused by an inherited defect in a *gene*. The defect is recessive, which means that one faulty gene must be inherited from each parent before any abnormality appears. People with only one defective gene have no symptoms but are "carriers" and can pass the gene on to their children.

The defective gene causes a biochemical abnormality in which the faulty movement of ions across cell membranes affects mucus formation. As a result, the mucus-forming glands in several organs do not function properly. Most seriously, the glands in the lining of the bronchial tubes produce thick mucus, which predisposes the person to chronic lung infections. Another serious malfunction is poor or absent secretion of pancreatic enzymes, which are involved in the breakdown and absorption of fats in the intestine. The sweat glands are also affected and excrete excessive amounts of salt.

SYMPTOMS AND COMPLICATIONS

The course and severity of CF vary. Typically, a child passes unformed, pale, oily, foul-smelling *faeces* and may fail to thrive. Often, growth is stunted and the child has recurrent respiratory infections. Without prompt treatment, *pneumonia*, *bronchitis*, and *bronchiectasis* may develop, causing lung damage. Most males and some females are infertile. Excessive salt loss from sweating may lead to *heat stroke* and collapse.

DIAGNOSIS AND TREATMENT

Early diagnosis, confirmed by simple sweat and blood tests, improves the outlook for children with CF. Prompt treatment with intensive *physiotherapy* and *antibiotics* helps to reduce the severity and frequency of lung infections. In addition, lung function may be improved by treatment with *dornase alfa*, a genetically engineered version of a human enzyme, which is administered by *nebulizer*. *Pancreatin* and a diet rich in proteins and calories are given to bring about weight gain and encourage more normal faeces. Supervision of the treatment is best carried out from a special centre that is staffed by paediatricians, nurses, and physiotherapists who have particular knowledge of the disease.

OUTLOOK

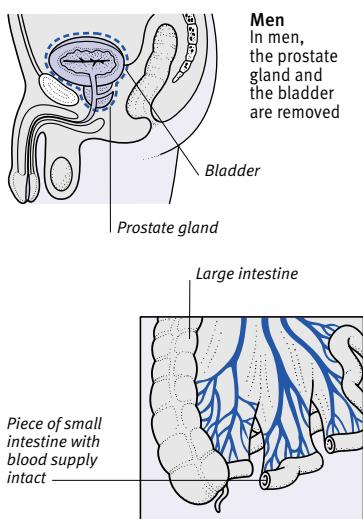

The highly specialized treatment now available for people with CF maximizes their chances of a reasonable quality of life. About 9 in 10 children survive into their teens; many live well into their 40s. Progressive respiratory failure is the usual cause of death, but in some cases a heart-lung transplant may be considered.

cystinosis

A rare *genetic disorder* in which the *amino acid* cystine accumulates in cells throughout the body.

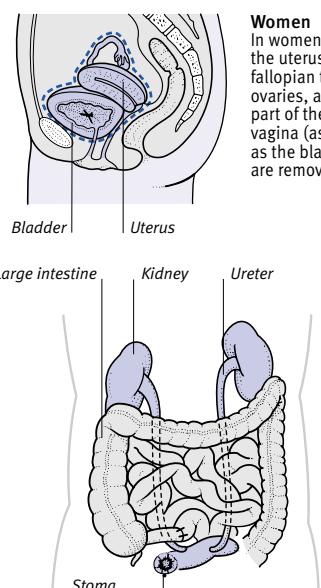

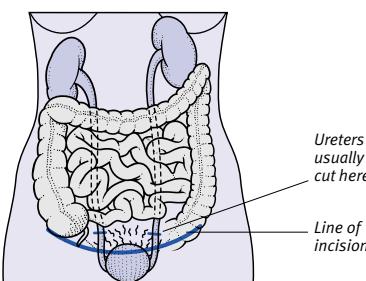

HOW CYSTECTOMY IS DONE

Radical cystectomy is a major procedure performed under general anaesthesia. An incision is made in abdomen, and the ureters are cut and tied. The bladder and other lower abdominal organs are removed. The stoma is then formed from part of the small intestine. After the operation, the patient is given intravenous infusions of fluids, salt, and glucose until the intestines are functioning normally again.

Formation of the stoma

A short section of small intestine, with its blood vessels, is detached from the remainder of the intestines. The two ureters are joined to this loop of intestine. One end of the loop is then sealed, and the other inserted through the abdominal wall to form the stoma.

Urine expulsion

Urine produced by the kidneys is channelled via the ureters and intestinal loop to the stoma, where it leaves the body.

The juvenile form of cystinosis becomes apparent in the first year of life, at which time cystine deposits damage the eyes, resulting in impaired vision. The deposits also lead to potentially fatal *kidney failure*.

In the adult form, which is less severe, the main symptoms are eye problems, including extreme sensitivity to light (see *photophobia*). The kidneys are much less likely to be affected in adults than in children.

cystinuria

An inherited disorder (see *metabolism, inborn errors of*) in which the kidneys are unable effectively to process certain *amino acids* (the chemical compounds that make up proteins). Cystinuria is inherited in an autosomal recessive manner (see *genetic disorders*) and occurs in around one in 1,000 births.

Under normal circumstances, blood is filtered as it passes through the *kidneys*; a wide range of substances is removed, then useful compounds, such as amino acids, are reabsorbed. In cystinuria, this process does not work effectively. As a result, high levels of four amino acids, particularly cystine, occur in the urine. This excess cystine can result in the development of a rare form of kidney stones (see *renal calculi*) in both adults and children.

Cystinuria is usually detected in people who have symptoms of kidney stones, or in those who have passed stones that, on analysis, are found to contain cystine. The diagnosis can be confirmed by urine tests that measure the levels of amino acids. Treatment involves drinking large amounts of fluids regularly in order to dilute the urine and reduce the concentration of cystine. If the levels of cysteine remain high, the drug *penicillamine* may be required to help prevent the formation of new stones.

cystitis

Inflammation of the lining of the *bladder* that is usually the result of a bacterial infection.

CAUSES

Cystitis is more common in women than men because the *urethra* is short, so it is relatively easier for the bacteria that cause the disorder to pass into the bladder. A *bladder calculus* (stone), a *bladder tumour*, or a *urethral stricture* can obstruct urine flow and increase the risk of infection. In men, cystitis is

rare; it usually occurs when an obstruction, such as an enlarged prostate gland (see *prostate, enlarged*), compresses the urethra. Cystitis in children is often associated with a structural abnormality of the *ureters*, which allows *reflux* (backward flow) of urine towards the kidneys.

The use of catheters (see *catheterization, urinary*) also carries the risk of infection. People with *diabetes mellitus* are especially susceptible to urinary tract infections because they have higher-than-normal levels of glucose in their urine which encourages the growth of bacteria.

SYMPTOMS

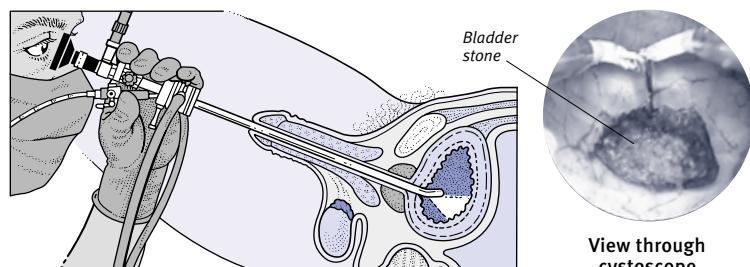

The main symptoms are a frequent urge to pass *urine* and a burning pain on urinating. The urine may be foul-smelling or may contain blood. There may also be fever and chills, and lower abdominal discomfort. However, in children there are frequently no symptoms relating to the urinary tract, and they may have only generalized symptoms, such as fever and vomiting.

TREATMENT

Symptoms of mild cystitis may be relieved by drinking 0.5 litre of fluid every four hours, which helps to flush out the bladder. Any bacterial infection is treated with *antibiotic drugs* to prevent bacteria from spreading upwards to the kidneys and causing *pyelonephritis* (infection of the kidneys).

PROCEDURE FOR CYSTOSCOPY

Cystoscopy involves passing a viewing instrument (cystoscope) up the urethra and into the bladder under local or general anaesthesia. There is no risk of damage to the genital organs or urinary tract, although the patient may feel some discomfort when passing urine for the first few days afterwards.

cystocele

A swelling in the front of the *vagina* that forms where the *bladder* pushes against weakened tissues in the vaginal wall. A cystocele may be associated with a prolapsed uterus (see *uterus, prolapse of*). Occasionally, a cystocele may pull the urethra out of position, causing *stress incontinence* or incomplete emptying of the bladder, which may lead to infection of the retained urine (see *cystitis*).

Pelvic floor exercises may help to relieve symptoms. Surgery may be performed to lift and tighten the tissues at the front of the vagina.

cystometry

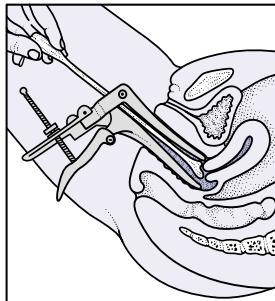

A procedure that is used to assess the function of the *bladder* and also to investigate urinary *incontinence* or poor bladder emptying; it is also used to detect abnormalities of the *nerves* supplying the bladder. In this procedure, a catheter is inserted into the bladder, then the internal pressure is measured as the bladder is filled and then emptied. (See *urodynamics*.)

cystoscopy

The examination of the *urethra* and *bladder* using a cystoscope inserted up the urethra. A cystoscope is a viewing instrument, which can be rigid or flexible, sometimes with a camera at the tip (see *endoscopy*).

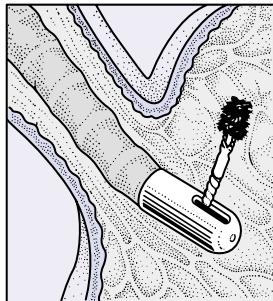

CYTOLGY METHODS

Cells for examination are obtained in several ways, depending on the part of the body being investigated. Cells from body surfaces may be collected by scraping or swabs; those from internal structures may be obtained by biopsy or aspiration.

Cells from the cervix

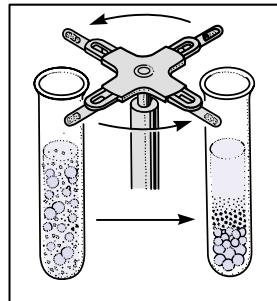

The vagina is held open with a speculum. Cells are scraped from the surface of the cervix with a spatula (above) or a special brush.

Cells from the respiratory tract or oesophagus

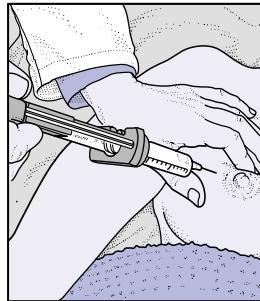

These cells are usually obtained by using an *endoscope* fitted with a small brush or suction tube.

Improvements in collection techniques have made it possible to take cells from previously inaccessible sites. If a cytologist can make a diagnosis from cells removed in these ways, the patient may be spared an exploratory operation.

Cells from body fluids

These cells are obtained either by passing the fluid through a filter or centrifugation (spinning the fluid rapidly to separate out the cells).

Aspiration biopsy

In this procedure, a very fine needle is passed into a suspected tumour and a biopsy sample of cells is withdrawn.

Cystoscopy is used to inspect the bladder for *calculi* (stones), *bladder tumours*, sites of bleeding and infection, and, in children, to investigate *vesicoureteric reflux*. Cystoscopy is also used to take urine samples from the *ureters* so that doctors can look for infection or tumour cells. *Radiopaque* dye may be injected into the ureters by means of the cystoscope during the X-ray procedure of retrograde pyelography (see *urography*).

Certain treatments can also be performed through the cystoscope. These include the removal of bladder tumours or calculi and the insertion of *stents* (narrow tubes) into a ureter to relieve an obstruction.

cystostomy

The surgical creation of a hole in the *bladder*. Cystostomy is usually carried out to drain *urine* in cases where the introduction of a *catheter* (flexible tube) would be either inadvisable or simply impossible.

cystourethrography, micturating

An X-ray procedure that is used for studying the *bladder* during the passing of urine. Micturating cystourethrography is most commonly used in young children to detect abnormal *reflux* of urine (backflow of urine up the ureters) as the bladder empties. (See *urodynamics*.)

-cyte

A suffix denoting a *cell*. For example, a leukocyte is a white blood cell; an *erythrocyte* is a red blood cell.

cyto-

A prefix that means "related to a *cell*", as in *cytology*, the study of cells.

cytokine

A protein released by cells in response to the presence of harmful organisms such as *viruses*. Cytokines (such as *interferons*) bind to other cells, activating the immune response (see *immune system*).

cytology

The study of cells. The main use of cytology is to detect abnormal cells; it is widely used to screen for cancer (as in the *cervical smear test*) or to confirm a diagnosis of cancer, and is increasingly used in antenatal screening to detect certain fetal abnormalities. Examination of cells from body fluids helps doctors to determine the cause of conditions such as *pleural effusion* (fluid in the pleural cavity around the lungs) and *ascites* (abnormal accumulation of fluid in the abdominal cavity); for example the tests can identify whether cancer or infection is present.

Cells are collected by procedures such as scraping or fine-needle aspiration *biopsy*. For antenatal tests, cells from the fluid that surrounds and cush-

ions the fetus in the uterus are obtained by means of *amniocentesis* or *chorionic villus sampling*.

cytomegalovirus

One of the most common *herpes* viruses. Cytomegalovirus (CMV) infection causes infected cells to appear enlarged. The virus may produce an illness that is similar to glandular fever (see *mononucleosis, infectious*), but usually there are no symptoms. Individuals with impaired immunity are more seriously infected. CMV in a pregnant woman can cause birth defects and brain damage in the baby.

cytopathology

The microscopic study of *cells* in health and disease. (See also *cytology*.)

cytoplasm

The jellylike substance that contains the internal structures of a *cell*. Cytoplasm is 90 per cent water, but it also contains enzymes, amino acids, and other chemicals that are required for cell function.

cytotoxic drugs

A group of *anticancer drugs* that kill or damage abnormal *cells*. Cytotoxic drugs may also damage or kill healthy cells, especially those that multiply rapidly, such as the cells in hair follicles or those in the intestinal lining.

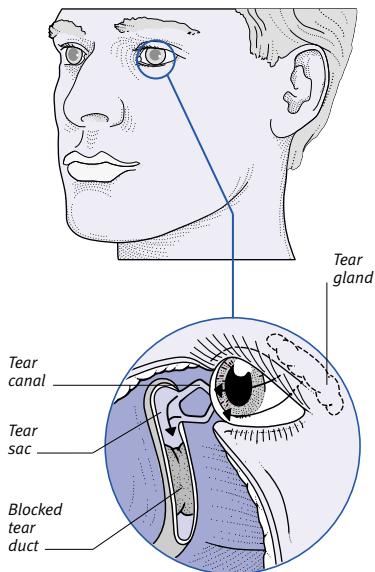

D

dacryocystitis

Inflammation of the tear sac, usually resulting from the blockage of the tear duct. The condition sometimes occurs in infants if the tear duct has not developed normally. In adults, it may follow inflammation in the nose or an injury. The cause is often unknown.

Symptoms include pain, redness, and swelling between the inner corner of the eyelids and the nose. Infection may occur and cause a discharge.

The obstruction may be cleared by flushing the tear duct with saline. *Antibiotic* eye-drops or ointment are given for infection. In infants, massaging the tear sac may clear a blockage. Surgery to drain the tear sac (dacryocystorhinostomy) is occasionally necessary.

Mechanism of dacryocystitis

Inflammation of the tear sac may occur when the duct through which tears drain away from the tear sac becomes blocked.

dactylitis

Inflammation of the fingers or toes. Dactylitis sometimes occurs in people who have the inherited blood disorder

sickle cell anaemia. Less commonly, the condition can be associated with *tuberculosis* or *syphilis* infection.

Daktacort

A brand name for a cream containing a combination of synthetic *hydrocortisone* (a corticosteroid drug) and *miconazole* (an antifungal drug). Daktacort is used to treat inflamed skin conditions, such as *eczema* and *dermatitis*, where a fungal infection is also suspected.

Daktarin

A brand name for *miconazole*, an antifungal drug used in the treatment of *athlete's foot* and other common fungal skin infections. Daktarin gel is used to treat oral thrush (see *candidiasis*).

Dalacin

A brand name for *clindamycin*, an antibiotic that may be applied to the skin to treat severe *acne* or as a vaginal cream in the treatment of bacterial vaginal infections. Due to its toxic side effects, Dalacin is given as tablets or by injection only for serious infections, when other antibiotics cannot be used.

danazol

A drug used for treating *endometriosis* (a condition in which fragments of the uterine lining occur elsewhere in the pelvic cavity), noncancerous breast disease, and *menorrhagia* (heavy periods).

Danazol suppresses the release of *gonadotrophin hormones* (pituitary hormones that stimulate activity in the ovaries), which in turn reduces the production of the hormone oestrogen. This action usually prevents ovulation and causes irregularity or absence of menstrual periods.

Possible adverse effects include nausea, rash, and weight gain. Pregnancy should be avoided while taking danazol.

D and C

An abbreviation for dilatation and curettage, a gynaecological procedure in which the *cervix* (neck of the *uterus*) is dilated, then the *endometrium* (lining of the uterus) is scraped away and a sample is removed for analysis. D and C was once used to diagnose disorders of the uterus, but has largely been replaced by hysteroscopy, an endoscopic technique for viewing the uterus lining or taking a *biopsy* (tissue sample) from the lining. Endometrial biopsies can also be taken using a small vacuum suction device.

dander

Minute scales that are shed from an animal's skin, hair, or feathers. Dander from humans and pets floats in the air or settles on surfaces, making up a large proportion of household dust. Some people are allergic to animal dander and develop the symptoms of *allergic rhinitis* (hay fever) or of *asthma* if they inhale the scales.

dandruff

A harmless condition in which dead skin is shed from the scalp, often producing white flakes. The usual cause is a rash called *seborrhoeic dermatitis*. Frequent use of an antidandruff shampoo usually controls dandruff.

dantron

See *dantron*.

dantrolene

A *muscle-relaxant drug* used to relieve muscle spasm caused by *spinal injury*, *stroke*, or neurological disorders such as *cerebral palsy*. The drug does not cure the underlying disorder, but it often improves mobility.

dantron

A stimulant *laxative drug* used to treat constipation in the terminally ill. Constipation is common in these patients as a side effect of treatment with opioid *analgesic drugs* (painkillers). Dantron may colour the urine red.

dapsone

An *antibacterial drug* used to treat *Hansen's disease* (leprosy) and *dermatitis herpetiformis*. Combined with *pyrimethamine*, dapsone is also used to prevent *malaria*. The drug may cause nausea, vomiting, and, rarely, damage to the liver, red blood cells, and nerves.

Darier's disease

A rare, progressive skin disorder, also known as *keratosis follicularis*, that is inherited as an autosomal dominant genetic trait (see *genetic disorders*). The disease is characterized by the development of a number of greasy, pigmented *papules* (raised spots) on the scalp, the face and neck, behind the ears, and along the middle of the back.

daydreaming

The conjuring up of pleasant or exciting images or situations in one's mind during waking hours.

day surgery

Surgical treatment carried out in a hospital or clinic without an overnight stay. The proportion of all operations performed on a day-surgery basis has risen substantially in recent years. Modern anaesthetics and surgical techniques, in particular *minimally invasive surgery*, allow a swifter recovery than in the past, so that patients can often return home within a few hours of surgery.

DDAVP

A brand name for *desmopressin*, which is a synthetic form of *ADH* (antidiuretic hormone).

DDT

The abbreviation for the insecticide dichlorodiphenyltrichloroethane. DDT was once widely used in the fight against diseases transmitted by insects, particularly in hot climates. However, some insects have developed resistance to the toxic effects of DDT, and this resistance can be passed on to their offspring. (See also *pesticides*.)

deafness

Complete or partial loss of hearing in one or both ears. There are two types of deafness: conductive deafness, which is caused by faulty propagation of sound from the outer to the inner ear; and sensorineural deafness, in which there is a failure in the transmission of sounds to the brain.

CAUSES

The most common cause of conductive deafness in adults is *earwax*. *Otosclerosis*, a condition in which the stapes (a small bone in the middle ear) loses its normal mobility, is a less common cause. In children, conductive deafness is usually due to *otitis media* (middle-ear infection) or *glue ear* (accumulation of sticky fluid in the middle ear). In rare cases, deafness results from a ruptured eardrum (see *eardrum, perforated*).

Sensorineural deafness may be present from birth. This type of deafness may result from a *birth injury* or damage resulting from maternal infection with *rubella* in early pregnancy. Damage to the inner ear may also occur soon after birth as the result of severe neonatal *jaundice*.

In later life, sensorineural deafness can be due to damage to the cochlea and/or labyrinth of the inner ear. It may result from prolonged exposure to loud noise, or be caused by *Ménière's disease*, certain drugs, or some viral

infections. The cochlea and labyrinth also degenerate naturally with old age, resulting in *presbyacusis*. Sensorineural deafness due to damage to the acoustic nerve may be the result of an *acoustic neuroma* (a noncancerous tumour that develops on the nerve).

SYMPOTMS AND SIGNS

A baby who is congenitally deaf fails to respond to sounds, and, although crying is often normal, he or she does not babble or make the usual baby noises that lead to speech. In an adult who has started to become deaf, sounds heard are not only quieter than before, but may be distorted and less clear.

Deafness may be accompanied by *tinnitus* (noises in the ear) and *vertigo* (dizziness and loss of balance). Sometimes deafness can lead to confusion and sometimes to *depression*.

DIAGNOSIS

Examination of the ear with an *otoscope* (a viewing instrument with a light attached) can show if the outer-ear canal is blocked by wax, or if the eardrum is inflamed, perforated, or has fluid behind it.

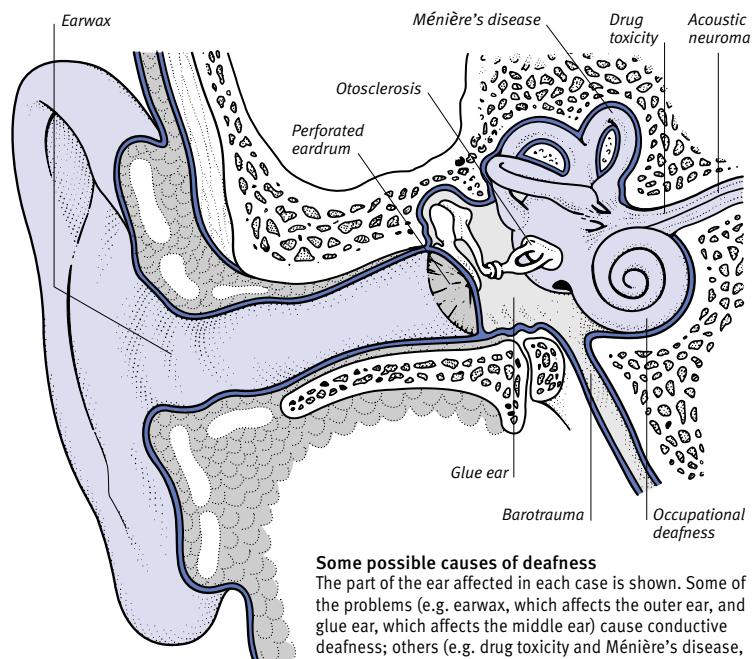

After a physical examination, *hearing tests* may be performed; these tests can determine whether deafness is conductive or sensorineural.

TREATMENT

The treatment depends on the exact cause of the deafness. Removal of excess earwax remedies conductive deafness in many cases. Otosclerosis is generally treated by an operation known as *stapedectomy*, in which the stapes is replaced with an artificial substitute. Glue ear may also be treated by surgery (see *myringotomy*) and by the insertion of a *grommet* (a small tube that allows fluid to drain away from the middle ear).

Many children who are born deaf can learn to communicate effectively, often by using sign language. *Cochlear implants* (electrodes implanted in the inner ear that can receive sound signals) may help profoundly deaf adults and children, but they are not suitable for everyone. People who have sensorineural deafness usually need *hearing aids* to increase the volume of sound reaching the inner ear. *Lip-reading* is invaluable for people who have difficulty hearing, whatever the type and severity of their deafness. Other aids, such as an amplifier for the earpiece of a telephone, are available to help deaf people perform everyday tasks. (See also *ear; hearing*.)

DEAFNESS

Some possible causes of deafness

The part of the ear affected in each case is shown. Some of the problems (e.g. earwax, which affects the outer ear, and glue ear, which affects the middle ear) cause conductive deafness; others (e.g. drug toxicity and Ménière's disease, which affect the inner ear) cause sensorineural deafness.

death

Permanent cessation of all vital functions. The classic indicators of death are the permanent cessation of heart and lung function, and, in almost all cases, these remain the criteria by which death is certified. *Brain death* is the irreversible cessation of all functions of the entire brain, including the *brain-stem* (the part of the brain that controls involuntary actions such as breathing).

The diagnosis of death under normal circumstances, when the individual is not on a *ventilator*, is based on the absence of breathing, absence of heart-beat, and on the pupils being fixed wide open and unresponsive to light.

When an individual has been placed on a ventilator machine, the criteria for diagnosing brain death are based on clear evidence of irreversible damage to the brain; persistent deep *coma*; no attempts at breathing when the patient is taken off the ventilator; and complete lack of brainstem function. (See also *death, sudden; mortality*.)

death rate

See *mortality*.

death rattle

A noisy form of breathing resulting from the retention of *sputum* (mucous material) in the airways of a dying person who is no longer able to swallow it or cough it up. Although unpleasant for the person's companions, it does not appear to cause distress to him or her.

death, sudden

Unexpected death in a person who previously seemed to be healthy. The most common cause of sudden death in adults is *cardiac arrest* (cessation of the heartbeat). *Cardiomyopathy* (disease of the heart muscle) may cause sudden death at any age, and its presence may have been unsuspected. Sudden death may also occur as a result of *stroke* or in people with unsuspected *myocarditis* (inflammation of the heart muscle) or *pneumonia*. Less common causes of a sudden death include *anaphylactic shock* (a severe allergic reaction), a severe attack of *asthma*, and *suicide*.

In infants, death without warning is termed *sudden infant death syndrome* (SIDS), or cot death.

The sudden death of a person of any age must be reported to the coroner, who decides whether there should be an *autopsy* (postmortem examination).

death, sudden infant

When a baby is put to bed and later found dead for no identifiable reason. See *sudden infant death syndrome (SIDS)*.

debility

Generalized weakness and lack of energy. It may be due to a physical disorder (such as *anaemia*) or to a psychological disorder (such as *depression*).

debridement

Surgical removal of foreign material and/or dead, damaged, or infected tissue from a wound or burn in order to expose healthy tissue. Such treatment promotes the healthy healing of badly damaged skin, muscle, and other tissues in the body.

decalcification, dental

The dissolving of minerals in a tooth. Dental decalcification is the first stage of tooth decay. It is caused by bacteria in *plaque* acting on the refined carbohydrates (mainly sugars) in food to produce acid, which, after prolonged or repeated exposure, causes changes to occur on the surface of the tooth. If the decalcification penetrates the enamel layer, it spreads into the dentine and permits bacteria to enter the inner pulp. (See also *caries, dental*.)

decay, dental

See *caries, dental*.

decerebrate

The state of being without a functioning *cerebrum*, the main controlling part of the brain. This situation occurs if the *brainstem* is severed, which effectively isolates the cerebrum.

decidua

The lining of the *uterus* (womb) during the course of pregnancy. The surface layers of the decidua are shed from the body during *childbirth*.

deciduous teeth

See *primary teeth*.

decompensation

The loss of an organ's ability to meet the requirements of the body. The term "decompensation" is usually used to describe lessening function in an organ that has been progressively damaged by disease. For example, if the heart decompensates, it becomes unable to maintain an adequate circulation.

The word can also be used with regard to mental illness, as in *depression*, when an individual may lose his or her usual compensation mechanisms (strategies by which a person makes up for real or imagined deficiencies) and suddenly deteriorate.

decomposition

The gradual breakdown of organic matter (such as food or dead tissue) into other chemical compounds by way of bacterial and/or fungal action, heat, or other processes.

decompression sickness

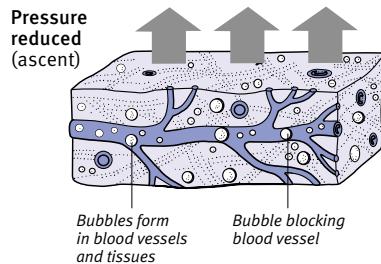

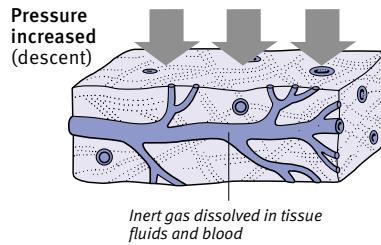

A hazard of divers and of others who work in or breathe compressed air or other mixtures of gases. Decompression sickness is also called "the bends". It results from gas bubbles forming in the tissues and impeding the flow of blood.

CAUSE

At depth, divers accumulate inert gas in their tissues from the high-pressure gas mixture they breathe (see *scuba-diving medicine*). Problems can usually be avoided by allowing the excess gas in their tissues to escape slowly into the lungs during controlled slow ascent or release of pressure. If the ascent is too rapid and the pressure falls too quickly, gas can no longer be held within the tissues and is released as bubbles.

SYMPTOMS

Bubbles of gas may block blood vessels, causing symptoms such as skin itching

**How decompression sickness occurs**

On ascent, pressure is reduced rapidly and the gas may form bubbles that may, in turn, cause symptoms. Divers avoid this by ascending slowly.

and mottling and severe pain in and around the larger joints. Symptoms of nervous system impairment (such as leg weakness or visual disturbances) are particularly serious, as is a painful, tight feeling across the chest.

TREATMENT

Divers with decompression sickness are immediately placed inside a recompression chamber. Pressure within the chamber is raised, causing the bubbles within the tissues to redissolve. Subsequently, the pressure in the chamber is slowly reduced, allowing the excess gas to escape safely via the lungs.

OUTLOOK

If treated promptly by recompression, most divers with the “bends” make a full recovery. In serious, untreated cases, however, there may be long-term complications such as partial paralysis. Repeated episodes may lead to degenerative disorders of the bones or joints.

decompression, spinal canal

Surgery to relieve pressure on the spinal cord or a nerve root emerging from it (see *microdiscectomy*). Pressure may have various causes, including a *disc prolapse* (“slipped” disc); a tumour or abscess of the spinal cord; or a tumour, abscess, or fracture of the ver-

tebrae. Any of these conditions can cause weakness or paralysis of the limbs and loss of bladder control.

To treat major disc prolapses and tumours, a *laminectomy* (removal of the bony arches of one or more vertebrae) to expose the affected part of the cord or nerve roots may be performed.

Recovery after treatment depends on the severity and duration of the pressure, the success of the surgery in relieving the pressure, and whether any damage is sustained by the nerves during the operation.

decongestant drugs

Drugs used to relieve *nasal congestion*, commonly in people who have upper *respiratory tract infections*. The drugs are thought to work by narrowing the blood vessels in the membranes lining the nose. This action reduces swelling, inflammation, and the amount of mucus that is produced by the nasal lining. Common decongestants include ephedrine, oxymetazoline, and phenylephrine. Small amounts of these drugs are found in many over-the-counter cold remedies.

There is little objective evidence that decongestants effectively relieve respiratory disorders. Taken by mouth, they may cause tremor and palpitations, and,

taken for longer than five days, they become ineffective; if they are stopped at this stage, symptoms may be worse than at the start of treatment. Therefore, they should not be used continuously for more than five days without medical advice. Decongestants may be unsuitable for people with certain medical conditions and must be avoided in people taking MAOIs.

decubitus

The position of reclining or lying down, as in a decubitus ulcer (see *bedsore*).

decubitus ulcer

See *bedsore*.

decussation

A point at which two or more structures in the body cross over each other to the opposite side. An example is the point at which nerve fibres intercross in the *central nervous system*.

deep vein thrombosis

See *thrombosis*, *deep vein*.

defaecation

The expulsion of waste material as *faeces* from the body through the anus.

defence mechanisms

Techniques used by the mind to lessen unpleasant or unwelcome emotions, impulses, experiences, or events, and to avoid external or internal conflict.

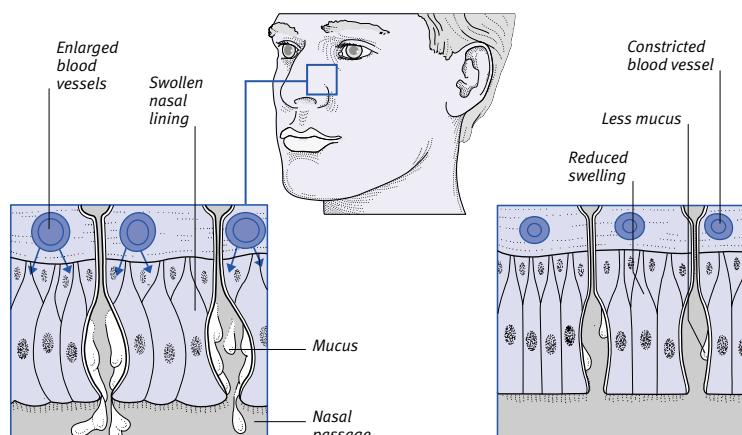

TYPES

The principal defence mechanism is repression, which is the suppression of unacceptable thoughts. Other types of defence mechanism include displacement, rationalization, projection, reaction formation, and isolation.

In displacement, dangerous thoughts or feelings are redirected at a harmless object; for example, someone who is angry at another person may kick the furniture instead of hitting that person. Rationalization involves reinterpreting thoughts or actions in a more acceptable way; for example, a person may criticize someone else but claim “It’s for your own good”. In projection, a person attributes his or her own faults to someone else, for example by thinking “that person hates me” when in fact he or she hates that person. In reaction formation, an unacceptable feeling is hidden by actions that suggest the opposite; for example, someone may disguise hatred for another person by showing great concern for that person.

THE ACTION OF DECONGESTANTS

Decongestants work by narrowing blood vessels in the membranes that line the nose. This action reduces swelling, inflammation, and the amount of mucus produced by the nasal lining.

Congested nasal lining

When blood vessels enlarge in response to infection or irritation, increased amounts of fluid pass into the lining, which swells and produces more mucus.

Effect of decongestants

Chemicals stimulate constriction of the blood vessels in the nasal lining, which reduces swelling, mucus production, and nasal congestion.

In the mechanism of isolation, unpleasant memories (for example, of being assaulted) are retained but the feelings that go with them are hidden, so that a person may recall such an event apparently without emotion.

d defibrillation

Administration of one or more brief electric shocks to the heart, usually via two metal plates, or paddles, placed on the chest over the heart. It is performed to return the heart's rhythm to normal in some types of *arrhythmia* (irregular or rapid heartbeat), such as *atrial fibrillation* or *ventricular fibrillation*.

Defibrillation can be carried out as an emergency procedure to treat ventricular fibrillation, which is a cause of *cardiac arrest* and most commonly occurs after a heart attack (see *myocardial infarction*). It can also be used as a planned treatment, in which case it is performed under a brief general *anaesthesia*. Breathing may be maintained by artificial means for the duration of the procedure.

deficiency anaemia

A type of anaemia. See *anaemia, iron-deficiency; pernicious anaemia*.

defluoridation

The removal of excess fluoride from drinking water, often using domestic water filters, to prevent *fluorosis* (mottling of tooth enamel) in consumers. (See also *fluoridation; fluoride*.)

defoliant poisoning

The toxic effects of plant poisons that cause leaves to drop off. Defoliants are poisonous if they are swallowed. Widely used defoliant poisons include sodium *chlorate*, potassium chlorate, phenoxy herbicides, and *paraquat*.

deformity

Any malformation or distortion of part of the body. Deformities may be congenital (present from birth), or they may be acquired as a result of injury, disorder, or disuse.

Most congenital deformities are relatively rare. Among the more common are club-foot (*talipes*) and *cleft lip and palate*. Injuries that can cause deformity include burns, torn muscles, and broken bones. Disorders that may cause deformity include certain nerve problems, some deficiencies, such as *rickets*, and *Paget's disease* of the bone. Disuse

of a part of the body can lead to deformity through stiffening and *contracture* of unused muscles or tendons.

Many deformities can be corrected by means of orthopaedic techniques, *plastic surgery*, or specific exercises.

degeneration

Physical and/or chemical changes in cells, tissues, or organs that reduce their efficiency. Degeneration is a feature of aging and may also be due to disease processes. Other known causes include injury, reduced blood supply, poisoning (by alcohol, for example), or a diet deficient in a specific vitamin. (See also *degenerative disorders*.)

degenerative disorders

A term covering a wide range of conditions in which there is progressive impairment in the structure and function of a body system, organ, or tissue. The number of specialized cells or structures in the organ affected is usually reduced, and cells are replaced by *connective tissue* or scar tissue. In many cases, the cause of the disease is poorly understood, but degenerative disorders are the subjects of intensive research.

Degenerative nervous system disorders include *Alzheimer's disease*, *motor neuron disease*, *Huntington's disease*, and *Parkinson's disease*. Degenerative disorders of the eye include Leber's *optic atrophy* and senile *macular degeneration*. Degenerative disorders of the joints include *osteoarthritis*. Muscle degeneration occurs in *muscular dystrophies*.

Some degree of hardening of the arteries seems to be a feature of normal aging, but in certain people degenerative changes in the muscle coat of the arteries are unusually severe, and calcium deposits may be seen on *X-rays* (as in Monckeberg's *sclerosis*, a type of *arteriosclerosis*).

In most cases, there is little that can be done to slow the progress of the disease, but it is often possible to relieve symptoms with drug treatment (for example, in Parkinson's disease).

Degos syndrome

A rare disorder that affects the linings of small and medium-sized arteries throughout the body, particularly in the skin, intestine, and nervous system, causing the vessels to become blocked. The cause is unknown.

The disease typically produces multiple small skin lesions that initially appear as red, raised spots and then

form depressed, white scars. Lesions may then form in arteries supplying other parts of the body, such as the intestine and the nervous system. This development may cause severe or even life-threatening problems, such as *stroke* from lesions that have formed in the brain and perforation of the intestine by lesions that penetrate through the intestine wall (see *peritonitis*).

dehiscence

The splitting open of a partly healed wound. The term is most commonly used to refer to the splitting open of a surgical incision that has been closed with sutures or clips.

dehydration

A condition in which a person's *water* content is at a dangerously low level. Water accounts for about 60 per cent of a man's body weight and about 50 per cent of a woman's. The total content of water (and mineral salts and other substances that are dissolved in the body's fluids) must be kept within fairly narrow limits to enable the healthy functioning of cells and tissues.

CAUSES

Dehydration occurs due to inadequate intake of fluids or excessive fluid loss. The latter may occur as a result of severe or prolonged vomiting or diarrhoea, or in people who have poorly controlled *diabetes mellitus*, *diabetes insipidus*, and certain types of *kidney failure*. Children are particularly susceptible to dehydration due to diarrhoea.

SYMPTOMS

The symptoms of severe dehydration are extreme thirst; dry lips and tongue; an increase in heart rate and breathing rate; dizziness; confusion; lethargy; and eventual *coma*. The skin looks dry and loses its elasticity. Any urine passed is small in quantity and dark-coloured. If there is also salt depletion (for example, due to heavy sweating), there may be headaches, cramps, and pallor.

TREATMENT

Drinking bottled mineral water helps to maintain the intake of salts. In cases of persistent vomiting and diarrhoea, *rehydration therapy* is required; salt and glucose rehydration mixtures are available from chemists.

In severe cases of dehydration, fluids may be given intravenously, and the water/salt balance is carefully monitored by means of blood tests and is adjusted as necessary.

déjà vu

French for “already seen”. A sense of having already experienced an event that is happening at the moment. Frequent occurrence may sometimes be a symptom of *temporal lobe epilepsy*.

Dejerine-Roussy syndrome

A rare neurological disorder, also called thalamic syndrome or central pain syndrome, that results from damage to the *thalamus*, the part of the brain that processes sensory information.

The main symptom is severe pain, possibly accompanied by other abnormalities such as loss of sensation or a “crawling” feeling in the skin.

delayed allergy

A type of *hypersensitivity* reaction that, unlike most forms of *allergy*, does not develop immediately on exposure to a particular *allergen* (a normally harmless substance that causes a reaction in people who have become sensitized to it).

Delayed allergies, also called type IV hypersensitivity reactions, may result from bacterial, viral, fungal, or protozoal infections or from *vaccination* with a live virus vaccine. Examples of such delayed allergic reactions include *contact dermatitis* and the body's response to infection in *tuberculosis*.

delayed dentition

The late *eruption of teeth*. The term “delayed dentition” may refer to the eruption of the first deciduous teeth (see *primary teeth*) after the end of the 13th month of life or to the eruption of the first *permanent teeth* after the seventh year of life. Delayed dentition is a feature of various conditions that result in generally restricted growth (see *short stature*), such as *hypothyroidism*.

delayed puberty

Onset of *puberty* (sexual maturation) after the age of 14. In most cases, the child is simply developing at a slower rate than normal, a tendency that often runs in families, but in some cases there may be an underlying disorder.

One possible underlying cause of delayed puberty is underproduction of sex hormones. Rarely, the condition results from a problem with the *hypothalamus* or the *pituitary gland*, which are responsible for secreting sex hormones; a genetic abnormality affecting sexual development, such as *Klinefelter's syndrome* in boys or *Turner's syndrome* in

girls; or a long-term illness, such as *Crohn's disease*. Certain lifestyle factors, such as excessive exercise or an inadequate diet, may also delay puberty.

Treatment depends on the underlying cause. If delayed puberty runs in the child's family, no action may be needed. In some cases, however, conditions causing delayed puberty may also lead to *infertility*, so the child may need further investigations in the future if he or she wishes to have children.

delayed shock

A common term for severe mental or physical reactions that may occur some time after a traumatic event (see *post-traumatic stress disorder*; *shock*; *stress*.)

Delhi belly

A popular name for *gastroenteritis* and infective diarrhoea caused by ingesting contaminated food or water.

delinquency

Criminal behaviour in a young person who is below the official age at which he or she can be prosecuted. The term is often extended to include behaviour such as *drug abuse*, playing truant, or running away from home. Delinquency that occurs in juveniles is probably a result of a combination of social, psychological, and biological factors. *Child guidance* or *family therapy* may be recommended. Persistent offenders may be sent to special schools, taken into care, or made wards of court.

delirium

A state of acute mental confusion, commonly brought on by physical illness. Symptoms vary according to personality, environment, and the severity of illness. They may include failure to understand events or remember what has been happening, physical restlessness, mood swings, hallucinations, and panic. Fever and disturbances of body chemistry are often contributory factors.

Children and older people are most susceptible to delirium, particularly as a result of infection, following surgery, or when there is a pre-existing brain disturbance (such as *dementia* in an elderly person). Drugs, poisons, and alcohol are common precipitants.

delirium tremens

A state of confusion accompanied by trembling and vivid hallucinations. It usually arises in chronic alcoholics after

withdrawal or abstinence from alcohol. Early symptoms include restlessness, agitation, trembling, and sleeplessness. The person may then develop a rapid heartbeat, fever, and dilation of the pupils. Sweating, confusion, hallucinations, and convulsions may also occur.

Treatment consists of rest, rehydration, and sedation. Vitamin injections, particularly of thiamine (see *vitamin B complex*), may be given, as some symptoms are linked to thiamine deficiency.

delivery

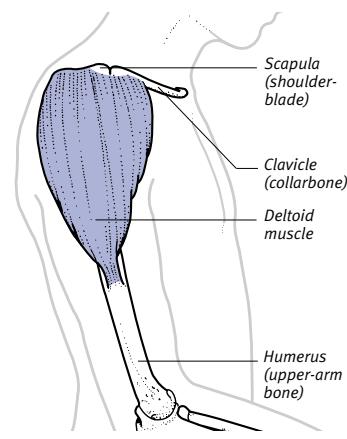

The expulsion or extraction of a baby from the mother's uterus. In most cases, the baby lies lengthwise in the uterus with its head facing downwards; it is delivered head first through the vaginal opening by a combination of uterine contractions and the mother's pushing (see *childbirth*). If the baby is lying in an abnormal position (see *breech delivery*; *malpresentation*), if uterine contractions are weak, or if the baby's head is large in relation to the size of the mother's pelvis, a *forceps delivery* or *vacuum extraction* may be required. If a vaginal delivery is impossible or dangerous to the mother or the baby, a *caesarean section* is necessary.

deltoid

The triangular muscle of the shoulder region that forms the rounded flesh of the outer part of the upper arm, and

LOCATION OF THE DELTOID

The deltoid muscle of the shoulder region forms the rounded, outer part of the upper arm and is attached to the scapula and clavicle.

passes up and over the shoulder joint. The wide end of the muscle is attached to the scapula (shoulderblade) and the clavicle (collarbone). The muscle fibres meet to form the apex of the triangle, which is attached to the humerus (the upper-arm bone) at a position about halfway down its length.

The central, strongest part of the deltoid muscle raises the arm sideways. The front and back parts of the muscle are used to twist the arm.

delusion

A fixed, irrational idea not shared by others and not responding to reasoned argument. The central idea in a paranoid delusion involves persecution or jealousy; for instance, a person may falsely believe that he or she is being poisoned or that a partner is persistently unfaithful (see *paranoia*).

Persistent delusions are an indication of serious mental illness, particularly *schizophrenia* and *manic-depressive illness*. (See also *hallucination*; *illusion*.)

demand pacemaker

A permanent artificial cardiac *pacemaker* (a device that sends electrical impulses to the *heart* to maintain a regular *heartbeat*) that discharges impulses only when the *heart rate* is abnormal. Such a pacemaker may be set to function only if the heart rate slows, or alternatively to override an abnormally rapid rate. (See also *fixed-rate pacemaker*.)

demasculinization

The loss, in a male, of normal male secondary sexual characteristics (see *sexual characteristics, secondary*). This includes reduced facial hair growth, along with testicular *atrophy* (wasting away of the testes) and shrinkage of the *prostate* gland. Demasculinization may occur in a range of conditions in which the testes are damaged or diseased. It may also result from disorders such as *cirrhosis* and *kidney failure*, which interfere with the processing in the body of the female sex hormone *oestrogen*. (See also *feminization*; *intersex*; *masculinization*; *sex determination*.)

dementia

A condition characterized by a generalized deterioration in brain function. Dementia most commonly affects the elderly; about 1 in 20 people over the age of 65, and up to 1 in 5 people over the age of 80, have the disorder.

CAUSES AND TYPES

Dementia is caused by damage to brain tissue. It is most commonly due to *Alzheimer's disease*, which causes changes in the structure and chemistry of the brain. The second most common form is *multi-infarct dementia*. In this condition, narrowed or blocked arteries in the brain deprive the tissue of blood and oxygen; repeated small *strokes* (episodes of tissue damage due to a lack of blood) occur, causing deterioration that develops gradually and in stages. Other, rare forms of dementia include Lewy body dementia (in which small, spherical structures called Lewy bodies appear in the brain tissue); *AIDS-related dementia*; and deterioration that occurs as a result of progressive brain disorders such as *Parkinson's disease*.

SYMPTOMS

The main symptoms of dementia are progressive memory loss, disorientation, and confusion. The affected person may not remember recent events, he or she may become easily lost in a familiar neighbourhood, and may be confused over days and dates. These symptoms may come on gradually and they may be hardly noticeable at first; in addition, the person may cover up any problems by *confabulation* (making up explanations in order to fill the gaps in his or her memory).

Sudden outbursts or embarrassing behaviour may be the first obvious signs of dementia. Unpleasant personality traits may be magnified; families of those affected may have to endure accusations, unreasonable demands, or even assault. *Paranoia*, *depression*, and *delusions* may occur as the disease progresses. Irritability or anxiety gives way to indifference towards all feelings and events. Personal care and hygiene are neglected, and speech becomes incoherent. Affected people may eventually need total nursing care.

TREATMENT

The management of the most common Alzheimer-type illness is based on the treatment of symptoms. The affected person should be kept clean and well-nourished, in comfortable surroundings and with good nursing care. *Sedative drugs* may be given to reduce restlessness or paranoid beliefs. These measures can help to ease distress for both the patient and their family.

For some people with mild to moderate Alzheimer's disease, drug treatment with *acetylcholinesterase inhibitors* such

as donepezil may halt the deterioration in mental function, or may even restore function to the level the person experienced six months previously. Regardless of treatment, however, Alzheimer's disease is progressive, and usually leads to death within 10 years of onset.

dementia praecox

An outdated term formerly used to describe severe *schizophrenia*, especially that affecting adolescents or young adults.

demineralization

Excessive loss of the *minerals* calcium and phosphate from bone. Generalized demineralization can occur as a result of immobility following an illness or injury, or may be due to a bone disease such as *osteomalacia*. Patchy demineralization can be due to bone metastases (cancerous tumours that have spread from elsewhere in the body); this condition causes areas of bone to weaken, increasing the risk of *fractures*.

De Morgan's spots

See *Campbell de Morgan's spots*.

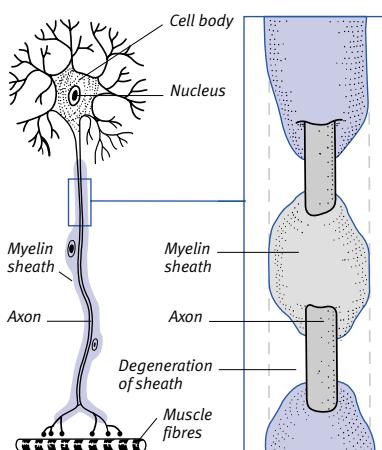

De Morsier's syndrome

Also called septo-optic dysplasia, a rare disorder that results from the abnormal development of the *optic disc* in the eye, the *pituitary gland*, and parts of the brain. De Morsier's syndrome causes eye problems, including blindness in one or both eyes, abnormal eye movements such as *nystagmus*, *squint*, and dilation of the pupils (rather than the normal contraction) in response to light. Other symptoms of the syndrome include *seizures*, *hypotonia* (poor muscle tone), and hormonal problems, commonly a deficiency in growth hormone leading to short stature.

Treatment aims to relieve symptoms such as hormonal deficiencies, and to provide *rehabilitation* for affected people who have impaired vision.

demyelination

Breakdown of the fatty sheaths that surround and electrically insulate nerve fibres. The sheaths provide nutrients to the nerve fibres and are vital to the passage of electrical impulses along them. Demyelination "short-circuits" the functioning of the nerve, which causes loss of sensation, coordination, and power in specific areas of the body. The affected nerves may be within the *central nervous system* (CNS), comprising

Mechanism of demyelination

The fatty myelin sheaths that surround and insulate nerve fibres break down, causing the affected nerves to "short-circuit".

ing the brain and the spinal cord, or may be part of the *peripheral nervous system*, which links the CNS to sense receptors, muscles, glands, and other organs throughout the body.

Patches of demyelination are visible on *MRI* scans of the brain in people who have *multiple sclerosis*, a disease with symptoms that include blurred vision, muscle weakness, and loss of coordination. The cause of the demyelination in multiple sclerosis is not known. In many cases of the disease, episodes of demyelination alternate with periods of partial or complete recovery of nerve function.

In the rare disorder *encephalomyelitis*, there is inflammation of nerve cells in the CNS and sometimes also areas of demyelination along the nerves.

dendritic ulcer

A type of *corneal ulcer* (affecting the transparent dome that forms the front of the eyeball) with threadlike extensions that branch out from the centre. Dendritic ulcers are commonly due to infection with *herpes simplex* virus.

denervation

The loss of the *nerve supply* to an area of skin, a muscle, an organ, or another body part. Nerves may be damaged by injury or by disease, or as a result of surgery. A denervated area loses all sensation, and its functioning may be impaired; for example, muscles may become paralysed. In some cases, the affected nerves may regrow, but often the damage is permanent.

dengue

A tropical disease caused by a virus spread by the mosquito *AEDES AEGYPTI*. The symptoms include fever, headache, rash, and joint and muscle pains, which often subside after about three days. There is no specific treatment for dengue. Prevention involves protection against mosquito bites (see *insect bites*).

densitometry

An imaging technique that uses low-dose *X-rays* to measure bone density, as determined by the concentration of calcified material within bone tissue. Densitometry is used to diagnose and assess the severity of *osteoporosis* (wasting away of bone tissue), especially in the spine and the femur (thigh bone), and to assess its response to treatment.

During the procedure, *X-rays* are passed through the body. A computer assesses the amount of *X-rays* absorbed by the body and uses this information to calculate the bone density.

density

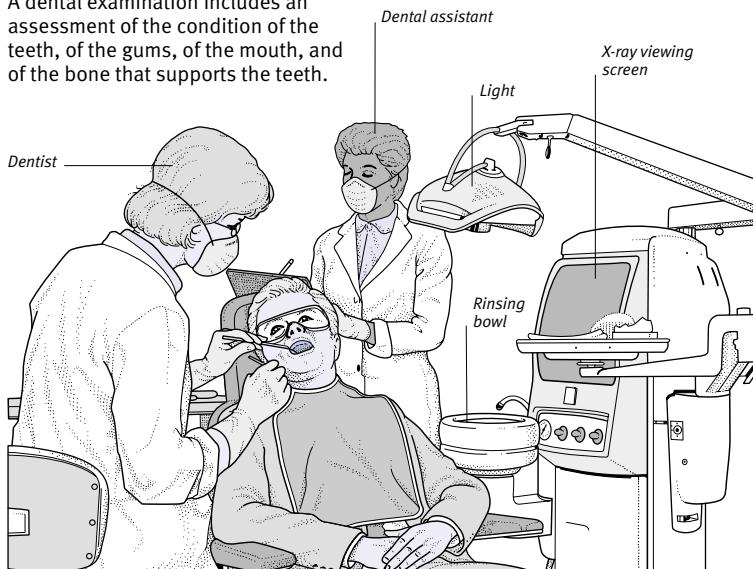

The "compactness" of a substance, defined as its mass per unit volume. In radiology, the term relates to the amount of radiation absorbed by the structure being *X-rayed*. Bone absorbs radiation well and appears white on *X-ray film*. A lung, which contains mostly air, absorbs little radiation and is dark on the film. The same is true for *CT scanning* and *MRI*. (See also *specific gravity*.)

dental emergencies

Injuries or disorders of the teeth and gums that require immediate treatment because of severe pain and/or because delay could lead to poor healing or to complications. A tooth that has become dislodged by injury can be reimplanted (see *reimplantation, dental*) into the gum successfully if this is done without delay, usually within 30 minutes of the injury. A partly dislodged tooth should be manipulated back into the socket in the gum immediately.

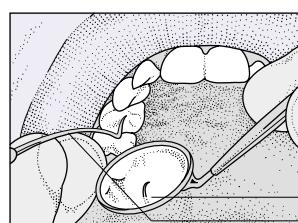

SCOPE OF DENTAL EXAMINATION

A dental examination includes an assessment of the condition of the teeth, of the gums, of the mouth, and of the bone that supports the teeth.

Constructing a dental record

During the dental examination, the dentist checks for the presence or absence of individual teeth. Any abnormalities and all fillings are recorded (by the dentist's assistant).

Instruments used

The dentist uses a mirror to see the backs of the teeth and into the back of the mouth; a metal instrument is used to probe for dental cavities or chipped teeth.

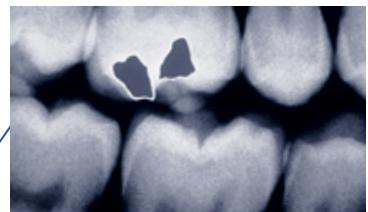

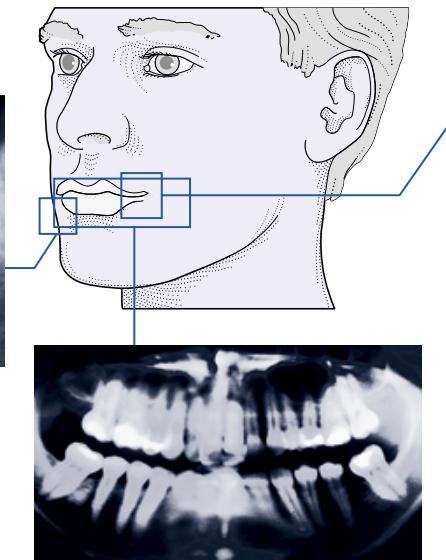

Mirror
Probe

TYPES OF DENTAL X-RAY

There are three types of X-ray. Each of the different types is useful for revealing particular dental problems.

**Periapical X-rays**

These X-rays give detailed pictures of whole teeth and the surrounding gums and bone. They show unerupted or impacted teeth, root fractures, abscesses, cysts, tumours, and the characteristic bone patterns of some skeletal diseases. The film, in a protective casing, is placed in the patient's mouth and is held in position behind the teeth to be X-rayed.

**Bite-wing X-rays**

These X-rays show the crowns of the teeth. They are useful for detecting areas of decay between teeth and changes in bone that are caused by periodontal (gum) disease. The film is in a holder with a central tab on to which the patient bites.

**Panoramic X-rays**

These X-rays show all the teeth and surrounding structures on one large film. They are invaluable for finding unerupted or impacted teeth, cysts, jaw fractures, or tumours. Pictures are recorded continuously on to film as the camera swings around from one side of the jaw to the other.

Other dental emergencies include a broken tooth (see *fracture, dental*); severe *toothache*, which may be due to an abscess (see *abscess, dental*); Vincent's disease (see *gingivitis, acute ulcerative*), which causes ulceration, and bleeding of the gums; and eruption of wisdom teeth that cut into the tongue.

dental examination

An examination of the mouth, gums, and teeth by a dentist as a routine check or during the assessment of a suspected problem.

Routine examinations are recommended so that tooth decay (see *caries, dental*), gum disease (see *gingivitis*), or *mouth cancer* can be detected and treated at an early stage, before they cause serious damage. During the examination, the dentist uses a metal instrument to probe for dental cavities, chipped teeth, or fillings. (See the illustrated box on p.219.) *Dental X-rays* are sometimes carried out to detect problems, for example with the jaw, that may not be visible. The dentist also checks the bite, that is how well the upper and the lower teeth come together. Regular examinations in children enable a dentist to monitor the replacement of primary teeth by permanent, or secondary, teeth. Referral for *orthodontic* treatment may be made.

dental extraction

See *extraction, dental*.

dental floss

A fine thread or tape, usually made of nylon, that is used to remove plaque (see *plaque, dental*) and food particles from hard-to-reach areas between the teeth and around the line of the gums (see *flossing*). Floss may be waxed or unwaxed, and some types contain fluoride. Flossing should be carried out regularly, in addition to toothbrushing.

dental impaction

See *impaction, dental*.

dental X-ray

An image of the teeth and jaws that provides information for the detection, diagnosis, and treatment of conditions that can threaten oral and general health. The part to be imaged is placed between a tube emitting *X-rays* and a photographic film. Because X-rays are unable to pass easily through hard tissue, a shadow of the teeth and bone is seen on the film. There are three types of dental X-ray: periapical X-ray, bite-wing X-ray, and panoramic X-ray.

Periapical X-rays are taken using X-ray film held behind the teeth. They give detailed images of whole teeth and the surrounding tissues. They can show unerupted or impacted teeth, root fractures, abscesses, cysts, and tumours, and can help diagnose some skeletal diseases. Bite-wing X-rays show the crowns of

the teeth and can detect areas of decay and changes in bone due to *periodontal disease*. Panoramic X-rays show all the teeth and the surrounding structures on one large film. They can show unerupted or impacted teeth, as well as cysts, jaw fractures, or tumours.

The amount of radiation received from dental X-rays is extremely small; however, routine dental X-rays should be avoided during pregnancy.

dentifrice

A paste, powder, or gel used with a toothbrush to clean the teeth. Dentifrice usually contains a mild abrasive, along with detergents, colourings and flavourings, binding and moistening agents, and thickening agents. It also usually has *fluoride* added, and, sometimes, desensitizing agents.

dentigerous cyst

A fluid-filled *cyst* (lump or swelling) surrounding the crown of an unerupted tooth (see *eruption of teeth*). This type of cyst may produce swelling or resorption (loss of substance) of the adjacent tooth roots. Treatment is by extraction of the affected tooth and by surgical removal of the cyst.

dentine

The hard tissue that surrounds the pulp of a tooth (see *teeth*).

dentistry

The science or profession concerned with the teeth and their supporting structures. Most dentists work in general dental practice; others practise a specialized branch of dentistry.

Dentists in general practice undertake all aspects of dental care. They may refer patients to a consultant in one of the specialized branches of dentistry, such as *orthodontics* (correction of the alignment of teeth), *prosthetics* (fitting of bridgework and dentures), *endodontics* (treatment of diseases of the tooth pulp), and *periodontics* (treatment of disorders affecting the tissues supporting the teeth).

Dental hygienists carry out scaling (removal of hard deposits on the teeth) and demonstrate methods to keep the teeth and gums healthy.

dentition

The arrangement, number, and type of teeth in the mouth. In young children, primary dentition comprises 20 teeth (incisors, canines, and molars). These teeth are replaced between the ages of 6 and 13 years by the secondary (permanent) dentition. Secondary dentition comprises 32 teeth (incisors, canines, premolars, and molars). Often, the third molars (wisdom teeth) do not erupt until the age of 18–25, or even older in some cases; sometimes, they fail to erupt at all. (See also *eruption of teeth*.)

denture

An appliance that replaces missing natural teeth. A denture consists of a metal and/or acrylic (hard plastic) base that is mounted with acrylic teeth. The artificial teeth are matched to the person's original teeth. Denture baseplates, which are created from impressions taken from the upper and lower gums, fit the mouth accurately.

deodorant

A substance that removes unpleasant odours, especially body odours.

deossification

The loss or removal of *bone* tissue, as in *osteoporosis*. (See also *ossification*.)

deoxygenation

In *respiration*, the release of *oxygen* from red *blood cells* to supply other tissues.

deoxyribonucleic acid

See *DNA*; *nucleic acids*.

dependence

Psychological or physical reliance on persons or drugs. An infant is dependent on its parents, but, as he or she grows, this dependence normally wanes. Some adults never become fully independent (see *dependent personality*).

Alcohol and drugs may induce physical or emotional dependence in users; a person who has a dependency may develop physical symptoms, such as sweating or abdominal pains, or become distressed if deprived of the drug. (See also *alcohol dependence*; *drug dependence*.)

dependent oedema

A form of *oedema* (the accumulation of fluid in body tissues) that mainly affects the lower parts of the body. It may be a feature of congestive *heart failure*. Oedema affecting the ankles may have various possible causes, such as immobility, *varicose veins*, and *pregnancy*.

dependent personality

A *personality disorder* characterized by an inability to function without significant guidance from others, feelings of helplessness when alone or when close relationships end, and a fear of separation. Other features of a dependent personality include difficulty in making decisions, low self-esteem, and hypersensitivity to criticism.

Dependent personality disorder is of unknown cause and normally first manifests itself in early adulthood. There is no specific treatment for the condition, but *psychotherapy* may gradually help sufferers to make their own choices. Medication, for example with

antianxiety drugs or *antidepressant drugs*, may sometimes be effective in relieving associated symptoms.

depersonalization

A state of feeling unreal, in which an individual has a sense of detachment from self and surroundings. Depersonalization is frequently accompanied by *derealization*, in which the world is experienced as unreal. It is rarely serious and usually comes on suddenly and may last for moments or for hours. Depersonalization most often occurs in people who have *anxiety disorders*. Other causes include certain drugs and *temporal lobe epilepsy*.

depilatory

A chemical hair remover, such as barium sulphide, supplied as a cream and applied for cosmetic reasons or to treat *hirsutism* (excessive hairiness in women).

Depixol

A brand name for flupentixol, an *antipsychotic drug* used in the treatment of *schizophrenia* and other related illnesses. The drug may be given either orally or by injection. Possible adverse effects include an increased risk of *parkinsonism* (a set of neuromuscular symptoms including tremors, muscle rigidity, and slow movements).

Depo-provera

A brand name for *medroxyprogesterone*, a long-acting *progestogen drug* that is given by *depot injection* as a contraceptive. It is similar to *progesterone hormone*, a natural female sex hormone.

TYPES OF DENTURES

Partial dentures

Partial dentures are used when only some of the teeth are missing. They fill unsightly gaps, make chewing easier, maintain clear speech, and keep the remaining teeth in the correct position. Teeth on either side of a gap may tip (making cleaning more difficult) or drift (placing unnatural stress on the tissues of the mouth). Partial dentures are held in place by metal clasps that grip adjacent teeth or by clasps combined with metal rests (extensions of the denture plate that rest on the surface of the tooth).

Full dentures

Full dentures are needed when there are no teeth left in the mouth. They stay in place by resting on the gum ridges and, in the case of upper dentures, by suction. Fitting is sometimes delayed after extraction of teeth to allow the gums to shrink and change shape as they heal.

Immediate dentures

Immediate dentures are fitted immediately after extraction of teeth. They protect the gum and control bleeding from extraction sites. Since a toothless period is avoided, they are particularly useful for replacing front teeth. However, they can be expensive and require follow-up visits so that they continue to fit comfortably. They may also need replacing within a short time.

depot injection

An intramuscular injection of a drug that gives a slow, steady release of its active chemicals into the bloodstream. Release of the drug is slowed by the inclusion of substances such as oil or wax, and can be made to last for hours, days, or weeks.

A depot injection can be useful for patients who may not take their medication correctly. It also prevents the necessity of giving a series of injections over a short period. Drugs that may be given by depot injection include hormonal contraceptives (see *contraception, hormonal methods of*), *corticosteroid drugs*, and *antipsychotic drugs*. Side effects may arise due to the uneven release of the drug into the bloodstream.

depressed skull fracture

A fracture in which a part of a skull bone is pushed inwards towards the brain (see *skull, fracture of*). A depressed skull fracture usually results from a high-energy blow to a small surface area of the skull.

depression

Feelings of sadness, hopelessness, and a loss of interest in life, combined with a sense of reduced emotional well-being. Most people experience these feelings occasionally, usually as a normal response to an upsetting event; for example, it is natural to feel depressed when a close relative dies. When a person's behaviour and physical state are also affected, however, this is an indication that the symptom is part of a depressive illness.

Depression that occurs without any apparent cause, deepens, and persists may occur as part of a variety of psychiatric illnesses. Some people who suffer from depression are eventually diagnosed as having *manic-depressive illness* (also known as bipolar affective disorder) a condition characterized by episodes of depression alternating with mania (periods of overly excitable mood and uncontrolled behaviour).

SYMPOTMS

Symptoms vary with the severity of the condition. In a person suffering from mild depression, the main symptoms are anxiety and a variable mood; the person may also have fits of crying that occur for no apparent reason. More severe depression may cause loss of appetite, difficulty in sleeping, tiredness, loss of interest in social activities,

and impaired concentration. Movement and thinking become slower; alternatively, the opposite occurs, and the person may become extremely anxious. Severely depressed people may have thoughts of committing *suicide* and feelings of worthlessness. *Hallucinations* or *delusions* may occur in extreme cases.

CAUSES

Often, there is no single obvious cause, and a combination of factors may be involved. Depression may be triggered by physical illnesses (such as a viral infection), by hormonal disorders (such as *hypothyroidism*), or by the hormonal changes that occur following childbirth (see *postnatal depression*). Certain drugs, such as *oral contraceptives*, may contribute to the condition. Inheritance may play a part in manic-depressive illness. Some people become depressed in the winter (see *seasonal affective disorder syndrome*), probably in response to the long hours of darkness.

Aside from these causes, there are social and psychological factors that may play a role. Depression may also be related to the number of disturbing changes or events in a person's life.

INCIDENCE

Depression is the most common serious psychiatric illness. The World Health Organization ranks it fourth in the ten leading causes of disease worldwide. One person in six is estimated to suffer some degree of depression in their lifetime, and one person in 20 develops clinical depressive illness.

Depression is particularly common in people over 50, and appears to be more common in women; twice as many women as men seek help for the condition. This difference may result from the fact that women are more prepared to seek help for their symptoms, while men may be more likely to express their discontent in the form of problems such as alcohol abuse and violence.

TREATMENT

There are three main forms of treatment for depression, depending on the type and severity of the illness.

Treatment usually includes a form of *psychotherapy*, given either individually or in a group. This form of treatment is most useful for people whose personality and life experiences are the main causes of their illness. Types of therapy range from *counselling* to help deal with practical problems to more structured approaches such as *cognitive-behavioural therapy* or *psychoanalysis*.

Antidepressant drugs may be very effective, with up to seven in ten affected people responding well to the first drug that is offered. Antidepressants are not addictive. Many drugs, however, do not start to take effect until about two weeks into treatment, and all types need to be continued after the symptoms of depression have cleared.

ECT (electroconvulsive therapy) is infrequently used in the UK, but it is still considered to be an effective treatment for people suffering from life-threatening depression. ECT may be life-saving, but it can cause mild, temporary memory impairment.

OUTLOOK

Depression is often a recurrent disorder; up to three-quarters of people who have needed hospital treatment for depression will have another episode within 10 years. However, long-term antidepressant medication and psychological therapies can greatly reduce the risk of recurrence.

Despite the effectiveness of drug treatment, suicide remains a serious risk; nearly half of all deaths in people with recurrent depression are due to suicide. This risk can, however, be substantially reduced by maintenance treatment with antidepressive drugs.

De Quervain's disease

An inflammatory condition that affects one of the *tendons* of the muscles that are used to move the *thumb*. In de Quervain's disease, the sheath (covering) of this tendon becomes so inflamed and thickened that the tendon can no longer move through the sheath smoothly, and thumb movements are painful. The inflammation is often caused by overuse of the thumb.

Treatment is with rest, *nonsteroidal anti-inflammatory drugs* (NSAIDs), and *corticosteroid drug* injections into the affected tendon sheath, which may be helpful in relieving the inflammation, but in severe cases surgery is needed to loosen the sheath.

De Quervain's thyroiditis

A form of *thyroiditis* (inflammation of the thyroid gland) that is uncommon and is caused by a viral infection; the condition often follows a viral infection of the nose and throat.

The thyroid gland, which is situated in the front of the neck, may become painful and swollen; this swelling is sometimes accompanied by fever. There

is a temporary rise in thyroid hormone levels (*hyperthyroidism*) lasting for a few weeks, as damage to the thyroid gland causes it to release its hormone stores. This is followed by insufficient levels (*hypothyroidism*) when the stores then become depleted.

Aspirin is used to treat the inflammation, with a short course of the corticosteroid drug *prednisolone* given in more severe cases. Thyroid function usually returns to normal once the illness has been treated.

Dercum's disease

Also called adiposis dolorosa, a disorder characterized by the accumulation of localized, symmetrical fat deposits under the skin, mainly on the forearms and thighs. The swellings are uncomfortable or painful. Other symptoms of the disease include muscle weakness and headaches. The disease may cause death from heart failure. Dercum's disease mainly affects middle-aged women and is thought to be an autosomal dominant *genetic disorder*.

derealization

Feeling that the world has become unreal. It usually occurs together with *depersonalization* and may be caused by fatigue, *hallucinogenic drugs*, or disordered brain function.

dermabrasion

Removal of the surface layer of the skin by high-speed sanding to improve the appearance of scars, such as from *acne*, or to remove tattoos.

dermatitis

Inflammation of the skin, sometimes due to an *allergy*. Dermatitis is the same as *eczema*, and the terms can be used interchangeably. The following are types of dermatitis.

SEBORRHOEIC DERMATITIS

This condition is a red, scaly, itchy rash that develops on the face (particularly the nose and eyebrows), scalp, chest, and back. It often develops during times of stress and is probably caused by an excessive growth of yeast on the skin. *Corticosteroid drugs* and drugs that kill microorganisms may help.

CONTACT DERMATITIS

Contact dermatitis results from a reaction to some substance that comes in contact with the skin. Common causes are detergents, nickel, certain plants, and cosmetics. It may be treated with

Contact dermatitis

An allergic reaction to the metal (often nickel) in a ring has produced a red, inflamed area of skin around the finger.

topical corticosteroids. A patch test (see *skin tests*) may be performed in order to identify the cause.

PHOTODERMATITIS

This form of dermatitis occurs in people whose skin is abnormally sensitive to light. A cluster of spots or blisters occurs on any part of the body exposed to the sun (see *photosensitivity*).

dermatitis artefacta

Any self-induced damage to the skin. It may range from scratches to extensive mutilation that produces severe ulcers or other lesions. When given a medical examination, the affected person may vigorously deny having any part in causing the problem. Psychiatric assessment and treatment is required to control the behaviour. (See also *factitious disorder*.)

dermatitis herpetiformis

A chronic skin disease in which clusters of tiny, red, intensely itchy blisters occur in a symmetrical pattern, most commonly on the back, elbows, knees, buttocks, and scalp. It usually develops in adult life and is believed to be related to *coeliac disease*, a condition in which the lining of the small intestine reacts to gluten, a constituent of wheat, rye, and some other cereals.

dermatology

The branch of medicine that is concerned with the *skin*, *hair*, and *nails*, and their disorders.

dermatome

An area of skin that is supplied with nerve fibres by a single spinal nerve from the cervical, thoracic, lumbar, or sacral regions of the spinal cord.

The entire body surface is an interlocking pattern of dermatomes, which is similar from one person to another.

Abnormal sensation in a dermatome signifies damage to a particular nerve root, commonly due to a *disc prolapse* ("slipped" disc).

dermatome, surgical

A surgical instrument for cutting varying thicknesses of skin for use in skin grafting procedures.

dermatomyositis

A rare *autoimmune disorder* in which the muscles and skin become inflamed. In most cases the cause is unknown, but in some instances the disease is linked to an underlying *cancer*.

Dermatomyositis causes a skin rash that may first appear on the bridge of the nose and cheeks, followed by a purple discoloration on the eyelids and sometimes a red rash over the knees, knuckles, and elbows. Muscles become weak, stiff, and painful, particularly those in the shoulders and pelvis; affected people may find that they cannot raise their hands above their head, or cannot raise themselves from a squatting position. Calcium may be deposited in the muscles, particularly in affected children.

The diagnosis is made by medical examinations, *blood tests*, and *biopsy* of muscle tissue. Treatment is with *corticosteroids* and/or *immunosuppressant drugs* and *physiotherapy*. In about half of all cases, full recovery occurs after a few years. The remainder have persistent muscle weakness. In some cases, the disease eventually affects the lungs and other organs and may be fatal.

dermatophyte infections

A group of common fungal infections affecting the skin, hair, and nails, also called *tinea* or, popularly, ringworm.

dermis

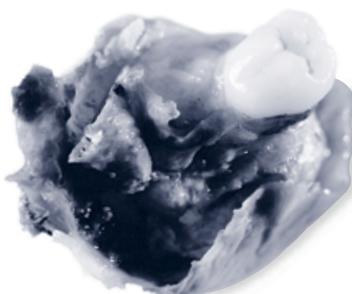

The inner layer of the *skin*.

dermographism

Abnormal sensitivity of the skin to mechanical irritation, to the extent that firm stroking leads to the appearance of itchy weals. The condition is a form of *urticaria* (nettle rash). It is most common in fair-skinned people who have a tendency to allergic conditions.

dermoid cyst

A noncancerous tumour with a cell structure similar to that of skin. The growth contains hairs, sweat glands,

**Dermoid cyst of the ovary**

Dermoid cysts commonly occur in the ovaries. They can contain fragments of cartilage, bone, and, in this case, a whole tooth.

and sebaceous glands. Dermoid cysts may also contain fragments of cartilage, bone, and even teeth. The cysts can occur in various parts of the body, but they are most commonly found in the ovaries and on the skin around the head or neck, causing small, painless swellings. Dermoid cysts only rarely become cancerous.

Surgical removal of the cysts is usually recommended. (See also *teratoma*.)

dermoid tumour

See *dermoid cyst*.

Dermovate

A brand name for clobetasol, a topical *corticosteroid drug* that is applied to the skin. Dermovate is only prescribed for severe skin disorders that have not responded to treatment with another, weaker topical corticosteroid.

De Sanctis–Cacchione syndrome

A hereditary condition that is transmitted as an autosomal recessive trait (see *genetic disorders*). De Sanctis–Cacchione syndrome is characterized by *xeroderma pigmentosum* (extreme sensitivity of the skin to sunlight), impaired intellectual development, growth retardation (see *short stature*), and underdevelopment of the gonads (the *testes* or *ovaries*).

desensitization

A technique that is used in *behaviour therapy* for the treatment of *phobias*. The patient is gradually exposed to the feared object or situation while using *relaxation techniques* to control his or her feelings. The exposure is carried out repeatedly over several weeks or months, until the person no longer feels afraid when confronted with the object or situation.

desensitization, allergy

See *hypersensitization*.

desferrioxamine

A drug used to rid the body tissues of excess *iron* that accumulates as a result of repeated blood transfusions in certain types of *anaemia*, such as aplastic anaemia and *thalassaemia*. It is also used to treat iron poisoning, and may be used to treat excess *aluminium* in people on *dialysis*.

The drug is administered by intravenous injection or by subcutaneous infusion. It may be given with *vitamin C* to boost excretion of the iron. Side effects may include gastrointestinal disturbances, dizziness, and skin reactions.

designer drugs

A group of illegally produced chemicals that mimic the effects of specific drugs of abuse. Made in illicit laboratories, they are cheap to produce and undercut the street prices of drugs. Designer drugs can cause *drug dependence* and *drug poisoning*.

TYPES

There are three major types: drugs that are derived from opioid *analgesic* drugs (painkillers) such as fentanyl; drugs that are similar to *amphetamines*, such as ecstasy; and variants of *phencyclidine* (PCP), a hallucinogenic drug.

RISKS

These highly potent drugs are not tested for adverse effects or for the strength of the tablets or capsules, making their use hazardous. For example, some derivatives of fentanyl are 20–2,000 times as powerful as morphine. Amphetamine derivatives can cause brain damage at doses only slightly higher than those required for a stimulant effect. Many designer drugs contain impurities that can cause permanent damage.

WARNING

Designer drugs carry a high risk of drug dependence, with severe *withdrawal reactions*, and of drug poisoning, causing effects such as brain damage.

desmoid tumour

A growth, usually in the abdominal wall. The tumour feels hard and it occurs most frequently in women who have had children, possibly due to stretching of abdominal muscles during pregnancy. They may also arise at the sites of old surgical incisions. Removal of the tumour is the usual treatment, but recurrence is common.

desmopressin

A synthetic form of *ADH* (antidiuretic hormone) that is used to treat *diabetes insipidus* and bed-wetting (see *enuresis*).

desogestrel

A *progestogen drug* that is used with *ethynodiol* as an ingredient of some combined *oral contraceptives*. Desogestrel is reported to have a slightly higher risk of venous *thromboembolism* than older drugs. Possible side effects of desogestrel include weight changes and fluid retention. There may, in addition, be nausea, vomiting, headache, depression, and breast tenderness.

desquamation

The process by which the surface of the *epidermis* (the outer layer of the skin) is shed in the form of scales or small sheets. This process is a feature of *seborrhoeic dermatitis* (see *dermatitis*) and *ichthyosis* (an inherited scaling condition of the skin). Desquamation of the skin may occur after illnesses involving fever, particularly *scarlet fever*.

detached retina

See *retinal detachment*.

detergent poisoning

The toxic effects that can result from swallowing cleaning agents that are present in shampoos, laundry powders, and household cleaning liquids. These effects include vomiting, diarrhoea, and swelling of the abdomen.

detoxify

To remove the toxicity (the poisonous property) from a substance or to neutralize the substance's toxic effects. Detoxification is one of the functions carried out by the *liver*.

The term "detoxification" is used to describe treatment for alcohol dependence and also a short-term diet in which toxins such as *caffeine* and *alcohol* are excluded and foods high in fats and sugar are avoided. "Detox" diets are usually based on fruits, vegetables, starches such as brown rice, and drinking plenty of water. People who follow these diets often feel physically and mentally refreshed afterwards, although there is no scientific evidence that the diets eliminate toxins faster than normal. Detox diets should be used only for a few days, and preferably with guidance from a doctor or dietician. They are not recommended for children

or adolescents, people with *diabetes mellitus* or *eating disorders*, or those who have any other medical condition.

detrusor instability

Inappropriate contraction of the detrusor muscle in the wall of the *bladder* that causes an uncontrollable release of urine even when the bladder is not sufficiently full to trigger urination. It may have various causes, including bladder inflammation, obstruction of the bladder outlet (for example, by a stone or, in men, by an enlarged *prostate gland*), or damage to the nerves supplying the bladder. (See also *incontinence, urinary*.)

Deutschländer's disease

A tumour of one of the *metatarsal bones* in the foot.

development

The process of growth and change by which an individual matures physically, mentally, emotionally, and socially. It takes place in major phases: during the first two months of pregnancy (see *embryo*), and, to a lesser extent, during the rest of pregnancy (see *fetus*); during the first five years of life (see *child development*); and then again during *puberty* and *adolescence*.

developmental delay

A term used if a baby or young child has not acquired new skills within the expected time range. Normally, new abilities and new patterns of behaviour appear at given ages, and existing behaviour patterns change and sometimes disappear (see *child development*).

Delays vary in severity, and may affect the development of one or more of the following skills: hand-eye coordination, walking, listening, language, speech, or social interaction.

GENERALIZED DELAY

A child who is late in most aspects of development usually has a generalized problem. This may be due to a severe visual or hearing impairment, limited intellectual abilities (see *learning difficulties*), or damage to the brain before, during, or after birth. For further information on possible causes of generalized delay, see the table above.

SPECIFIC FORMS OF DELAY

Delay in movement and walking often has no serious cause. In some cases, however, there are specific causes; these can include *muscular dystrophy* and *spina bifida*. Delay in developing manipulative

CAUSES OF DEVELOPMENTAL DELAY

- Physical or emotional deprivation (child abuse). Lack of affection, stimulation, or teaching.
- Severe visual impairment. Vision is vital for normal development in all areas. Children learn to recognize objects before learning their names, they learn about sounds by seeing which objects make which sounds, and they become motivated to crawl and walk by the desire to explore their surroundings (see *vision, disorders of; blindness*).
- Severe hearing impairment (see *deafness*).
- Learning difficulties.
- Damage to the brain before, during, or after birth, or in infancy. The results of damage depend on which parts of the brain are damaged and on severity (see *brain damage; cerebral palsy*).
- Severe, prolonged disease of any organ or body system (such as bone, heart, kidney, muscle, and nutritional disorders).

skills (the ability to pick up and use objects with the hands) is often due to lack of adequate stimulation.

Delayed speech development may have various causes. The most important is *deafness*, which may cause the child to be unresponsive to sound. *Autism* is a rare cause; in this condition, hearing is normal but the child may be unresponsive to the human voice. Another possible cause is generalized difficulty with muscle control, which may affect speech production; this may occur in children who have cerebral palsy. Damage to, or structural defects of, the speech muscles, the larynx (voicebox), or the mouth may also cause speech difficulties, as may any disorder that affects the speech area of the brain (see *aphasia; dysarthria; dysphonia; speech disorders*).

Children vary enormously in the age at which they gain control of bladder and bowel function. Usually, bowel control is acquired first. Delay in bladder control is much more common than delay in bowel control. Such delays have many possible causes (see *enuresis; encopresis; soiling*).

ASSESSMENT

Delays may first be noticed by parents; if this is the case, a health visitor or

doctor should be consulted promptly. Delays may also be detected during routine developmental checks with a health visitor, family doctor, or paediatrician. These checks are performed at various ages, but usually at birth, six weeks, six to eight months, 18 to 24 months, three years, and five years.

A child who shows signs of developmental delay should undergo a full assessment. This will usually include a physical examination, along with *hearing tests, vision tests*, and a thorough developmental assessment. The child may need to undergo further investigations, such as blood tests, to check for any genetic abnormality, or referral to a specialist such as a neurologist, speech therapist, or physiotherapist.

TREATMENT

The treatment depends on the severity and probable cause of the delay. It may include a course of *speech therapy* or *family therapy*, or provision of physical aids such as *glasses* or a *hearing aid*. Parents are often of prime importance in providing help for their child. In some cases, however, the child may also benefit from being admitted to a school or special unit that provides education for children with specific difficulties.

developmental hip dysplasia

A disorder present at birth in which the head of the *femur* (thigh-bone) fails to fit properly into the cup-like socket in the *pelvis* to form a normal joint. One or both of the hips may be affected.

CAUSE AND INCIDENCE

The cause of developmental hip dysplasia is not known. The condition is more common in girls, especially in babies born by *breech delivery* or following pregnancies in which there was an abnormally small amount of amniotic fluid surrounding the fetus.

TREATMENT

If the dislocation is detected in early infancy, *splints* are applied to the thigh to manoeuvre the ball of the joint into the socket and keep it in position. These splints are worn for about three months and usually correct the problem. Progress may be monitored by *ultrasound scanning* and *X-rays*. Corrective surgery may also be required.

OUTLOOK

If treatment is delayed, there may be lifelong problems with walking. Without treatment, the dislocation often leads to shortening of the leg, limping, and early *osteoarthritis* in the joint.

deviated nasal septum

See *nasal septum*.

deviation, sexual

An abnormal form of sexual behaviour, most common in men, in which sexual intercourse between adults is not the final aim. Forms of sexual deviation include *exhibitionism*, *fetishism*, *paedophilia*, and *transvestism*.

Devic's disease

A rare condition, sometimes called *neuromyelitis optica*, in which there is *demyelination* of the fibres in the optic nerves and the spinal cord. The condition begins with inflammation of the optic nerves (see *optic neuritis*), leading to loss of vision. There are also attacks of numbness, muscle weakness, and loss of coordination in the parts of the trunk and limbs below the diseased area of the spine. In addition, the spinal cord damage may lead to disruption of urinary and bowel control and impairment of sexual function.

dexamethasone

A *corticosteroid drug* prescribed as a nasal spray to relieve *nasal congestion* caused by allergic *rhinitis* (hay fever), as eye drops in the treatment of *iritis* (inflammation of the iris), and as eardrops in the treatment of *otitis externa* (outer-ear infection).

Dexamethasone is given in tablet form or by injection to treat severe *asthma* and other inflammatory disorders, and to reduce inflammation of the brain due to *head injury*, *stroke*, or a *brain tumour*. It may also be injected into an inflamed joint to relieve the symptoms of *osteoarthritis*.

Dexamethasone nasal spray may cause nosebleeds; eye drops may cause irritation of the eyes. Prolonged use or high doses of dexamethasone tablets may cause the adverse effects common to the corticosteroid group of drugs.

dexamfetamine

A central nervous system stimulant (see *amphetamine drugs*; *stimulant drugs*) sometimes used to treat *narcolepsy* (a sleep disorder). It is also used in children with *attention deficit hyperactivity disorder* who have not responded to treatment with methylphenidate.

Because of its stimulant properties, dexamfetamine has become a drug of abuse. Excessive use leads to *anxiety* and *drug psychosis*. With prolonged use,

physical tolerance develops: the drug's stimulant effects lessen and a higher dose must then be taken to produce the same effect. *Drug dependence* (a physical or mental need for the drug) also develops after repeated use.

DEXA scan

Dual-energy X-ray absorptiometry, a technique that measures bone density by passing beams of low-dose radiation through bone. DEXA scans are used to assess the severity of the bone disorder *osteoporosis*. (See also *densitometry*.)

dextran

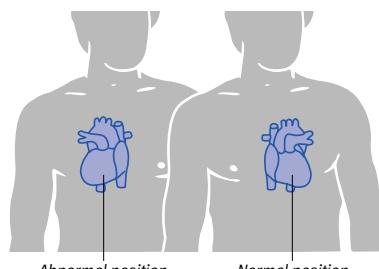

A polysaccharide (a type of *carbohydrate*) consisting of branched chains of glucose units. Dextrans that are formed by the action of bacteria on sucrose in the mouth produce *plaque* (a rough, sticky coating on the teeth), which is a major cause of tooth decay (see *caries, dental*).

Commercially manufactured preparations of synthetic dextran solution may be used in surgery or in emergency treatment for *shock*, to increase the volume of the *plasma* (the fluid part of the blood) in the circulation. Dextrans used for this purpose are known as plasma expanders.

dextrocardia

A rare condition, which is present from birth, in which the heart is situated in, and points towards, the right-hand side of the chest instead of the left. The heart may also be malformed. Sometimes, the position of the abdominal organs is also reversed, so that the liver is on the left-hand side and the stomach is on the right. The cause of dextrocardia is not known.

No treatment is necessary unless the heart is malformed, in which case surgical correction may be performed.

**Heart positions**

In dextrocardia, the heart is situated in, and points towards, the right-hand side of the chest instead of the left-hand side.

dextromethorphan

A cough suppressant that is available over the counter as an ingredient in many *cough remedies*.

dextromoramide

An opioid *analgesic drug* related to opium that is used to relieve severe pain following injury or surgery and during long-term illnesses. It relieves pain quickly but has only a short duration of action. Regular use of dextromoramide can produce *drug dependence*.

dextropropoxyphene

A weak opioid *analgesic drug* that is included in some compound analgesic preparations. The drug works rapidly and relieves mild to moderate pain for about four hours. Adverse effects of this drug may include drowsiness, dizziness, nausea, and vomiting.

dextrose

Another name for *glucose*.

diabetes, bronze

Another name for *haemochromatosis*, a rare genetic disease in which excessive amounts of iron are deposited in tissues. Bronze diabetes causes a bronze skin coloration, and sufferers often develop *diabetes mellitus*.

diabetes insipidus

A rare condition that is characterized by excessive thirst and the passing of large quantities of dilute urine. A person with diabetes insipidus may pass between five and 20 litres of urine every 24 hours, provided that this output is matched by a sufficient intake of water. If the lost water is not replaced, dehydration may occur, leading to confusion, stupor, and coma.

Diabetes insipidus usually results from a failure of the *pituitary gland* to secrete *ADH* (antidiuretic hormone), which normally regulates the amount of water excreted in the urine. This failure may be due to a disease of the pituitary gland, or may temporarily follow brain surgery. A rare form of the disease, called *nephrogenic diabetes insipidus*, is due to failure of the kidneys to respond to ADH.

Diagnosis mainly involves blood and urine tests. A doctor may measure output of urine over 24 hours. He or she may also measure urine output when fluid has been withheld for several hours; an affected person will continue

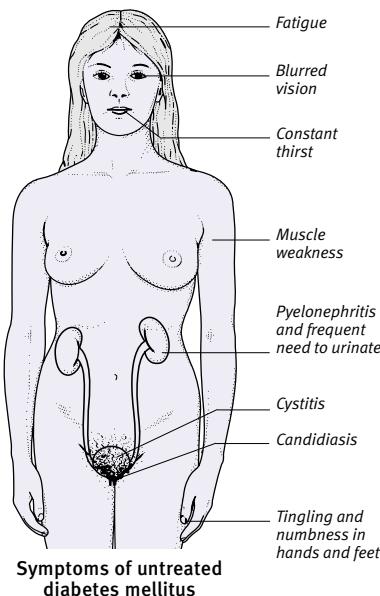

LIVING WITH DIABETES MELLITUS

As the level of glucose in the blood rises, the volume of urine required to carry it out of the body is increased, causing not only a frequent need to urinate but also constant thirst. The high levels of sugar in the blood and urine impair the body's ability to fight infection, leading to urinary tract infections (such as *cystitis* and *pyelonephritis*), vaginal yeast infections (*candidiasis*), and recurrent skin infections.

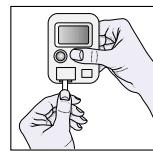

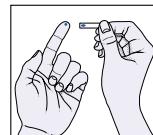

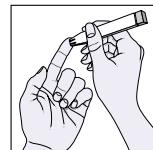

Because the body's cells are starved of glucose, the sufferer feels weak and fatigued (see right). The cells are able to obtain some energy from the breakdown of stored fat, resulting in weight loss. The chemical processes involved in this breakdown of fat are, however, defective, especially in insulin-dependent diabetics. They lead to the production of acids and substances known as ketones, which can cause coma and sometimes death.

Other possible symptoms of undiagnosed diabetes include blurred vision, boils, increased appetite, and tingling and numbness in the hands and the feet.

Symptoms will develop in every untreated person who has insulin-dependent (Type 1) diabetes, but will appear in only one third of those who have the noninsulin-dependent form (Type 2). There are many people with Type 2 diabetes who are unaware of it. The disease is often diagnosed only after complications of the diabetes have been detected.

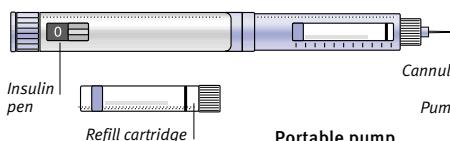

SELF-MONITORING OF BLOOD GLUCOSE LEVELS

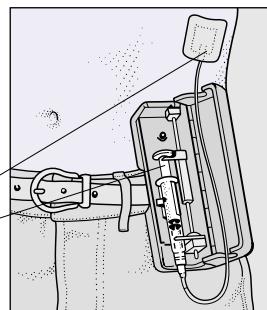

Testing of blood glucose
A spring-loaded pricking device is used to obtain blood from the fingertip. A drop of blood is spread on to a chemically impregnated strip. The strip is inserted into a digital glucose meter, which analyses the blood and gives an almost instant reading of the glucose level.

DEVICES FOR INJECTING INSULIN

Insulin can be injected using a disposable syringe and needle or a pen with refill cartridges (below), or it may be infused continuously from a portable pump (right).

Portable pump
The pump infuses insulin by way of a cannula inserted through the skin.

to pass a large volume of urine. The person's response to synthetic ADH may also be tested; if the urine output remains high even after the person has taken ADH, this indicates the nephrogenic form of the disease.

Treatment of ADH-related diabetes insipidus is with desmopressin (synthetic ADH). Treatment of nephrogenic diabetes insipidus is by a low-sodium diet and thiazide diuretic drugs.

diabetes mellitus

A disorder that develops when the cells of the body do not receive enough *insulin*. This hormone is produced by the *pancreas*; it normally enables body cells to take in glucose from the blood

to generate energy, and enables the *liver* and fat cells to take in glucose for storage. A lack of insulin in the cells may occur because the *pancreas* produces too little, or none at all; alternatively, it may occur because the tissues are resistant to the hormone's effects.

TYPES, CAUSES, AND INCIDENCE

There are two main types of diabetes mellitus, both of which tend to run in families. Type 1 (insulin-dependent) diabetes usually develops suddenly in childhood or adolescence. This type of diabetes is an *autoimmune disorder* in which the immune system destroys insulin-secreting cells in the pancreas and insulin production ceases. Affected people may be genetically predisposed

to developing the condition; the disease process may be triggered by viral infection. They must have insulin injections or they may fall into a coma and die.

Type 2 (non-insulin-dependent) diabetes tends to develop gradually, mainly in people over the age of 40. This type is becoming more common in younger people, however, and is probably linked to dieting. Although insulin is still produced, there is not enough to meet the body's needs because the tissues become relatively resistant to its effects. Obesity and inheritance are possible contributory factors; many people who develop Type 2 diabetes are overweight, and affected people often have close relatives with the condition.

Diabetes mellitus affects more than 120 million people worldwide. Type 2 diabetes is by far the more common form of the disease. About 1 in 50 people in the UK has this type. It is three to four times more common in black people, and seven times more common in Asians. It also becomes more common with increasing age.

SYMPOTMS

Lack of insulin causes high levels of glucose to remain in the blood. This, in turn, results in a high level of glucose in the urine. This condition, termed *glycosuria*, causes the passage of large quantities of urine, excessive thirst, and *urinary tract infections*. Lack of glucose in the cells causes weight loss, hunger, and fatigue, and leads to chemical imbalances. For further information on the symptoms, see the illustrated box on the previous page.

In Type 1 diabetes, symptoms such as thirst, weight loss, and excessive urination usually develop rapidly over a few weeks. If it is not promptly diagnosed and treated at this stage, it may lead to *diabetic ketoacidosis*, which is a potentially fatal condition.

Type 2 diabetes may be present for months or years while causing few noticeable symptoms. It may only be diagnosed when a complication (see below), such as poor vision, is detected during a medical check-up.

COMPLICATIONS

Some complications of diabetes mellitus result from damage to capillaries (tiny blood vessels) throughout the body. These conditions include *retinopathy* (damage to the retina, which is the light-sensitive part of the eye) and *diabetic nephropathy* (kidney damage). Damage to the blood vessels supplying nerves causes *diabetic neuropathy* (damage to nerve fibres); this may first appear in the fingers and toes, then spread up the limbs. The loss of sensation, and poor circulation, may result in *ulcers* on the feet and legs. Other problems include dizziness on standing and, in men, *impotence*.

People with diabetes have a greater risk of developing *atherosclerosis* (accumulation of fatty deposits on the lining of the arteries), *hypertension* (high blood pressure), other *cardiovascular disorders*, and *diabetic cataract* (opacity in the lens of the eye).

DIAGNOSIS AND TREATMENT

If diabetes mellitus is suspected, a urine sample will be taken and tested for the presence of glucose. The diagnosis is

confirmed by a blood test to detect abnormally high levels of glucose in the blood. If the results of this test are unclear, a glucose tolerance test may be done. The person is asked to fast for several hours, and then is given glucose; the blood and the urine are tested at 30-minute intervals to show how efficiently the body is utilizing the glucose. Tests may also be carried out to detect and assess damage to organs such as the eyes, kidneys, and heart.

Treatment aims to keep blood glucose levels as normal as possible. Dietary control is an essential element. The ideal diet for a person with diabetes resembles the sort of healthy eating plan recommended for everyone (see *diabetic diet*). If the person is overweight, and particularly if he or she has Type 2 diabetes, weight loss can be achieved by a reduced-calorie diet. Also, regular exercise and treatment with *antidiabetic drugs* may be required.

In addition to general treatment, all people with Type 1 diabetes need to have regular injections of insulin. The injections are usually self-administered two, three, or four times a day. The insulin doses need to be matched to activity levels and food intake. If the glucose/insulin balance is not maintained, *hyperglycaemia* (too much glucose in the blood) or *hypoglycaemia* (too little glucose in the blood) may develop. Careful monitoring of blood glucose levels is also an essential part of self-treatment. Pancreas transplants have been tried as a possible cure for the condition, but with little success. Research is being done on a possible treatment involving transplantation of clusters of insulin-producing cells.

Treatment of type 2 diabetes usually consists of dietary measures, weight reduction, exercise, and antidiabetic drugs, often *hypoglycaemic* drugs such as sulphonylureas. Some people eventually need insulin injections.

In general, careful control of blood glucose levels reduces the risk of complications or, if such problems have already developed, slow their progression. People with diabetes should have regular medical check-ups so that any complications can be detected as early as possible. Additional tests, such as measurement of *glycosylated haemoglobin* (which shows blood glucose levels over the previous three months) and urine tests to detect *proteinuria*, can improve medical control and aid early detection of problems.

OUTLOOK

With modern treatment and efficient self-monitoring, people with diabetes mellitus can usually live a normal life; however, the disease is irreversible and life expectancy is reduced.

diabetic arthropathy

Joint damage associated with *diabetes mellitus*. It results from the loss of protective pain sensation that can occur when peripheral nerves are damaged (see *diabetic neuropathy*). The condition often affects the joints in the legs; the ankle is particularly vulnerable.

Affected joints (called neuropathic joints or Charcot's joints) tend to be swollen and deformed but painless. Treatment includes fitting a special cast to reduce swelling in the limb, and the use of supportive footwear.

diabetic cataract

An opacity in the lens of the eye (see *cataract*) due to *diabetes mellitus*. The slow-growing opacities that often appear in old age (senile cataracts) tend to develop 10–15 years earlier than usual in people who have diabetes. Occasionally, young people with poorly controlled diabetes develop juvenile cataracts, which are diffuse opacities that develop rapidly. Treatment for diabetic cataract is the same as for other forms of cataract.

diabetic coma

A life-threatening state of unconsciousness and unresponsiveness, due either to *diabetic ketoacidosis* or to *hypoglycaemia*. The latter condition may be induced either by excessive doses of *oral hypoglycaemic* drugs or by an inadequate intake of food.

diabetic diet

A nutritional regime designed to prevent complications of *diabetes mellitus* by controlling the timing and amount of *energy* intake, thereby minimizing the occurrence of *hyperglycaemia* (high blood glucose levels) or *hypoglycaemia* (low blood glucose levels).

People with diabetes should follow the same kind of healthy diet that is recommended for people in general (see *nutrition*). The diet should be rich in complex carbohydrates (such as bread and pasta) and contain less than 30 per cent fat. In addition, the energy intake (see *calorie*) needs to be controlled in order to maintain a healthy

body weight. People who take insulin need to coordinate their meals with the times for their insulin injections.

diabetic ketoacidosis

A severe, acute complication of Type 1 *diabetes mellitus*, a condition in which the *pancreas* produces too little *insulin*. If levels of insulin are too low, the *liver* generates more glucose, but the tissues are unable to take up the glucose properly and have to break down fats to obtain energy, causing the production of acidic chemicals called ketone bodies. Diabetic ketoacidosis may be the first sign that a person has insulin-dependent diabetes, or it may develop in a person known to have the condition who has taken insufficient insulin.

The features of diabetic ketoacidosis include nausea; vomiting; deep, rapid breathing; breath that smells of acetone (like nail polish remover); and confusion. The condition can progress to severe *dehydration* and *coma*.

Treatment of diabetic ketoacidosis involves giving insulin to correct the deficiency and fluids containing salts to relieve dehydration.

diabetic maculopathy

See *maculopathy*, *diabetic*.

diabetic nephropathy

Kidney damage resulting from long-standing or poorly controlled *diabetes mellitus*. The disorder includes damage to capillaries (tiny blood vessels) in the kidneys and hardening of the tissues. As a result, the kidneys become less able to filter the blood efficiently. Protein may escape into the urine, depleting the body's supplies (see *nephrotic syndrome*). In severe cases, chronic *kidney failure* may develop. Many affected people have *hypertension* (high blood pressure), which may also cause damage to the blood vessels.

People with diabetes should have regular check-ups so any kidney problems can be treated as soon as possible. Checks may include urine tests for protein, as well as *kidney function tests*.

diabetic neuropathy

Any of various types of *neuropathy* (disease of or damage to the nerves) that result from longstanding or poorly controlled *diabetes mellitus*.

The most common type of diabetic neuropathy is called peripheral sensory neuropathy. In the early stages of this

disorder, intermittent pain and tingling are felt in the extremities, particularly in the feet. The pain gradually worsens until, finally, pain sensation is lost to an area. People with sensory neuropathy in the feet can develop cuts, scrapes, or blisters that they may not notice. If left untreated, serious complications may result from such injuries. Daily observation of the feet is critical.

Another form of diabetic neuropathy is damage to motor nerves (which initiate movements). This problem causes weakened muscles. The foot is particularly susceptible, and may undergo a change of appearance as a result. A further form, diabetic amyotrophy, causes painful wasting of the thigh muscles.

Autonomic neuropathies affect the nerves that regulate involuntary vital functions. Symptoms and signs include postural *hypotension* (low blood pressure on standing); diarrhoea at night; inability to empty the bladder completely, which may lead to urinary tract infection; and *impotence*. Cranial neuropathies affect nerves that supply the

head and face; damage to nerves supplying the eye muscles causes impaired vision and eye pain.

diabetic pregnancy

Pregnancy associated with *diabetes mellitus*. The term "diabetic pregnancy" may refer to a pregnancy in a woman with pre-existing diabetes, or to diabetes that develops during pregnancy; in the latter case, the condition is known as gestational diabetes.

Women with established diabetes can have a normal pregnancy provided that the diabetes is well controlled. Careful control of blood glucose levels must begin well before conception. Poor control may affect the baby's growth, and increase the risk of fetal malformations and complications during pregnancy.

In gestational diabetes, the mother does not produce enough insulin to keep blood glucose levels normal. The condition is usually detected in the second half of pregnancy, when urine tests reveal the presence of glucose. Treatment is the same as for women who

STEPS IN DIAGNOSING A CONDITION

A doctor may go through several steps to ascertain the cause of a person's problem. The medical history, physical examination, and tests may prove vital clues. A doctor usually makes at least

a provisional diagnosis before beginning any treatment because treatment can mask symptoms, making the doctor's task of establishing an exact diagnosis more difficult.

Taking the medical history

Perhaps the most important part of the diagnostic procedure is the patient's own account of his or her illness – the medical history. "Listen to the patients, they are telling you their diagnosis" is the traditional teaching

given to medical students. Many doctors believe that the medical history provides the strongest basis for ascertaining a diagnosis. The added information derived from the physical examination may be small, but, at times, critical.

Conducting a physical examination

After the medical history has been obtained, the doctor has in mind a short list of probable diagnoses. A physical examination helps shorten the list. The doctor is then left with a differential diagnosis. A differential diagnosis

is a group of possible diseases that could account for patterns of symptoms and signs (i.e., physical findings, such as enlargements of lymph nodes or tenderness in a specific region of the abdomen).

Ordering special tests

Next, based on his or her provisional diagnosis, the doctor may order a series of laboratory tests on the blood (and sometimes the urine) and may also arrange for diagnostic imaging of suspect organs by techniques such as ultrasound

scanning, X-rays, CT scanning, MRI, or radionuclide scanning. The results of these tests either confirm the doctor's provisional diagnosis or narrow the possibilities so the doctor may be confident in making the correct diagnosis.

Using a computer

Doctors today also use computer systems and algorithms to help reach a diagnosis. Both approaches rely on analysis of large numbers of patient records to quantify probabilities and to devise an orderly series of questions – a decision tree. The main purposes of computer

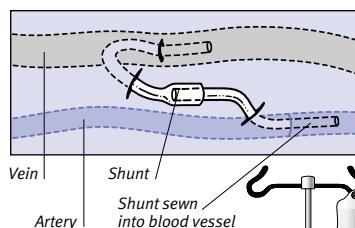

assistance is to remind the doctor of the full range of possible diagnoses for a particular set of symptoms, thereby making it less likely that any possibility will be overlooked. It remains the task of the doctor to integrate the facts and decide upon a diagnosis.

PROCEDURE FOR DIALYSIS

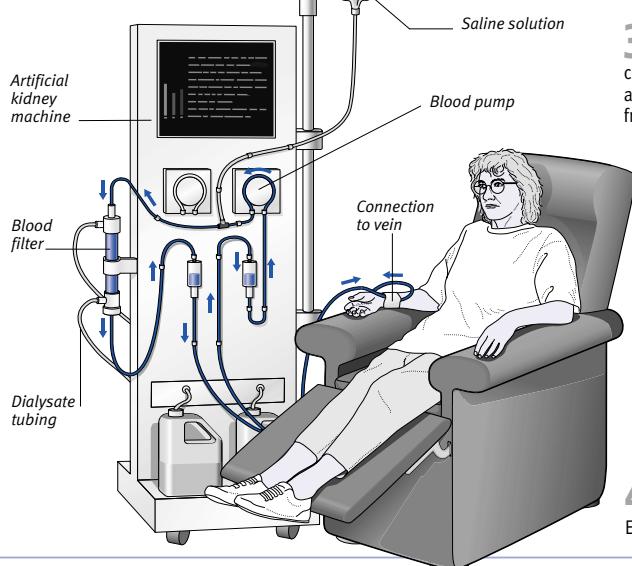

There are two methods of removing wastes from the blood and excess fluid from the body when the kidneys have failed. The first, haemodialysis, may also be used as emergency treatment in some cases of poisoning or drug overdose. It makes use of an artificial kidney (or "kidney machine") and can be carried out at home. Peritoneal dialysis needs an abdominal incision, which is performed in hospital but may also be done at home.

HOW HAEMODIALYSIS IS DONE

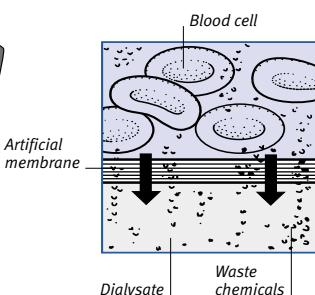

1 Access to the bloodstream for dialysis is obtained by a shunt (in the short term or in an emergency) or an arteriovenous fistula, in which an artery is joined surgically to a vein.

2 A needle inserted into the shunt or fistula carries blood to the machine. The machine pumps the blood through a filter attached to its side. Once inside the filter, the blood flows on one side of a membrane, and dialysate fluid flows on the other. Waste products and water pass from the blood, across the membrane, and into the dialysate fluid. The filtered blood returns from the machine to the body via another needle inserted into the shunt or fistula.

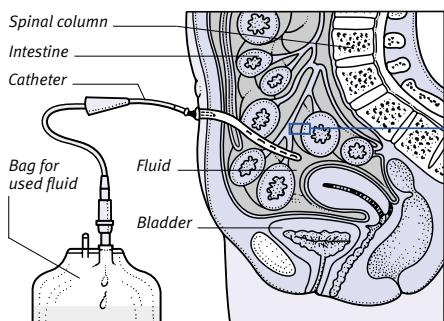

3 The membrane separates the patient's blood from a special fluid called dialysate. Wastes, toxic molecules, and excess fluid pass across the membrane from the blood into the dialysate.

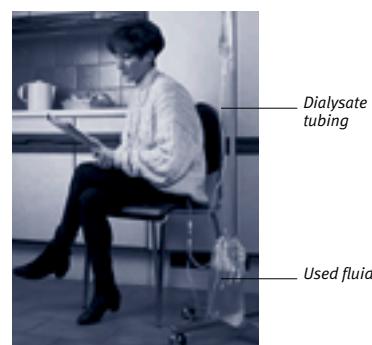

4 The dialysate is discarded and the purified blood returned to the patient. Each session lasts from two to six hours.

HOW PERITONEAL DIALYSIS IS DONE

1 A small abdominal incision is made, and a catheter is inserted into the peritoneal cavity. A bag of dialysate is attached to the catheter; the fluid passes into the cavity, where it is left for several hours. Used fluid is then drained out of the abdomen.

2 Waste products, and excess water from the blood vessels lining the peritoneal cavity, seep through the peritoneal membrane into the cavity and mix with the dialysate. The fluid is allowed to drain out (by the release of a clamp) through the catheter and into the empty dialysate bag.

3 The bag is discarded and replaced with a bag containing fresh dialysate. The procedure, which takes about an hour, can be performed during the day or overnight.

WHY IT IS DONE

In people with damaged kidneys, the process of maintaining the balance of electrolytes and water, and of excreting waste products, may fail, causing harmful, even life-threatening, effects. Dialysis can take over the function of the kidneys until they start working normally again. Or dialysis can function for the kidneys for the rest of a seriously affected person's life if a kidney transplant is not performed.

Diseased kidney

The kidney at left was removed from a person with adult polycystic kidney disease – one of many disorders that may damage kidney function to the extent that dialysis is needed.

have pre-existing diabetes mellitus. Gestational diabetes disappears after the birth, but it is associated with an increased risk of the woman developing Type 2 diabetes in later life.

diabetic retinopathy

See *retinopathy*.

diagnosis

The process of identifying or finding out the nature of a disorder. The doctor listens to a patient's account of his or her illness, and may carry out a physical examination. If further information is needed, tests or imaging procedures may be ordered after a provisional diagnosis has been formed (see *Steps in diagnosing a condition* box, previous page).

diagnostic ultrasound

The use of high-frequency sound waves to form images of internal organs and so help doctors to make diagnoses (see *ultrasound scanning*). Certain forms of ultrasound scanning are used to form moving images, such as images of the flow of blood through the heart (see *Doppler echocardiography*).

dialysis

A filtering technique used to remove waste products from the blood and excess fluid from the body as a treatment for *kidney failure*.

WHY IT IS DONE

Each day, the kidneys normally filter about 1,500 litres of blood. They help to maintain the fluid and *electrolyte* balance of the body. Important minerals and nutrients, such as potassium, sodium, calcium, amino acids, glucose, and water are reabsorbed into the blood. *Urea*, excess minerals, toxins, and drugs are excreted in the urine.

Dialysis is used to perform this function in people whose kidneys have been damaged due to acute or chronic kidney failure. Without dialysis, wastes accumulate in the blood and the electrolyte levels become unbalanced; this may be life-threatening. In chronic kidney failure, patients may need to have dialysis several times a week for the rest of their lives or until they can be given a *kidney transplant*. In acute kidney failure, dialysis is carried out more intensively until the kidneys are working normally.

HOW IT IS DONE

There are two methods: haemodialysis and peritoneal dialysis. In both procedures, excess water and wastes in the

blood pass across a membrane into a solution called a dialysate, which is then discarded.

Haemodialysis filters out wastes by passing blood through an artificial kidney machine. The process needs to be performed three or four times a week, and each session lasts two to six hours. In peritoneal dialysis, the abdominal cavity is filled with dialysate, which is changed regularly, and the *peritoneum* (the membrane lining the abdominal cavity) acts as a natural filter. The procedure is often carried out overnight or continuously during the day and night.

RISKS

Both types of dialysis carry the risk of upsetting body chemistry and fluid balance, which can cause complications. In addition, peritoneal dialysis carries a risk of infection in the peritoneum.

diamorphine

A synthetic, opioid *analgesic* similar to *morphine*; diamorphine is another name for *heroin*. It is used to relieve severe pain and to relieve distress in acute *heart failure*. Diamorphine carries the risk of dependence. It may cause nausea, vomiting, and constipation. (See also *heroin abuse*.)

Dianette

A brand name for a combination of *ciproterone acetate* with *ethynodiol diacetate* (synthetic sex hormones). Dianette may be used to treat severe *acne* or *hirsutism* (excessive hairiness) in women.

diaphragmatic hernia

The protrusion of an abdominal structure through the *diaphragm muscle* into the thorax (chest cavity). The most common form of this problem is a *hiatus hernia*, in which part of the stomach protrudes through the space in the diaphragm that is normally occupied by the *oesophagus*.

diaphragm, contraceptive

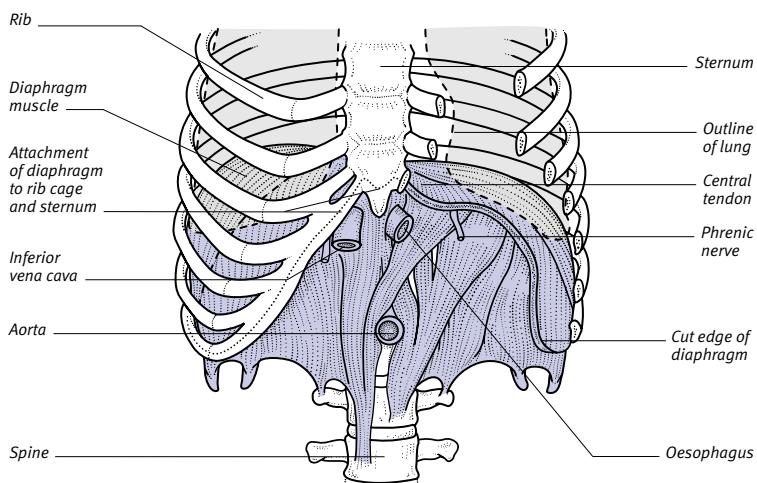

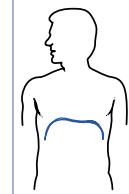

A female barrier method of contraception in the form of a hemispherical dome of thin rubber with a metal spring in the rim. The diaphragm is inserted into the vagina and positioned over the cervix. (See also *contraception, barrier methods*.)

diaphragm muscle

The dome-shaped sheet of muscle that separates the chest from the abdomen. The diaphragm is attached to the spine,

ANATOMY OF THE DIAPHRAGM

The diaphragm is attached to the spine, the lower pairs of ribs, and the lower end of the sternum (breastbone). Its muscle fibres converge on the central tendon, which is a thick, flat plate of dense fibres. There are openings in the diaphragm for the oesophagus, the phrenic nerve (which controls diaphragm movements and hence breathing), and the aorta and vena cava (the body's main blood vessels).

ribs, and sternum (breastbone). It has openings for the oesophagus and major nerves and blood vessels.

The diaphragm plays an important role in breathing. During inhalation, its muscle fibres contract, causing it to move downwards and drawing air into the lungs. During exhalation, the diaphragm muscle relaxes and it moves upwards, causing air to leave the lungs. (See also *breathing*.)

diaphysis

The shaft, or central portion, of a long bone, such as the *femur* (thigh-bone). During bone formation, the *epiphysis* (end of the long bone) develops independently from the diaphysis, as they are initially separated by a mass of cartilage known as the epiphyseal plate. The diaphysis and epiphysis eventually fuse to form a complete bone.

diarrhoea

An increase in the fluidity, frequency, or volume of bowel movements, as compared to the usual pattern for a particular individual. Diarrhoea may be acute or chronic. The condition can be very serious in infants and in elderly people because of the risk of severe, potentially fatal, *dehydration*.

CAUSES

Acute diarrhoea is usually a result of consuming food or water contaminated with certain bacteria or viruses (see *food poisoning*). Infective *gastroenteritis* also causes diarrhoea and may be acquired as a result of droplet infection. Other causes of acute diarrhoea include anxiety and, less commonly, *amoebiasis*, *shigellosis*, *typhoid fever* and *paratyphoid fever*, drug toxicity, *food allergy*, and *food intolerance*.

Chronic diarrhoea generally takes the form of repeated attacks of acute diarrhoea. Such a pattern may be the result of an intestinal disorder such as *Crohn's disease*, *ulcerative colitis*, cancer of the colon (see *colon, cancer of*), or *irritable bowel syndrome*. Diarrhoea that recurs, persists for more than a week, or is accompanied by blood requires medical investigation.

TREATMENT

The water and electrolytes (salts) lost during a severe attack of diarrhoea need to be replaced to prevent dehydration. Ready-prepared powders of electrolyte mixtures can be bought from chemists (see *rehydration therapy*). *Antidiarrhoeal drugs*, such as *diphenoxylate* and *loperamide* may help if the diarrhoea is disabling. They should not, however, be used to treat attacks of diarrhoea in children.

late and *loperamide* may help if the diarrhoea is disabling. They should not, however, be used to treat attacks of diarrhoea in children.

diastole

The period in the heartbeat cycle when the heart muscle is at rest; it alternates with *systole*, the period of muscular contraction. (See also *cardiac cycle*.)

diastolic pressure

The lowest level of *blood pressure* measured in the main arteries. Diastolic pressure is the pressure between heartbeats, when the *ventricles* (the lower chambers of the heart) are relaxed and filling with blood. Systolic pressure, the highest level of blood pressure in the main arteries, occurs when the ventricles of the heart contract.

The normal range of blood pressure varies with age and between individuals, but a young adult usually has a diastolic pressure of about 80 mmHg (mm of mercury) and a systolic pressure of about 120 mmHg. A persistently high diastolic pressure occurs in most cases of *hypertension*.

diathermy

The production of heat in a part of the body using high-frequency electric currents or microwaves. Diathermy can be used to increase blood flow and to reduce some types of deep-seated pain, for example in rheumatic or arthritic conditions. Diathermy can also be used to destroy tumours and diseased areas of tissue without causing bleeding. A diathermy knife is used by surgeons to coagulate bleeding vessels or to separate tissues without causing them to bleed (see *electrocoagulation*).

diathermy, short-wave

See *short-wave diathermy*.

diathesis

A predisposition towards certain disorders. For example, a bleeding diathesis is present when a *bleeding disorder* (such as haemophilia) makes a person susceptible to prolonged bleeding after an injury. A diathesis may be inherited or it may be acquired as a result of an illness or an injury.

diazepam

One of the *benzodiazepine drugs*, used mainly for the short-term treatment of *anxiety* and *insomnia*. Diazepam is also

prescribed as a *muscle-relaxant drug*, as an *anticonvulsant drug* in the emergency treatment of *epilepsy*, and to treat alcohol withdrawal symptoms in people who are dependent on alcohol. It may also be administered intravenously in order to produce sedation in people undergoing certain medical procedures, such as *endoscopy*.

Diazepam may cause drowsiness, dizziness, and confusion; therefore, driving and hazardous work should be avoided while taking the drug. Alcohol increases the sedative effects of the drug, and should not be consumed while diazepam is being used.

Like other benzodiazepines, diazepam can be habit-forming if it is taken regularly, and its effects diminish with prolonged use. Individuals who have been taking diazepam regularly for more than two weeks should never stop their treatment suddenly; instead, they should gradually decrease the dose of the drug, under medical supervision, in order to avoid withdrawal symptoms (such as anxiety, sweating, or, rarely, after large doses, *seizures*).

DIC

See *disseminated intravascular coagulation*.

diclofenac

A *nonsteroidal anti-inflammatory drug* (NSAID) that is used to relieve pain and stiffness in *arthritis* and to hasten recovery following injury to muscles or ligaments. Possible adverse effects of the drug include nausea, abdominal pain, and peptic ulcer.

Didronel

A brand name for disodium etidronate (see *etidronate, disodium*), which is a *bisphosphonate drug*. Didronel is used to treat bone disorders such as *Paget's disease* and *osteoporosis*.

diet

See *nutrition*.

diet and disease

A variety of diseases are linked with diet. Diseases due to a deficiency of *nutrients* are a major problem in poor countries. In children, starvation or malnutrition may result in *marasmus* or *kwashiorkor*, while vitamin deficiencies may cause *rickets* or *keratomalacia* (a condition that causes blindness). Vitamin deficiencies may lead to *beriberi*, *pellagra*, or *scurvy*.

GOOD DIETARY HABITS

- Eat fresh rather than preserved, packaged, or convenience foods.
- Eat plenty of vegetables and at least five portions of fruit every day. When raw or lightly cooked, they retain a higher nutritional value.
- Eat whole-grain products, including wholemeal bread.
- Cut down consumption of red meat; instead, eat fish, poultry, and pulses.
- Keep the fat content of your diet low and use polyunsaturated fats and vegetable oils rather than saturated fats.
- Cut down on sugar and salt in all foods.
- When choosing filling foods, eat potatoes in their skins, pasta, or rice.

In affluent countries, diseases due to deficiency are rare, occurring only in certain groups of people (such as alcoholics). Instead, many disorders are due at least partly to overconsumption of food. Overeating causes weight gain and, in severe cases, *obesity*. The latter condition places a person at increased risk of disorders such as *diabetes mellitus*, *stroke*, *coronary artery disease*, and *osteoarthritis*. Diets causing weight gain tend to be high in fats and sugar, but may be low in valuable components such as fibre and vitamins.

FATS

A diet that is high in fats, particularly saturated fats (see *fats and oils*), may contribute to *atherosclerosis* (narrowing of the arteries due to accumulation of fatty deposits on the arterial walls); this, in turn, may lead to cardiovascular diseases such as coronary artery disease, stroke, and peripheral vascular disease. A high-fat diet has also been linked with cancer of the bowel (see *colon*, *cancer of*) and *breast cancer*.

ALCOHOL

Overconsumption of *alcohol* can lead to *alcohol-related disorders*. In the digestive system, it may cause *cirrhosis* of the liver, *pancreatitis*, and oesophageal cancer (see *oesophagus*, *cancer of*); in addition, people who are dependent on alcohol often become malnourished. Drinking too much alcohol may cause cardiovascular problems such as *hypertension*.

(high blood pressure) and *heart failure*; neurological disorders such as *Wernicke–Korsakoff syndrome*; and mental or behavioural problems such as *depression* or violence.

SALT

A high salt intake may predispose a person to hypertension.

FIBRE

Fibre, found in fruit, vegetables, and grains, provides bulk, which helps the passage of food through the intestine and also aids the absorption of nutrients (see *fibre*, *dietary*). A lack of fibre is thought to be a contributory factor in digestive disorders such as *diverticular disease* (a condition in which abnormal pouches form in the colon), chronic *constipation*, and *haemorrhoids*.

VITAMINS

Many people's diets contain too few natural vitamins; to remedy this problem, it is better to eat vitamin-rich foods than to take vitamin supplements. Women who are planning a pregnancy need to increase their intake of *folic acid* in order to reduce the risk of *neural tube defects* in the baby.

FOOD ALLERGIES

Many illnesses are commonly ascribed to *food allergy*, but it is only rarely that a definite link is proved. Nut allergies, which may cause the life-threatening reaction *anaphylaxis*, and *coeliac disease* (a reaction to the protein gluten, which is found in wheat and other cereals) are examples of genuine food allergies. (See also *nutritional disorders*.)

dietary amenorrhoea

A form of *amenorrhoea* (cessation of menstruation) caused by major weight loss, although not necessarily by a lack of food. In some cases, the weight loss is deliberate and severe (see *anorexia nervosa*). Absence of menstrual periods occurs because the loss of body fat disrupts the levels of the female sex hormone *oestrogen*.

dietary fibre

See *fibre*, *dietary*.

dietetics

The application of nutritional science to maintain or restore health. Dietetics involves not only a knowledge of the composition of foods, the effects of cooking and processing various foods, and dietary requirements, but also of psychological aspects of diet, such as eating habits (see *nutrition*).

diethylstilbestrol

A synthetic form of the female sex hormone *oestrogen*, occasionally used to treat prostate cancer (see *prostate*, *cancer of*) and, in postmenopausal women only, to treat *breast cancer*. Common adverse effects include nausea, *oedema* (fluid retention) and breast enlargement (*gynaecomastia*) in men.

differential diagnosis

One of two or more different disorders that could be the cause of a patient's symptoms. If certain symptoms, such as abdominal pain, might be caused by various disorders, a doctor will carry out further tests, observe the patient's response to particular treatments, or monitor the course of the disease in order to arrive at the true diagnosis.

differentiation

The process by which the cells of the early *embryo*, which are almost identical and have not yet taken on any particular function, gradually diversify to form the distinct tissues and organs of the more developed embryo.

The word "differentiation" is also used in the assessment of cancer; it means the degree to which the microscopic appearance of cancerous tissue resembles normal tissue.

diffusion

The spread of a substance (by movement of its molecules) in a fluid from an area of high concentration to one of lower concentration, thus producing a uniform concentration throughout.

diflunisal

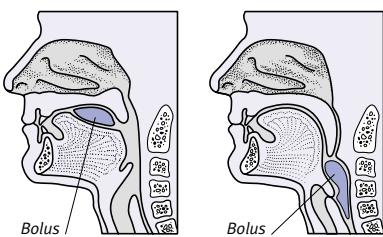

A *nonsteroidal anti-inflammatory drug* (NSAID) used to relieve joint pain and stiffness in types of *arthritis*. The drug is also given for back pain, sprains, and strains. Side effects include nausea, diarrhoea, and a rash.

DiGeorge syndrome

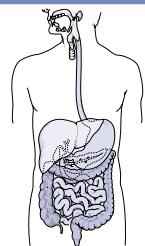

An *immunodeficiency disorder* that results in a failure of the *immune system*'s cells to fight infection. The disorder is hereditary and congenital (present at birth). In DiGeorge syndrome, the *thymus* gland is absent or fails to develop normally. The thymus is a key part of the immune system, so its absence may allow persistent, serious infections to develop. Children with DiGeorge syndrome are susceptible to *opportunistic infections*, such as *candidiasis* (thrush),

THE DIGESTIVE PROCESS

Digestion starts when food enters the mouth. It continues as the food is propelled through the digestive tract by waves of muscular contractions (peristalsis). The digestive process also involves various organs (the salivary glands, liver, gallbladder, and pancreas), which produce enzymes and acids that help to break down the food.

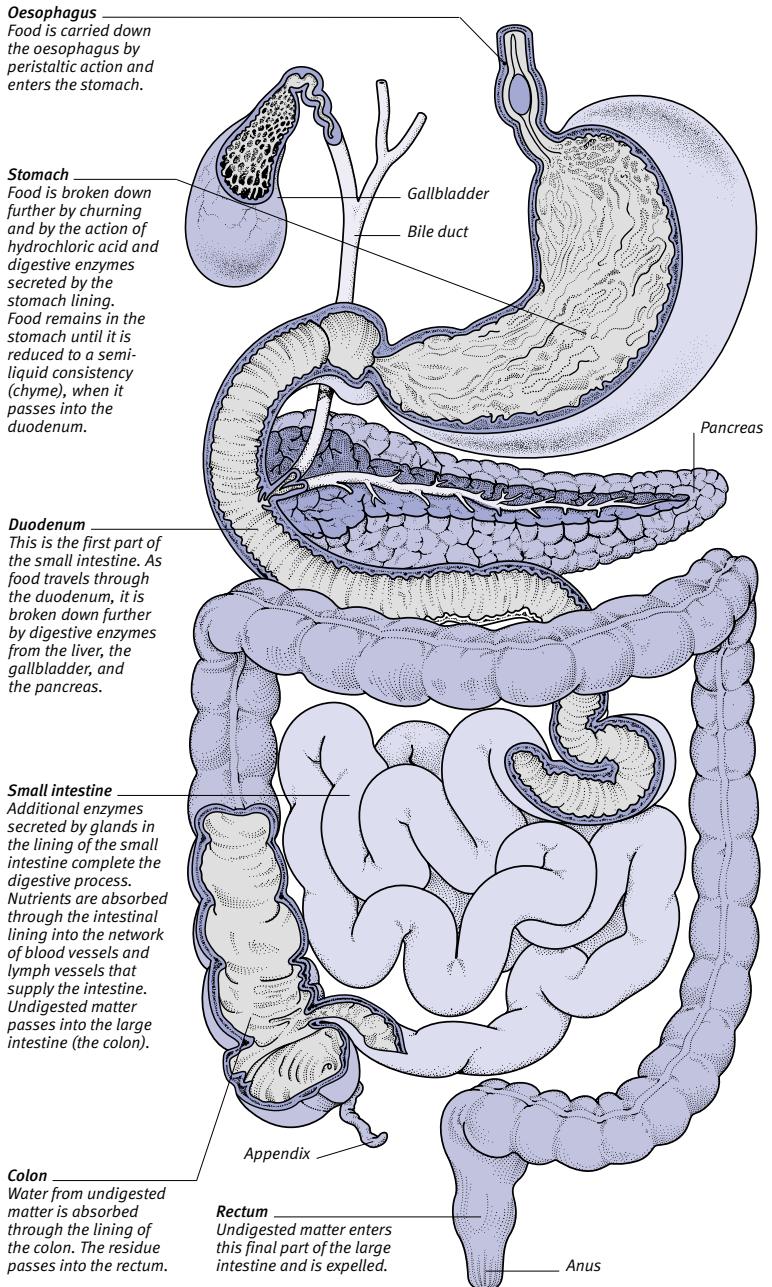

Swallowing
In the mouth, food is cut and ground by the teeth and mixed with saliva, which softens it and breaks down certain carbohydrates. After swallowing, the food mass (bolus) enters the oesophagus.

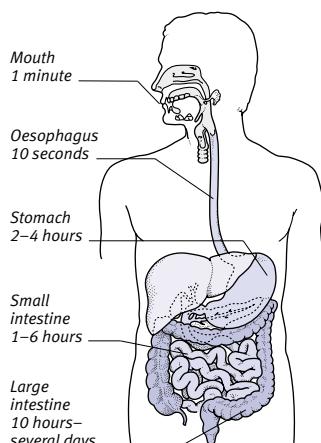

ACTION OF DIGESTIVE AGENTS

Agent or enzyme (where produced)	Digestive action
Amylase (mouth and pancreas)	Converts starch (a carbohydrate) to maltose
Sucrase, maltase, and lactase (pancreas and small intestine)	Break down vegetable and milk sugars into glucose, fructose, and galactose
Hydrochloric acid (stomach), Pepsin (stomach), Trypsin (pancreas), Peptidase (small intestine)	Assist in the breakdown of proteins into polypeptides, peptides, and amino acids
Lipase (pancreas) Bile salts and acids (liver – stored in the gallbladder)	Break down fats into glycerol and fatty acids

TIME SCALE

The approximate period food spends in each part of the digestive system is shown below.

and there may be evidence of failure to thrive (restricted growth). In addition, heart abnormalities and *hypocalcaemia* (abnormally low levels of calcium in the blood) may occur.

Transplants of thymus tissue, or *bone marrow transplants*, may be successful in treating the immunodeficiency.

digestion

The process by which food is broken down into smaller components that can be transported and used by the body. (See also *digestive system*).

digestive system

The group of organs responsible for *digestion*. The digestive system consists of the digestive tract (also known as the alimentary tract or canal) and various associated organs.

STRUCTURE

The *mouth*, *pharynx* (throat), *oesophagus* (gullet), *stomach*, *intestines*, and *anus* make up the digestive tract. The intestines consist of the small intestine (comprising the *duodenum*, *jejunum*, and *ileum*) and the large intestine (comprising the *caecum*, *colon*, and *rectum*). Associated organs, such as the *salivary glands*, the *liver*, and *pancreas*, secrete digestive juices that help break down food as it goes through the tract.

FUNCTION

Food and the products of digestion are moved from the throat to the rectum by *peristalsis* (waves of muscular contractions of the intestinal wall).

Food is broken down into simpler substances before being absorbed into the bloodstream. Physical breakdown is performed by the teeth, which cut and chew, and the stomach, which churns the food. Chemical breakdown of food is performed by the action of *enzymes* (biological catalysts), acids, and salts. *Carbohydrates* are broken down into simple sugars. *Proteins* are broken down into *polypeptides*, *peptides*, and *amino acids*. *Fats* are broken down into *glycerol*, *glycerides*, and *fatty acids*.

In the mouth, saliva lubricates food and contains enzymes that begin to break down carbohydrates. The tongue moulds food into balls (called *boli*) for easy swallowing. The food then passes into the pharynx, from where it is pushed into the oesophagus and is then squeezed down into the stomach. Once in the stomach, the food is mixed with hydrochloric acid and pepsin. These substances, produced by the stomach

lining, help to break down proteins. When the food has been converted to a semi-liquid consistency, it passes into the duodenum, where bile salts and acids (produced by the liver) help to break down the fats it contains. Digestive juices released by the pancreas into the duodenum contain enzymes that further break down food.

Breakdown concludes in the small intestine, carried out by enzymes that are produced by glands in the intestinal lining. Nutrients are absorbed in the small intestine through tiny projections from the intestinal wall, called *villi*. The food residue enters the large intestine, where much of the water it contains is absorbed by the lining of the colon. Undigested matter is expelled via the rectum and anus as *faeces*.

digit

A division, such as a *finger* or *toe*, that is located at the end of a limb.

digitalis drugs

A group of drugs that are extracted from plants belonging to the foxglove family. They are used to treat heart conditions, most commonly *atrial fibrillation* (irregular, rapid beating of the upper chambers of the heart). Those most frequently used are *digitoxin* and *digoxin*.

digital subtraction angiography

See *angiography*.

digitoxin

A long-acting *digitalis drug* that is used to treat *heart failure* and certain types of *arrhythmia* (irregular heartbeat).

digoxin

The most widely used of the *digitalis drugs*. Digoxin is used in the treatment of *heart failure* and certain types of *arrhythmia* (irregular heartbeat), such as *atrial fibrillation*.

Blood tests are sometimes needed to ensure the correct digoxin dose, especially in patients with kidney disease. An excessive dose may cause headache, loss of appetite, nausea and vomiting, and visual disturbances. Digoxin occasionally disrupts the normal heartbeat, causing *heart block*.

Di Guglielmo's disease

A form of acute myeloblastic leukaemia (see *leukaemia, acute*) characterized by excessive numbers of red blood cells in the bone marrow and bloodstream.

dihydrocodeine

A type of opioid *analgesic drug* (pain-killer). Side effects of dihydrocodeine include nausea and vomiting.

dilatation

A condition in which a body cavity, passage, or opening is enlarged or stretched due to normal physiological processes (such as *childbirth*) or because of the effects of disease.

The term "dilatation" also refers to medical procedures for achieving such enlargement, as in dilatation and curettage (see *D and C*).

dilatation and curettage

See *D and C*.

dilation

A term that is sometimes used as an alternative to *dilatation*.

dilator

An instrument used for stretching and enlarging a narrowed body cavity, passage, or opening, for example to enable an investigative procedure or surgery.

diltiazem

A *calcium channel blocker* drug that is used in the treatment of *hypertension* (high blood pressure) and *angina pectoris* (chest pain due to impaired blood supply to the heart muscle). Side effects of diltiazem may include headaches, loss of appetite, nausea, constipation, and swollen ankles.

dimeticone

A silicone-based substance, also known as simeticone, that is used in *barrier creams* and as an antifoaming agent in *antacid* preparations.

dioptre

A unit of the power of *refraction* (the "strength") of a lens; the greater the power, the stronger the lens. Lenses that cause parallel light rays to converge have a positive dioptic number and are used to correct longsightedness (see *hypermetropia*). Those that cause light rays to diverge have a negative number and are used to correct shortsightedness (see *myopia*).

dioxin

The name of a highly toxic group of chemicals. Dioxins are contaminants of some defoliant weedkillers (see *defoliant poisoning; Agent Orange*).

diphenhydramine

An *antihistamine drug* that is used to treat allergic disorders such as *urticaria* (nettle rash) and allergic *rhinitis* (hay fever). Diphenhydramine is also used for the relief of temporary sleep disturbance, and is an ingredient in some *cough remedies*. It can cause drowsiness, dry mouth, and blurred vision.

diphenoxylate

An *antidiarrhoeal drug* that is chemically related to the opioid *analgesic drugs* (painkillers). Diphenoxylate lessens the contractions of the muscles in the walls of the intestines, thereby reducing the frequency of bowel movements.

diphtheria

A bacterial infection that causes a sore throat, fever, and sometimes serious or even fatal complications. Diphtheria is caused by the bacillus *CORYNEBACTERIUM DIPHTHERIAE*. The disease is now rare in developed countries as a result of mass *immunization*. In the UK, the vaccine is given at 2, 3, and 4 months, 3–5 years, and 13–18 years of age.

SYMPOTMS

The infection may begin in the throat or in the skin. In the throat, multiplication of bacteria causes the formation of a membrane that may cover the tonsils and spread up over the palate or down to the larynx (voicebox) and the trachea (windpipe), causing *breathing difficulty* and a husky voice. Other symptoms include enlarged *lymph nodes* in the neck, an increased heart rate, and mild fever. If infection is confined to the skin, the bacteria may produce a yellowish lesion covered by a hard membrane.

Life-threatening symptoms occur only in people who are not immune to the disease. They are caused by a toxin that is released by the bacteria and affects the heart and nervous system. Occasionally, a victim collapses and dies within a day of developing throat symptoms. More often, the victim is recovering from diphtheria when *heart failure* or paralysis of the throat or limbs develops. These complications can occur up to seven weeks after the onset of infection in the throat.

TREATMENT

Diphtheria is treated with antibiotics; in addition, an antitoxin is given to neutralize the bacterial toxin. If severe breathing difficulties develop, a *tracheostomy* (the surgical introduction of a breathing tube into the windpipe) may also be necessary.

diplegia

Paralysis affecting both sides of the body (both legs and, to a lesser extent, both arms). (See also *spastic diplegia*.)

diplopia

The medical term that is used to describe *double vision*.

dipsomania

A form of *alcohol dependence* in which periods of excessive drinking and craving for drink alternate with periods of relative sobriety.

dipyridamole

A drug that reduces the stickiness of platelets in the *blood* and thereby helps to prevent the formation of abnormal blood clots within arteries. Dipyridamole may be used with *aspirin* or *warfarin* to prevent the formation of blood clots following *stroke* or *transient ischaemic attack* or in people who have artificial heart valves.

Possible adverse effects may include headache, flushing, and dizziness.

disability

A loss or impairment of normal functioning or activity as the result of a physical or mental impediment. (See also *handicap*; *rehabilitation*.)

disaccharide

A *carbohydrate* comprising two linked *monosaccharide* units. Lactose, maltose, and sucrose are all disaccharides.

disectomy

A procedure in which part or all of a damaged intervertebral disc (see *disc, intervertebral*) is surgically removed. Disectomy relieves the symptoms of *disc prolapse* (in which an intervertebral disc ruptures and part of its pulpy core protrudes) by relieving the pressure that the protruding tissue places on nerves or nerve roots.

discharge

A visible emission of fluid from an orifice or a break in the skin (such as a wound or burst boil). A discharge may be a normal occurrence, as in some types of *vaginal discharge*, but it could also be due to an infection or to inflammation, as occurs, for example, in *rhinitis* (inflammation of the lining of the nasal passages), *urethritis* (infection of the urethra), or in *proctitis* (infection of the rectum).

disciformis, keratitis

A form of *keratitis* (inflammation of the cornea at the front of the eye) in which a disc-like opacity forms in the corneal tissue, usually as an *immune response* to a viral infection.

disc, intervertebral

One of the flat, circular, platelike structures containing *cartilage* that line the joints between adjacent *vertebrae* (bones) in the *spine*. Each intervertebral disc is composed of a fibrous outer layer and a soft, gelatinous core. The discs act as shock absorbers to cushion the vertebrae during movements of the spine. With increasing age, intervertebral discs become less supple and more susceptible to damage from injury; one of the most common problems is *disc prolapse* ("slipped" disc).

disclosing agents

Dyes that make the *plaque* deposits on teeth more visible so that they can be seen and removed.

discoid lupus erythematosus

A form of the chronic autoimmune disorder *lupus erythematosus* that is confined to the skin. It causes a red, itchy, scaly rash to appear, particularly on the face and scalp, behind the ears, and on any parts of the body that are exposed to sunlight. The disorder most commonly occurs in women between the ages of 25 and 45, and tends to run in families. Over a period of several years, discoid lupus erythematosus may subside and recur repeatedly with different degrees of severity. Diagnosis is by a *skin biopsy*, and treatment is with topical corticosteroid drugs or drugs such as hydroxychloroquine.

discoloured teeth

Teeth vary in colour from individual to individual and, in general, secondary teeth are darker in colour than primary teeth. In addition, teeth often get darker with age. The term discoloured teeth, however, refers to teeth that are abnormally coloured or stained.

EXTRINSIC STAINS

Extrinsic stains (those found on the tooth's surface) are common. They are usually easily removed by polishing and can be prevented by regular tooth cleaning. Smoking tobacco produces a brownish-black deposit on the teeth. Pigment-producing bacteria can leave a visible, usually green, line along the

teeth, especially in children. Some dyes in foodstuffs can cause yellowing; dark brown spots may be due to areas of thinned enamel stained by foods. Some bacteria produce an orange-red stain. Stains may also follow the use of drugs containing metallic salts.

INTRINSIC STAINS

Intrinsic stains (within the tooth's substance) are permanent, but they can be reduced by *bleaching*. Causes include the death of the pulp inside the tooth or the removal of the pulp during *root-canal treatment*. The antibiotic drug *tetracycline* can be absorbed by developing teeth, and may cause yellowing of the teeth if given to children.

Mottling of the tooth enamel occurs if excessive amounts of fluoride are consumed during development of the enamel (see *fluorosis*). *Hepatitis* (liver disease) during infancy may lead to

discoloration of the primary teeth. The teeth of children with *congenital* malformation of the *bile ducts* may be similarly affected.

TREATMENT

Many stains can be covered or diminished with whitening toothpastes or with cosmetic dental procedures such as *bonding* and bleaching.

disc, optic

See *optic disc*.

disc prolapse

A common disorder of the *spine*, in which one of the pads between the vertebrae (see *disc, intervertebral*) ruptures and part of its pulpy core protrudes. Commonly known as a slipped disc, it causes painful and at times disabling pressure on a nerve root or, less commonly, on the spinal cord. The lower

back is most commonly affected, but disc prolapse can affect any of the vertebrae, including those in the neck.

CAUSES

A prolapsed disc may sometimes be caused by a sudden strenuous action (such as lifting a heavy weight), but it usually develops gradually, due to degeneration of the discs with age.

SYMPTOMS

Symptoms depend on the location of the affected disc. If the sciatic nerve root is compressed, it causes *sciatica*, which may be accompanied by numbness and tingling, and, eventually, by weakness in the muscles of the leg. A prolapsed disc in the neck causes neck pain and stiffness and weakness in the arm and hand.

TREATMENT

The symptoms of disc prolapse often improve with time, as the swelling around the protruding disc tissue

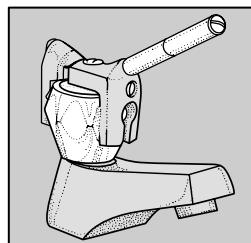

PHYSICAL AIDS FOR THE DISABLED

A variety of specially designed or adapted articles are available to help disabled people carry out everyday activities. Such aids include prostheses, supports, and mobility aids to improve disabled people's general functioning, as well as items designed to help them perform specific tasks more easily.

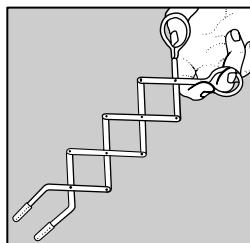

Devices that help vision, hearing, and movement improve the ability of disabled people to cope with all aspects of daily life. Such devices include walking frames, glasses, hearing-

aids, artificial limbs, corsets, and wheelchairs. For people with very severe conditions, ventilators, home dialysis, and artificial feeding devices are used to sustain life.

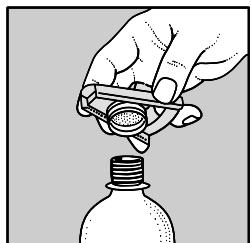

There are various household aids available that can help people to cook, feed themselves, wash, dress, use the toilet, and get in and out of beds and chairs. Specially designed furniture and other devices can help disabled parents to care for their children. Sexual aids can facilitate an active sex life.

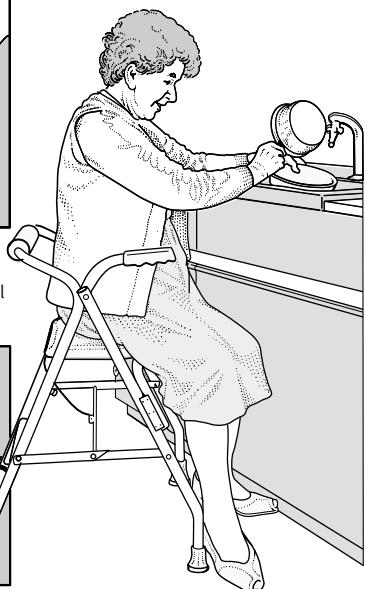

Tap turner
A device that helps with gripping and turning taps.

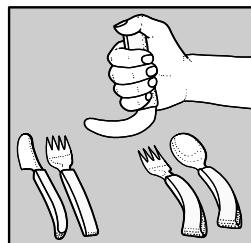

Tongs
Extending tongs to pick up dropped items. The tongs close up to fit in a pocket or handbag.

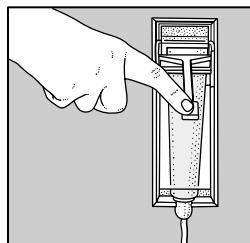

Bottle opener
A small hand-held device designed to grip and open small bottle tops.

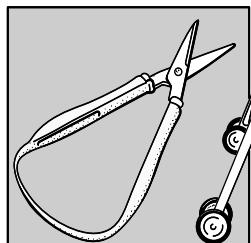

"A" frame
A lightweight walking frame that doubles as a seat and can be folded flat.

Cutlery
A range of knives, forks, and spoons with thick, moulded handles for easy manipulation.

Toothpaste extruder
A wall-mounted device that dispenses toothpaste with minimal finger pressure.

Scissors
Self-opening scissors with easy-grip handles.

SYMPTOMS AND TREATMENT OF DISC PROLAPSE

A prolapsed disc in the lower back causes low back pain and, if a sciatic nerve root is compressed, *sciatica* (pain running down the back of the leg from the buttock to the ankle), sometimes accompanied by numbness and tingling. Low back pain and sciatica are usually aggravated by coughing, sneezing, bending, and sitting for long periods. Prolonged pressure on the sciatic nerve can lead to weakness in the muscles of the leg.

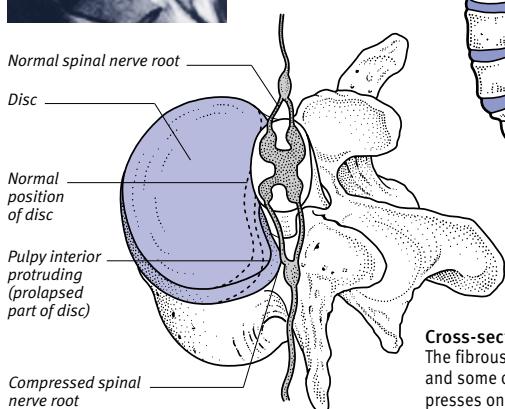

A prolapsed disc in the neck causes neck pain and stiffness. If the disc compresses the root of a nerve that supplies the arm, there will be tingling and weakness in that arm and hand.

In rare cases, pressure is exerted on the spinal cord itself, sometimes leading to paralysis of the legs and loss of bladder or bowel control.

Before treatment
This MRI scan of the lower back shows a prolapse of the disc between the fifth lumbar vertebra and the first fused vertebra of the sacrum.

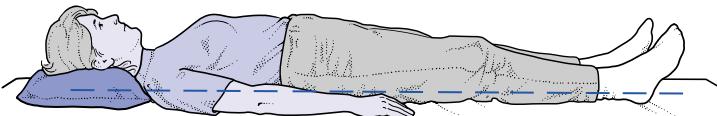

Prolapse

Cross-section of a prolapsed disc
The fibrous outer layer of the disc is ruptured, and some of its pulpy interior protrudes and presses on a spinal nerve root.

TREATMENT

Disc prolapse often responds to analgesics, and special exercises (see *physiotherapy*) are helpful. Patients are usually advised to be as mobile as possible. For resting or sleep, they should lie flat on a firm mattress, with the head supported and the shoulders, hips, and ankles aligned to ease pressure on the spine. If these measures fail and nerve root compression is causing muscle weakness, an operation may relieve the pressure (see *discectomy; decompression, spinal canal*).

subsides. In the meantime, painkillers are often needed. In severe cases, surgical techniques, such as the removal of part of the vertebra (see *decompression, spinal canal*) or removal of the protruding material and repair of the disc (see *discectomy*), may be used.

disc, slipped

See *disc prolapse*.

disease

Illness or abnormal functioning of a body part or parts due to a specific cause, such as an infection, and identifiable by certain *symptoms* and *signs*.

disease-modifying antirheumatic drugs

A group of *antirheumatic drugs*, known as DMARDs, that are used in the treatment of *rheumatoid arthritis*. Certain *antimalarial drugs*, *anticancer drugs*, and *immunosuppressant drugs* are used for this purpose. Examples of DMARDs are *sulfasalazine*, *chloroquine*, *methotrexate*, *gold compounds* (for example *auranofin*), and *penicillamine*.

DMARDs not only improve the symptoms and signs of inflammatory joint disease, but they also slow the course of the illness. (In contrast, *nonsteroidal anti-inflammatory drugs* relieve symptoms but do not alter the progress of the disease.) Some DMARDs are cytotoxic, which means that they kill rapidly dividing cells. Gold compounds and penicillamine may impede the *immune system* from producing specialized proteins called antibodies (see *antibody*) that contribute towards damage to joints. Sulfasalazine interferes with a variety of inflammatory processes in the body, and chloroquine suppresses the effects of arthritis.

In general, DMARDs may need to be used for several months before the full effects are felt. For this reason, many specialists recommend starting therapy early to prevent or delay the progression of joint damage. Treatment with a combination of DMARDs may be more effective than a single drug, and may enable lower doses of each drug to be used, reducing the risk of adverse effects.

Possible side effects depend on the drug taken. They include diarrhoea, rash, *anaemia* (a reduced level of the oxygen-carrying pigment *haemoglobin* in the blood), *leukopenia* (a low white blood cell count), and increased susceptibility to infection. Regular *blood*

tests and urine tests (see *urinalysis*) are needed during treatment to monitor the effects of DMARDs on the bone marrow, kidneys, and liver.

disinfectants

Substances that kill microorganisms and thus prevent infection. The term is usually applied to strong chemicals that are used to decontaminate objects, such as items of medical equipment.

dislocation, joint

Complete displacement of the two bones in a joint so that they are no longer in contact, usually as a result of injury. (Displacement that leaves the bones in partial contact is called *subluxation*.) It is usually accompanied by tearing of the joint ligaments and damage to the membrane encasing the joint.

SYMPOTMS AND COMPLICATIONS

Dislocation restricts or prevents the movement of the joint; it is usually very painful. The affected joint looks misshapen and swells. Injuries that are severe enough to cause dislocation often also cause *fractures*. In some cases, dislocation is followed by complications such as *paralysis*.

TREATMENT

The joint may be X-rayed to confirm dislocation and check for fracture. The bones are then manipulated back into their proper position, or an operation is performed to reset them. The bones are then immobilized in a *splint* or *cast* to allow healing to take place.

disodium etidronate

See *etidronate disodium*.

disopyramide

An *antiarrhythmic drug* that is used to treat an abnormally rapid heartbeat, as may occur after a *myocardial infarction* (heart attack). It reduces the force of heart muscle contraction. As a result, it may aggravate pre-existing *heart failure*. Other possible side effects include dry mouth and constipation.

disorder

Any abnormality of physical or mental function.

disorientation

Confusion as to time, place, or personal identity. Speech and behaviour tend to be muddled, and the affected person often cannot answer questions about time, date, present location, name, or

address. Disorientation is usually due to a *head injury*, *intoxication*, or a chronic brain disorder, such as *dementia*. It may occasionally be due to *somatization disorder* (a psychological illness). (See also *confusion*; *delirium*.)

dispense

To prepare and distribute medicines to a patient according to the details on a doctor's *prescription*.

displacement

The transference of feelings from one object or person to another. Displacement is usually performed consciously to obtain emotional relief in a manner that will not cause harm to oneself or to another person. Some psychotherapists believe that displacement is an unconscious *defence mechanism*.

dissecting aneurysm

An *aneurysm* (ballooning of an artery) that usually affects the first part of the *aorta*. It is caused by a tear in the inner layer of the arterial wall, which results in the inner layer peeling away from the outer layer. This results in blood collecting in the space between the inner and outer layers.

A dissecting aneurysm may rupture or may compress the blood vessels leaving the aorta, producing *infarction* (localized tissue death due to lack of blood supply) in the organs supplied by them. The patient will suffer from severe chest pain that often spreads to the back or the abdomen. Surgical repair may help relieve the symptoms.

dissection

Cutting of body tissues during surgery or for the purpose of anatomical study.

disseminated intravascular coagulation (DIC)

A type of *bleeding disorder* in which abnormal clotting of blood leads to a depletion of coagulation factors in the blood; the consequence may be severe and spontaneous bleeding.

disseminated lupus erythematosis

An alternative name for systemic *lupus erythematosus*.

disseminated tuberculosis

A state in which the infectious disease *tuberculosis* has spread from the site of the original infection to affect several

other parts of the body, either via the *lymphatic system* or in the bloodstream (see *miliary tuberculosis*).

dissociative disorders

A group of psychological conditions in which a particular mental function becomes cut off from the rest of the mind. Examples of dissociative disorders include hysterical amnesia (see *hysteria*), *fugue*, *multiple personality disorder*, and *depersonalization*. (See also *conversion disorder*.)

dissociative reaction

A psychological *defence mechanism* in which a person views unpleasant ideas or events, such as being assaulted, in an unusually detached way in order to protect himself or herself from overwhelming feelings such as fear. In more severe cases, certain mental processes are split off from the rest of a person's mental activity and may function independently (see *dissociative disorders*).

dissonance

A term that is used in social psychology to describe a state that arises when an individual has minimal awareness of any discord, disagreement, or conflict within himself or herself. (See also *cognitive dissonance*.)

distal

A term describing a part of the body that is further away from another part with respect to a central point of reference, such as the trunk. For example, the fingers are distal to the arm. The opposite of distal is *proximal*.

Distalgic

A brand name for *co-proxamol*, an *analgesic drug* containing *paracetamol* and the weak opioid *dextropropoxyphene*.

disulfiram

A drug that acts as a deterrent to drinking *alcohol*. It is prescribed for people who request help in overcoming *alcohol dependence*. Treatment with the drug is usually combined with a counselling programme.

Disulfiram causes a buildup of acetaldehyde in the body, causing flushing, headache, nausea, dizziness, and palpitations. Symptoms may start within 10 minutes of drinking alcohol and can last for several hours. Occasionally, large amounts of alcohol taken during treatment can cause unconsciousness.

dithranol

A drug that is used in the treatment of the skin condition *psoriasis*. Dithranol is prescribed as an ointment, paste, or cream and works by slowing the rate at which skin cells multiply. This effect can be boosted by ultraviolet light treatment (see *phototherapy*). Dithranol can cause skin inflammation.

D

diuretic drugs

Drugs that help to remove excess water from the body by increasing the amount that is lost as *urine*. Diuretic drugs are used in the treatment of a variety of disorders, including *hypertension* (high blood pressure), *heart failure*, the eye condition *glaucoma*, *nephrotic syndrome* (a kidney disorder), and *cirrhosis* of the liver.

TYPES

There are various types of diuretic drug, which differ markedly in their speed and mode of action. Thiazide diuretics cause a moderate increase in urine production. Loop diuretic drugs are fast-acting, powerful drugs that are

often used as an emergency treatment for heart failure. Potassium-sparing diuretics are used along with thiazide and loop diuretics, both of which may cause the body to lose too much potassium. Carbonic anhydrase inhibitors block the action of the enzyme carbonic anhydrase, which affects the amount of bicarbonate ions in the blood; these drugs increase urine output moderately but are effective only for short periods of time. Osmotic diuretics are used to maintain urine output following serious injury or major surgery.

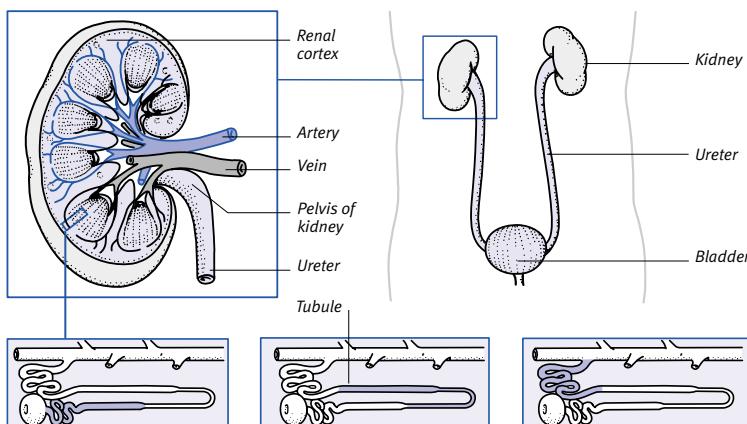

POSSIBLE ADVERSE EFFECTS

Diuretics may cause chemical imbalances in the blood. The most common is hypokalaemia (low blood levels of potassium). This is usually treated with potassium supplements or potassium-sparing diuretic drugs. A diet rich in potassium may also be helpful. Some diuretics raise the blood level of uric acid, which increases the risk of *gout*. Certain diuretic drugs increase the blood glucose level, which may worsen *diabetes mellitus*.

HOW DIURETICS WORK

The normal filtration process of the kidneys (which takes place in the tubules) removes water, salts (mainly potassium and sodium), and waste products from the bloodstream. Most of the salts and water are returned to the bloodstream, but certain amounts are expelled from the body together with the waste products in the urine.

Diuretics interfere with this normal kidney action. Osmotic, loop, and thiazide diuretics reduce the amount of sodium and water taken back into the blood, thus increasing the volume of urine. Modifying filtration in this way reduces the blood's water content. Less water in the blood causes excess water in the tissues to be expelled in urine.

**Osmotic diuretics**

These act on the first part of the tubules to reduce the reabsorption of water into the bloodstream.

Loop diuretics

These drugs take effect on the middle part of the tubules and block sodium and chloride reabsorption.

Thiazide diuretics

This group acts on the last part of the tubules to reduce the reabsorption of sodium into the bloodstream.

diurnal rhythms

A biological pattern that is based on a daily cycle; also called *circadian rhythms*. (See also *biorhythms*.)

diverticula

Small sacs or pouches that protrude externally from the wall of a hollow organ (such as the colon). They are thought to be caused by pressure forcing the lining of the organ through areas of weakness in the wall. Their presence in the walls of the intestines is characteristic of *diverticular disease*.

diverticular disease

The presence of small protruding sacs or pouches called diverticula in the intestinal wall, and the symptoms or complications caused by them. The term *diverticulosis* signifies the presence of diverticula in the intestine. *Diverticulitis* is a complication produced by inflammation in one or more diverticula.

diverticulitis

Inflammation of *diverticula* (abnormal pouches) in the wall of the intestine, particularly in the *colon*. Diverticulitis is a form of *diverticular disease* and a complication of *diverticulosis*.

SYMPTOMS AND COMPLICATIONS

The symptoms include fever, abdominal pain, vomiting, and rigidity of the abdomen. Intestinal haemorrhage may cause bleeding from the rectum.

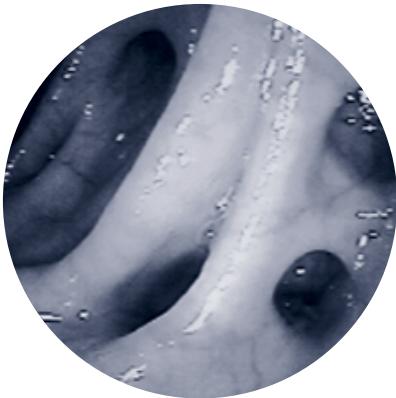

Diverticula may perforate, or abscesses may form in the tissue around the colon, leading to *peritonitis* (inflammation of the lining of the abdomen). Other complications include intestinal bleeding, narrowing in the intestine, or a *fistula* (an abnormal channel between one part of the intestine and another).

TREATMENT

Diverticulitis usually subsides with bed rest and *antibiotics*. In severe cases, a liquid diet or *intravenous infusion* may be required. Surgery may be needed, in which the diseased section of the intestine is removed and the remaining sections are then joined back together. Some patients are given a temporary *colostomy* (an operation in which part of the colon is attached to the abdominal wall to form an opening for the discharge of faeces).

diverticulosis

A form of *diverticular disease* in which *diverticula* (abnormal pouches) exist in the wall of the intestine, particularly in

Diverticulosis of the colon

Diverticula (pouches) are clearly visible in this endoscopic view of the wall of the colon. The condition is thought to be due to a low-fibre diet.

the colon. Complications of diverticulosis may include intestinal bleeding and *diverticulitis*. The cause is believed to be a lack of fibre in the diet (see *fibre, dietary*). Diverticulosis is very rare in developing countries, where high-fibre foods make up much of the diet.

SYMPTOMS

Symptoms occur in only a minority of people who have diverticulosis. They usually result from spasm or cramp of the intestinal muscle near diverticula. Many patients have symptoms similar to those of *irritable bowel syndrome*, including abdominal pain, a bloated sensation, and changes in bowel habits. In severe cases of diverticulosis, intestinal haemorrhage can lead to bleeding from the rectum.

TREATMENT

In people with cramps, a high-fibre diet, fibre supplements, and *antispasmodic drugs* may relieve the symptoms. A high-fibre diet also reduces the incidence of complications. Bleeding from diverticula usually subsides without treatment, but surgery is an option.

diving medicine

See *scuba-diving medicine; decompression sickness*.

Dixarit

A brand name for *clonidine*, an *anti-hypertensive drug* that is also used in the treatment of *migraine* and, in meno-pausal women, *hot flushes*.

dizziness

A sensation of unsteadiness and light-headedness. Dizziness may be a mild, brief symptom that occurs by itself, or

it may be part of a more severe, prolonged attack of *vertigo* (a condition typified by a spinning sensation) with nausea, vomiting, sweating, or fainting.

CAUSES

Most attacks are harmless and are due to a fall in the pressure of blood to the brain. This can occur when getting up quickly from a sitting or lying position (called *postural hypotension*). Similar symptoms may result from a *transient ischaemic attack*, in which there is a temporary, partial blockage in the arteries that supply the brain.

Other possible causes include tiredness, stress, fever, *anaemia*, *heart block* (impairment of electrical activity in the heart muscle), *hypoglycaemia* (low blood sugar levels), and *subdural haemorrhage* (bleeding between the outer two membranes that cover the brain).

Dizziness as part of vertigo is usually due to a disorder of the inner ear, the *acoustic nerve*, or the *brainstem*. The principal disorders of the inner ear that can cause dizziness and vertigo are *labyrinthitis* and *Ménière's disease*. Disorders of the acoustic nerve, such as *acoustic neuroma*, are rare causes of dizziness and vertigo. Brainstem disorders that can cause dizziness and vertigo include a type of *migraine*, *brain tumours*, and *vertebrobasilar insufficiency*.

TREATMENT

Brief episodes of mild dizziness usually clear up after taking a few deep breaths or after resting for a short time.

Severe, prolonged, or recurrent dizziness should be investigated by a doctor. Treatment depends on the underlying cause. For example, certain cases of dizziness and vertigo due to a disorder of the inner ear are treated with *anti-emetic drugs* or *antihistamine drugs*.

dizygotic twins

Nonidentical *twins*, also called fraternal twins. Dizygotic twins are the result of the simultaneous *fertilization* of two egg cells (*ovum*). They each have a *placenta* of their own and may be of different sexes. (See also *monozygotic twins*.)

DLE

Discoid lupus erythematosus.

DMARDs

See *disease-modifying anti-rheumatic drugs*.

DMSA scan

A type of *kidney imaging* technique (see *radionuclide scanning*).

DNA

The abbreviation for deoxyribonucleic acid. DNA is the principal molecule carrying genetic information in almost all organisms; the exceptions are certain viruses that use *RNA*.

DNA is found in the *chromosomes* of cells; its double-helix structure allows the chromosomes to be copied exactly during the process of cell division. A special form of DNA exists in *mitochondria*, the tiny energy-producing structures within cells (see *mitochondrial DNA*). Sections of DNA can also be created artificially (see *recombinant DNA*) during genetic engineering. (See also *meiosis; mitosis; nucleic acids*.)

DNA fingerprinting

See *genetic fingerprinting*.

dobutamine

A drug that is used in the treatment of *heart failure* and *shock*, and sometimes after *cardiac arrest* (a halt in the pumping action of the heart). The drug may be given by intravenous drip.

Dobutamine stimulates nerve cells in the heart to increase the heart rate and raise the blood pressure. For this reason, the drug may be used in a *cardiac stress test* to investigate potential *coronary artery disease* in cases where the patient is unable to exercise on a treadmill (see *exercise ECG*).

doctor

A qualified medical practitioner who is licensed to practise by the appropriate medical authority in his or her country, such as the General Medical Council in the UK.

dogs, diseases from

Infectious or parasitic diseases that are acquired from contact with dogs. They may be caused by viruses, bacteria, fungi, protozoa, worms, insects, or mites living in or on a dog.

Many parasites that live on dogs can be transferred to humans, for example through stroking the dog's fur.

The most serious disease from dogs is the viral infection *rabies*. The UK is free of rabies, but travellers to countries in which rabies exists should treat any dog bite with suspicion. Dog bites can cause serious bleeding and shock and may become infected.

Toxocariasis and *hydatid disease* are potentially serious diseases caused by the ingestion of worm eggs from dogs.

In the tropics, walking barefoot on soil that is contaminated with dog faeces can lead to dog *hookworm infestation*.

Bites from dog *fleas* are an occasional nuisance. *Ticks* and *mites* from dogs, including a canine version of the *scabies* mite, are other common problems. The fungi that cause *tinea* infections in dogs can be caught by humans.

Some people become allergic to animal *dander* (tiny scales from fur or skin). They may, for example, suffer from attacks of *asthma* or *urticaria* (nettle rash) when a dog is in the house. (See also *zoonoses*.)

dominant

A term used in *genetics* to describe the characteristics of a *gene*. Many characteristics are determined by a single pair of genes, one of each pair being inherited from each parent. The dominant gene of the pair overrides its equivalent *recessive* gene, allowing it to be expressed.

For example, the gene for brown eye colour is dominant, so that if a child inherits the gene for brown eyes from one parent and the gene for blue eyes from the other parent, he or she will have brown eyes.

Some genetic disorders are determined by a dominant abnormal gene that overrides the effect of an equivalent normal gene that is recessive. Examples of such disorders include *Marfan syndrome* and *Huntington's disease*. In this case, a child will have the disease if he or she inherits the gene from one or both parents.

dominant characteristic

An inherited characteristic (external or internal physical feature) that appears in offspring even if they have inherited the *gene* for it from only one of their parents. See *dominant*.

dominant gene

See *dominant*.

dominant trait

An inherited *trait* (a characteristic or condition) that appears when just a single copy of the *gene* for that trait is present, as opposed to a *recessive* trait, which only appears when two copies of the appropriate gene are present. *Dominant* genes always mask the presence of recessive genes, and dominant traits can be inherited from one parent alone.

domperidone

An *antiemetic drug* used to relieve nausea and vomiting associated with some gastrointestinal disorders or during treatment with certain drugs or *radiotherapy*. Adverse effects may include breast enlargement and secretion of milk from the breast.

donepezil

An *acetylcholinesterase inhibitor* that is used to treat mild to moderate *dementia* due to *Alzheimer's disease*.

donor

A person who provides blood for *transfusion*; body tissues or organs for *transplantation*; or eggs or semen for *artificial insemination*. The organs that are most frequently donated are kidneys, corneas, heart, lungs, liver, and pancreas. Certain organs can be donated during a person's lifetime; some are only used following *brain death*.

All donors should be free of cancer, serious infection (such as hepatitis B), and should not carry *HIV*. Organs for transplantation must be removed within a few hours of brain death, and before or immediately after the heartbeat has stopped. In some kidney transplants, the kidney is provided by a living donor, usually a relative whose tissues match well on the basis of *tissue-typing*. Tests are performed to ensure that both kidneys are healthy before one is removed.

Suitable related donors may also provide bone marrow for transplantation and sometimes skin for grafting. (See also *blood donation*; *bone marrow transplant*; *organ donation*; *transplant surgery*.)

Doose syndrome

A rare, inherited form of *epilepsy*. The condition is typified by muscular jerking, especially symmetrical jerking of the arms and shoulders and, in severe cases, twitching of the facial muscles. In addition, the affected person may fall to the ground and briefly lose consciousness. Doose syndrome can be treated with *anticonvulsant drugs*.

dopa

An amino acid that the body uses to form *dopamine*, an important neurotransmitter. Dopa is also formed as an intermediate stage when the body makes *epinephrine*, *norepinephrine*, and *melanin*. *Levodopa*, a form of dopa, is used to correct dopamine deficiency in people who have *Parkinson's disease*.

dopa-decarboxylase inhibitors

Drugs used in the treatment of the movement disorder *Parkinson's disease*. The two principal dopa-decarboxylase inhibitors, co-beneldopa and co-careldopa, are a combination of *levodopa* and benserazide and levodopa and carbidopa, respectively. These drugs stop levodopa from being activated except within the brain, which reduces the incidence of common side effects such as nausea and vomiting.

dopamine

A *neurotransmitter* (chemical released from nerve endings) found in the brain and around some blood vessels. It helps to control body movements: a deficiency of dopamine in the *basal ganglia* (groups of nerve cells deep in the brain) causes *Parkinson's disease*.

Synthetic dopamine is injected as an emergency treatment for shock caused by a *myocardial infarction* (heart attack) or *septicaemia* (blood infection) and as a treatment for severe *heart failure*.

Doppler echocardiography

An investigation in which blood flow through the *heart* is assessed by the use of *ultrasound* (high-frequency sound waves). An ultrasound transducer is moved over the chest in the area of the heart. The waves emitted by the transducer are reflected by blood, forming echoes that are recorded to give a picture of blood flow. This allows the direction and speed of the blood flow to be measured.

Doppler echocardiography can be used to investigate the presence of some conditions of the heart and circulation, including abnormalities of the heart valves (see *valvular heart disease*). The procedure is painless and takes between 15 and 30 minutes to perform.

Doppler effect

A change in the frequency with which sound waves from a given source reach an observer when the source is in rapid motion with respect to the observer. Approaching sounds seem higher in pitch (frequency) than sounds that are moving away. This is due to the fact that the wavelengths of sounds from an approaching source are progressively foreshortened, whereas those from a receding source are stretched.

The Doppler effect is used in various medical *ultrasound scanning* techniques (see *Doppler ultrasonography*).

Doppler ultrasonography

A type of *ultrasound scanning* in which shifts in the frequency of ultrasonic waves are used to measure the velocity of moving structures. An emitter sends out pulses of ultrasound (inaudible, high-frequency sound) of a specific frequency. When the pulses bounce off a moving object (for example, blood flowing through a blood vessel), the frequency of the echoes is changed from that of the emitted sound. A sensor is able to detect the frequency changes and converts the data into useful information (about how fast the blood flows, for example).

Doppler ultrasonography is widely used to detect narrowing of arteries in the neck due to *atherosclerosis* (accumulation of fatty deposits on the artery walls) and to detect blood clots in veins (as occurs in *deep vein thrombosis*). In addition, Doppler ultrasound techniques are used to monitor the fetal heartbeat, to detect air bubbles during *dialysis* and in *heart-lung machines*, and to measure blood pressure. (See also *Doppler echocardiography*.)

Dorfman–Chanarin syndrome

A very rare, autosomal recessive *genetic disorder* affecting fat metabolism (see *lipidosis*). The disease is *congenital* (present from birth). It is characterized by *ichthyosis* (thickened, scaly skin); *myopathy* (degeneration of muscle), and sometimes also defects in vision and in hearing. Blood tests show abnormal white *blood cells* containing vacuoles (tiny spaces) filled with fat.

dorsal

Relating to the back, located on or near the back, or describing the uppermost part of a body structure when a person is lying face-down. For example, *dorsalgia* describes pain in the back, and the dorsal part of the hand is the back of the hand. In human anatomy, the term *dorsal* means the same as *posterior*. The opposite of *dorsal* is *ventral* (meaning anterior or front).

dose

A term used to refer to the amount of a drug to be taken at a particular time, or to the amount of radiation to which an individual is exposed during a session of *radiotherapy*. Drug dose may be expressed in terms of the weight of the active substance, the volume of liquid to be taken, or its effects

on body tissues. The amount of radiation that is absorbed by body tissues during a session of radiotherapy is expressed in units called millisieverts (see *radiation units*).

dosulepin

A tricyclic *antidepressant drug* used in the treatment of *depression*. The drug has a sedative action and is particularly useful in cases of depression accompanied by *anxiety* or *insomnia*. Possible adverse effects include blurred vision, dizziness, flushing, and rash.

dothiepin

The former name for *dosulepin*.

double-blind

A type of *controlled trial* that tests the effectiveness of a particular treatment or compares the benefits of different treatments. In double-blind trials, neither the patients undergoing the treatments nor the doctors who are assessing them know which of the patients are receiving which treatment. This eliminates any expectations about which treatment will be most effective.

double contrast enema

Radiologic investigation (see *radiology*) of the *intestine* (the main part of the digestive tract). A *contrast medium* (a substance opaque to *X-rays*) is introduced into the passage or cavity to be examined. The area is then distended (widened) by the introduction of air. A thin coating of the contrast medium is left on the walls of the intestine. As a result, the area to be examined is shown in outline on X-ray images. (See also *barium X-ray examinations*.)

double vision

Also known as *diplopia*, double vision is a condition in which a person sees two visual images of a single object instead of only one image. The two images are separate, but each of them is quite clearly focused.

CAUSES

It is usually a symptom of a squint, especially of paralytic squint, in which paralysis of one or more of the eye muscles impairs eye movement. Other causes include a tumour in the eyelid or a tumour or blood clot behind the eye. Double vision can also occur in *exophthalmos*, when the eyeballs protrude as the result of an underlying hormonal disorder.

TREATMENT

Double vision needs immediate investigation. The treatment depends on the underlying cause.

douche

The introduction of water and/or a cleansing agent into the vagina using a bag and tubing with a nozzle. Douching is unnecessary for hygiene and is ineffective *contraception*. It may cause infection or spread existing infection into the uterus or fallopian tubes.

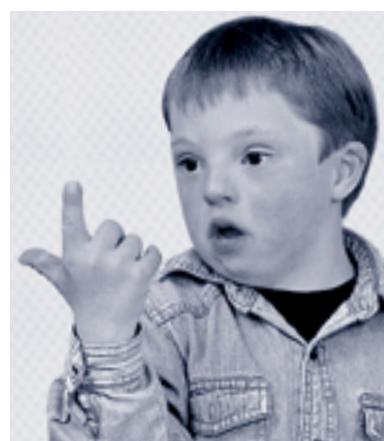

Down's syndrome

A *chromosomal abnormality* that results in a variable degree of *learning difficulty* and a characteristic physical appearance in affected individuals.

CAUSES

People with Down's syndrome have an extra *chromosome* (47 instead of the normal 46). Affected individuals have three copies of chromosome number 21 instead of two; for this reason, the disorder is also called trisomy 21. In most cases, it is the result of a sperm or egg being formed with an extra chromosome 21, due to the failure of the chromosome 21 pair to part and enter separate cells during *meiosis*. If one of these abnormal egg or sperm cells takes part in fertilization, the baby will also have the extra chromosome. This type of abnormality is more likely if the mother is aged over 35.

A less common cause is a chromosomal abnormality called a *translocation*, in which part of one parent's own

Down's syndrome child using sign language

There is a greater than normal risk of congenital deafness in Down's babies. Typical features of the condition include upward sloping eyes that are covered at the corners, small facial features, and a large tongue that tends to stick out.

chromosome number 21 has joined with another chromosome. The parent is unaffected but has a high risk of having Down's children.

SYMPOTMS

Typical physical features of a person with Down's syndrome include small face and features; upward-sloping eyes with folds of skin that cover their inner corners; large tongue; flattened back to the head; short, broad hands, with a single horizontal crease on the palm (see *simian crease*); and short stature. *Learning difficulties* are very common, and range from mild to severe; however, affected people often have cheerful, friendly personalities.

People with Down's syndrome have a greater than normal risk for certain disorders. One possible problem is a heart defect at birth (see *heart disease, congenital*), which affects up to two in five babies. Others include intestinal *atresia* (a narrowing in the intestines) and congenital *deafness*. Acute *leukaemia* is more common than in other children. Down's syndrome children are also especially susceptible to ear infections. Affected adults over the age of 40 have a higher than normal risk of developing *Alzheimer's disease*.

DIAGNOSIS

Screening tests during early pregnancy, including a *nuchal thickness scan* (a form of *ultrasound scanning* to measure the skin at the back of the neck) indicate those fetuses likely to have the syndrome. *Amniocentesis* is then offered; this test involves *chromosome analysis* of fetal cells. In some cases, Down's syndrome is only recognized once the baby has been born. The diagnosis is confirmed by *chromosome analysis* of cells from the baby.

OUTLOOK

There is no cure for the condition, but many Down's syndrome children can make the most of their capacities with appropriate environmental and educational stimulation and support. Some children learn skills such as reading and writing, and some adults may be able to work; however, most affected people cannot live independently and need long-term care from their families or in a residential home.

doxazosin

An *antihypertensive drug* taken to reduce high blood pressure (see *hypertension*). Possible side effects include dizziness, headache, and nausea.

doxorubicin

An *anticancer drug* given by injection, often with other anticancer drugs. It is used in the treatment of a variety of cancers, including *lung cancer*.

doxycycline

A *tetracycline drug* used in the treatment of chronic *prostatitis*, *pelvic inflammatory disease*, *acne*, and chest infection in chronic *bronchitis*. It is also used to prevent and treat *malaria*. Taking the drug with food reduces possible side effects.

drainage angle

The gap between the outer edge of the *iris* (the coloured ring of muscle in the eye) and the *cornea* (the transparent covering of the eyeball). This structure, and the network of tissue behind it (the trabecular network), allows excess *aqueous humour* to drain from the front chamber of the eye. Blockage of the drainage angle causes acute *glaucoma*.

drain, surgical

An appliance that is inserted into a body cavity or a wound in order to release air or permit drainage of fluid. Drains range from simple soft rubber tubes that pass from a body cavity into a dressing to wide-bore tubes that connect to a collection bag or bottle. Suction drains are thin tubes containing many small holes to help collect fluid or air, which is then drawn into a vacuum bottle.

dream analysis

The interpretation of a person's dreams as part of *psychoanalysis* or *psychotherapy*. First developed by Sigmund Freud, it is based on the idea that repressed feelings and thoughts are revealed, in a disguised way, in dreams.

dreaming

Mental activity that takes place during *sleep*. Dreaming is thought to occur only during periods of REM (rapid eye movement) sleep, which last for about 20 minutes and occur four to five times a night. Compared to other phases, the REM phase of sleep is active. Blood flow and brain temperature increase, and there are sudden changes in heart rate and blood pressure.

Dreams usually closely mirror the day's preoccupations. Dreaming can be seen as a process in which the mental impressions, feelings, and ideas are sorted out. People roused during REM sleep report especially vivid dreams.

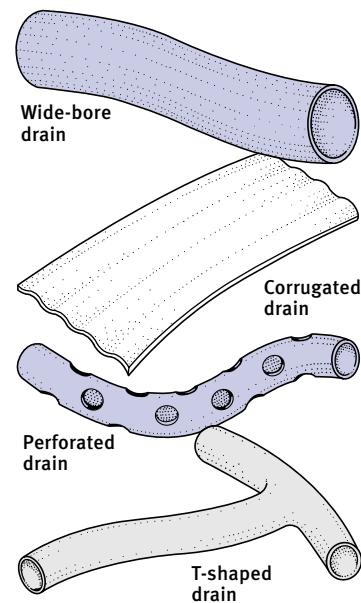

dressings

Protective coverings for *wounds* that are used to absorb blood or other body secretions, prevent contamination, or retain moisture. Pressure dressings are applied to stem bleeding or to reduce swelling at the site of injury.

Dressler's syndrome

An uncommon disorder, also known as postinfarction syndrome, that may occur following a *myocardial infarction* (heart attack) or heart surgery. Dressler's syndrome is characterized by fever, chest pain, *pericarditis* (inflammation of the membrane lining the heart), and *pleurisy* (inflammation of the membrane around the lungs). Treatment is with *aspirin* or, in severe cases, with *corticosteroid drugs*.

TYPES OF DRAINS

dribbling

Involuntary leakage of urine from the bladder (see *incontinence, urinary*) or of saliva from the mouth (drooling). Dribbling of saliva is normal in infants. In adults, it may be due to poorly fitting dentures; alternatively, it may be the result of facial paralysis, dementia, or another disorder of the nervous system, most commonly *Parkinson's disease*. Dribbling of saliva may also be caused by an obstruction in the mouth that interferes with swallowing.

drip

See *intravenous infusion*.

drip, postnasal

See *postnasal drip*.

driving, health and

Safe driving depends in part on the health of the vehicle's driver. Any state or medical disorder that affects a driver's physical condition, or impairs mental faculties such as judgment, alertness, or speed of reaction, increases the risk of injury to the driver and also to other road users and pedestrians.

One of the most obvious hazards is being under the influence of *alcohol*. There are strict laws regarding the maximum blood alcohol level allowed, because alcohol is known to impair judgment and to slow reaction times. Illicit drugs (see *drug abuse*) have a similarly harmful effect. Some prescribed *drugs* can also affect ability to drive; for example, some antihistamines (used to treat disorders such as hay fever) can cause drowsiness. The combination of drugs and alcohol is more potent than either used alone. Other states that can be hazardous include *fatigue* and any type of *stress* reaction such as anger and *anxiety*. Driving when tired is one of the most common causes of road accidents.

Impaired vision obviously affects a person's fitness to drive. Various other health problems should be disclosed to the driver's vehicle licensing authority, and in some cases may preclude driving for a period of time. Drivers who have *diabetes mellitus* must inform their vehicle licensing authority as well as their insurance company if they begin *insulin* therapy. Careful monitoring of blood sugar levels is of vital importance, because abnormally high or low levels may impair the person's judgment or cause loss of consciousness. People who have had a *stroke*, or who have had a *pacemaker* fitted, may also be subject to driving restrictions. Stricter regulations are in place for certain groups of drivers, for example people with epilepsy.

Regardless of the medical condition, it is extremely important that the patient contacts the vehicle licensing authority for advice on fitness to drive if there is the least cause for concern.

drooping eyelid

See *ptosis*.

drop attack

A brief disturbance that affects the nervous system, causing a person to fall to the ground without warning. Unlike in *fainting*, the person may not lose consciousness, but injuries can occur from the fall. Elderly women make up the group most commonly affected.

CAUSES

The causes are not fully understood, but they may be a form of *transient ischaemic attack* (TIA) in which there is a fall in blood flow to nerve centres in the *brainstem*. Elderly men may have a drop attack while passing urine or while standing, possibly due to low blood pressure or an abrupt alteration in heart rhythm. Akinetic seizures (a rare form of *epilepsy*) are also sometimes described as drop attacks; the sufferer falls to the ground but does not have muscular spasms.

TREATMENT

There is no treatment for drop attacks in elderly people. Akinetic seizures usually respond to *anticonvulsant drugs*.

drop, foot

See *foot-drop*.

dropped beat

A type of cardiac arrhythmia (see *arrhythmia, cardiac*) characterized by the absence of a single ventricular contraction. The next heartbeat often comes slightly early, and is more forceful than usual; this beat is often the one that is noticed, rather than the dropped one. Dropped beat is very common and may be caused by alcohol, caffeine, and some medications. Single, infrequent dropped beats are very unlikely to be due to heart disease.

dropsey

An outmoded term for generalized *oedema* (fluid accumulation in body tissues). It is not a disease in itself, but a sign of disease, especially of congestive *heart failure* or kidney disease.

drowning

Death caused by suffocation and *hypoxia* (a lack of oxygen) associated with immersion in a fluid. Most often, the person inhales liquid into the lungs; but sometimes no liquid enters the lungs, a condition called dry drowning (see *drowning, dry*). People who are resuscitated after prolonged immersion are said to be victims of "near drowning". (See also *Types of drowning*, p.246.)

MECHANISM OF DROWNING

Initially, automatic contraction of a muscle at the entrance to the windpipe, a mechanism known as the laryngeal reflex, prevents water from entering the lungs; instead, the water enters the oesophagus and stomach. However, the laryngeal reflex impairs breathing and can quickly lead to hypoxia and to loss of consciousness. If the person is buoyant at this point and floats face-up, his or her chances of survival are reasonable because the laryngeal reflex begins to relax and normal breathing may then resume.

FIRST AID AND TREATMENT

An ambulance should be called and the person's condition assessed. If he or she is not breathing and/or the pulse is absent, resuscitative measures should be started (see *artificial respiration*; *cardiopulmonary resuscitation*) and continued until medical help arrives.

Victims can sometimes be resuscitated despite a long period immersed in very cold water (which reduces the body's oxygen needs). In all cases of successful resuscitation, the person should be sent to hospital, because life-threatening symptoms may develop some hours after rescue if water has passed from the lungs into the blood.

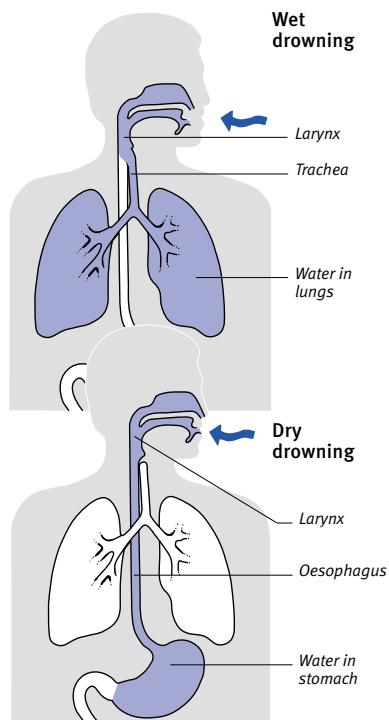

drowning, dry

A form of *drowning* in which no fluid enters into the lungs. Some fatal drowning cases are "dry". Victims of dry drowning have a particularly strong laryngeal reflex, which diverts water into the stomach instead of the lungs, but at the same time impairs breathing. As with cases of "wet" drowning, death occurs by suffocation.

drowsiness

A state of consciousness between full wakefulness and *sleep* or *unconsciousness*. Drowsiness is medically significant if a person fails to awaken after being shaken, pinched, and shouted at, or wakes but relapses into drowsiness.

Abnormal drowsiness must be treated as a medical emergency. It may be the result of a *head injury*, high fever, *meningitis* (inflammation of the membranes surrounding the brain and spinal cord), *uraemia* (excess urea in the blood due to *kidney failure*), or *liver failure*. Alcohol or drugs may also produce this effect. In a person with *diabetes mellitus*, drowsiness may be a result of *hypoglycaemia* (low blood sugar levels) or of *hyperglycaemia* (high blood sugar levels).

Types of drowning

In four-fifths of deaths due to drowning, the victim has inhaled liquid into his or her lungs. In the other fifth, no liquid is present in the lungs; this condition is called dry drowning. In both cases, death is by suffocation.

drug

A chemical substance that alters the function of one or more body organs or the process of a disease. Drugs include prescribed medicines, over-the-counter remedies, and various substances (such as alcohol, tobacco, and drugs of abuse) that are used for nonmedical purposes.

CLASSIFICATION AND LICENSING

Drugs normally have a chemical name, an officially approved generic name (see *generic drug*), and often a brand name. Drugs for medical use are either licensed for prescription by a doctor only or can be bought over the counter at a chemist's or supermarket.

Most drugs are artificially produced to ensure a pure preparation with a predictable potency (strength). Some drugs are genetically engineered. A drug is classified according to its chemical make-up, or the disorder it treats, or according to its specific effect on the body. All new drugs are tested for their efficiency and safety. In the UK, drugs are licensed by the Medicines and Healthcare products Regulatory Agency

(MHRA). A licence may be withdrawn if toxic effects are reported or if the drug causes serious illness.

USES

Drugs can be used to relieve physical or mental symptoms, to replace a natural substance that is deficient, or to stop the excessive production of a *hormone* or other chemical by the body. Some drugs are given to destroy foreign organisms, such as bacteria or fungi. Others, which are known as *vaccines*, are given to stimulate the body's *immune system* to form *antibodies*.

METHODS OF ADMINISTRATION

Drugs are given by mouth or injection, or are applied directly or indirectly to the affected site via transdermal, nasal, and other direct routes (for example, to the lungs through an inhaler). Drugs that are injected take effect more rapidly than those taken by mouth because they enter the bloodstream directly, without passing first through the digestive system. There are different routes for injection. The fastest is intravenous; intramuscular is also fast because muscles have a good blood supply; subcutaneous injection is the slowest method, but is easier for self-administration of drugs.

ELIMINATION

Unabsorbed drugs are broken down in the liver. Those taken orally are excreted in faeces; those that have entered the bloodstream are eliminated in urine.

ADVERSE EFFECTS

Most drugs can produce adverse effects. These effects may wear off as the body adapts to the drug. Adverse effects are more likely if there is a change in the absorption, breakdown, or elimination of a drug (caused, for example, by liver disease). Unexpected reactions sometimes occur due to a genetic disorder, an allergic reaction, or the formation of antibodies that damage body tissues. Some drugs interact with food, alcohol, or other drugs.

Many drugs can cross the placenta; some affect the growth and development of the fetus if taken by a pregnant woman. Most drugs can pass into the breast milk of a nursing mother, and some have adverse effects on the baby.

drug abuse

Use of a drug for a purpose other than that for which it is normally prescribed or recommended. Commonly abused drugs include *stimulant drugs*, such as *cocaine* and *amphetamine drugs*; central nervous system depressants, such as

alcohol and *barbiturate drugs*; *hallucinogenic drugs*, such as *LSD*; and narcotics (see *opioid drugs*), such as *heroin*. Some drugs are abused in order to improve performance in sports (see *sports, drugs and steroids, anabolic*).

Problems resulting from drug abuse may arise from the adverse effects of the drug, accidents that occur during intoxication, or from the habit-forming potential of many drugs, which may lead to *drug dependence*.

drug addiction

Physical or psychological dependence on a drug (see *drug dependence*).

drug dependence

The compulsion to continue taking a drug, either to prevent the ill effects that occur when it is not taken, or to produce the desired effects of taking it.

TYPES

Drug dependence can be psychological or physical, or more commonly both. A person is psychologically dependent if he or she experiences craving or distress when the drug is withdrawn. In physical drug dependence, the body has adapted to the drug, causing the symptoms and signs of *withdrawal syndrome* when the drug is stopped. These symptoms are relieved if the drug is taken again.

CAUSE

Dependence develops as a result of regular or excessive drug use, and it develops most frequently with drugs that alter mood or behaviour.

SYMPTOMS AND SIGNS

Drug dependence may cause physical problems, for example lung and heart disease from smoking and liver disease from excessive *alcohol* consumption. Mental problems, such as anxiety and depression, are common during drug withdrawal. Dependence may also be linked with drug tolerance, in which increasing doses of the substance are needed to produce the same effect.

COMPLICATIONS

Complications such as *hepatitis* or *AIDS* are a particular risk for people who abuse drugs by injection. Death may occur as a result of taking a contaminated drug, or be due to accidental overdose from taking a purer, more potent preparation than usual.

TREATMENT AND OUTLOOK

Controlled withdrawal programmes are available in special centres and hospitals, which usually offer gradual, supervised reductions in dose. Alternative, less

harmful drugs may be given, as well as treatment for any withdrawal symptoms. Social service agencies and support groups may provide follow-up care. The success of treatment depends on the motivation of the affected person. Problems often recur if people return to the circumstances that originally gave rise to the drug abuse.

drug eruption

An adverse, allergic reaction (see *allergy*) that is provoked by the ingestion or topical application of a particular *drug*. A drug eruption is usually manifested as a *rash* on the surface of the skin.

drug-induced disease

Any disorder resulting from the use of a *drug*. Examples include drug-induced *lupus erythematosus*, haemolytic anaemia (see *anaemia, haemolytic*), and *parkinsonism*. Factors that may increase the risk of drug-induced disease are age, sex, individual sensitivity, underlying disease (especially of the kidneys or liver), and the combination of drugs a patient is taking. Adverse effects associated with the use of medications may lead to hospitalization, disability, or even death. (See also *side effect*.)

drug interaction

The effect of a *drug* when it is taken in combination with other drugs or with substances such as alcohol.

drug overdose

The taking of an excessive amount of a drug, which may cause toxic effects (see *drug poisoning*).

drug poisoning

The harmful effects on the body that occur as a result of an excessive dose of a particular drug.

INCIDENCE AND CAUSES

Accidental poisoning most commonly occurs in young children. Child-resistant drug containers have helped to reduce this risk. In adults, drug poisoning usually occurs in elderly or confused people who are unsure about their treatment and dosage requirements. Accidental poisoning may also occur in *drug abuse*. Deliberate self-poisoning may be a cry for help (see *suicide; suicide, attempted*).

Drugs that are most commonly taken in overdose include *benzodiazepine drugs* and *antidepressant drugs*.

TREATMENT

Anyone who has taken a drug overdose, and any child who has swallowed tablets belonging to someone else, needs immediate medical attention. It is important to identify the drugs that have been taken.

Treatment in hospital may involve washing out the stomach by passing water through a tube introduced into the mouth (see *lavage, gastric*). *Charcoal* may be given by mouth to reduce the absorption of the drug from the intestine into the bloodstream. To eliminate the drug, urine production may be increased by an *intravenous infusion*. Antidotes are available only for a few specific drugs. Such antidotes include *naloxone* (for *morphine*) and *methionine* (for *paracetamol*).

COMPLICATIONS

Drug poisoning may cause drowsiness, breathing difficulty, irregular heartbeat, and, rarely, cardiac arrest, fits, and kidney

and liver damage. *Antiarrhythmic drugs* can be given to treat heartbeat irregularity. Fits are treated with *anticonvulsant drugs*. Blood tests to monitor liver function and careful monitoring of urine output are carried out if the drug is known to damage the liver or kidneys.

drug psychosis

A mental condition in which a person loses contact with reality during or following use of certain drugs (see *drug abuse*). Drug psychosis may be produced by drugs such as *amphetamines, cocaine, LSD* (lysergic acid diethylamide) and *cannabis*. The condition may also be caused by prescribed drugs, particularly by high doses of *corticosteroid drugs*.

Other possible effects associated with drug psychosis include abnormal behaviour, *hallucinations, delusions*, and extreme emotion, such as excitement or a dazed, unresponsive state. Treatment involves withdrawal from the drug and the use of *antipsychotic drugs* to relieve symptoms.

drunkenness

See *alcohol intoxication*.

drusen

Abnormal yellowish deposits that build up in the *retina* (the light-sensitive layer at the back of the eye), which can lead to a disturbance of central vision. Drusen may be a sign of age-related *macular degeneration*.

dry drowning

See *drowning, dry*.

dry eye

See *keratoconjunctivitis sicca*.

dry gangrene

A type of *gangrene*.

dry ice

Frozen *carbon dioxide*. Carbon dioxide changes from a gas to a solid when cooled, without passing through a liquid phase. Dry ice may be applied to the skin in *cryosurgery*, a freezing technique that is used, for example, to treat *warts*.

dry mouth

See *mouth, dry*.

dry socket

Infection at the site of a recent tooth extraction, causing pain, bad breath, and an unpleasant taste in the mouth. Dry socket occurs when a blood clot fails to

METHODS OF DRUG ADMINISTRATION

How taken	Action
By mouth	Drugs are digested and absorbed from the intestine in the same way as nutrients. How quickly the tablet or liquid works depends on how rapidly it is absorbed. This, in turn, depends on such factors as the drug's composition, how quickly the drug dissolves and the effect of digestive juices on it. Some drugs are inactivated as soon as they reach the liver and never enter the circulation.
By injection	Drugs given by injection have a very rapid effect and are given if digestive juices would destroy a drug.
Topical	These drugs have a local effect on the parts of the body that are exposed to them as well as a systemic (generalized) effect if some of the drug is absorbed into the bloodstream from the site of application.

form in the tooth socket after a difficult extraction, such as removal of a wisdom tooth (see *impaction*, *dental*). The clot itself may become infected, or infection may already have been present before extraction. The inflamed socket appears dry, and exposed bone is often visible.

The socket is irrigated to remove debris and may then be coated with an anti-inflammatory paste. The infection usually clears up within a few days.

DSM-IV

The fourth edition of the Diagnostic and Statistical Manual of Mental Disorders, published by the American Psychiatric Association. It classifies psychiatric illnesses and is widely used in other countries.

dTaP/IPV

A combined vaccine, introduced in 2004, that provides immunity against *diphtheria* (in a low dose), *tetanus*, *pertussis* (whooping cough), and *poliomyelitis*. It is given to children aged three to five years as part of the childhood immunization programme. (See *Typical childhood immunization schedule*, p.414.)

DTaP/IPV/Hib

A combined vaccine, introduced in 2004, that provides immunity against *diphtheria*, *tetanus*, *pertussis* (whooping cough), *poliomyelitis*, and *Hib*. In this vaccine (and in the dTaP/IPV vaccine), the polio and pertussis parts have been altered to minimize the risk of adverse effects.

HOW IT IS DONE

The injection is given in three doses to infants at two, three, and four months of age, so that they are protected as soon as possible. (Meningitis C vaccination is given at the same time.) The childhood immunization schedule also includes a preschool booster (see *dTaP/IPV*), and a further diphtheria, tetanus, and polio booster before leaving school. (See *Typical childhood immunization schedule*, p.414.)

PROTECTION

The vaccine provides a very high level of immunity to diphtheria, tetanus, pertussis, polio, and Hib infections.

POSSIBLE ADVERSE EFFECTS

DTaP/IPV/Hib is less likely to cause reactions than the older vaccines. Any side effects are usually mild and tend to occur within 12–24 hours. They include a slightly raised temperature, irritability and fretfulness, and a small lump, redness, and swelling at the injection site. Severe side effects are very rare.

The vaccine should not be given to children who have reacted severely to a preceding dose or to the old DTP vaccine, or to children who could have a severe reaction to *neomycin*, *streptomycin*, or *polymyxin B* (see *polymyxins*), which may exist in the vaccine in trace amounts.

DTP vaccine

An injection providing immunity against *diphtheria*, *pertussis* (whooping cough), and *tetanus*. In 2004, the DTP vaccine was replaced, in the UK, by the *dTaP/IPV* and *DTaP/IPV/Hib* vaccines.

dual personality

See *multiple personality*.

Dubin–Johnson syndrome

An inherited disorder that is caused by an autosomal recessive genetic trait (see *genetic disorders*). Dubin–Johnson syndrome is characterized by long-standing, mild jaundice (yellowing of the skin and the whites of the eyes), which may not become apparent until puberty or adulthood. There is an abnormality in the transportation of *bilirubin* (the main pigment found in bile) from the *liver* to the *biliary system*, which causes the bilirubin to accumulate in the liver.

No specific treatment is available. Affected people are advised to avoid drinking alcohol, and to avoid taking a range of medications that are processed by the liver, for example *oral contraceptives*. *Genetic counselling* may be offered to prospective parents who have a family history of Dubin–Johnson syndrome.

Duchenne's dystrophy

The most common and severe form of *muscular dystrophy*.

duct

A tube or a tube-like passage leading from a gland to allow the flow of fluids, such as the tear ducts.

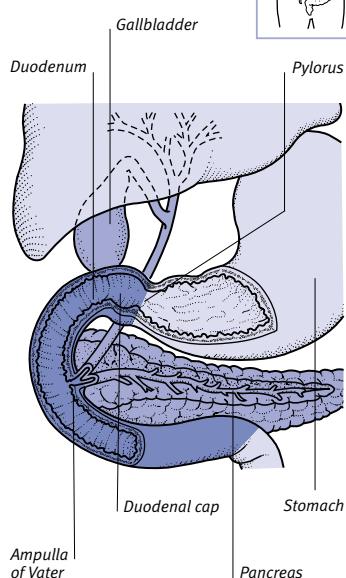

ductal carcinoma

Any *carcinoma* (a cancerous tumour arising from cells in an organ's surface layer or lining membrane) of a duct (a tube or tube-like passage leading from a gland).

Examples of ducts that are most frequently affected by carcinomas are the pancreatic duct (see *pancreas*) and the milk ducts in the female *breast*. Ductal carcinomas of the breast that have not yet spread into the breast tissue can usually be cured by surgery.

LOCATION OF THE DUODENUM

The duodenum is about 25 cm long and shaped like a C; it forms a loop around the head of the pancreas.

Duke's classification

A staging system for *carcinomas* (cancerous tumours arising from cells in an organ's surface layer or lining membrane) in the lower gastrointestinal tract. Carcinomas of the *colon* (the main part of the large intestine) or *rectum* (the muscular tube that connects the large intestine to the anus) are classified according to this system.

dumbness

See *mutism*.

dumping syndrome

Symptoms that include sweating, fainting, and palpitations due to the rapid passage of food from the stomach into the intestine. Dumping syndrome (also known as rapid gastric emptying) is uncommon but mainly affects people who have had a *gastrectomy* (surgical removal of the stomach).

Symptoms may occur within about 30 minutes of eating (early dumping) or after 90–120 minutes (late dumping). Some very anxious people may experience the symptoms of dumping even though their stomach is intact.

CAUSES

Gastric surgery interferes with the normal mechanism for emptying food from the stomach (see *digestion*). If a meal containing a high level of carbohydrates is "dumped" too quickly from the stomach, the upper intestine may swell. This, together with excessive amounts of certain hormones released into the bloodstream, causes the symptoms of early dumping. As sugars are absorbed from the intestine, they rapidly increase the blood glucose level, causing excess *insulin* hormone release. This may, in turn, later lower the blood glucose level below normal, causing the symptoms of late dumping.

PREVENTION

A person who has had a gastrectomy can prevent symptoms by eating frequent, small, dry meals that contain no refined carbohydrates. Symptoms may also be prevented by lying down for a rest after a large meal. Adding *guar gum* to food is also sometimes effective.

duodenal cap

The upper area of the first part of the *duodenum*; this is revealed in a *barium X-ray examination*.

duodenal ulcer

A raw area in the wall of the *duodenum* (the first part of the small intestine) due to erosion of its inner surface lining. Duodenal and gastric (stomach) ulcers are types of *peptic ulcer*, and have similar causes, symptoms, and treatment.

duodenitis

Inflammation of the *duodenum* (the first part of the small intestine), producing vague gastrointestinal symptoms. It is diagnosed by oesophagogastroduodenoscopy (see *gastroscopy*): examination of the walls of the upper digestive tract with a flexible viewing instrument. The treatment for duodenitis is similar to that for a duodenal ulcer (see *peptic ulcer*).

duodenum

The first part of the small intestine. The duodenum begins at the duodenal cap, just beyond the pylorus (the muscular valve at the lower end of the stomach). It extends to the ligament of Treitz, which marks the boundary with the second part of the small intestine (the jejunum). (See *Location of the duodenum*, opposite page.)

The duodenum is about 25 cm long and C-shaped; it forms a loop around the head of the *pancreas*. Ducts from the

pancreas, *liver*, and *gallbladder* feed into it through a small opening. Digestive enzymes in the pancreatic secretions and chemicals in the bile are released into the duodenum through this opening.

duplex kidney

Two fused kidneys on one side of the body. Another structural abnormality of the kidney is duplex renal pelvis, in which a single kidney has two renal pelvises (urine-collecting chambers). A third possibility is duplex ureter, in which there are two ureters leading from one kidney. The ureters may open into the bladder, or, in females, one may open into the vagina. These malformations arise during formation in the *embryo*. Surgical correction may be necessary to prevent complications such as infections.

duplex uterus

Duplication of part or all of the *uterus*. There may be two uteri joined to one vagina, or two uteri with two vaginas.

A more common condition is *septate uterus*, in which a band of tissue (septum) divides the uterine cavity into two spaces instead of one.

Dupuytren's contracture

A disorder of the hand in which one or more fingers become fixed in a bent position. In about half of the cases, both hands are affected. In most cases there is no apparent cause, but the disease may be, in part, inherited. Men over the age of 40 are most often affected.

The tissues just under the skin in the fingers or palm become thickened and shortened, which causes difficulty in straightening the fingers. Surgery can correct deformity of the fingers, but in some cases the condition recurs.

**Dupuytren's contracture**

A band of tissue in the hand thickens and contracts, gradually pulling the fingers into a permanently bent position.

dura mater

The outer of the three membranes (*meninges*) covering the brain.

Duroziez's disease

A congenital (present at birth) form of *mitral stenosis* (a narrowing of the opening of the mitral valve, which is situated on the left side of the *heart*).

dust diseases

Lung disorders caused by dust particles inhaled and absorbed into the lung tissues. There, they may cause *fibrosis* (formation of scar tissue) and progressive lung damage. The main symptoms are a cough and breathing difficulty. It may take at least ten years of exposure to dusts containing coal, silica, talc, or asbestos before serious lung damage develops (see *pneumoconiosis*). Hypersensitivity to moulds on hay or grain may lead to allergic *alveolitis*.

Preventive measures, such as the installation of dust extraction machinery, have reduced the incidence of dust diseases, and replacements have been found for especially hazardous substances such as asbestos.

DVT

Deep vein thrombosis (see *thrombosis*, *deep vein*).

dwarfism

See *short stature*.

dydrogesterone

A drug that is derived from the female sex hormone *progesterone*. It is used to treat *premenstrual syndrome* and certain menstrual problems (see *menstruation*, *disorders of*). Dydrogesterone is also given together with an *oestrogen drug* as *hormone replacement therapy* to women after or during the menopause. Dydrogesterone may be prescribed to treat *endometriosis* or to prevent *miscarriage*. Possible side effects include swollen ankles, weight gain, breast tenderness, and nausea.

dying, care of the

Physical and psychological care that is given with the aim of making the final months or days of a dying person's life as free from pain, discomfort, and emotional distress as possible.

Carers may include doctors, nurses, and other medical professionals, counsellors, social workers, clergy, and the person's family and friends.

PHYSICAL CARE

Pain can be relieved by regular low doses of *analgesic drugs*. Opioid analgesics, such as *morphine*, may be given if pain is severe. Other methods of pain relief include *nerve blocks*, *cordotomy*, and *TENS*. Nausea and vomiting may be controlled by drugs. Constipation can be treated with *laxatives*. Breathlessness is another common problem in the dying, and this may be relieved by administering morphine.

Towards the end, the dying person may be restless and may suffer from breathing difficulty due to *heart failure* or *pneumonia*. These symptoms can be relieved by drugs and by placing the patient in a more comfortable position.

EMOTIONAL CARE

Emotional care is as important as the relief of physical symptoms. Many people who are terminally ill feel angry or depressed, and feelings of guilt or of regret are common responses. Loving, caring support from family, friends, and others is very important.

HOME OR HOSPICE?

Many terminally ill people would prefer to die at home, and few terminally ill patients need specialized nursing for a prolonged period. Specially trained nurses or health-care workers from a hospital, hospice, or charity may be able to provide additional support for the dying person and his or her carers.

Care in a hospice may be offered. Hospices are small units that have been established specifically to care for terminally ill people and their families.

dys-

A prefix meaning abnormal, difficult, painful, or faulty, as in *dysuria* (pain on passing urine).

dysarthria

A *speech disorder* caused by disease or damage to the physical apparatus of speech or to the nerves controlling this apparatus. Affected people can formulate, select, and write out words and sentences grammatically; the problem is with vocal expression only.

CAUSES

Dysarthria is common in many degenerative neurological conditions, such as *multiple sclerosis* and *Parkinson's disease*. It may also result from a *stroke*, *brain tumour*, or an isolated defect or damage to a particular nerve. Structural defects of the mouth, as occur in *cleft lip and palate*, can also cause dysarthria.

TREATMENT

Drug or surgical treatment of the underlying disease or structural defect may improve the person's ability to speak clearly. *Speech therapy* is also useful.

dyscalculia

A disorder in which there is difficulty in solving mathematical problems. (See also *learning difficulties*.)

dyschondroplasia

A rare disorder, also called multiple enchondromatosis or Ollier's disease, that is present from birth and characterized by the presence of multiple tumours of cartilaginous tissue within the bones of a limb. It is caused by a failure of normal *ossification* during bone development. The bones are shortened, resulting in deformity. Rarely, a tumour in the bone may become cancerous (see *chondrosarcoma*).

dysentery

An intestinal infection, causing diarrhoea (often mixed with blood, pus, or mucus) and abdominal pain. There are two distinct forms of dysentery: *shigellosis*, which is due to shigella bacteria; and *amoebic dysentery*, which is caused by the protozoan parasite *ENTAMOEBA HISTOLYTICA*. The main risk with dysentery is *dehydration* caused by loss of fluid in the diarrhoea.

dysfunction

An abnormality or impairment in the functioning of an organ or body system. (See also *bleeding*, *dysfunctional uterus*; *minimal brain dysfunction*; *psychosexual dysfunction*.)

The term "dysfunctional" may be used to describe a poor relationship between two or more people.

dysgraphia

Problems with writing (see *learning difficulties*).

dyskaryosis

Abnormal changes in the nuclei of cells, particularly in the early stages of *cancer*. Dyskaryosis may be detected by microscopic examination of cells in procedures such as a *cervical smear test*.

dyskeratosis

An abnormality in keratinization (the deposition of the tough protein *keratin*) in the surface of the skin or nails. One form is due to a rare, inherited disorder

that is most often caused by an X-linked recessive genetic trait, although autosomal dominant and autosomal recessive forms also exist (see *genetic disorders*). The condition affects more males than females and first become apparent in childhood.

Dyskeratosis is characterized by premature thickening of epithelial cells (see *epithelium*) in the skin; *leukoplakia* (raised white patches on the mucous membranes of the mouth or vulva); nail dystrophy (a disorder caused by inadequate nutrition); and *pancytopenia* (a simultaneous decrease in the number of red cells, (*anaemia*), white cells (*neutropenia*), and platelets (*thrombocytopenia*) in the blood).

dyskinesia

Abnormal muscular movements. These uncontrollable twitching, jerking, or writhing movements cannot be suppressed, and they may affect control of voluntary movements. The disorder may involve the whole body or be restricted to a group of muscles.

Types of dyskinesia include *chorea* (jerking movements), *athetosis* (writhing movements), *choreoathetosis* (a combined form), *myoclonus* (muscle spasms), *tics* (repetitive fidgets), and *tremors*.

Dyskinesia may result from brain damage at birth or may be a side effect of certain drugs (see *tardive dyskinesia*), which often disappears when the drug is stopped. Otherwise, dyskinesia is difficult to treat. (See also *parkinsonism*.)

dyslexia

A reading disability characterized by difficulty interpreting written symbols.

CAUSE

Dyslexia is more common in males, and evidence suggests that a specific, sometimes inherited, neurological disorder underlies true dyslexia.

SYMPTOMS

A child with dyslexia has normal intelligence, but his or her attainment of reading skills lags far behind other scholastic abilities.

While many young children tend to reverse letters and words (for example, writing or reading p for q, or was for saw), most soon learn to correct such errors. Dyslexic children continue to confuse these symbols. Letters are often transposed (as in pest for step), and spelling errors are common. The children may even be unable to read words that they can spell correctly.

TREATMENT

It is very important to recognize the problem early to prevent added frustrations. Specific teaching can help an affected child develop "tricks" to overcome the deficit. Avoidance of pressure from parents combined with praise for what the child can do is equally important in helping progress.

dysmenorrhoea

Pain or discomfort experienced during or just before a menstrual period.

TYPES AND CAUSES

Primary dysmenorrhoea is common in teenage girls and young women. It usually starts two to three years after menstruation begins, but often diminishes after the age of 25. The exact cause is unknown. One possibility is excessive production of, or undue sensitivity to, *prostaglandins*, which are hormone-like substances that stimulate spasms in the uterus.

Secondary dysmenorrhoea is due to an underlying disorder, such as *pelvic inflammatory disease* or *endometriosis*, and usually begins in adult life.

SYMPTOMS

Cramp-like pain or discomfort is felt in the lower abdomen, sometimes accompanied by a dull ache in the lower back. Some women also have nausea and vomiting.

TREATMENT

Mild primary dysmenorrhoea is often relieved by *analgesic drugs* (painkillers). In severe cases, symptoms can usually be relieved by taking *oral contraceptives* or other hormonal preparations that suppress ovulation. The treatment of secondary dysmenorrhoea depends on the cause of the condition.

dysmorphia

An abnormality in the shape of a body tissue or structure.

dyspareunia

Painful sexual intercourse (see *intercourse, painful*).

dyspepsia

The medical term for *indigestion*.

dysphagia

The medical term for *swallowing difficulty*.

dysphasia

A disturbance in the ability to select the words with which to speak and write and/or to understand speech or writ-

ing. It is caused by damage to speech and comprehension regions of the brain. (See also *aphasia*.)

dysphonia

Defective production of vocal sounds in speech, either as a result of disease or of damage to the larynx (voicebox) or to the nerve supply to the laryngeal muscles. (See also *larynx, disorders of, speech disorders*.)

dysphoria

A feeling of disquiet or restlessness. Dysphoria may be a side effect of certain drugs, or it may be a symptom of a psychiatric disorder.

Gender dysphoria is a persistent feeling that one has been born the wrong sex (see *gender identity*).

dysplasia

Any abnormality of growth. The term applies to deformities in structures such as the skull and to abnormalities of single cells. Abnormal cell features include the size, shape, and rate of multiplication of cells (see, for example, *cervical dysplasia*).

dyspnoea

The medical term for shortness of breath (see *breathing difficulty*).

dysrhythmia, cardiac

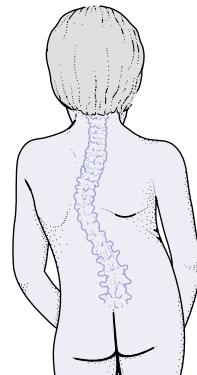

A medical term meaning disturbance of heart rhythm, sometimes used as an alternative to arrhythmia (see *arrhythmia, cardiac*).

dystocia

A term that means difficult or abnormal labour (see *childbirth*). Dystocia may occur, for example, if the baby is very large, or if the mother's pelvis is abnormally shaped or too small for the baby to pass through. (See also *childbirth, complications of*.)

dystonia

Abnormal muscle rigidity, which causes painful spasms, unusually fixed postures, or strange movement patterns. Dystonia may affect a localized area of the body, or may be more generalized. The most common types of localized dystonia are *torticollis* (painful neck spasm), and *scoliosis* (an abnormal sideways curvature of the spine), which is caused by an injury to the back that produces muscle spasm. Generalized dystonia may be caused by

**Scoliosis due to dystonia**

Injury to the back may result in dystonia and abnormal spasm of the back muscles. This problem, in turn, may lead to *scoliosis* (abnormal sideways curvature of the spine).

neurological disorders such as *Parkinson's disease*, or it may be a side effect of *antipsychotic drugs*.

Dystonia may be reduced by treatment with *anticholinergic drugs* or with *benzodiazepine drugs*. In some cases, *biofeedback training* may be helpful. Injections of botulinum toxin into the affected muscles are effective in treating some types of dystonia.

dystrophy

Any disorder in which the structure and normal activity of cells within a body tissue have been disrupted by inadequate nourishment of that part. The cause is usually unknown, but may be poor circulation of blood through the tissue, nerve damage or deficiency of a specific enzyme in the tissue.

Examples of dystrophy include *muscular dystrophies* and *leukodystrophies*. Corneal dystrophies, in which cells lining the cornea of the eye are damaged, are a rare cause of blindness.

dysuria

The medical term for pain, discomfort, or difficulty in passing urine (see *urination, painful*).

E

E

Eales' disease

A rare condition seen mainly in young men that is characterized by inflammation of the retinal veins and recurrent vitreous haemorrhage (leakage of blood into the *vitreous humour*, the gel-like substance that fills the rear chamber of the *eye*). The presence of blood in the vitreous humour may affect vision and lead to headaches. If vision is impaired, *laser treatment* may be performed to prevent further haemorrhage.

ear

The organ of hearing and balance. The ear consists of three parts: the outer ear, the middle ear, and the inner ear. The outer and middle ear are concerned mainly with the collection and transmission of sound. The inner ear is responsible for analysing sound waves; it also contains the mechanism by which the body keeps its balance.

OUTER EAR

The outer ear comprises the pinna (the visible part of the ear), which is composed of folds of skin and *cartilage*, and the ear canal, which is approximately 2.5 cm long in adults.

The outer part of the ear canal is composed of cartilage and produces *earwax*, which traps dust and foreign bodies. The canal is closed at its inner end by the eardrum, a thin, fibrous, circular membrane that is covered with a layer of skin. The eardrum vibrates in response to the changes in air pressure that constitute sound.

MIDDLE EAR

The middle ear is a small cavity between the eardrum and the inner ear that conducts sound to the inner ear by means of three tiny, linked, movable bones known as *ossicles*. The first bone, the malleus, is joined to the inner surface of the eardrum. The second, the incus, has one broad joint with the malleus (which lies almost parallel to it) and a delicate joint to the third bone, the stapes. The base of the stapes fills the oval window leading to the inner ear.

The middle ear is cut off from the outside by the eardrum. However, it is not completely airtight; a ventilation passage, called the *eustachian tube*, runs forwards and downwards into the back of the nose. The eustachian tube is normally kept closed, but it opens by muscular contraction when an individual yawns or swallows.

The middle ear acts as a transformer, passing the vibrations of sound from the air outside (which is a thin medium) to the fluid within the inner ear (which is a thicker medium).

INNER EAR

The inner ear is an intricate series of structures contained deep within the bones of the skull. It consists of a maze of winding passages, collectively known as the *labyrinth*. The front part, called the cochlea, is a tube that resembles a

snail's shell, containing nerve fibres that detect different sound frequencies. (For more information about how this system works, see *hearing*.)

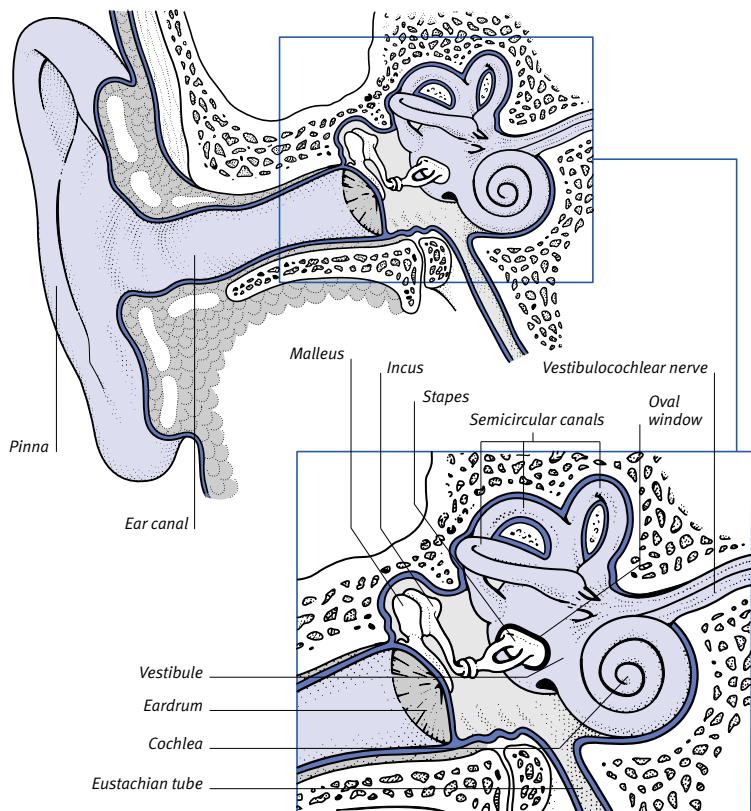

The rear part of the inner ear contains three semicircular canals and is concerned with balance. The semicircular canals are connected to a cavity called the *vestibule* and contain hair cells bathed in fluid. Some of these cells are sensitive to gravity and acceleration; others respond to the positions and movement of the head. Information from the inner ear is conducted to the brain via the *vestibulocochlear nerve*. (See also *disorders of the ear* box.)

earache

Pain in the *ear*, which may originate in the ear itself or may result from a disorder in one of the structures situated

ANATOMY OF THE EAR

The outer ear comprises the pinna and ear canal; the middle ear – the eardrum, malleus, incus, stapes, and eustachian tube; and the inner ear – the vestibule, semicircular canals, and cochlea. Sensory impulses from the inner ear pass to the brain via the *vestibulocochlear nerve*.

near the ear. Earache is an extremely common symptom, especially in infancy and childhood.

CAUSES

A frequent cause of earache is acute *otitis media* (infection of the middle ear), which occurs most commonly in young children and results in severe, stabbing pain. There may also be loss of hearing and a raised temperature.

Another common cause of earache is *otitis externa* (inflammation of the ear canal), which is often caused by infection. Infection can affect the whole canal, or it may be localized, sometimes taking the form of a boil or abscess. The earache may be accompanied by irritation in the ear canal and a discharge of pus.

Intermittent earache may also occur in people with dental problems, *tonsillitis*, throat cancer (see *pharynx, cancer of*), pain in the jaw or neck muscles, and other disorders affecting areas near the ear. Earache in such cases occurs because the ear and nearby areas are supplied by the same nerves; the pain is said to be "referred" to the ear.

DIAGNOSIS AND TREATMENT

To determine the cause of earache, the ear is inspected (see *ear, examination of*). The mouth, throat, and teeth may also be examined.

Analgesic drugs (painkillers) may be prescribed to relieve the pain. Other treatment depends on the underlying cause of the earache. *Antibiotic drugs* may be prescribed for an infection. Pus in the outer ear may be removed by suction. Pus in the middle ear may be drained through a hole in the eardrum, a procedure known as *myringotomy*.

ear, cauliflower

See *cauliflower ear*.

ear, discharge from

Also called otorrhoea, emission of fluid from the ear. Not all discharge is the same; it may be watery or thick, clear or coloured, odourless or foul-smelling, and intermittent or continuous.

CAUSES

A discharge from the ear may be due to an outer-ear infection (see *otitis externa*). It may also follow perforation of the eardrum (see *eardrum, perforated*), which is usually due to a middle-ear infection (see *otitis media*). Rarely, after a skull fracture (see *skull, fracture of*), *cerebrospinal fluid* or blood may be discharged from the ear.

DISORDERS OF THE EAR

The *ear* is susceptible to many disorders, some of which can lead to *deafness*.

Congenital defects

In rare cases, the ear canal, *ossicles* (small bones in the middle ear), or *pinna* (visible part of the ear) are absent or deformed at birth. *Rubella* (German measles) in early pregnancy can damage the baby's developing ear, leading to deafness. Most cases of congenital *sensorineural deafness* (deafness due to problems with the inner ear, nerves, or the brain's auditory area) are genetic.

Infection

Infection is the most common cause of ear disorders. Infection in the ear canal leads to *otitis externa*; in the middle ear, it causes *otitis media*. This can lead to perforation of the eardrum (see *eardrum, perforated*). *Glue ear* (buildup of fluid in the middle ear), often due to infection, is the most common cause of childhood hearing difficulties. Viral infection of the inner ear may cause *labyrinthitis* with severe *vertigo* or sudden hearing loss.

Injury

Cauliflower ear occurs as the result of one major or several minor injuries to the pinna. Perforation of the eardrum can result from poking objects into the ear or from loud noise. Prolonged exposure to loud noise can cause *tinnitus* (noises within the ear) and/or deafness.

DIAGNOSIS AND TREATMENT

A swab of the discharge may be taken and sent to a laboratory for analysis to identify the cause of any infection. *Hearing tests* may also be performed. *X-rays* of the bones of the skull will be taken if there has been a *head injury* or if a serious type of middle-ear infection is suspected from the symptoms.

Treatment depends on the cause and usually includes *antibiotic drugs*.

eardrum

The circular membrane that separates the outer *ear* from the middle ear. The eardrum vibrates in response to sound waves, conducting the sound to the inner ear through the *ossicles* (the three small bones in the middle ear).

Pressure changes associated with flying or scuba diving can also cause minor damage (see *barotrauma*).

Tumours

Acoustic neuroma is a rare, noncancerous tumour of the *acoustic nerve* that may press on structures in the ear to cause deafness, tinnitus, and problems with balance. In *cholesteatoma*, skin cells accumulate in the middle ear.

Obstruction

Obstruction of the ear canal is often due to *earwax*, although in small children, an object may have been pushed into the ear (see *ear, foreign body in*).

Other disorders

In *otosclerosis*, a hereditary condition, a bone in the middle ear becomes immobilized, causing deafness. *Menière's disease* is a rare condition in which deafness, vertigo, and tinnitus occur due to buildup of fluid in the inner ear. Progressive, age-related hearing loss is a condition known as *presbyacusis*.

Certain drugs, such as *aminoglycoside drugs* and some *diuretic drugs*, can also damage ear function.

INVESTIGATION

Hearing and balance are explored using *hearing tests*, *caloric tests*, and *electronystagmography*. The ear canal and eardrum are viewed with an *otoscope*.

eardrum, perforated

The rupture or erosion of the *eardrum*. Perforation of the eardrum can cause brief, intense pain. There may also be slight bleeding, a discharge from the ear (see *ear, discharge from*), and a reduction in hearing.

CAUSES

Most commonly, perforation occurs as a result of buildup of pus in the middle ear due to acute *otitis media* (middle-ear infection). Perforation may also be associated with *cholesteatoma* (accumulation of skin cells and debris in the ear). Another cause is injury, for example from insertion of an object into the ear, a loud noise, *barotrauma* (damage caused by pressure changes) or a fracture to the base of the skull (see *skull, fracture of*).

In some cases, a doctor may deliberately puncture the eardrum to drain pus from the middle ear (see *myringotomy*).

DIAGNOSIS AND TREATMENT

Diagnosis is confirmed by examination of the ear (see *ear, examination of*). *Hearing tests* may also be performed to assess any hearing loss.

Analgesic drugs (painkillers) may help to relieve any pain and *antibiotic drugs* may be prescribed to treat or prevent infection. Most perforations heal very quickly, usually within a month. However, if the perforation has failed to heal after about six months, *myringoplasty* (an operation to repair the eardrum) may be required.

ear, examination of

The *ear* may be examined to investigate the possible causes of *earache*, discharge from the ear (see *ear, discharge from*), hearing loss, a feeling of fullness in the ear, disturbed *balance*, *tinnitus* (noises within the ear), or swelling of lymph nodes (see *glands, swollen*) below or in front of the ear.

HOW IT IS DONE

The doctor begins by examining the *pinna* (the visible part of the outer ear) for any evidence of swelling, tenderness, ulceration, or deformity. To view the ear canal and eardrum, an *otoscope* (a viewing instrument for examining the ear) may be used.

To obtain images of the middle and inner ears, *X-rays*, or *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures), may be carried out. Hearing and balance can be assessed by means of *hearing tests* or *caloric tests*. *Electronystagmography* is a technique in which balance is assessed by observing the movements of the eye as water is poured into the ear.

ear, foreign body in

Foreign bodies can easily enter the ear canal. Children often insert small objects, such as peas or stones, into their ears, and insects may crawl or fly in.

If people try to remove objects from the ear themselves, they may push the items further into the ear canal and risk damaging the eardrum. Foreign bodies in the ear must always be removed by doctors. This can be done by syringing (see *syringing of ears*) or by using fine-toothed *forceps*. Insects can sometimes be floated out using warmed olive oil or lukewarm water.

ear, nose, and throat surgery

See *otorhinolaryngology*.

ear piercing

Making a hole in the earlobe or another, usually cartilaginous, part of the external ear to accommodate an earring. Ear piercings are best cleaned twice a day with salt water. Earlobe piercing takes about 4 weeks to heal; cartilage piercing may take 8–12 weeks.

ears, pinning back of

See *otoplasty*.

earwax

A yellow or brown secretion, also called cerumen, produced by glands in the outer ear canal. In most people, wax is produced in small amounts, comes out on its own, and causes no problems. However, some people produce so much wax that it regularly obstructs the canal. Excess earwax may produce a sensation of fullness in the ear and, if the canal is blocked completely, partial *deafness*. These symptoms are worsened if water enters the ear and makes the wax swell. Prolonged blockage may irritate the skin of the ear canal.

TREATMENT

Wax that causes blockage or irritation may come out after being softened with warmed olive oil or almond oil. Otherwise, the wax should first be softened and then removed by a doctor or nurse (see *syringing of the ears*).

eating disorders

Illnesses that are characterized by obsessions with weight and body image. Eating disorders are most common in young adolescent females, but they can also affect males.

In the eating disorder *anorexia nervosa*, patients, despite being painfully thin, perceive themselves as fat and starve themselves. Binge-eating followed by self-induced vomiting is one of the main features of *bulimia*, although, in this disorder, weight may be normal. The two conditions sometimes occur together. In morbid *obesity*, there is a constant desire to eat large quantities of food.

Ebola fever

A dangerous and highly contagious viral infection that causes severe haemorrhaging (see *bleeding*) from the skin and the *mucous membranes* (the thin, moist tissue that lines body cavities). Ebola fever

occurs predominantly in Africa. There is no specific treatment for the disease, which is fatal in many cases.

eburnation

The conversion of *bone* into an ivorylike mass. The *cartilage* that covers an articulating bone surface wears away, exposing the underlying bone tissue, which becomes increasingly dense and worn. Eburnation is a feature of *osteoarthritis*.

EB virus

See *Epstein-Barr virus*.

ecchymosis

The medical term for a *bruise* that is visible through the skin.

eccrine gland

A type of *sweat gland*.

ECG

The abbreviation for *electrocardiography*, a method of recording the electrical activity of the *heart* muscle. An ECG is useful for diagnosing heart disorders, many of which produce electrical patterns that deviate from normal. Electrodes connected to a recording machine are placed on the patient's chest, wrists, and ankles. The machine displays the heart's electrical activity on a screen or as a trace. (See also *ambulatory ECG*; *exercise ECG*.)

echinacea

A preparation of the plant genus *ECHINACEA*. Three species of echinacea are used in herbal medicine; they are believed to boost the body's *immune system* and therefore increase its resistance to bacterial, viral, and fungal infections.

echocardiography

A method of obtaining an image of the structure and movements of the *heart* using *ultrasound* (inaudible, high-frequency sound waves).

WHY IT IS DONE

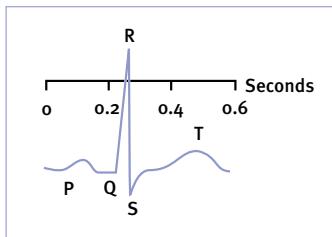

Echocardiography is a diagnostic technique that is used to detect structural, and some functional, abnormalities of the heart wall, heart chambers, *heart valves*, and large *coronary arteries*.

The procedure is also used to diagnose congenital heart disease (see *heart disease, congenital*), *cardiomyopathy* (heart muscle disorders), *aneurysms* (ballooning of the heart or blood vessel walls), *pericarditis* (inflammation of the membrane that surrounds the heart), and blood clots in the heart.

ELECTROCARDIOGRAPHY

Electrocardiography causes no discomfort. Electrodes connected to a recording machine are applied to the chest, wrists, and ankles. The machine displays the electrical activity in the heart as a trace on a moving graph or a screen. Any abnormality is thereby revealed to the doctor, nurse, or paramedic. Normal and abnormal recordings are shown, below right.

An ECG can be taken at home, in the doctor's surgery, or in the hospital; a recording lasting 24 hours or longer can be obtained from a monitoring device worn by the patient.

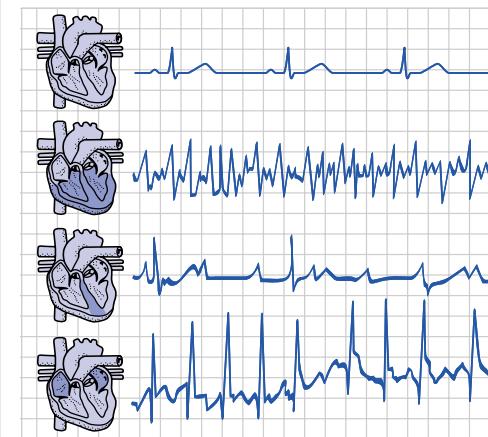

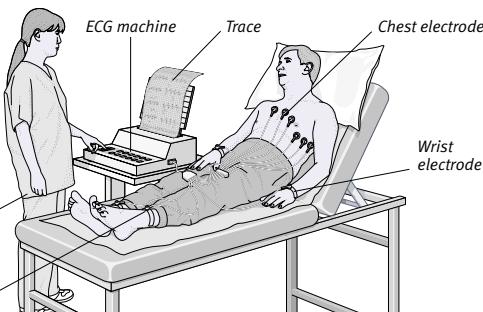

Normal ECG

This tracing shows the electrical activity associated with one normal heartbeat. The blue line shows the current flowing toward the recording lead. The rise at P occurs just before the atria (upper heart chambers) begin to contract, the QRS "spike" occurs just before the ventricles (lower chambers) begin to contract, and the rise at T occurs as the electrical potential returns to zero.

HOW ECG IS DONE

Small electrodes, connected by leads to the recording machine, are attached to the chest, wrists, and ankles using conducting jelly or pads. Signals from the electrodes produce a trace.

Technician
Ankle electrode

Normal rhythm

The heart chambers are contracting regularly.

Ventricular fibrillation

Here, the contractions of the lower heart chambers are extremely irregular.

Complete heart block

The upper and lower heart chambers are beating independently.

Atrial fibrillation

Here, the upper heart chambers are beating fast and irregularly, triggering irregular contraction of the ventricles.

HOW IT IS DONE

Echocardiography is harmless and causes no discomfort. A transducer (an instrument that sends out and receives sound signals) is placed on the patient's chest, or an ultrasound probe is passed into the oesophagus using a flexible *endoscope* (viewing tube). Ultrasound waves are reflected differently by each part of the heart, resulting in a complex series of echoes. These are viewed on a screen and may be recorded, or the results can be printed out.

DEVELOPMENTS

Developments such as multiple moving transducers and computer analysis have helped to provide clear anatomical pictures of the heart.

Doppler echocardiography is used to measure the velocity (speed) of blood flow through the heart. It allows for the assessment of structural abnormalities such as a *mitral valve prolapse* and *septal defects*.

echo-free

A term used in *ultrasound scanning* to denote a structure that does not give rise to reflections (echoes) of ultrasound waves. A cyst filled with clear fluid, for example, is echo-free.

echogenic

A term used in *ultrasound scanning* to denote a structure that gives rise to reflections (echoes) of ultrasound waves.

echolalia

The compulsive repetition of something spoken by another person. The tone and accent of the speaker are copied as well as the words. Echolalia is sometimes seen in *schizophrenia* and may occur in people with *learning difficulties* or *autism*.

ECHO virus

The name for a specific group of RNA viruses. There are 32 types of ECHO virus, and these cause a wide range of

conditions, including skin rashes, colds (see *cold*, *common*), gastrointestinal disorders, and viral *meningitis*.

eclampsia

An uncommon but serious condition that develops in a woman in late *pregnancy*, during *childbirth*, or after delivery. Eclampsia is characterized by *hypertension* (high blood pressure), *proteinuria* (protein in the urine), *oedema* (accumulation of fluid in body tissues), and the development of *seizures*. The condition is life-threatening for both the mother and the baby.

Eclampsia occurs as a complication of moderate or severe, although not mild, *pre-eclampsia*.

SYMPTOMS

The warning symptoms of impending eclampsia include headaches, confusion, blurred or disturbed vision, and abdominal pain. If untreated, seizures may occur and may be followed by

coma (a state of unconsciousness and unresponsiveness to stimuli). Levels of blood *platelets* may fall severely, resulting in bleeding; liver and kidney function may also be affected.

TREATMENT AND OUTLOOK

Careful monitoring of blood pressure and proteinuria throughout pregnancy is required to enable prompt treatment of impending eclampsia, and immediate delivery, often by *caesarean section*, together with *antihypertensive drugs* and *anticonvulsant drugs* is needed. Patients may need intensive care to prevent the development of complications, such as kidney failure.

Blood pressure often returns to normal in the months following delivery, although it may remain high. There is a risk of a recurrence of eclampsia in subsequent pregnancies.

econazole

An *antifungal drug* used as a cream in the treatment of fungal skin infections (such as *athlete's foot* and *tinea*), and in cream or pessary form to treat vaginal *candidiasis* (thrush). Skin irritation is a rare side effect.

Ecstasy

An illegal *designer drug*, related to the *amphetamine drugs*. Ecstasy has a mildly hallucinogenic effect and generates feelings of euphoria, making users feel alert and sociable. In most people, the drug has no ill effects in the short-term, but repeated use carries a risk of liver damage. The most common side effect is *hyperthermia* (very high body temperature). Taking the drug causes intense thirst; drinking large quantities of water to combat this may result in fatal damage to the body, including brain swelling.

ECT

The abbreviation for *electroconvulsive therapy*, a treatment for very severe *depression*. ECT is less commonly used today than it was in the past, since the introduction of newer, more effective *antidepressant drugs*; however, the procedure usually relieves depression more rapidly than drugs, and it may be life-saving in severe cases that are resistant to other forms of treatment.

In this procedure, an electric current is passed through the brain in order to induce a *seizure*. ECT is administered under a short-lived general anaesthetic (see *anaesthesia, general*) and in combination with a *muscle-relaxant drug*,

which reduces the physical effects of the induced seizure. The treatment is usually given once or twice a week, for six weeks. Temporary *amnesia* (memory loss) is a possible side effect.

ectasia

A term that means widening, usually used to refer to a disorder of a *duct*. For example, mammary duct ectasia is an abnormal widening of the ducts that carry secretions from the breast tissue to the nipple.

ectomorph

A term formerly used to describe an individual with a tall, thin body, a low level of body fat, slender limbs, small bones, and little muscle mass. (See also *endomorph; mesomorph*.)

ectomy

A suffix that denotes surgical removal. For example, tonsillectomy is surgical removal of the tonsils.

ectoparasite

A *parasite* that lives in or on its host's skin. An ectoparasite derives nourishment from the skin or by sucking the host's blood. Various *lice*, *ticks*, *mites*, and some types of *fungi* are occasional ectoparasites of humans. By contrast, endoparasites live inside the body.

ectopic

A term used to describe a body structure that occurs in an abnormal location or position or a body function that occurs at an abnormal time.

ectopic heartbeat

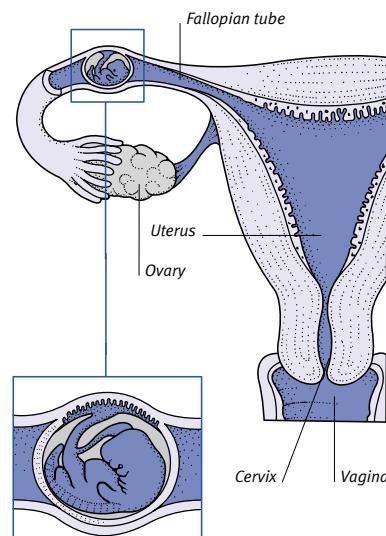

A contraction of the heart muscle that is out of normal timing. An ectopic *heartbeat* occurs shortly after a normal beat and is followed by a longer-than-usual interval before the next one.

Ectopic beats can occur in a healthy heart and may be symptomless. Multiple ectopic beats can cause *palpitations* (awareness of a rapid or forceful heartbeat). When occurring after a *myocardial infarction* (heart attack), such multiple beats are a sign of damaged heart muscle. They may lead to a condition called *ventricular fibrillation*, a rapid, uncoordinated, potentially fatal heartbeat.

Multiple ectopic beats that are causing palpitations, or those that occur after a myocardial infarction, are often treated with an *antiarrhythmic drug*. (See also *arrhythmia, cardiac*.)

ectopic pregnancy

A *pregnancy* that develops outside the *uterus*, most commonly in a *fallopian tube*, but sometimes in an *ovary*, the abdominal cavity, or the *cervix* (neck of the uterus). As the pregnancy develops, it may damage surrounding tissues, causing serious bleeding. An ectopic pregnancy is potentially life-threatening and requires emergency treatment.

Location of an ectopic pregnancy

The pregnancy usually develops in the fallopian tube; occasionally it develops in the ovary, the abdominal cavity, or the cervix.

CAUSES

The fertilized ovum (egg) may become stuck in the fallopian tube if there is a *congenital* abnormality of the tube or if the tube has been damaged in any way. Damage is most commonly due to a pelvic infection (see *pelvic inflammatory disease*) or from surgery on the fallopian tubes. Ectopic pregnancy has also been associated with the use of some types of *IUD* (intrauterine contraceptive device) and progestogen-only *oral contraceptives*.

SYMPTOMS

The majority of ectopic pregnancies are discovered in the first two months, often before the woman even realizes that she is pregnant. Symptoms usually include severe pain in the lower abdomen and bleeding from the vagina. Internal bleeding may cause symptoms of *shock*, which include pallor, sweating, and faintness.

DIAGNOSIS AND TREATMENT

Diagnosis is made by a transvaginal *ultrasound* examination, in which an

ultrasound probe is inserted into the vagina, and it can be confirmed by *laparoscopy* (internal examination using a viewing instrument).

If the diagnosis is made early on, treatment using the drug *methotrexate* may be considered. In most cases, surgery, usually *minimally invasive surgery*, is carried out to remove the embryo (which is usually already dead), the placenta, and any damaged tissue at the site of the pregnancy. If blood loss is severe, *blood transfusions* may be necessary. An affected fallopian tube is removed if it cannot be repaired.

OUTLOOK

It is still possible to have a normal pregnancy even if one fallopian tube has been removed, although the chances of conception are slightly reduced. Women with two damaged tubes may require *in vitro fertilization* to achieve an intrauterine pregnancy.

ectopic testis

See *testis, ectopic*.

ectropion

A turning outwards of the *eyelid* so that the inner surface is exposed. Ectropion is most common in elderly people, in whom it usually affects the lower lid and is due to weakness of the muscle surrounding the eye.

The condition may also be caused by the contraction of scar tissue in the skin near either lid. Ectropion often follows *facial palsy*, which causes paralysis of the muscles around the eye.

Even slight ectropion interferes with the normal drainage of tears by distortion of the opening of the tear duct. Chronic *conjunctivitis* may result, causing redness, discomfort, and overflow of tears so that the skin becomes damp and inflamed. Constant wiping tends to pull the lid farther from the eye.

Surgery to tighten the affected eyelid may be required.

eczema

An inflammation of the skin, usually causing itching and sometimes scaling or blisters. There are several different types of eczema and some forms are better known as *dermatitis* (such as contact dermatitis and photodermatitis). Eczema is sometimes the result of an *allergy*, but is often of unknown cause.

TYPES

Atopic eczema Atopic eczema is a chronic, superficial inflammation that occurs in

people who have an inherited tendency towards allergy. The condition is common in babies. An intensely itchy rash occurs, usually on the face, in the elbow creases, and behind the knees. The skin often scales and small red pimples may appear. Infection may occur if the rash is scratched, breaking the skin.

For mild cases, *emollients* (such as petroleum jelly) help to keep the skin soft. In severe cases, ointments containing *corticosteroid drugs* may be used. *Antihistamine drugs* may be prescribed to reduce itching. Excluding certain foods from the diet may help to control the condition. Atopic eczema often clears up on its own as a child grows older.

Nummular eczema Nummular eczema usually occurs in adults and is of unknown cause. It produces round, itchy, scaling patches on the skin that are similar to those of *tinea* (ringworm). Topical corticosteroids may reduce inflammation, but the eczema is often persistent.

Hand eczema Hand eczema is usually caused by irritant substances such as detergents, but it may occur for no apparent reason. Itchy blisters develop, usually on the palms, and the skin may become scaly and cracked.

Hand eczema usually improves if emollients are used and if cotton gloves with rubber gloves over them are worn when coming into contact with irritants. If the eczema is severe, corticosteroids may be prescribed.

Stasis eczema Stasis eczema occurs in people with *varicose veins*. The skin on the legs may become irritated, inflamed, and discoloured. The swelling of the legs may be controlled with compression bandages or stockings. Application of ointments containing corticosteroids may give temporary relief.

GENERAL TREATMENT

To reduce irritation and the risk of scratching, a soothing ointment should

Atopic eczema

In this example of atopic eczema, the skin on the backs of the knees is raw and inflamed.

be applied to the affected areas; these may then be covered with a dressing to prevent scratching. Absorbent, non-irritating materials (such as cotton) should be worn next to the skin; irritants (such as wool, silk, and rough synthetics) should be carefully avoided.

EDD

The abbreviation for expected date of delivery, the date on which a baby is due to be born. The EDD is calculated as 40 weeks from the first day of the woman's last menstrual period (see *period, menstrual*). In practice, babies are rarely born exactly on their EDD.

edentulous

A term meaning without *teeth*, a condition arising either because the teeth have not yet grown or because they have fallen out or been removed by a dentist.

Edwards' syndrome

A *genetic disorder*, also known as trisomy 18 syndrome, that is associated with the presence of a third copy of chromosome 18. Edwards' syndrome affects about three times as many girls as boys.

Characteristics of Edwards' syndrome include a low birth weight, severe *learning difficulties*, low-set and malformed ears, a small jaw, hand abnormalities, opacities in the cornea of the eye, congenital heart disease (see *heart disease, congenital*), hernias, *ventricular septal defect* (a hole between the lower chambers of the heart), and kidney abnormalities.

Approximately half the babies born with Edwards' syndrome do not survive beyond the first week of life. Very few infants live longer than a year. People with a family history of Edwards' syndrome should consider *genetic counselling* before starting a family.

EEG

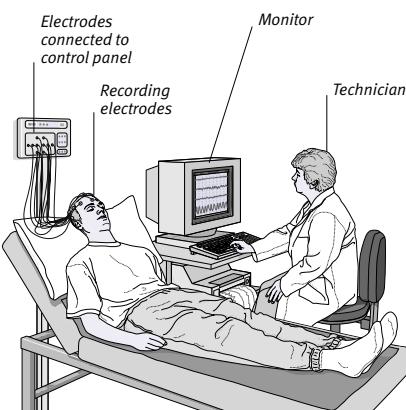

The abbreviation for electroencephalography, a method of recording the electrical activity of the *brain*. A trace of the activity is displayed on a monitor or printed out on a moving strip of paper.

In EEG, small electrodes are attached to the scalp and connected to an instrument that records minute electrical impulses produced by the brain's activity. By revealing characteristic wave patterns, an EEG can help in diagnosing different types of epilepsy and identifying areas in the brain where abnormal electrical activity develops. (See also *How electroencephalography is done* box, overleaf.)

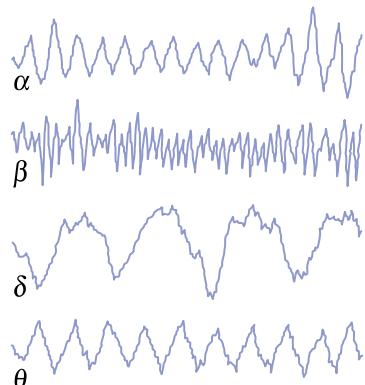

HOW ELECTROENCEPHALOGRAPHY IS DONE

A number of small electrodes are attached to the scalp. Shaving of the scalp is unnecessary. The electrodes are connected to an instrument that measures the brain's impulses in microvolts and amplifies them for recording purposes. The technique is painless, produces no side effects, and takes about 45 minutes.

Recordings are taken while the subject is at rest, with the eyes open and then shut, during and after hyperventilation (overbreathing), and while looking at a flashing light. Electroencephalography is also helpful to record activity as the patient goes to sleep, especially when epilepsy is suspected.

EEG WAVE PATTERNS

Alpha waves

The prominent pattern of an awake, relaxed adult whose eyes are closed.

Beta waves

The lower, faster oscillation of a person who is concentrating on an external stimulus.

Delta waves

The typical pattern of sleep, also found in young infants; rarely, delta waves indicate the presence of a brain tumour.

Theta waves

The dominant waves of young children. In adults, they may indicate an abnormality of the brain.

the affected joint is rested, bandaged firmly, cooled with ice-packs, and kept elevated. In some cases, the excess fluid is drawn out of the joint using a needle and syringe.

egg

See *ovum*.

ego

The conscious sense of oneself. In Freudian *psychoanalytic theory*, the ego maintains a balance between the primitive, unconscious instincts of the *id*, the controls of the *superego*, and the demands of the outside world.

Ehlers–Danlos syndrome

An inherited disorder of *collagen*, the most important structural protein in the body. Individuals with Ehlers–Danlos syndrome have abnormally stretchy, thin skin that bruises easily. Wounds are slow to heal and leave paper-thin scars, and the joints are loose and prone to recurrent dislocation. Sufferers bleed easily from the gums and digestive tract.

Ehlers–Danlos syndrome is most commonly inherited in an autosomal dominant pattern (see *genetic disorders*). There is no known specific treatment for the condition, although unnecessary accidental injury, such as that which may occur in contact sports, should be avoided by sufferers.

Eisenmenger complex

A condition in which deoxygenated blood flows directly back into the circulation rather than through the lungs. This is due to an abnormal connection between the left and right sides of the heart and to *pulmonary hypertension* (in which there is abnormally high blood pressure in the arteries supplying the lungs). The resultant *hypoxia* (lack of oxygen in the blood) causes *cyanosis* (bluish coloration of the skin), fainting, and difficulty in breathing.

Eisenmenger complex occurs most commonly in individuals who have certain uncorrected congenital heart defects (see *heart disease, congenital*), such as *ventricular septal defect*.

The diagnosis of Eisenmenger complex may be confirmed by cardiac *catheterization* (the insertion, under X-ray control, of a thin tube into the heart via a blood vessel). Once the condition has developed, surgical correction of the original defect will not help. Drug treatment may help control the symptoms.

effusion

The process by which fluid escapes. The term effusion also describes an abnormal collection of fluid (such as blood, *pus*, or *plasma*) in the tissues or a body cavity. An effusion can form as a result of inflammation or changes in pressure within blood vessels; alternatively, it can be due to changes in the blood constituents, such as in *nephrotic syndrome* (a kidney disorder).

Effusion commonly occurs around the lung (see *pleural effusion*) or heart (see *pericardial effusion*) or within joints, causing swelling (see *effusion, joint*).

effusion, joint

The accumulation of fluid in the space around a *joint*, resulting in swelling, limitation of movement, and usually also pain and tenderness. All joints are enclosed by a capsule lined with a membrane called the *synovium*. The synovium normally secretes small amounts of fluid (known as *synovial fluid*) to

lubricate the joint. However, if the synovium is damaged or inflamed (for example, as a result of *arthritis*), it produces excessive fluid.

The pain and inflammation may be relieved by *analgesic drugs* (painkillers) and *nonsteroidal anti-inflammatory drugs* and by having injections of *corticosteroid drugs*. The swelling usually reduces if

Location of knee joint effusion

Excessive production and accumulation of fluid within the right knee joint (left in image) as a result of injury or inflammation.

ejaculation

The emission of *semen* from the penis at *orgasm*. Just before ejaculation, muscles around the epididymides (ducts in which *sperm* are stored; see *epididymis*), the *prostate gland*, and the *seminal vesicles* contract rhythmically, forcing the sperm from the epididymides to move forwards and mix with secretions from the seminal vesicles and the prostate. At ejaculation, this fluid is propelled out of the body through the *urethra*.

Because both semen and urine leave the body by the same route, the bladder neck closes during ejaculation. This not only prevents ejaculate from going into the bladder but also stops urine from contaminating the semen. (See also *reproductive system, male*.)

ejaculation, disorders of

A group of conditions in which the normal process or timing of *ejaculation* is disrupted.

TYPES

Premature ejaculation In premature ejaculation, semen emission occurs before or almost immediately following penetration. Premature ejaculation is the most common sexual problem in men, particularly in young men who have only recently become sexually active. It is often due to over-stimulation or to anxiety about sexual performance. If the problem occurs frequently, sexual counselling and techniques for delaying ejaculation may help (see *sex therapy*).

Inhibited ejaculation This is a rare condition in which erection is normal, or even prolonged, but ejaculation is abnormally delayed or fails to occur. The problem may be psychological in origin, in which case counselling may help, or it may arise as a complication of a disorder such as *diabetes mellitus* or *alcohol dependence*. In some cases, inhibited ejaculation occurs as a side effect of certain drugs, such as some *antihypertensive drugs* and *antidepressant drugs*.

The cause is treated where possible; if drug treatment is thought to be the cause, a change to another drug may resolve the problem.

Retrograde ejaculation In retrograde ejaculation, the neck of the *bladder*, which normally closes during ejaculation, stays open. As a result, semen is forced backwards into the bladder and none is expelled from the penis.

Retrograde ejaculation may be due to a neurological disease, surgery on the bladder, or *prostatectomy* (removal of

the prostate gland). There is no treatment, but sexual intercourse with a full bladder can sometimes result in normal ejaculation. If an affected man and his partner wish to have a baby, it is sometimes possible to harvest sperm from the bladder for use in *in vitro fertilization*. (See also *azoospermia*; *psychosexual dysfunction*; *sexual problems*.)

elasticated bandage

A type of stretchable *bandage* that is especially useful in the treatment of *joint* injuries and for swelling of the legs due to *varicose veins*. An elasticated bandage helps to minimize swelling while not impeding movement.

elbow

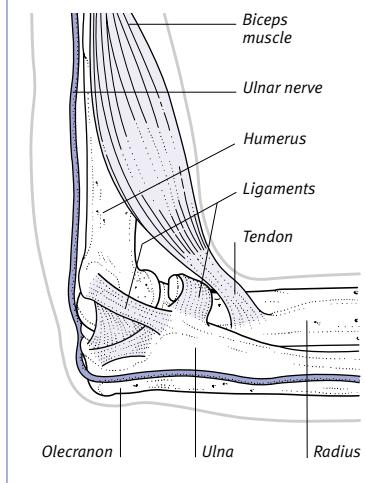

The hinge joint formed where the lower end of the *humerus* (upper-arm bone) meets the upper ends of the *radius* and *ulna* (the forearm bones). The elbow is stabilized by *ligaments* at the front, the back, and the sides. The elbow joint enables the arm to be bent and straightened, and the forearm to be rotated through almost 180 degrees around its long axis without more than a very slight movement of the upper arm.

DISORDERS

Disorders of the elbow include *arthritis* and various injuries to the joint and its

ANATOMY OF THE ELBOW

The elbow is a hinge joint between the lower end of the humerus and the upper ends of the radius and ulna. The biceps muscle bends and rotates the arm at the elbow.

surrounding muscles, tendons, and ligaments. Repeated strain on the tendons of the forearm muscles, where they attach to the elbow, can result in inflammation that is known as *epicondylitis*. There are two main types of epicondylitis: *tennis elbow* and *golfer's elbow*. Alternatively, a *sprain* of the ligaments around the elbow joint may occur.

Olecranon *bursitis* develops over the tip of the elbow in response to local irritation. Strain on the elbow joint can produce an *effusion* (the accumulation of fluid in a joint) or traumatic *synovitis* (inflammation of the membranes that line the joint capsule).

A sharp blow on the olecranon process (the bony tip of the elbow, also known as the "funny bone") may impinge on the *ulnar nerve* as it passes in a groove in this area, causing temporary discomfort: a pins-and-needles sensation and lancing pains that shoot down the arm into the fourth and fifth fingers.

A fall onto an outstretched hand or onto the tip of the elbow can cause a fracture or dislocation of the elbow.

elderly, care of the

Appropriate care to help minimize physical and mental deterioration in the elderly. For example, failing vision and hearing are often regarded as inevitable in old age, but removal of a *cataract* (loss of transparency in the lens of the eye) or use of a *hearing-aid* can often improve quality of life.

Isolation or inactivity leads to *depression* in some elderly people. Attending a day-care centre can provide social contact and introduce new interests.

Many elderly people are cared for by family members. Voluntary agencies can often provide domestic help in order to ease the strain on carers. The option of sheltered housing allows independence while providing a degree of supervision and assistance when it is needed. Elderly people who have *dementia* (loss of normal brain function) or a physical disability may require more supervision, in a residential care or hospital setting. (See also *geriatric medicine*.)

elective

A term used to describe a procedure, usually a surgical operation, that is not urgent and can be performed at a scheduled time. Elective surgery includes the correction of nonurgent medical conditions, such as *haemorrhoids*, and some cosmetic procedures, such as *rhinoplasty*.

electrical injury

Damage to tissues caused by an electric current passing through the body and the associated heat release. The internal tissues of the body, being moist and salty, are good conductors of electricity.

Dry skin provides a high resistance to current flow, but moist skin has a low resistance and thus allows a substantial current to flow into the body. Serious injury or death from domestic voltage levels is therefore more likely to occur in the presence of water.

PHYSICAL EFFECTS

All except the mildest electric shocks may result in unconsciousness. Alternating current (AC) is more dangerous than direct current (DC): it causes sustained muscle contractions, which may prevent the victim from releasing the source of the current. A current as small as 0.1 amp passing through the heart can cause a fatal *arrhythmia* (irregular heartbeat). The same current passing through the *brainstem* may cause cessation of the heartbeat and breathing.

Larger currents may cause charring of tissues, especially where the current enters and exits the body.

electric shock treatment

See *ECT*.

electrocardiography

See *ECG*.

electrocautery

A technique for destroying tissue using heat produced by an electric current. Electrocautery is used to remove skin blemishes such as *warts*. (See also *cauterization*; *diathermy*; *electrocoagulation*.)

electrocoagulation

Use of a high-frequency electric current to seal blood vessels by heat, stopping *bleeding*. Electrocoagulation is used in surgery; the current is delivered through a surgical knife, enabling the surgeon to make bloodless incisions. The procedure is also used to stop nosebleeds and to destroy abnormal blood vessel formations, such as *spider naevi*, in which case current is applied through a fine needle.

electroconvulsive therapy

See *ECT*.

electrode

A device through which an electrical current is transmitted or received. In *ECG*, for example, electrodes are applied

to the chest wall to detect electrical impulses from the heart. Other procedures using electrodes include certain types of *physiotherapy*, in which electrodes are attached to the skin and emit electrical impulses to stimulate the underlying muscles. (See also *ECT*; *electrocautery*; *electrocoagulation*; *electrolysis*; *electronystagmography*.)

electroencephalography

See *EEG*.

electrolysis

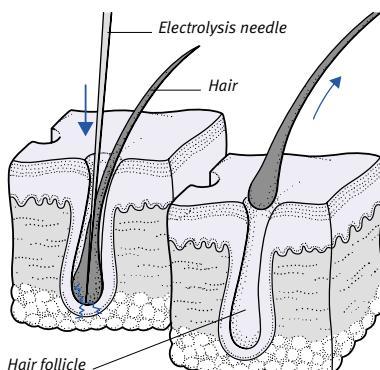

Permanent removal of unwanted hair by introducing a short-wave electric current into the hair *follicle*. The current destroys the hair root either by causing a chemical reaction (a process that is called *galvanism*) or by generating heat, which seals off the blood vessels supplying the hair (see *diathermy*).

WHY IT IS DONE

Hair on the face and body can be removed temporarily by shaving or plucking or by the use of depilatory creams, abrasives, or wax preparations. However, electrolysis is the only method of permanent hair removal.

AREAS THAT CAN BE TREATED

With a few exceptions, electrolysis can be safely used on any part of the body. Its use should be avoided on the lower margins of the eyebrows because the skin above the eyelids is very delicate and easily damaged. It is also questionable whether the technique should be used on the armpits due to the risk of bacterial infection. Electrolysis has no harmful effect on the breasts (where

**How electrolysis is done**

To remove each hair, a fine needle is inserted into the follicle and a small electric current is passed through it. The current destroys the root of the hair and the hair is then pulled out. The procedure may cause some pain, but, in skilled hands, it is harmless. If the treatment is successful, there should be no further hair growth from that follicle.

hair sometimes grows around the areola, the pigmented area surrounding the nipple) and does not affect *breastfeeding*. The legs are not well suited to electrolysis because treatment of this extensive area requires so many sessions that the procedure would be very time-consuming and expensive.

NEWER TREATMENTS

Alternative methods of hair removal, which are faster and less painful than electrolysis, are now available.

One new method is a form of *laser treatment* in which hair follicles are disabled by a laser beam. The treatment can be used on several hundred hair follicles simultaneously. It works best on people with pale skin and dark hair, because the melanin (dark pigment) in the hair absorbs energy from the laser, while the skin (which has little melanin) is relatively unaffected.

Another new technique, known as *photo-epilation*, involves the use of intense pulsed light to disable hundreds of hair follicles at the same time, with minimal side effects.

electrolyte

A substance whose molecules dissociate (split) into its constituent *ions* (electrically charged particles) when dissolved or melted. For example, sodium chloride (table salt) dissociates into sodium cations (positively charged ions) and chloride anions (negatively charged ions) when dissolved in water.

electromyography

See *EMG*.

electronystagmography

A method of recording types of *nystagmus* (abnormal, jerky movements of the eye) in order to investigate their cause. In electronystagmography, electrical changes caused by eye movements are picked up by *electrodes* that are placed near the eyes and are recorded on a graph.

electrophoresis

The movement of electrically charged particles that are suspended in a *colloid* solution under the influence of an electric current. The direction, distance, and rate of movement of the particles vary according to their size, shape, and electrical charge.

Electrophoresis is used to analyse mixtures (to identify and quantify the proteins in blood, for example), and it

may be used as a diagnostic test for *multiple myeloma*, a bone marrow tumour that produces abnormally high blood levels of a specific *antibody* (a protein manufactured by the immune system).

elephantiasis

A disease that occurs in the tropics and is characterized by massive swelling of the legs, the arms, and, in men, the scrotum (the pouch behind the penis that contains the testes). There is also thickening and darkening of the skin. Most cases of elephantiasis are due to chronic lymphatic obstruction caused by *filariasis* (a worm infestation).

elimination diet

A dietary programme used to identify a *food allergy* or *food intolerance*. Test foods, such as milk, are gradually omitted from the diet one at a time to see if they are responsible for the symptoms. (See also *exclusion diet*.)

ELISA test

A laboratory blood test used in the diagnosis of infectious diseases. ELISA stands for enzyme-linked immunosorbent assay. (See also *immunoassay*.)

elixir

A clear, sweetened liquid, which often contains alcohol, that forms the basis of many liquid medicines, such as *cough remedies*.

ellipsoidal joint

A type of mobile *joint*, such as the wrist joint, that allows all types of movement except full rotation.

Eltroxin

A brand name for *levothyroxine*, a synthetic *thyroid hormone*.

emaciation

Abnormal thinness or wasting away of the body, which may be the result of a variety of conditions including *malnutrition*, *worm infestation*, or diseases such as *tuberculosis* or *cancer*.

embolectomy

Surgical removal of an embolus (a fragment of material, often a blood clot, that is carried in the bloodstream and has blocked an *artery*; see *embolism*).

There are two methods of embolectomy. In one procedure, an incision is made in the affected artery and the embolus is removed through a suction

tube. In balloon embolectomy, a *balloon catheter* (a flexible tube with a balloon at its tip) is passed into the affected blood vessel, to just beyond the embolus. The balloon is inflated and the catheter is withdrawn from the body, bringing the embolus out with it.

embolism

Blockage of an *artery* by an embolus (a fragment of material carried in the bloodstream). An embolus may consist of various substances. It is usually formed from a blood clot. Other substances that may form an embolism include a bubble of air or other gas; a piece of tissue or tumour; a clump of bacteria, bone marrow, cholesterol, or fat; or, rarely, amniotic fluid forced into a woman's circulation during *childbirth*.

TYPES

A blood clot that has broken off from a larger clot elsewhere in the circulation is the most common type of embolus.

Pulmonary embolism is a disorder that may be due to a blood clot. The condition is usually the result of a fragment breaking off from a deep vein thrombosis (see *thrombosis*, *deep vein*) and being carried via the heart to block an artery supplying the lungs. Pulmonary embolism may cause sudden death. Blood clots may form inside the heart after a

myocardial infarction (heart attack), or in the atria (upper chambers of the heart) in *atrial fibrillation*, and then travel to the brain. This results in a cerebral embolism, which is an important cause of *stroke* (damage to part of the brain due to interruption to its blood supply).

Air embolism, in which a small artery is blocked by an air bubble, is rare. Fat embolism, in which a vessel is blocked by fat globules, is a possible complication of a major *fracture* of a limb; it occurs when fat is released from the marrow of the broken bone. Amniotic fluid embolism occurs during labour or immediately after delivery of the baby. This rare complication of childbirth is often fatal.

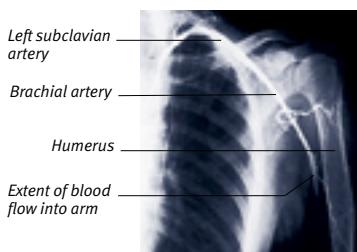

SYMPTOMS

Symptoms of an embolism depend on the site of the embolus. Pulmonary embolism can lead to breathlessness and chest pains. If the embolus lodges in the brain, a stroke may occur, affecting speech, vision, or movement. If an embolism blocks an artery to the leg, the limb will become painful and turn pale. If left untreated, *gangrene* (tissue death) may develop.

In serious cases of fat embolism, heart and breathing rates rise dramatically and there may be restlessness, confusion, and drowsiness.

TYPES OF EMBOLISM

Embolisms are named after the part of the circulation affected by the embolus involved (for example, a fat embolism is caused by fat globules, sometimes released from a bone fracture). When an embolus is released, it is carried through branches of an artery until it becomes lodged. Blood is prevented from reaching parts of the body beyond.

Angiogram of embolism in the arm

This X-ray was taken after injection of a contrast medium into the blood vessel. It shows the obstruction, by an embolus, of the normal flow of blood through the subclavian artery and the brachial artery beside the humerus.

Cerebral embolism
A blockage of one of the arteries that supply blood to the brain; it is one of the most common causes of stroke.

Pulmonary embolism
A blockage of one of the arteries that supply blood to the lungs. This may cause chest pain, breathlessness, and sudden death.

Amniotic fluid embolism
The escape of some of the fluid that surrounds the baby in the uterus into the mother's circulation. This may cause blockage of an artery in one of her lungs.

Embolism in leg
An embolism may block one of the arteries that supply blood to the leg. Gangrene may occur below the blockage.

TREATMENT

If a severe embolism causes the person to collapse, emergency life-saving measures are undertaken to maintain the breathing and circulation (see *cardiopulmonary resuscitation*).

Embolectomy (surgical removal of the blockage) may be possible. If the embolus is formed from a blood clot and surgery is not possible, *thrombolytic drugs* (drugs that dissolve blood clots) and *anticoagulant drugs* (drugs that prevent clot formation) may be given.

embolization

Deliberate obstruction of a blood vessel using an artificial embolus (a fragment of material carried in the bloodstream) made of material such as gel foam, PVA (resin), liquid sclerosants (hardeners), or medical glue. Embolization is carried out to stop uncontrollable internal bleeding or to cut off the blood supply to a *tumour*, especially a *fibroid*. In the latter case, embolization can relieve pain; cause the tumour to shrivel, making surgical removal easier; or stop the tumour from spreading. Embolization can also be used to block flow through vascular abnormalities such as *haemangiomas*, in both the skin and internal organs.

A *catheter* (flexible tube) is introduced into a blood vessel near the one to be blocked. An embolus is released through the catheter; it lodges inside the vessel, blocking blood flow to the affected area.

embolus

A fragment of material, usually a blood clot, that is carried in the bloodstream and obstructs an *artery*. An embolus is life-threatening if it blocks blood flow through a vital artery (see *embolism*).

embrocation

A medication rubbed into the skin in order to relieve muscular or joint pain.

embryo

The unborn child during the first eight weeks of its development following *conception*; for the rest of the pregnancy it is known as a *fetus*.

Development of the embryo is governed internally by *genes* inherited from the parents and externally by factors such as the mother's diet and any drugs taken during pregnancy.

THE FIRST TWO WEEKS

The embryo develops from an *ovum* (egg) that has been fertilized by a *sperm* (see *fertilization*). It starts as a single cell,

but divides several times as it travels along the *fallopian tube* to the *uterus* (womb) to form a spherical mass of cells.

About six days after conception, this mass becomes embedded in the uterus lining. At the site of attachment, the outer layer of cells obtains nourishment from the woman's blood; this part will later become the *placenta*. In the cell mass, a flat disc forms, consisting of layers of cells from which all the baby's tissues will form. The *amniotic sac* develops around the embryo.

THE THIRD WEEK

Early in the third week, the disc of cells becomes pear-shaped. The head of the embryo forms at the rounded end and the lower spine at the pointed end. A group of cells develops along the back of the embryo to form the notochord, a rod of cells that constitutes the basis for the spine. From this time onwards, the embryo has two recognizable halves that develop more or less symmetrically.

The notochord then furrows and the edges grow towards each other before fusing to form the neural tube. Later, the neural tube will develop into the *brain* and *spinal cord*.

THE FOURTH WEEK

During the fourth week, the embryo's back grows more rapidly than its front, giving it a C-shape. The neural tube extends towards the embryo's head, where a fold that will eventually form the brain becomes visible.

Developing ears appear as pits and rudimentary eyes form as stalks. Within the embryo, buds of tissue form that will become the lungs, pancreas, liver, and gallbladder. A heart starts to develop in the form of a tube. Outer layers of the embryo begin to form the limb buds and paired bulges appear on the sides of the neural tube that will eventually become the cartilage, bone, and muscle of the back.

THE FIFTH WEEK

During the fifth week of pregnancy, the embryo's external ears become visible; pits mark the position of the nose; the jaws form; and the limb buds extend, becoming flattened at the ends where the hands and feet will develop. Folds of tissue fuse to form the front wall of the chest and abdomen. The *umbilical cord* develops.

THE SIXTH TO EIGHTH WEEKS

During weeks six to eight, the embryo's face becomes recognizably human, the neck forms, the limbs become jointed, and fingers and toes appear.

After eight weeks, the embryo is about 2.5 cm long. Most of the internal organs have formed and all the external features are present.

embryo diagnosis

Also called preimplantation diagnosis, a procedure carried out on *embryos* at an early stage of development to determine whether they are affected by a *genetic disorder*. Embryo diagnosis may be carried out following *in vitro fertilization* (IVF) if the parents are known to be carriers of a specific disorder.

Several eggs are fertilized; they are grown for a few days in specialized laboratories until the first two or three cell divisions have taken place and the clusters contain approximately eight cells. One cell from each cluster is removed in order for its *DNA* to be analysed. Embryos that are found to be healthy can then be implanted in the mother's uterus (womb).

embryology

The study of the development and growth of the *embryo* and then the *fetus* from *conception* through the months of gestation until birth.

Embryology is an essential part of a medical student's training because it leads to a greater understanding of the anatomy of an adult and of the ways in which structural defects in the body may arise. For example, the occurrence of congenital heart defects is easier to understand when the stages of fetal heart development are explained. (See also *embryo diagnosis*.)

embryoma of the kidney

An alternative name for *Wilms' tumour*.

emergency

Any condition requiring urgent medical treatment, such as *cardiac arrest* (a halt in the pumping action of the heart), or any procedure that must be performed immediately, such as *cardiopulmonary resuscitation*.

emergency contraception

See *contraception, emergency*.

emesis

The medical term for *vomiting*.

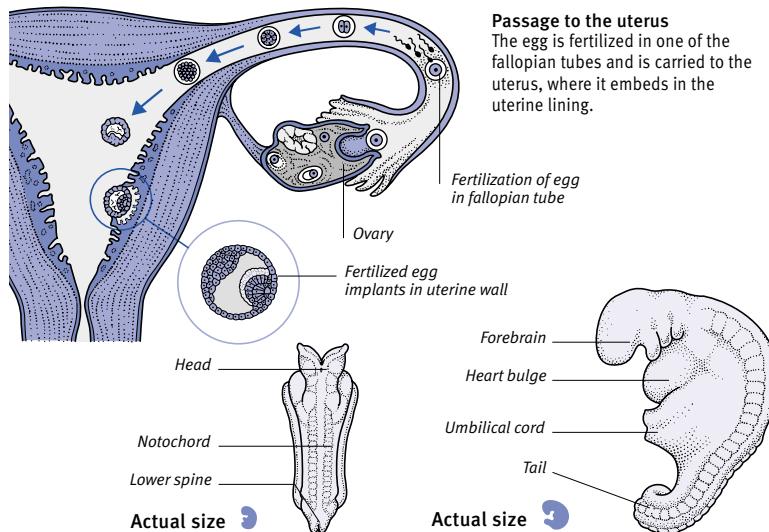

emetic

A substance that causes *vomiting*, used to treat some types of poisoning and drug overdose. Emetics act by stimulating the

THE DEVELOPING EMBRYO

From the time of conception until the eighth week, the developing baby is known as an embryo. At conception, the fertilized egg consists of a single cell, the zygote, which contains genetic material from the sperm and the ovum. The zygote divides several times to form a ball of cells, which then implants into the lining of the uterus. At the point of

attachment, the outer layer of cells forms the placenta, while a group of cells within one area of the cell ball develops into the embryo. A sac filled with amniotic fluid forms around the embryo to protect it. As the embryo grows, it begins to form features and, by the fifth week, it has developed a recognizable head and limb buds.

Three weeks

The embryo now becomes pear-shaped, with a rounded head, pointed lower spine, and notochord running along its back.

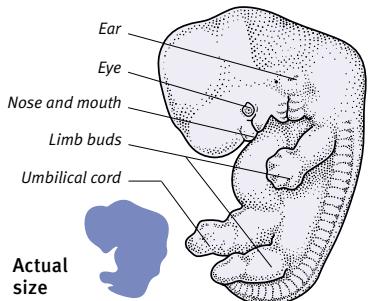

Four weeks

The embryo now becomes C-shaped and a tail is visible. The umbilical cord forms and the forebrain enlarges.

Embryo at about six weeks

The embryo is floating in the amniotic sac. The smaller sac above (the yolk sac) provides nourishment for the early embryo.

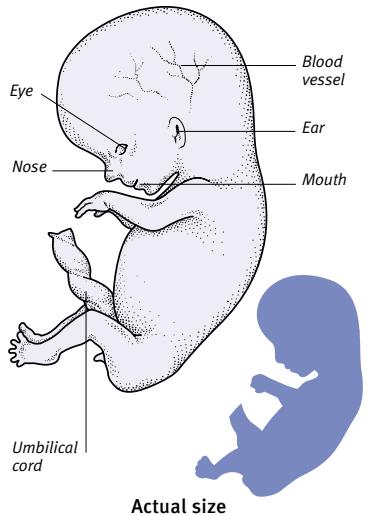

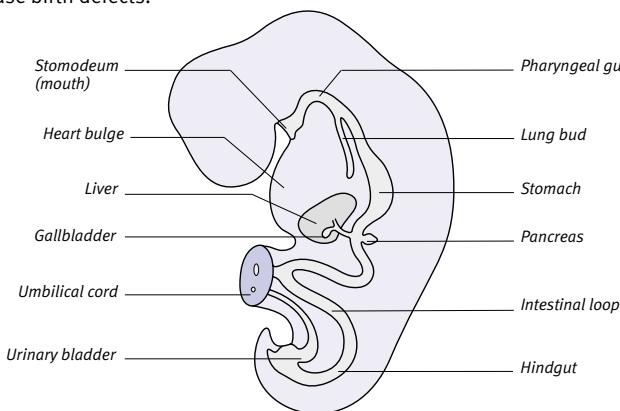

Six weeks

Eyes are visible and the mouth, nose, and ears are forming. The limbs grow rapidly from initial tiny buds.

INTERNAL ORGANS AT FIVE WEEKS

All the internal organs (such as the liver, pancreas, stomach, kidneys, heart, lungs, and sex organs) have begun to form by the fifth week. During this critical stage of development, the embryo is highly vulnerable to harmful substances that are consumed by the mother (such as alcohol and medication), which may cause birth defects.

Eight weeks

The face is more "human", the head is more upright, and the tail has gone. Limbs become jointed and digits appear.

part of the brain that controls vomiting and/or by directly irritating the lining of the stomach. The most widely used emetic is *ipecacuanha*.

EMG

The abbreviation for electromyogram, a recording of the electrical activity within a *muscle*.

WHY IT IS DONE

An EMG can help to diagnose muscle disorders, such as *muscular dystrophy*, or conditions in which the nerve supply to the muscle is impaired, such as *neuropathy*, *radiculopathy*, or *motor neuron disease*. In cases of nerve injury, the actual site of the nerve damage can often be located.

HOW IT IS DONE

Electrical activity is measured during muscle contraction and at rest. Small disc electrodes are attached to the skin over the muscle; alternatively, needle electrodes are inserted into the muscle. The impulses from the muscle are displayed on an oscilloscope screen, which shows muscle contraction and relaxation in the form of a wave pattern and reveals whether or not the muscle activity is normal. A permanent record can be made of the EMG. The procedure has no side effects.

EMLA

An acronym for "eutectic mixture of local anaesthetics". (The word "eutectic" means "easily melted".) EMLA is a brand-named cream applied to the skin to produce local anaesthesia (see *anaesthesia, local*). It is used to reduce discomfort before intravenous injection and *venepuncture*, particularly in children, and before treating localized skin conditions such as genital warts (see *warts, genital*).

emollient

A substance, such as lanolin or petroleum jelly, that has a soothing and softening effect when applied to the skin. Emollients have a moisturizing effect on the skin because they form an oily film on its surface, which prevents loss of water. Emollients are used in creams, ointments, lotions, and bath additives.

emotional deprivation

A lack of sufficient loving attention and of warm, trusting relationships during early childhood, causing normal emotional development to be inhibited. Emotional deprivation may result if

bonding does not occur in the early months of life or if a child is frequently separated from his or her parents for long periods during the first five years.

Emotionally deprived children may be impulsive, unable to cope with frustration, hungry for attention, and may have impaired intellectual development.

emotional overlay

A term used by some doctors to describe physical symptoms that they feel have been worsened by emotional difficulties. For example, it is common for symptoms of a condition to worsen when an individual is unhappy or worried. (See also *pain*.)

emotional problems

A common term for a range of psychological difficulties, often related to *anxiety* or *depression*. Emotional problems may have various causes.

empathy

The ability to understand and share the thoughts and feelings of another person. In *psychoanalysis*, the therapist partly relies on empathy to establish a relationship with a patient.

emphysema

A disease in which the walls of the alveoli (see *alveolus, pulmonary*) are progressively destroyed, thereby reducing the area of lung available for exchange of gases. The alveoli, of which there are many millions in each lung, are groups of air sacs at the end of bronchioles (tiny air passages). Through their thin walls, inhaled oxygen is passed into the bloodstream and carbon dioxide is removed from the capillaries to be breathed out.

Emphysema usually develops along with chronic *bronchitis*, in a condition known as chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*).

CAUSES

In almost all cases, emphysema is a direct result of smoking. In rare cases, an inherited deficiency of a chemical called alpha₁-antitrypsin in the body results in emphysema and, in a minority of people, also affects the liver (see *alpha₁-antitrypsin deficiency*).

Tobacco smoke and other air pollutants are believed to cause emphysema by provoking the release of chemicals within the alveoli that cause damage to the alveolar walls. Alpha₁-antitrypsin is

thought to protect against this chemical damage; therefore, people with a deficiency of this substance are particularly badly affected by emphysema.

The damage is slight at first, but in heavy smokers it becomes progressively worse; the alveoli burst and merge to form fewer, larger sacs with less surface area, which consequently impairs oxygen and carbon dioxide exchange. Over the years the lungs become increasingly less elastic, which further reduces their efficiency.

SYMPOTMS AND SIGNS

Initially, there are no symptoms, but as the disease progresses and the lungs suffer damage, there is an increasing shortness of breath. In some people, the chest becomes barrel-shaped as air is trapped in the lungs. There may also be a chronic cough (caused by the accompanying bronchitis) and a slight wheeze.

Eventually (sometimes after many years) the level of oxygen in the blood starts to fall. In some cases, *pulmonary hypertension* (raised blood pressure in the pulmonary artery) develops, leading to *cor pulmonale* (enlargement and strain on the right side of the heart). Affected people start to turn blue due to a lack of oxygen in the blood; their legs subsequently swell as a result of *oedema* (accumulation of fluid in the tissues). Other sufferers are able to compensate for oxygen deficiency to some extent by breathing faster, thereby retaining their normal colouring. Many people show signs falling somewhere between these two extremes.

DIAGNOSIS

A diagnosis is made from the patient's symptoms and signs, from a chest examination, and from various tests. A blood sample from an artery may be analysed to measure the concentration of oxygen and carbon dioxide in the blood; blood oxygen levels may alternatively be measured using an *oximeter*. A blood test for alpha₁-antitrypsin deficiency may be performed if there is a family history of the disorder. Chest *X-rays* are taken to exclude the possibility of another lung disease being responsible for the symptoms and to determine how great an area of the lungs has been affected. *Pulmonary function tests* are carried out to assess breathing capacity and the efficiency of the alveoli in exchanging gases.

TREATMENT AND PREVENTION

Once the damage to the lungs has occurred, there is no treatment that can

reverse it. However, giving up smoking will greatly reduce the rate at which the lungs deteriorate. The efficiency of the remaining lung tissue may be improved in various ways. For example, *bronchodilator drugs* may be given to widen the bronchioles and patients who are deficient in alpha₁-antitrypsin may be given replacement alpha₁-antitrypsin therapy.

To treat oedema, *diuretic drugs* may help to reduce the volume of fluid in the body by promoting its output through increased urine production. If the blood oxygen level is continually low, *oxygen therapy* at home may be needed.

People who have a localized area of emphysema in one lung may be offered surgery to remove the affected area of tissue, which will allow the remaining lung tissue to re-expand. A single lung transplant operation (see *transplant surgery*) may be considered if respiratory failure is life-threatening.

emphysema, surgical

The abnormal presence of air in tissues under the skin following surgery or injury. Surgical emphysema most commonly occurs as a complication of *pneumothorax* (the abnormal presence of air in the pleural cavity between the lung and the chest wall).

empirical treatment

Treatment that is given simply on the grounds that its effectiveness has been observed in previous, similar cases. Empirical treatment is different to treatment that is based on an understanding of the nature of a disorder and the way in which the particular method of treatment works.

empyema

An accumulation of *pus* in a body cavity or an internal organ. Empyema can occur around a lung as a rare complication of an infection such as *pneumonia* or *pleurisy*. The main symptoms are chest pain, breathlessness, and fever. Treatment is generally by *aspiration* (removal of the pus by suction) and the injection of *antibiotic drugs*. An operation to open the chest cavity and drain the pus may sometimes be performed.

Empyema of the *gallbladder* is a complication of *cholecystitis* (inflammation of the gallbladder), causing abdominal pain, fever, and *jaundice* (yellowing of the skin and the whites of the eyes). This type of empyema is treated by surgical removal of the gallbladder.

EMU

An abbreviation for early morning urine, a specimen of urine collected on the patient's first visit to the toilet after waking up. This type of urine specimen is often requested in an investigation for *tuberculosis* affecting the kidney.

emulsifying ointment

A type of *emollient* containing emulsifying wax, white soft paraffin, and liquid paraffin. Emulsifying ointment is used to smooth, soothe, and hydrate the skin in all dry or scaling conditions. Rarely, ingredients such as preservatives may result in skin sensitization.

enalapril

An *ACE inhibitor drug* that is used in the treatment of *hypertension* (high blood pressure) and *heart failure* (a reduced pumping efficiency of the heart). The drug inhibits a chemical reaction that causes blood vessels to constrict, and thus allows vessels to dilate (widen); as a result, it lowers blood pressure and reduces the workload of the heart.

One side effect of enalapril is a sudden drop in blood pressure on taking the first dose. For this reason, the patient should rest while the dose is taken and for two or three hours afterwards. More common adverse effects of the drug include headaches and dizziness; these effects should diminish with continued treatment.

enamel, dental

The hard outer layer of a tooth (see *teeth*) that protects the inner structures.

encephalitis

Inflammation of the *brain*, and sometimes also the *meninges* (the three membranes that cover and protect the brain and the spinal cord), usually due to a viral infection. Encephalitis varies in severity from a mild problem, in which symptoms are barely noticeable, to a serious and potentially life-threatening disorder.

CAUSES

Mild cases of encephalitis may be due to glandular fever (see *mononucleosis, infectious*) or may be a complication of viral diseases such as *mumps* or *measles*.

In Europe, the most common cause of life-threatening encephalitis is *herpes simplex*. In South-east Asia, *Japanese B encephalitis*, due to a virus spread by mosquitoes, is the most dangerous type. Occasionally, outbreaks of viral enceph-

alitis occur elsewhere in the world; for example, an outbreak of *West Nile virus*, another mosquito-borne form of the disease, occurred in New York in 1999.

People with *HIV* are particularly at risk from severe viral encephalitis, and may also develop cerebral abscesses (collections of pus in the brain tissue).

SYMPOTMS

Mild cases of encephalitis usually develop over several days and may cause only a slight fever and mild headache. In serious cases of encephalitis, the symptoms develop rapidly and include weakness or *paralysis*; speech, memory, and hearing problems; and a gradual loss of consciousness. *Coma* (a state of unconsciousness and unresponsiveness to external stimuli) and *seizures* may also occur. If the meninges are inflamed, certain other symptoms (for example, a stiff neck and abnormal sensitivity to light) may develop (see *meningitis*).

DIAGNOSIS AND TREATMENT

Diagnosis is based on results of blood tests; *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of the brain); *EEG* (a method of recording the electrical activity of the brain); *lumbar puncture* (taking a sample of fluid from the spinal canal for analysis); and, very occasionally, a *brain biopsy* (removal of a small sample of tissue for analysis).

Encephalitis due to herpes simplex is treated with *intravenous infusion* of the antiviral drug *aciclovir*, but there is no known treatment for encephalitis caused by other viral infections.

encephalitis lethargica

An epidemic form of *encephalitis* (brain inflammation). There have been no major outbreaks of the condition since the 1920s, but rare sporadic cases still occur. Symptoms of encephalitis lethargica are those of encephalitis, with additional lethargy and drowsiness.

Many survivors of the initial illness during the major epidemics developed a movement disorder that became known as post-encephalitic *Parkinson's disease*.

encephalocele

A type of *neural tube defect* resulting in defects of the brain rather than of the spinal cord, as occurs in *spina bifida*.

encephalomyelitis

Inflammation of the *brain* and *spinal cord*, resulting in damage to the *nervous system*, usually due to a viral infection.

CAUSES

Encephalomyelitis develops as a rare complication of *measles* or, less commonly, of other viral infections, such as *chickenpox*, *rubella* (German measles), or glandular fever (see *mononucleosis, infectious*). It may also occasionally follow vaccination against *rabies*.

SYMPOTMS

Symptoms of encephalomyelitis include fever, drowsiness, headache, seizures, partial *paralysis* or loss of sensation, and, in some cases, *coma* (a state of unconsciousness and unresponsiveness to internal or external stimuli).

DIAGNOSIS AND TREATMENT

Diagnosis is based on the results of blood tests; *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of the body structures); *EEG* (a method of recording the electrical activity of the brain); *lumbar puncture* (taking a sample of fluid from the spinal canal for analysis); and, rarely, a brain *biopsy* (removal of a small sample of brain tissue for microscopic analysis).

There is no cure for the disease, but *corticosteroid drugs* are given to reduce inflammation and *anticonvulsant drugs* to control seizures.

OUTLOOK

The disease is often fatal; those who survive may suffer permanent damage to the nervous system.

encephalomyelitis, myalgic

Another term for the disorder *chronic fatigue syndrome*.

encephalopathy

Any disorder affecting the *brain*, especially chronic degenerative conditions.

TYPES

Wernicke's encephalopathy is a degenerative condition of the brain caused by a deficiency of vitamin B_1 (see *Wernicke-Korsakoff syndrome*).

Hepatic encephalopathy is caused by the effect on the brain of *toxins* that have built up in the blood as a result of *liver failure*. It may lead to impaired consciousness, memory loss, a change in personality, tremors, and *seizures*.

In spongiform encephalopathy, the brain tissue shrinks and spaces develop within it; this leads to severe problems, such as *paralysis* and *dementia*. Bovine spongiform encephalopathy (BSE) is a disorder contracted by cattle after they are given feed containing material from sheep or cattle. The cause of BSE is believed to be an infective agent that is

known as a *prion*. Some cases of variant *Creutzfeldt-Jakob disease* in humans have been attributed to infection with the prions responsible for BSE, which were probably transmitted to humans via consumption of meat products. (See also *hypertensive encephalopathy*.)

enchondroma

A noncancerous bone tumour that originates in cartilage in the *metaphysis* (the area in which new tissue is added as the bone grows).

encoding

The first stage in the *memory* process, also called registration. In this stage, information received by one of the senses (such as hearing or sight) is registered and then modified ready for storage by the brain. The information can then be retrieved when it is needed.

encopresis

A type of *soiling* in which children pass normal faeces in unacceptable places after the age at which bowel control has been achieved. There is usually an underlying behavioural problem (see *behavioural problems in children*).

endarterectomy

An operation to remove the lining of an *artery* affected by *atherosclerosis* (narrowing due to deposits of fatty material). Removing the diseased lining restores normal blood flow to the part of the body supplied by the artery.

WHY IT IS DONE

Endarterectomy is used to treat *cerebrovascular disease* (in which the blood supply to the brain is seriously reduced) and *peripheral vascular disease* (in which blood supply to the limbs is impaired).

HOW IT IS DONE

Endarterectomy is a delicate procedure that may take several hours. The operation may be performed endoscopically (see *endoscopy*) or by open surgery. In open surgery, the artery is exposed, clamps are applied, an incision is made, and the diseased lining, as well as any thrombus (blood clot) that may have formed, are removed. The incision is closed with stitches.

RESULTS

New lining grows in the artery within a few weeks of surgery. When narrowing of the arteries is widespread (in other words, it is not confined to a single artery), *arterial reconstructive surgery* may have to be performed.

endarteritis

Inflammation of the inner (intimal) layer of an *artery* wall. Endarteritis most commonly occurs as a result of a bacterial infection such as *syphilis*. The causative infection is treated with *antibiotic drugs*, such as penicillin.

end artery

An *artery* (a blood vessel that carries blood away from the *heart*), or the final branch of an artery, that does not communicate with any other arteries. An end artery is therefore the sole supplier of blood to its surrounding tissues. If an end artery is damaged and can no longer supply blood to an area, the tissues of that area may die. End arteries are found in the *brain*, heart, retina, kidneys, and spleen.

endemic

A term applied to a disease or disorder that is constantly present in a particular region or in a specific group of people. *AIDS*, for example, has become endemic in central Africa. An endemic disease contrasts with an *epidemic*, which is not generally present but occasionally affects a large group of people.

endemic goitre

A type of *goitre* (a swelling of the neck due to enlargement of the *thyroid gland*) that occurs in certain parts of the world due to a deficiency of *iodine* in the diet. Iodine is necessary for the production of the *thyroid hormones* triiodothyronine (T3) and thyroxine (T4). If there is too little iodine in the diet, the thyroid gland compensates for the deficiency by enlarging in order to produce sufficient amounts of thyroid hormones.

Endemic goitre is rare in the developed world. It may be treated using dietary measures alone.

endocarditis

Inflammation of the endocardium (the membrane that lines the inside of the heart), particularly the endocardium lining the *heart valves*.

CAUSES AND INCIDENCE

Endocarditis is most often caused by infection with *bacteria*, *fungi*, or other microorganisms, which may be introduced into the body during surgery (including dental procedures); by *intravenous* injection using dirty needles; or through breaks in the skin or mucous membranes. The organisms travel in the bloodstream to the heart. As a result, the

lining of the valves becomes inflamed, the valves may be damaged, and blood clots may form on the affected areas.

People whose endocardium has previously been damaged by disease are particularly vulnerable to endocarditis, as are those with artificial heart valves or some forms of congenital heart disease. This is because clots that form on the injured surface trap the causative microorganisms, which then multiply rapidly at the site of damage.

Intravenous drug users are vulnerable to endocarditis, even if their hearts are healthy, because microorganisms from a dirty syringe or from unclean skin at the site of injection can be introduced into the bloodstream.

Those with a suppressed immune system are at increased risk of endocarditis due to a lowered resistance to infection; organisms that would normally be harmless can cause serious infection.

SYMPOTMS

Endocarditis may be either *subacute* or *acute*. In the subacute form, symptoms are often general and nonspecific; they may include fatigue, feverishness, and vague aches and pains. On physical examination, the only evident abnormality may be a heart *murmur*.

Acute endocarditis, which occurs less frequently, develops suddenly and causes shortness of breath, severe chills, high fever, and a rapid or irregular heartbeat. The infection quickly progresses and may destroy the heart valves, leading to *heart failure*.

DIAGNOSIS AND TREATMENT

Endocarditis is diagnosed by physical examination and analysis of blood samples. Tests performed on the heart may include *ECG* (measurement of the heart's electrical activity) and *echocardiography* (an ultrasound technique that produces detailed images of the heart). Echocardiography shows the structure and movement of the heart and can reveal any collections of infected material on the valves or in a chamber of the heart.

Treatment is with high doses of *antibiotic drugs*, usually given intravenously. Antibacterial drugs are given as preventive treatment for those people at risk. *Heart-valve surgery* may be needed to replace a damaged valve.

endocardium

The innermost of the three layers of the heart wall. The endocardium is formed of *endothelial* cells and is continuous with the linings of the blood vessels.

endocervix

The *mucous membrane* (layer of thin, moist tissue) that lines the cervical canal. The cervical canal connects the *uterus* to the vagina and runs through the centre of the *cervix* (the neck of the womb). (See also *endometrium*.)

endocrine gland

A type of *gland* that secretes *hormones* directly into the bloodstream rather than through a duct. The *thyroid gland*, *pituitary gland*, *ovaries*, testes (see *testis*), and *adrenal glands* are all endocrine glands. The endocrine glands in the body make up the *endocrine system*. (See also *exocrine gland*.)

endocrine system

The collection of glands around the body that produce *hormones* (chemical substances necessary for normal body functioning). These glands include the

thyroid gland, *pancreas*, *testes* (see *testis*), *ovaries*, and *adrenal glands*. Hormones that are produced by these glands are responsible for numerous bodily processes, including growth, metabolism, sexual development and function, and response to stress.

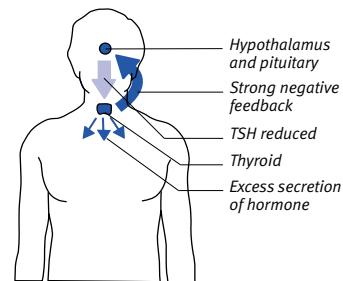

Any increase or decrease in the production of a specific hormone interferes with the process it controls. To prevent under- or overproduction, hormone secretion from many endocrine glands is regulated by the *pituitary gland*; the pituitary gland is, in turn, influenced by the *hypothalamus* in the brain according to a *feedback* mechanism (see *Control of hormone production* box, overleaf).

endocrinology

The study of the *endocrine system*, or hormonal system, including the investigation and treatment of its disorders. A physician who specializes in diseases and

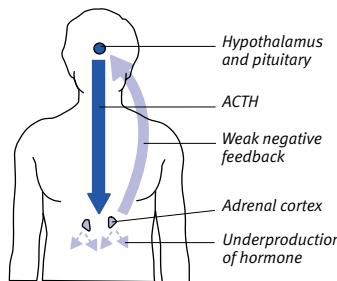

ENDOCRINE DISORDERS

In all endocrine disorders, there is either deficient or excess production of a hormone by a gland. Common causes of abnormal hormone production include a tumour or an autoimmune disease affecting a gland, or a disorder of the pituitary or the hypothalamus, which control many other glands. Abnormal hormone production often has a feedback effect on the secretion of trophic (stimulating) hormones by the pituitary and the hypothalamus, as in Addison's disease and Cushing's disease (shown below). The blood levels of different hormones may need to be measured in order to pinpoint the cause of a disorder.

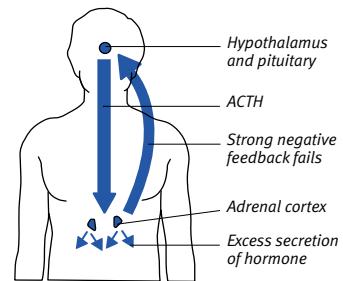

Thyrotoxicosis

This disorder is usually due to an autoimmune disease of the thyroid gland. Excess thyroid hormones cause the symptoms; the output of TSH and its hypothalamic-releasing hormone is reduced, but the thyroid gland continues to overproduce hormones.

Addison's disease

Symptoms result from reduced hormone production by the defective adrenal cortices (outer zones of the adrenal glands). Feedback is weak, so the pituitary gland pours out adrenocorticotrophic hormone (ACTH), but it fails to stimulate the adrenals.

Cushing's disease

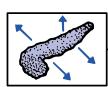

This disorder results from excess ACTH secretion by a pituitary tumour. The excess amounts of ACTH stimulate the adrenal cortices to make excess hydrocortisone, which causes the symptoms of the syndrome. Feedback fails to suppress ACTH secretion.

ENDOCRINE SYSTEM

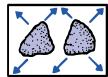

The system consists of a collection of hormone-producing glands. Many of these glands are regulated by trophic (stimulating) hormones secreted by the pituitary. The pituitary is itself influenced by hormones secreted by the hypothalamus in the brain. Shown here are the principal glands, with a note on the hormones they produce.

Pancreas

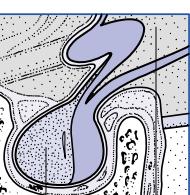

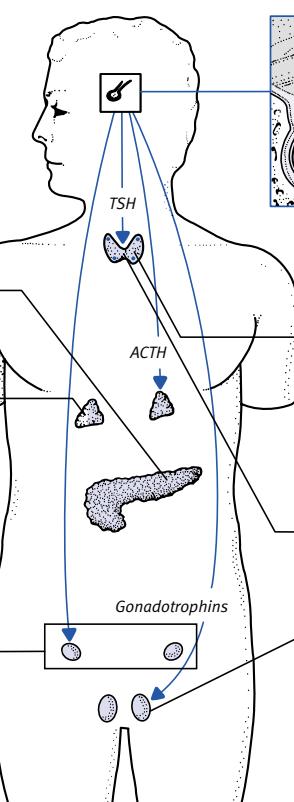

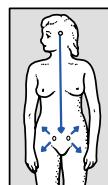

This gland secretes insulin and glucagon, which control the body's utilization of glucose.

**Adrenal cortex**

When stimulated by ACTH (adrenocorticotrophic hormone), the adrenal cortex produces hydrocortisone, which has widespread effects on metabolism; it also produces androgen hormones and aldosterone, which maintains blood pressure and the body's salt balance.

**Ovaries**

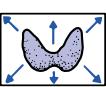

In females, the ovaries produce oestrogen and progesterone, which influence many aspects of female physiology. This hormone production is controlled by gonadotrophin hormones, secreted by the pituitary.

**Pituitary gland**

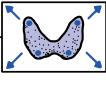

The pituitary gland secretes hormones that stimulate the adrenals, the thyroid, pigment-producing skin cells, and the gonads; it also secretes growth hormone, antidiuretic hormone, prolactin, and oxytocin.

Thyroid gland

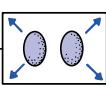

This gland produces the hormones thyroxine, triiodothyronine, and calcitonin, which stimulate metabolism, body heat production, and bone growth. Thyroid activity is controlled by TSH (thyroid-stimulating hormone), secreted by the pituitary.

**Parathyroid glands**

These glands, at the back of the thyroid, secrete parathyroid hormone, which maintains the calcium level in the blood.

**Testes**

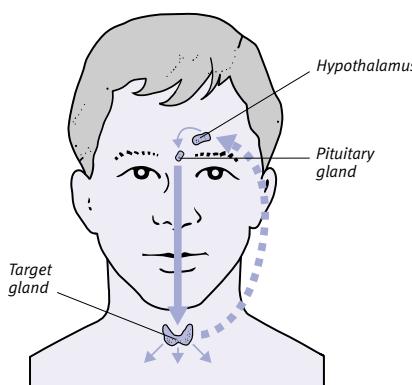

In males, the testes produce testosterone in response to gonadotrophins secreted by the pituitary. A combination of gonadotrophins and testosterone stimulates sperm production and the development of other male characteristics.

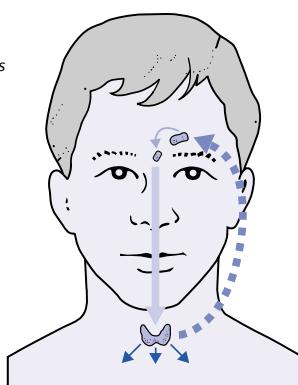

CONTROL OF HORMONE PRODUCTION

Production of too much or too little hormone by a gland is prevented by feedback mechanisms. Variations in the blood level of the hormones are detected by the part of

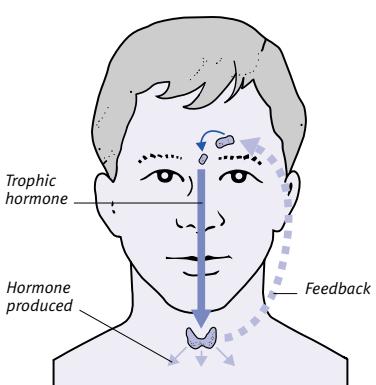

the brain known as the hypothalamus, which prompts the pituitary to modify its production of the appropriate trophic (gland-stimulating) hormones accordingly.

1 The production of hormone by the target gland (in this illustration, the thyroid gland) and of trophic hormone by the pituitary gland is normal.

2 If hormone production by the target gland rises, the feedback effect causes less trophic hormone to be produced, which tends to return the situation to normal.

3 If hormone production by the target gland drops, the feedback lessens and more trophic hormone is produced, which tends to return the situation to normal.

disorders of the endocrine glands and the hormones that they secrete is called an *endocrinologist*.

endodontics

A branch of *dentistry* concerned with the causes, prevention, diagnosis, and treatment of disease and injury that affect the nerves and pulp in *teeth* and the supportive tissues in the *gum*. Common endodontic procedures are *root-canal treatment* and *pulpotomy*.

endogenous

A term that refers to a disease or disorder that arises within the body. For example, an endogenous infection may occur if bacteria from the anus invade the urinary tract. Most disorders are *exogenous* (caused by external factors).

endogenous depression

A term formerly used for a type of *depression* (feelings of sadness, hopelessness, and a lack of interest in life) originating from biological factors in an individual. In contrast, "reactive depression" was seen to result from a stressful or emotional event or period of life. In many cases, however, depression is a combination of both of these types.

endolymph

The fluid contained within the membranous *labyrinth* (the structures in the inner ear that help to control *balance*). Endolymph flows around the labyrinth

as the body moves, causing nerve receptors in the labyrinth to send signals to the brain about the motion of the body. A significant increase in the volume of endolymph in the labyrinth may occur in *Ménière's disease*.

endometrial ablation

A treatment for persistent *menorrhagia* (heavy menstrual bleeding) involving removal of the *endometrium* (the inner lining of the uterus). In this procedure, *endoscopy* is used to view the interior of the uterus, while the endometrium is removed by *diathermy* (heat treatment), laser, or a microwave probe (MEA). Endometrial ablation can only be carried out if the woman has no desire to become pregnant in the future.

endometrial biopsy

A procedure in which a small sample of tissue is taken from the *endometrium* (the inner lining of the uterus) and sent for microscopic analysis. Endometrial biopsies are used to detect areas of abnormal tissue such as tumours (see *uterus, cancer of*). Samples may be taken during *hysteroscopy* (examination of the interior of the uterus with a viewing instrument) or collected using a small vacuum device that is introduced through the cervix. Mild cramping pains may be a side effect.

endometrial cancer

See *uterus, cancer of*.

endometriosis

A condition in which fragments of the *endometrium* (the lining of the inside of the uterus) are found in other parts of the body, usually in the pelvic cavity. Endometriosis can cause *infertility* in up to two in five affected women.

INCIDENCE AND CAUSES

Endometriosis most commonly occurs in women who are aged between 25 and 40. The cause of the disorder is not clear. In some cases, it is thought to be due to the failure of certain fragments of the endometrium, shed during *menstruation*, to leave the body. Instead, they travel up the fallopian tubes and into the pelvic cavity, where they can adhere to and grow on any pelvic organ. These displaced patches of endometrium continue to respond to hormones that are produced in the menstrual cycle and bleed each month.

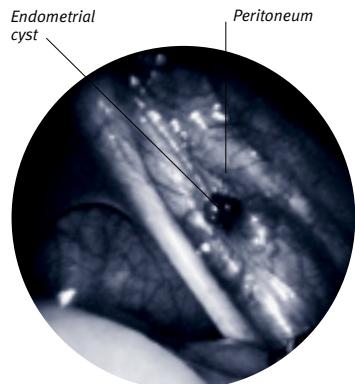

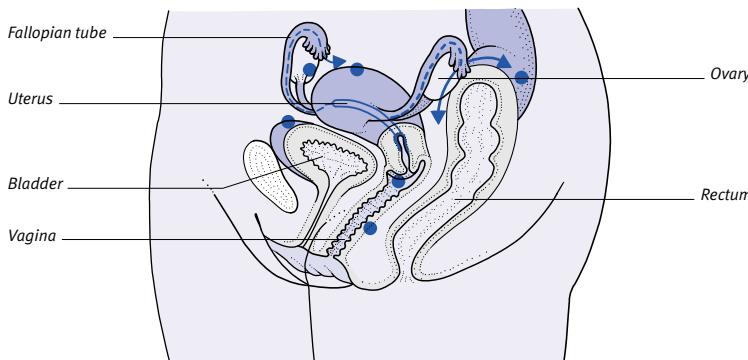

SYMPTOMS

The symptoms of endometriosis vary greatly. Some women have no symptoms, but the disorder most commonly causes abnormal or heavy menstrual bleeding. There may be severe abdominal pain and/or lower back pain during menstruation. Other possible symptoms include dyspareunia (see *intercourse, painful*), diarrhoea, constipation, and pain during defaecation.

The internal bleeding causes pain and is followed by healing, which produces internal scarring. Bleeding into an ovary may result in a blood-filled ovarian cyst

SITES OF ENDOMETRIOSIS

Fragments of the *endometrium* may travel from the uterus into the pelvic cavity via the fallopian tubes. They then implant on parts of the pelvic organs (such as the ovaries, vagina, cervix, bladder, and rectum) or on the peritoneum. The patches of endometrium continue to respond to the menstrual cycle and bleed every month. This causes the formation of painful cysts, which can be very small or may be as large as a grapefruit.

Peritoneal endometriosis

In this endoscopic view of the pelvic cavity, a fragment of endometrium has attached itself to the peritoneum (the membrane that lines the inside of the pelvic cavity) and a cyst has formed.

(known as a “chocolate cyst” because of its appearance). Endometrial tissue may be deposited in the muscular wall of the uterus (*myometrium*); this condition is called adenomyosis. In rare cases, there is bleeding from the rectum during menstruation.

DIAGNOSIS AND TREATMENT

Laparoscopy (examination of the abdominal cavity with a viewing instrument) confirms the diagnosis. Certain drugs (including *danazol*, *progestogen drugs*, *gonadorelin* analogues, or the combined *oral contraceptive pill*) may be given to prevent menstruation. Local ablation of the endometrial deposits, using either *laser treatment* or *electrocautery* (the application of heat produced by an electric current), may sometimes be needed.

If the woman is fertile, pregnancy often results in significant improvement. A *hysterectomy* (surgical removal of the uterus) and *oophorectomy* (surgical removal of the ovaries) may be offered if the woman does not have plans to have children.

endometritis

Inflammation of the *endometrium* (the inner lining of the uterus) resulting from infection. Endometritis is a feature of *pelvic inflammatory disease* (PID). It may also be a complication of *abortion* or childbirth, occur after insertion of an *IUD*, or be the result of a *sexually transmitted infection*.

Symptoms of endometritis include fever, vaginal discharge, and lower abdominal pain. Treatment includes removing any foreign body (such as an IUD or retained placental tissue) and *antibiotic drugs*.

endometrium

The inner lining of the *uterus*. The endometrium contains numerous *glands* and gradually increases in thickness during the menstrual cycle (see *menstruation*) until *ovulation* (release of an egg from the ovary) occurs. The surface layers of the endometrium are shed during menstruation if *conception* does not take place.

endomorph

A term formerly used to describe an individual with a round head and a large abdomen; short arms and legs with slender wrists and ankles; weak muscular and skeletal development; and a large proportion of body fat. (See also *ectomorph*; *mesomorph*.)

end organ

The specialized structure occurring at the end of a peripheral *nerve* that acts as a receptor for a particular *sensation*. An example of an end organ is one of the taste buds in the tongue.

endorphins

A group of pain-relieving *protein* molecules that are produced by the body. Endorphins relieve pain by activating *opiate* receptors in the *nervous system*. They have a similar chemical structure to the pain-relieving drug *morphine*. In addition, endorphins are thought to be involved in the body's response to stress, as well as in regulating intestinal contractions, determining mood, and controlling the release of certain hormones from the *pituitary gland*. (See also *enkephalins*.)

endoscope

A tubelike viewing instrument, with lenses and a light source attached, that is inserted into a body cavity for the purposes of investigating or treating disorders (see *endoscopy*). Endoscopes are named according to their use, and they can be flexible or rigid, depending on the part of the body to be examined. A selection of the common types of endoscope and their uses are shown in the illustrated box at right.

endoscopy

Examination of a body cavity by means of an *endoscope* (a rigid or flexible viewing tube) for the purposes of diagnosis and/or treatment. The technique makes use of both *fibre-optics* and video technology and enables almost any hollow structure in the body to be inspected directly. Many procedures that formerly required major surgery can now be performed much more simply and safely by endoscopy.

USES

Endoscopes are named according to the part of the body for which they are being used (see *endoscopes* box). The endoscope is inserted via a natural body opening, such as the mouth or vagina, or into a small incision. Endoscopy is also used in diagnosis to inspect hollow organs. The organ may be photographed and a *biopsy* (removal of a small sample of tissue for microscopic analysis) may be performed. Endoscopy can be repeated safely at frequent intervals to allow monitoring the progress of a condition and the response to treatment.

Many operations are now being performed by passing surgical instruments down an endoscope. The procedure is valuable in the treatment of acute emergencies, such as bleeding from the stomach or the removal of foreign bodies from the lungs. Operations such as female sterilization, the treatment of torn ligaments or cartilage within the knee joint, and the treatment of chronic infections of the nasal sinuses, are all routine endoscopic procedures. (See also *minimally invasive surgery*.)

endothelium

The layer of *cells* that lines the heart, blood vessels, and lymphatic ducts (see *lymphatic system*). Endothelial cells are squamous (thin and flat), providing a smooth surface that aids the flow of blood and lymph and helps to prevent the formation of thrombi (blood clots). (See also *epithelium*.)

endotoxin

A *poison* produced by certain *bacteria* that is not released until the death of those bacteria. Endotoxins cause fever when they are released in infected people. They also make the walls of the *capillaries* (the smallest blood vessels) more permeable, causing fluid to leak into the surrounding tissue. This sometimes results in a reduction in blood pressure, a condition called endotoxic shock. (See also *enterotoxin*; *exotoxin*.)

endotracheal tube

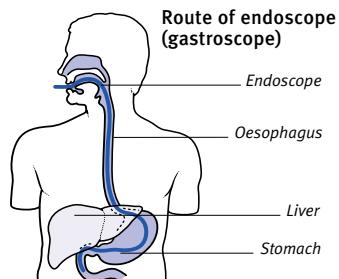

A tube that is passed into the *trachea* (windpipe) through the nose or mouth to enable delivery of oxygen during artificial *ventilation* or anaesthetic gases (see *anaesthesia*) during surgery. An inflatable cuff around the lower end of the endotracheal tube prevents any secretions or stomach contents from entering the lungs.

end stage

The most advanced stage of a disease, in which an affected organ or system is no longer able to carry out its normal functions. In these circumstances, the damage done to the body cannot be reversed; therefore, treatment is aimed at improving the patient's condition wherever possible and at relieving the symptoms (see *palliative care*). In some cases, a machine may be able to take over the function; for example, in end-stage kidney failure, filtering of the blood may be carried out by a dialysis

ENDOSCOPES

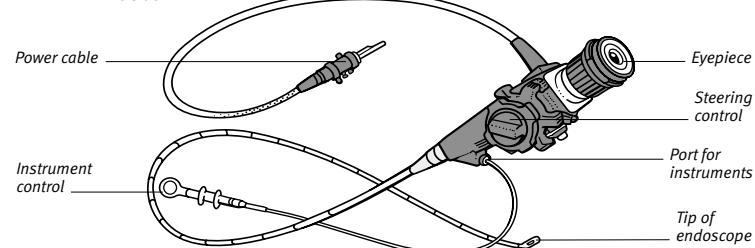

A typical flexible *fibre-optic* endoscope consists of a bundle of light-transmitting fibres. At one end is the head (featuring a viewing lens and steering device) and a power source. The tip has a light, a lens, and an outlet for air or water. Side channels enable attachments to be passed to the tip. In some endoscopes the tip may contain a camera that transmits a picture electronically to a screen. A rigid endoscope is a straight, narrow viewing tube that has a light source attached to it.

SOME COMMON TYPES OF ENDOSCOPE AND THEIR USES

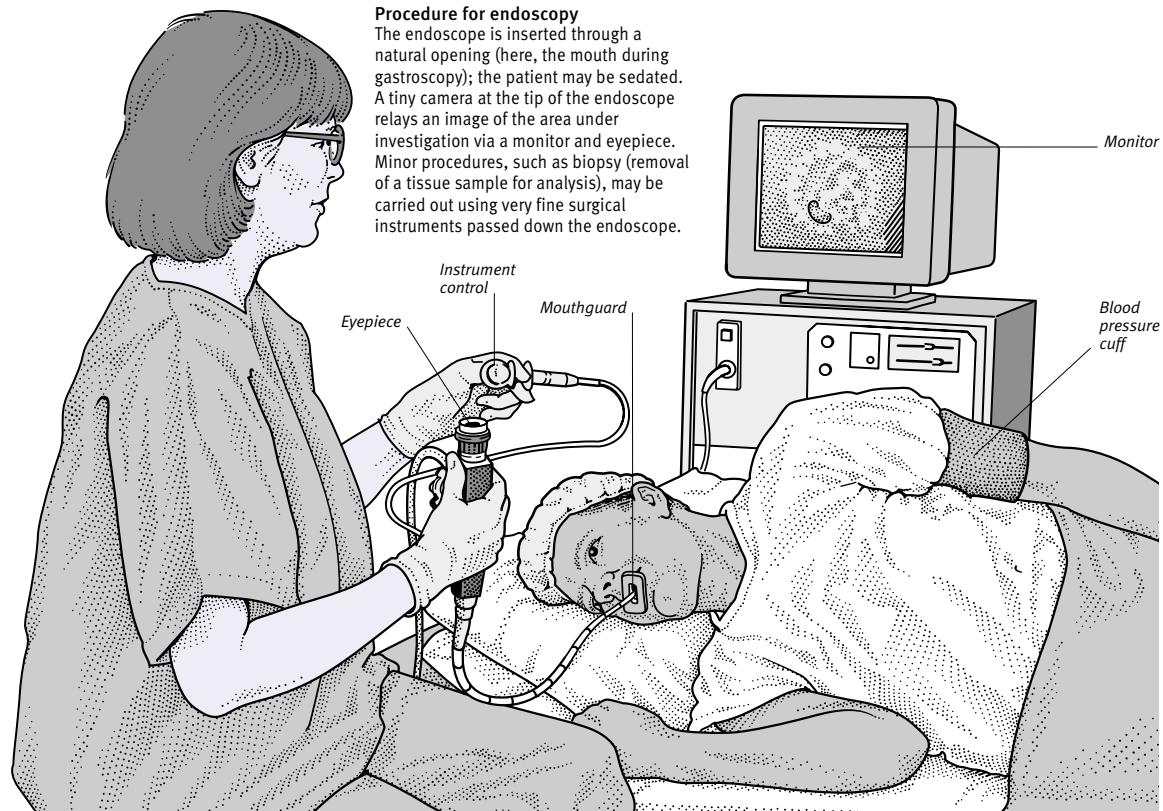

Instrument	Region	Endoscope type
Cystoscope	Bladder	Flexible or rigid
Bronchoscope	Bronchi (main airways of the lungs)	Flexible or rigid
Gastroscope	Oesophagus, stomach, and duodenum	Flexible
Colonoscope	Colon (large intestine)	Flexible
Laparoscope	Abdominal cavity	Rigid
Arthroscope	Knee joint	Rigid

FLEXIBLE ENDOSCOPE

Procedure for endoscopy

The endoscope is inserted through a natural opening (here, the mouth during gastroscopy); the patient may be sedated. A tiny camera at the tip of the endoscope relays an image of the area under investigation via a monitor and eyepiece. Minor procedures, such as biopsy (removal of a tissue sample for analysis), may be carried out using very fine surgical instruments passed down the endoscope.

machine. The term "end stage" is used in relation to many conditions, including cancer, advanced kidney failure, and chronic lung diseases.

enema

A procedure in which fluid is passed into the *rectum* through a tube that has been inserted into the *anus*. An enema may be performed as a treatment, to prepare the intestine for surgery, or as an aid to diagnosis.

WHY IT IS DONE

An enema may be given to clear the intestine of faeces, either to relieve constipation or in preparation for intestinal surgery. Enemas may also be used to administer medicine, such as *corticosteroid drugs* in the treatment of the inflammatory bowel condition *ulcerative colitis*. A barium enema is used to diagnose disorders of the large intestine (see *barium X-ray examinations*).

HOW IT IS DONE

Anaesthesia is not required, although the procedure may cause slight discomfort because the fluid stretches the intestine. The patient lies on his or her side with the hips raised on a pillow. A catheter (flexible tube), with a soft, well-lubricated tip, is gently inserted into the rectum and the enema fluid, warmed to prevent a sudden contraction of the intestine, is slowly introduced through it. Treatment doses are often packaged with their own applicators.

energy

The capacity to do work or effect physical change. Nutritionists use the term to refer to the fuel content of a food.

There are many different forms of energy, including light, sound, heat, chemical, electrical, and kinetic, and most of them play a role in the body. For instance, the *retina* (the light-sensitive inner layer at the back of the eye) converts light energy to electrical nerve impulses, making vision possible. The body's *muscles* use chemical energy obtained from food to produce kinetic energy, movement, and heat.

MEASUREMENT

Energy is measured in units called *calories* and *joules*. Because these units are extremely small, more practical units used in *dietetics* (nutritional science) are the kilocalorie (kcal, 1,000 calories) and kilojoule (kJ, 1,000 joules). *Carbohydrates* and *proteins* provide 4 kcal per gram (g), whereas *fats* provide 9 kcal per g (see *metabolism*).

ENERGY STORAGE AND USE

In general, the energy liberated from the breakdown of food is stored as chemical energy in *ATP* (adenosine triphosphate) molecules. The stored energy is then available to power processes that consume energy, such as muscle contraction or the repair and maintenance of body structures.

energy requirements

The amount of *energy* needed by an individual for cell *metabolism*, muscular activity, and growth. This energy is provided by the chemical breakdown of *fats*, *carbohydrates*, and *proteins* supplied by food in the diet and by stored *nutrients* in the liver, muscles, and *adipose tissue*.

ENERGY EXPENDITURE

Energy is needed to maintain the heartbeat, lung function, and constant body temperature. The rate at which these processes use energy, while the body is at rest, is called the basal metabolic rate (BMR). Any actions, such as movement or food digestion and absorption, increase energy expenditure above the BMR.

An individual's energy requirement increases during periods of growth and during *pregnancy* and *breast-feeding*.

ENERGY AND BODY WEIGHT

When more energy is ingested (in the form of food) than is used by the body, the surplus is stored and there is usually a gain in weight. When less energy is consumed than is spent, weight is usually lost as the stores are used up. (See also *nutrition*; *obesity*.)

enflurane

A liquid mixed with *oxygen* and inhaled as a vapour to induce and help to maintain general anaesthesia (see *anaesthesia, general*). Rarely, enflurane may cause arrhythmia (an abnormality of the rhythm or rate of the heartbeat; see *arrhythmia, cardiac*).

engagement

The descent of the head of the *fetus* into the mother's *pelvis*. In a woman's first pregnancy, engagement usually occurs by the 37th week but in subsequent pregnancies it may not occur until *labour* begins. Rarely, engagement fails to occur. This may happen, for example, if the baby's position in the uterus is abnormal; if the baby's head is too big for the mother's pelvis; or if there is a condition known as *placenta praevia* (an abnormal positioning of the placenta across the opening of the uterus).

Engelmann's disease

A rare, progressive, inherited form of bone *dysplasia* (a growth abnormality). In affected individuals, the bones become abnormally long and thick, which usually results in abnormal stature and, sometimes, in delayed walking (see *walking, delayed*). There may also be muscle wasting, pain or weakness in affected limbs, delayed *puberty*, and *hypogonadism* (underactivity of the testes or ovaries).

The disease is inherited in an autosomal dominant pattern (see *genetic disorders*) and affects more males than females. It is usually diagnosed in the first few years of life. There is no specific treatment available, although *nonsteroidal anti-inflammatory drugs* may be given to relieve pain.

engorgement

Overfilling of the breasts with *milk*. Engorgement is common a few days after childbirth, when the milk supply arrives quickly and forcibly. Engorgement causes the breasts and nipples to become swollen and tender, and can make *breast-feeding* difficult. The problem can be relieved by *expressing milk*.

enhancement

The process of augmentation. The term may be used of improvements made to body structures or functions, or may mean increasing the clarity of images in diagnostic imaging methods. For example, immunoenhancement is the process by which the body's *immune response* is increased by the use of antibodies (proteins made by the immune system).

enkephalins

A group of small *protein* molecules produced in the *brain* and by nerve endings elsewhere in the body (in the digestive system and adrenal glands, for example). Enkephalins have an analgesic (painkilling) effect and are also thought to affect mood. They are similar to *endorphins* but have a slightly different chemical composition and are released by different nerve endings.

enlarged prostate gland

See *prostate, enlarged*.

enophthalmos

A sinking inwards of the eyeball. Enophthalmos is most commonly caused by fracture of the eye socket or shrinkage of the eye due to the formation of scar tissue following injury.

ENT

The abbreviation for ear, nose, and throat (see *otorhinolaryngology*).

Entamoeba

A genus of amoebae (see *amoeba*), some of which are parasites of the human digestive tract.

Worldwide, *ENTAMOEBA HISTOLYTICA* is the most serious cause of amoebic disease, particularly in tropical areas. It is responsible for *amoebiasis* (amoebic dysentery), a disease in which the tissues of the intestinal lining are destroyed, causing the formation of *ulcers* in the intestines; and *abscesses* may form in the liver.

ENTAMOEBA GINGIVALIS is found in the mouths of humans and is associated with periodontal disease (any disorder of the tissues that surround and support the teeth) and *gingivitis* (inflammation of the gums). *ENTAMOEBA COLI* is a harmless intestinal parasite.

enteral feeding

A type of feeding that involves introducing nutrients directly into the intestines via a tube passed either through the abdominal wall or through a nostril and down the throat. Food may be provided in a partially broken-down form so that it does not need to be digested before being absorbed in the intestines. Enteral feeding is a useful method of feeding people with intestinal disorders, particularly inflammatory bowel disorders such as *Crohn's disease*. (See also *feeding, artificial*.)

enteric

Relating to or affecting the *intestine* (the main part of the digestive tract, which extends from the exit of the stomach to the anus).

enteric-coated tablet

A tablet whose surface is covered with a substance that is resistant to the action of *stomach* juices. Enteric-coated tablets pass undissolved through the stomach into the small intestine, where the covering dissolves and the contents are absorbed. Such tablets are used either when the drug might harm the stomach lining (as may occur with certain corticosteroid drugs) or when the stomach juices may affect the efficacy of the drug (as with sulphasalazine).

enteric fever

An alternative name for *typhoid fever* or *paratyphoid fever*.

enteritis

Inflammation of any part of the *intestine*, particularly the small intestine. Enteritis may be due to infection, particularly *giardiasis* and *tuberculosis*, or to *Crohn's disease*. Enteritis usually causes diarrhoea. (See also *colitis; gastroenteritis*.)

enteritis, regional

Another name for *Crohn's disease*.

enterobacteria

A group of rod-shaped, gram-negative (see *Gram's stain*) bacteria that live in the human or animal *intestine* (the principal part of the digestive tract, which extends from the exit of the stomach to the anus).

Some types of enterobacteria live harmlessly in the intestine. Several other types, however, cause intestinal diseases, with symptoms of diarrhoea and/or vomiting. Certain types are also responsible for urinary infections such as cystitis, which may occur when bacteria from the intestines gain access to the urethra. Examples of common enterobacteria include *ESCHERICHIA COLI*, *SALMONELLA*, *YERSINIA*, *ENTEROBACTER*, and *SHIGELLA*.

enterobiasis

The medical term for *threadworm infestation* of the intestines.

enterocele

A type of *hernia* in which part of the small intestine protrudes through a weakened area of the upper vaginal wall. An enterocele may develop when the muscles in a woman's vaginal canal become stretched, damaged, or weakened by any of the following: pregnancy, childbirth, surgery, or aging.

Pelvic floor exercises may help to improve the condition, but surgery may be needed to tighten the muscles. In some cases, *hysterectomy* (removal of the uterus) may be the best treatment. (See also *hernia repair*.)

Enterococcus

A genus of gram-positive (see *Gram's stain*) bacteria of the Streptococcaceae family. Enterococci are normally found in the human or animal *intestine* (the principal part of the digestive tract, which extends from the exit of the stomach to the anus).

They rarely cause problems in the intestine, but *urinary tract infections*, caused by enterococci entering the urethra, are common. If the bacteria spread

in the bloodstream they can cause *septicaemia* (blood poisoning) and infective *endocarditis* (inflammation of the membrane lining the inside of the heart). The infections are usually treated with *antibiotic drugs*.

enterocolitis

A combination of *enteritis* (inflammation of the small intestine) and *colitis* (inflammation of the colon). Possible causes include inflammatory bowel disorders such as *Crohn's disease*.

enteropathic

A term used to describe any condition or organism related to disease of the *intestine* (the main part of the digestive tract, extending from the exit of the stomach to the anus). Enteropathic bacteria, for example, are species that may cause intestinal disease; enteropathic arthritis is joint inflammation associated with *inflammatory bowel disease*.

enteropathy, gluten

See *coeliac disease*.

enterostomy

An operation in which a portion of small or large *intestine* is joined to another part of the gastrointestinal tract or to the abdominal wall. For example, when part of the colon (large intestine) is brought through an incision in the abdominal wall to allow the discharge of faeces into a bag attached to the skin, the operation is called a *colostomy*; when the ileum (the last section of the small intestine) is used, the procedure is called an *ileostomy*.

enterotoxin

A type of *toxin* released by certain *bacteria* that inflames the intestinal lining, leading to diarrhoea and vomiting. Enterotoxins cause the symptoms of *cholera* and *staphylococcal food poisoning* (see *staphylococcal infections*). (See also *endotoxin; exotoxin*.)

Entonox

A brand name for a mixture of *nitrous oxide* and oxygen used to produce pain relief without loss of consciousness.

entrapment neuropathy

A condition, such as *carpal tunnel syndrome*, in which local pressure on a *nerve* causes muscle pain, numbness, and weakness in the area of the body supplied by that nerve.

entropion

A defect of the *eyelids* in which the edges of the lids turn inwards, causing the lashes to rub against the *cornea* (the transparent dome that forms the front of the eyeball) and the *conjunctiva* (the membrane that covers the white of the eye and the inside of the eyelid).

CAUSES

Entropion may be congenital (present from birth), especially in overweight babies. In addition, it is common in elderly people, due to weakness of the muscles around the lower eye, allowing the lower lid plate to turn inwards. Entropion of the upper or lower lid may also be caused by scarring, such as that due to *trachoma*.

COMPLICATIONS AND OUTLOOK

Entropion in babies does not disturb the eye and usually disappears within a few months. In later life, entropion can cause irritation, *conjunctivitis*, damage to the cornea, or problems with vision. Surgery to correct entropion can prevent such conditions.

ENT surgery

The abbreviation for ear, nose, and throat surgery (see *otorhinolaryngology*).

enucleate

To remove an organ, a tumour, or another structure surgically in such a way that it comes out cleanly and completely. A common example of enucleation is the removal of an eyeball while leaving the other structures in place in the eye socket.

cleation is the removal of an eyeball while leaving the other structures in place in the eye socket.

enuresis, nocturnal

The medical term for bedwetting. It is a common condition in children, and boys are slightly more likely than girls to be affected. The problem tends to run in families.

CAUSES

Usually, enuresis results from slow maturation of nervous system functions concerned with bladder control. It may also result from psychological stress. In a small number of bedwetters, there is a physical cause, such as a structural abnormality of the *urinary tract*. *Diabetes mellitus* or a *urinary tract infection* may cause bedwetting in a child who was previously dry. In cases due to physical problems, the child also has difficulty with daytime bladder control (see *incontinence, urinary*).

INVESTIGATION AND TREATMENT

If a child wets the bed persistently, tests, including *urinalysis*, may be performed to rule out a physical cause. For bedwetting that is not caused by a physical disorder, treatment starts with training the child to pass urine regularly during the day. Systems such as rewarding the child for each dry night (for example, by putting stars on a chart) are often successful. Getting the child to go to the toilet just before bed may be helpful.

Punishing a child for bedwetting, however, will not help, and may actually worsen the problem by making the child anxious.

Alarm systems, known as buzzer and pad systems, that involve placing a humidity-sensitive pad in the child's bed are available. The child is woken by the alarm if urine is passed and eventually learns to wake before starting to pass urine.

The drug desmopressin is a synthetic form of antidiuretic hormone (see *ADH*) that may occasionally be given to reduce the amount of water that is excreted by the kidneys. Desmopressin is useful on the occasional nights when a child needs to stay dry, such as when staying overnight with friends.

environmental medicine

The study of the effects on health of natural environmental factors, such as climate, altitude, sunlight, and the presence of various minerals. Environmental medicine overlaps somewhat with *occupational medicine*, in which the effects on people of their working environments are studied.

CLIMATE

The symptoms of particular types of illness may be affected by certain climates. For example, sufferers from chest disorders, such as chronic *bronchitis* and *asthma*, usually obtain some relief from their symptoms in a warm,

THE GROWING IMPORTANCE OF ENVIRONMENTAL MEDICINE

Large areas of the world are naturally hostile to humans and were, in the past, avoided. Today, exploitation of natural resources has lured people into these regions and has highlighted the importance of environmental medicine.

Key

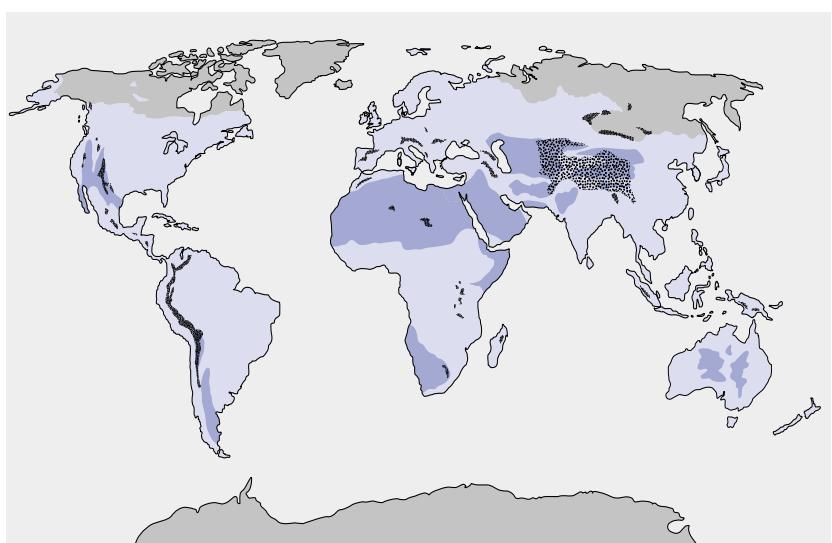

Desert regions

Cold regions with average winter temperature below -23°C

Mountain regions above 3,000 m

relatively dry climate. Most respiratory complaints, in contrast, are more common during the winter.

ALTITUDE

Although mountainous regions have much less atmospheric pollution, they are not necessarily beneficial to health because the air becomes thinner as altitude increases. People with a chest condition who ascend in a few days from sea level to 1,500 m may find that their breathing difficulty worsens. Above about 3,000 m, breathing becomes difficult even for healthy people. Rapid ascent from sea level to 3,600 m or higher carries a risk of altitude sickness (see *mountain sickness*), which can cause sleeplessness, nausea, *coma* (a state of unconsciousness and unresponsiveness to stimuli), or death.

Sustained life seems to be impossible above 6,000 m because at that level the blood cells increase in number to compensate for the lack of oxygen. This increase puts strain on the heart and causes a predisposition to *thrombosis* (abnormal blood clotting).

SUNLIGHT

Fair-skinned people who live in sunny climates may suffer ill effects from repeated exposure to sunlight (see *sunlight, adverse effects of*), including premature wrinkling of the skin and an increased risk of *cataract* (loss of transparency of the lens of the eye). There is also an increased risk of developing *skin cancers*, such as malignant melanoma (see *melanoma, malignant*) and *basal cell carcinoma*, as well as the precancerous condition *solar keratosis*. These risks have been increased by damage caused by environmental pollutants to the protective layers of ozone in the upper atmosphere. Health risks from sunlight may be reduced by protection of the skin, such as by using *sunscreens*.

MINERALS

Variations in the distribution of certain *minerals* in the environment are known to have an effect on health. For example, there is a higher-than-average incidence of cancer in areas where the radioactive gas *radon* is emitted from granitic rocks. In contrast, there is a lower-than-average incidence of tooth decay (see *caries, dental*) in populations in regions where the water has a high *fluoride* content.

enzyme

A *protein* that regulates the rate of a chemical reaction in the body. There are thousands of enzymes, each with a dif-

ferent chemical structure. It is this structure that determines the specific reaction regulated by the enzyme.

Every cell in the body produces various types of enzymes; different sets of enzymes occur in different tissues, reflecting their specialized functions. For example, the *pancreas* produces the digestive enzymes lipase, protease, and amylase, and among the numerous enzymes produced by the *liver* are some that metabolize drugs.

In order to function properly, many enzymes need an additional component, known as a coenzyme, which is often derived from a *vitamin* or *mineral*.

INDUCTION AND INHIBITION

Enzyme activity is influenced by many factors. One of these factors is the action of drugs. Liver enzyme activity is increased by certain drugs, such as *barbiturate drugs*, which affect the rate at which other drugs are metabolized by the liver cells. This effect, which is called enzyme induction, is responsible for a variety of important drug interactions (see *drug*).

Conversely, many drugs inhibit or block enzyme action. Some *antibiotic drugs* destroy bacteria by blocking bacterial enzymes while leaving human enzymes unaffected. Similarly, some *anticancer drugs* act by blocking enzyme activity in tumour cells, affecting normal body cells to a lesser degree.

ENZYMES AND DISEASE

Measuring enzyme levels in the blood can be useful in diagnosing certain disorders. For example, the level of heart muscle enzymes is raised following a *myocardial infarction* (heart attack) because the damaged heart muscle releases enzymes into the bloodstream, and muscle enzyme levels are raised in *muscular dystrophy*.

Many inherited metabolic disorders, including *phenylketonuria*, *galactosaemia*, and *G6PD deficiency*, are caused by defects in, or deficiencies of, enzymes. Abnormal enzymes or levels can be detected in tests on blood or other body fluids.

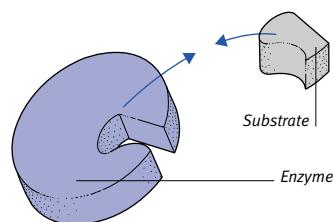

ENZYMES AND TREATMENT

Enzymes can play a valuable role in treating certain conditions. Pancreatic enzymes may be given to aid digestion in people who have *malabsorption* related to pancreatic disease.

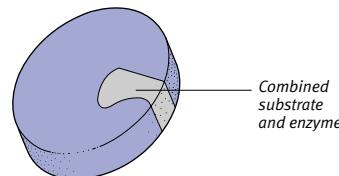

Enzymes such as *streptokinase* and *alteplase* (see *tissue-plasminogen activator*) are used to treat acute *thrombosis* and *embolism* (conditions that cause blockage of blood vessels) by dissolving clots.

THE ACTION OF ENZYMES

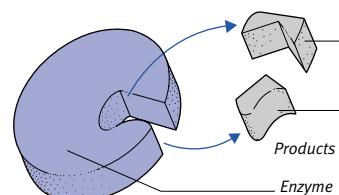

An enzyme is a protein that acts as a catalyst for a chemical change in the body (that is, it greatly speeds up the rate at which the change occurs). The change may be a small modification to the structure of a substrate (the particular chemical on which the enzyme acts) in a body tissue, the splitting of a substrate, or the joining of two substrates.

1 The shape of an enzyme determines its activity. Each enzyme molecule will combine only with a particular substrate that has molecules of a complementary shape.

2 When the enzyme and substrate combine, their interaction causes a chemical change within the substrate. In the example shown here, the chemical is split into two products.

3 After the chemical reaction has ended, the enzyme molecule remains unchanged and can move on to combine with another substrate molecule and repeat the process.

eosinophil

A type of leukocyte (*white blood cell*) that plays a role in allergic responses (see *allergy*) and fighting parasitic infections.

ependymoma

A rare *brain tumour* of the *glioma* type (arising from supporting glial cells in the *nervous system*) that occurs most commonly in children.

ephedrine

A drug that mimics the effects of the neurotransmitter *noradrenaline* (norepinephrine). Ephedrine is prescribed as a *decongestant drug* to treat nasal congestion. It may also be used to treat some cases of low blood pressure that are due to drug actions or disease.

epicanthic fold

E

A vertical fold of skin extending from the upper eyelid to the side of the nose. Epicanthic folds are common in East Asian people but rare in other races, except in babies, in whom they usually disappear as the nose develops. Abnormal epicanthic folds are a feature of *Down's syndrome*. If desired, the folds can be removed by cosmetic surgery.

epicardium

The outermost of the three layers that form the wall of the *heart*. The epicardium is a smooth membranous structure that envelops the *myocardium* (the muscle layer of the heart).

epicondyle

Any bony outgrowth to which *tendons* are attached (for example, at the lower end of the *humerus* (upper-arm bone) where it forms part of the *elbow joint*). Overuse of muscles, leading to repeated tugging on the tendons, can result in pain and inflammation at an epicondyle (see *epicondylitis*).

epicondylitis

Painful inflammation of an *epicondyle*, and specifically one of the bony prominences of the *elbow* at the lower end of the *humerus* (upper-arm bone). Epicondylitis is the result of overuse of the forearm muscles, which causes repeated tugging on the tendons at their point of attachment to the bone.

Epicondylitis that affects the prominence on the outer elbow is called *tennis elbow*. When the prominence on the inner elbow is affected the condition is called *golfer's elbow*.

epidemic

A term applied to a disease that for the majority of the time is rare in a community but that suddenly spreads rapidly to affect a large number of people.

Epidemics of new strains of *influenza* are common, occurring periodically when the influenza virus changes to a form to which the population has no resistance. (See also *endemic*.)

epidemiology

The branch of medicine that is concerned with the occurrence and distribution of disease, including *infectious diseases* (such as cholera or influenza) and noninfectious diseases (such as cancer and heart disease).

In epidemiological studies, the members of a population are counted and described in terms of such variables as race, sex, age, social class, and occupation. The *incidence* and *prevalence* of the disease of interest are then determined. These observations may be repeated at regular intervals in order to detect changes over time. The result is a statistical record that may reveal links between particular variables and distribution of disease.

In comparative epidemiological studies, two or more groups are chosen. For example, in a study of the link between smoking and lung cancer, one group may consist of smokers and the other of nonsmokers; the proportion with cancer in each group is calculated. In such cases, the epidemiologist is careful to make the two groups as identical as possible in all other relevant respects, and will carefully match factors such as age, sex, and weight.

epidermis

The thin outermost layer of the *skin*.

epidermoid cyst

A harmless nodule under the skin's surface that contains yellow, cheesy material. The terms *epidermoid cyst* and *sebaceous cyst* are often used interchangeably.

epidermolysis bullosa

A group of rare, inherited conditions, varying widely in severity, in which blisters appear on the skin after minor injury or occur spontaneously.

CAUSES

Epidermolysis bullosa is caused by a genetic defect that may show either an autosomal dominant or an autosomal recessive pattern of inheritance (see *genetic disorders*).

DIAGNOSIS AND TREATMENT

The conditions can be diagnosed by means of a skin *biopsy* (the removal of a small sample of tissue for microscopic analysis).

There is no specific treatment for the condition, but injury to the skin should be avoided and protective measures should be taken to prevent the rubbing of affected areas when blisters appear.

The outlook varies from gradual improvement in mild cases to progressive disease in the most severe cases.

epididymal cyst

A harmless, usually painless, swelling in the *epididymis* (the coiled tube at the back of the testis). Small cysts are fairly common in men over the age of 40 and need no treatment. Rarely, they enlarge or become tender, causing discomfort. In such cases, it may be necessary for the cysts to be surgically removed.

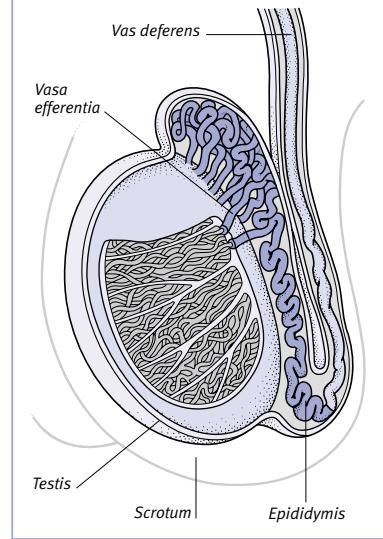

epididymis

A long, coiled tube that runs along the back of the *testis* and connects the *vasa efferentia* (small tubes leading from the testis) to the *vas deferens* (the sperm duct that leads to the urethra). Sperm cells, which are produced in the testis, mature as they pass slowly along the epididymis, until they are capable of fertilizing an egg, and they are then stored until *ejaculation* takes place.

Disorders of the epididymis include *epididymal cysts* (fluid-filled swellings in the epididymis) and *epididymo-orchitis* (inflammation of the testis and epididymis). Infection or injury can block the epididymis; if both testes are affected, *infertility* may result.

LOCATION OF THE EPIDIDYMIS

The epididymis runs along the back of the testis and links the *vasa efferentia* to the *vas deferens*.

epididymitis

See *epididymo-orchitis*.

epididymo-orchitis

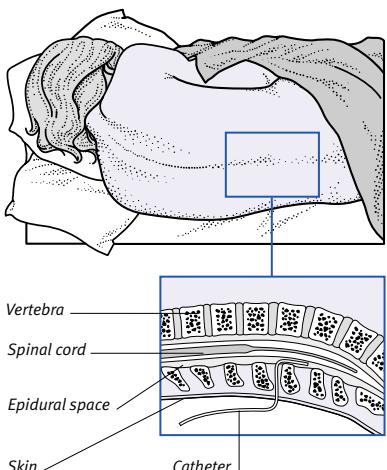

Acute inflammation of a *testis* and *epididymis* (coiled tube that runs along the back of the testis). Epididymo-orchitis causes acute pain and swelling at the back of the testis, and, in severe cases, swelling and redness of the *scrotum*.

The inflammation is caused by infection. Often, there is no obvious source of the infection, but sometimes the cause is a bacterial *urinary tract infection* that has spread via the *vas deferens* (the sperm duct leading to the urethra) to the epididymis.

Treatment is with *antibiotic drugs*. If there is an underlying urinary tract infection, its cause needs to be investigated. (See also *orchitis*.)

epidural anaesthesia

A method of administering pain relief in which a local anaesthetic (see *anaesthesia, local*) is injected into the epidural space (the space around the membranes that surround the spinal cord) in the middle and lower back. Epidural anaesthesia numbs the nerves that supply the chest and lower body. The technique is widely used to relieve pain during and after surgery, as well as during *childbirth*.

Administering an epidural anaesthetic
The anaesthetic is injected into the epidural space (the region surrounding the spinal cord within the spinal canal).

epidural space

The space between the outer membrane of the *spinal cord* and the walls of the vertebral canal that surround it. (See also *epidural anaesthesia*.)

epigastric hernia

A *hernia* (protrusion of an organ or tissue) through a weakened area in the upper central abdominal wall. The hernia may appear as a lump in the centre of the upper abdomen, between the base of the sternum (breastbone) and the navel. (See also *hernia repair*.)

epiglottitis

The flap of *cartilage* lying behind the tongue and in front of the entrance to the *larynx* (voice box). The epiglottis is usually upright to allow air to pass through the larynx and into the rest of the respiratory system. During swallowing, it tilts downwards to cover the entrance to the larynx, preventing food and drink from being inhaled into the trachea (windpipe).

epiglottitis

A potentially life-threatening infection causing inflammation and swelling of the *epiglottis* (the flap of cartilage at the back of the tongue that closes off the windpipe during swallowing). The swollen epiglottis obstructs breathing and can cause death by suffocation if the condition is not treated promptly.

Epiglottitis is now rare due to the routine *immunization* of infants against *HAEMOPHILUS INFLUENZAE*, the bacterium that causes the condition.

epilepsy

A tendency to have recurrent *seizures*. Seizures are defined as transient neurological abnormalities that are caused by abnormal electrical activity in the brain. Human activities, thoughts, and emotions are normally the result of the regulated and orderly electrical excitation of nerve cells in the brain. During a seizure, a chaotic and unregulated electrical discharge causes various physical and mental symptoms.

CAUSES

In many people with epilepsy, the cause is unclear, although a genetic factor may be involved. In other cases, seizures may be the result of brain damage from a head injury; birth trauma; brain infection (such as *meningitis* or *encephalitis*); *brain tumour*; *stroke* (damage to part of the brain caused by an interruption to its blood supply); drug or alcohol intoxication; or a *metabolic disorder*.

SYMPOTMS

Many people who suffer from epilepsy do not have any symptoms between

seizures. Some people experience an *aura* (a peculiar "warning" sensation) shortly beforehand. In some cases, a stimulus such as a flashing light triggers a seizure. Epileptic seizures may occur more frequently during times of illness or stress.

TYPES

Epileptic seizures can be classified into two broad groups: generalized and partial seizures.

Generalized seizures These seizures cause loss of consciousness and may affect all areas of the brain. There are two main types of generalized seizure: tonic-clonic (formerly grand mal) and absence (petit mal) seizures.

During a tonic-clonic seizure, there may initially be an aura, then the body becomes stiff and consciousness is lost. Breathing may be irregular or may stop briefly, then the body jerks uncontrollably. The episode usually ends spontaneously after a few minutes. The person may be drowsy and disorientated for a few hours afterwards, however, and may have no memory of the event. Prolonged tonic-clonic seizures are potentially life-threatening.

Absence seizures occur mainly in children. Periods of altered consciousness last for only a few seconds and there are no abnormal movements of the body. This type of seizure may occur hundreds of times daily.

Partial seizures These seizures are caused by abnormal electrical activity in a more limited area of the brain. They may be simple or complex.

In simple partial seizures, consciousness is not lost and an abnormal twitching movement, tingling sensation, or *hallucination* of smell, vision, or taste occurs, lasting several minutes.

In one type of partial seizure, called *temporal lobe epilepsy*, conscious contact with the surroundings is lost. The sufferer becomes dazed and may behave oddly. Typically, the person remembers little, if anything, of the event.

DIAGNOSIS

In order to make a diagnosis, a doctor needs as much information as possible about the seizures. The patient may not be able to recall the events, so an accurate account from a witness may be necessary. Examination of the nervous system is normally carried out between seizures. An *EEG* (a method of recording the activity of the brain), *CT scanning* or *MRI* of the brain, and blood tests may also be carried out.

TREATMENT

While a seizure is happening, any witnesses should make the surrounding area safe (for example, by removing hazardous objects) and ensure that the person can breathe while unconscious. Clothing around the neck should be loosened, and a soft item, such as a folded piece of clothing, should be placed under the head. Otherwise, witnesses should simply let the attack run its course. Once the convulsions have stopped, the person should be placed in the *recovery position*. A person having a seizure should never be restrained, and should never have anything put into his or her mouth.

Anticonvulsant drugs usually stop or reduce the frequency of recurrent seizures. The drugs may have unpleasant side effects, however, so the doctor will take care to find the one drug that works best for that patient. With very severe epilepsy, a combination of drugs may be needed to control seizures. If no seizures occur after two or three years of treatment, and depending on their cause, the doctor may suggest reducing or stopping the drug treatment.

Women who are taking anticonvulsant drugs and are planning a pregnancy will need to have their treatment reviewed before conceiving. They may need to change to another drug to reduce the risk of a fetal abnormality. Stopping treatment is not usually an option because seizures can be profoundly damaging to the fetus.

Surgery may be considered if a single area of damage to the brain is causing the seizures and drug treatment has not proved effective.

OUTLOOK

Epilepsy that develops during childhood may sometimes disappear soon after adolescence.

Affected adults can enjoy relatively normal lives, but may be restricted in their choice of work. For example, it is inadvisable for people with epilepsy to have occupations involving heights or operating dangerous machinery. In addition, there are certain restrictions on driving vehicles (see *driving, health and*). People with epilepsy are legally required to contact their vehicle licensing agency, who will explain the relevant restrictions.

Many people with epilepsy carry a special card, tag, or bracelet, such as those produced by *Medic-Alert*, which states that they have the condition.

Affected people should also advise their family, friends, and colleagues what to do if a seizure occurs.

epiloia

See *tuberous sclerosis*.

epinephrine

An alternative name for *adrenaline*.

EpiPen

A brand name for an assembled needle and syringe containing a dose of *adrenaline* (epinephrine) that is used for rapid administration to prevent or treat life-threatening allergic reactions (see *anaphylactic shock*). The EpiPen is designed for people who are prone to such reactions to use on themselves; it delivers the adrenaline directly into a muscle, usually a thigh muscle.

Anyone known to be at risk of an anaphylactic reaction should carry an EpiPen with them at all times and be taught how to administer it. An affected person's family, as well as other close contacts, such as teachers, colleagues, and friends, should also be aware of how to use the EpiPen.

epiphora

See *watering eye*.

epiphyseal fracture

A fracture (break) at the point where the epiphysis (the end section of a long bone) meets the diaphysis (the main shaft of the bone). This type of break may affect the subsequent growth of the fractured bone.

epiphyseal plate

The disc that separates the *epiphysis* (the end section of a long bone) from the *diaphysis* (the main shaft of the bone). During the period of growth, the epiphyseal plate is composed of *cartilage* (connective tissue formed of collagen). This cartilage is gradually replaced by bone as a result of *ossification*, a process by which cartilage cells multiply and absorb *calcium* to develop into bone.

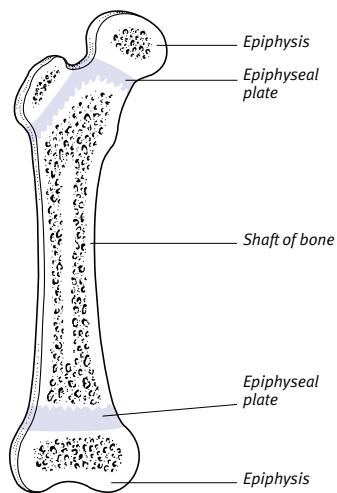

epiphysis

The end section of a long bone (such as the femur in the legs, or the humerus in the arms) that is separated from the diaphysis (the main shaft of the bone) by the *epiphyseal plate*.

Problems that affect the epiphysis or the epiphyseal plate during the period of growth, such as inflammation (a

LOCATION OF EPIPHYESES

Each epiphysis is situated at an end of a long bone of the body and is separated from the shaft of the bone by an area called the epiphyseal plate.

condition called *epiphysitis*), may retard the growth of the affected bone and cause it to become deformed.

epiphysis, slipped

See *femoral epiphysis, slipped*.

episcleritis

A localized patch of inflammation that affects the outermost layers of the *sclera* (white of the eye) in an area immediately underneath the *conjunctiva* (the transparent membrane that covers the sclera).

Episcleritis is usually of unknown cause and mainly affects middle-aged men. It may, at times, be a complication of *rheumatoid arthritis*. The inflammation may cause a dull, aching pain and there may be *photophobia* (abnormal sensitivity of the eyes to light).

The disorder usually disappears by itself within a week or so, but it may recur. Symptoms may be relieved by using *eye-drops* or ointment containing a *corticosteroid drug*.

episiotomy

A surgical procedure in which an incision is made in the *perineum* (the tissue between the vagina and the anus) in

order to facilitate the delivery of a baby. After delivery, the severed tissues are stitched back together.

WHY IT IS DONE

An episiotomy is advisable if the perineum fails to stretch over the baby's head and/or a large perineal tear is likely. The procedure prevents ragged tears that would be more painful, more difficult to repair, and more likely to lead to complications. Episiotomy is usually necessary in a *forceps delivery*, because the instruments occupy additional space in the vagina, and in a *breech delivery*, in which there is little opportunity for gradual stretching of the perineal tissues.

In most cases, however, the naturally elastic vagina should not have to be cut to allow a normal delivery.

epispadias

A rare congenital (present from birth) abnormality in which the opening of the *urethra* (the tube through which urine is excreted from the bladder) is not in the glans (head) of the *penis* but is on its upper surface. In some cases, the penis also curves upwards. Surgery is carried out during infancy, using tissue from the *foreskin* to reconstruct the urethra. (See also *hypospadias*.)

epistaxis

A medical term for *nosebleed*.

epithelioma

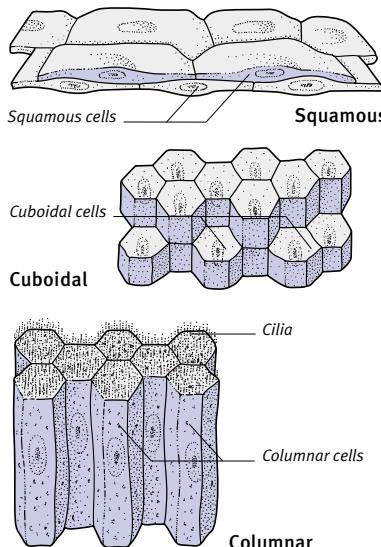

A noncancerous tumour arising from the *epithelium*, the tissue that covers the outer surface of the body and forms the membranous lining of internal organs. In some cases, an epithelioma may become cancerous, in which case it becomes known as a *carcinoma*.

epithelium

The layer of *cells* that covers the entire surface of the body and lines most of the structures within it. Epithelial cells vary in shape according to their function. There are three basic shapes: squamous (thin and flat), cuboidal, and columnar. These structures may vary further. For example, in the respiratory tract, epithelial cells bear brushlike filaments called *cilia* that create a current in the surrounding fluid. This current propels dust particles from inhaled air back up the bronchi (the large air passages in the lungs) and the trachea (windpipe).

Most internal organs lined with epithelium are covered with only a single layer of cells, but the skin, which is

subjected to more trauma, consists of many layers including a dead outer layer of cells that is constantly being shed. Structures that are not lined with epithelium are the blood vessels, the lymph vessels (see *lymphatic system*), and the inside of the heart, which are lined with *endothelium*, and the chest and abdominal cavities, which are lined with *mesothelium*.

Types of epithelium

The cells of the epithelium vary in shape and size according to function. The three basic types are squamous, cuboidal, and columnar.

epoetin

A genetically engineered preparation of the *hormone* erythropoietin, which is produced by specialized cells in the kidneys and stimulates the *bone marrow* to produce *red blood cells*.

Epoetin may be used in the treatment of *anaemia* (a reduced level of the oxygen-carrying pigment haemoglobin in the blood) due to the lack of erythropoietin that occurs in *kidney failure*. It is also used to boost the level of red blood cells before surgery; the patient donates blood to be used during or after the surgery beforehand. Epoetin may also be used as an alternative to blood transfusions in major orthopaedic (bone) surgery.

Epstein–Barr virus

A *virus* that belongs to the herpesvirus family. The Epstein–Barr virus (EBV) may cause glandular fever (see *mononucleosis, infectious*); after the initial infection, the virus remains dormant in the cells of the immune system and may later be

reactivated. Epstein–Barr virus is one of the few viruses with a proven role in the development of cancerous tumours. In Africa, it is associated with *Burkitt's lymphoma*, and in Southeast Asia it is associated with cancer of the nasopharynx (see *nasopharynx, cancer of*). Epstein–Barr virus may also cause lymphomas to develop in patients who have undergone transplant surgery.

Other disorders that are associated with Epstein–Barr virus include some cases of acute *hepatitis*. In people with AIDS, the virus may lead to the development of a condition called oral hairy *leukoplakia*; this condition is characterized by roughened, white patches on the sides of the tongue.

Erb–Charcot disease

A rare condition resulting from spinal cord damage due to *syphilis* (a sexually transmitted bacterial infection). The symptoms include numbness, a sensation of pins and needles, and muscle weakness in the legs.

Erb's palsy

Weakness or paralysis of the muscles in the upper arm and shoulder. Erb's palsy results from damage to the upper roots of the *brachial plexus* (a collection of nerve trunks formed from nerve roots near the top of the spine). Such an injury may occur during birth if excess pressure is applied to the baby's head during a difficult delivery, causing the fifth cervical root of the spinal cord to be damaged. It may also result from a road traffic accident, particularly in motorcycle riders, when an impact forces the head and neck to one side and severely strains the nerves on the opposite side. Erb's palsy is characterized by an arm that is rotated inwards at the shoulder and hangs limp down one side of the body.

ERCP

The abbreviation for endoscopic retrograde cholangiopancreatography, which is an *X-ray* procedure used for examining the *biliary system* and the pancreatic duct. ERCP is used mainly when other imaging techniques, such as *ultrasound scanning*, *CT scanning*, or *MRI*, fail to provide sufficiently detailed images of these body structures.

HOW IT IS DONE

An *endoscope* (a flexible viewing tube with a lens and a light attached) is passed down the oesophagus, through

the stomach, and into the *duodenum* (the upper part of the small intestine). A *catheter* (a fine, flexible tube) is passed through the endoscope into the common bile duct and pancreatic duct. Finally, a *contrast medium* (a substance opaque to X-rays) is introduced through the catheter to make the pancreatic duct and the biliary system visible on X-rays.

If a disease or disorder is detected during the procedure, it can sometimes be treated at the same time. For example, it may be possible to relieve a blockage due to a gallstone.

erectile dysfunction

Inability to achieve or maintain an *erection*; commonly known as *impotence*.

erection

The hardness, swelling, and elevation of the *penis* that occurs in response to sexual arousal or physical stimulation. The erectile tissue of the penis becomes engorged with blood as the blood vessels within it dilate. Muscles around the vessels then contract and keep blood in the penis, thereby maintaining the erection.

erection, disorders of

Conditions in which the *erection* of the penis is disrupted. Such conditions include total or partial failure to attain or maintain an erection (see *impotence*), persistent erection in the absence of sexual desire (see *priapism*), and curving of the penis during erection (see *chordee*).

ergocalciferol

An alternative name for vitamin D₂ (see *vitamin D*).

ergometer

A machine that measures and records the amount of physical work undertaken by the body and the body's response to a controlled amount of exercise. An ergometer makes continuous recordings, both during and after activity, of heart rate and rhythm (using an *ECG*); *blood pressure*; rate of breathing; and volume of oxygen taken in from the air.

ergometrine

A drug given after *childbirth*, *miscarriage*, or *abortion* to reduce the loss of blood from the *uterus* (womb). Ergometrine works by causing blood vessels in the uterine wall to contract, thereby reducing bleeding. The drug is often given in combination with *oxytocin*, which stimulates uterine contractions.

ergot

A product of *CLAVICEPS PURPUREA*, a *fungus* that grows on rye and various other cereals. Ergot contains poisonous *alkaloids* (nitrogen-containing substances), some of which have medicinal properties when taken in controlled doses.

The drugs *ergotamine*, used in the treatment of migraine, and *ergometrine*, given to control blood loss following childbirth, miscarriage, or abortion, are both produced from ergot.

ergotamine

A drug used to treat *migraine*. It works by constricting the dilated blood vessels around the brain. Side effects of ergotamine include nausea, vomiting, muscle cramps, and abdominal pain. It is now used infrequently, having been largely replaced by drugs such as *sumatriptan*.

erosion

The destruction and loss of surface tissue through physical or chemical processes (see *cervical erosion*; *erosion, dental*; *gastric erosion*).

erosion, dental

Loss of enamel from the surface of a tooth (see *teeth*) due to attack by *plaque* acids or other chemicals. The first sign of enamel loss is a dull, frosted appearance. As the condition progresses, smooth, shiny, shallow cavities form.

Erosion of the outer surfaces of the front teeth is most frequently caused by excessive intake of acidic fruit juices and carbonated drinks. Erosion of the inner surfaces of the molars may be a result of regurgitation of stomach acid, as occurs in people suffering from *acid reflux* or *bulimia*. Erosion may be combined with, and may also accelerate, the processes of abrasion (mechanical wearing away of teeth) and attrition (wearing down of the chewing surfaces). These problems may result in extensive damage to the teeth. (See also *caries, dental*.)

eroticism

The character and emotive nature of sexual excitement. Sexual arousal may be stimulated by erotic thoughts, by touching the erogenous zones, and by a variety of other sensations (such as the look and feel of certain clothes).

eruption

The process of breaking out, as of a skin rash or a new tooth. (See also *eruption of teeth; eruptive phase*.)

eruption of teeth

The process by which developing *teeth* grow from the jawbone, breaking through the *gum* to project into the mouth.

DECIDUOUS TEETH

Deciduous teeth (milk teeth) usually begin to appear at about six months of age. All 20 deciduous teeth have usually erupted by three years (see *teething*).

PERMANENT TEETH

Permanent teeth (which are also known as secondary teeth) usually begin to appear at about six years of age. The first permanent molars erupt towards the back of the mouth and appear in addition to the deciduous teeth. The eruption of permanent teeth nearer the front of the mouth is preceded by reabsorption of the roots of the deciduous teeth, which causes the teeth to become loose so that they fall out. Eventually, permanent teeth replace all of the deciduous teeth.

Wisdom teeth (the third molars) usually erupt between the ages of 17 and 21. In some people, however, they never appear; in others, the wisdom teeth are impacted (blocked from erupting) because of insufficient space in the jawbone (see *impaction, dental*).

eruptive phase

The phase in the course of a condition such as *chickenpox* in which skin lesions, for example spots or blisters, break out.

erysipelas

A disorder, caused by a *streptococcal infection*, that produces inflammation and blistering of the face and is associated with a high fever and *malaise*. Erysipelas most often affects young children and elderly people. Treatment is with *penicillin drugs*. (See also *cellulitis*.)

erythema

A term meaning redness of the skin. Disorders in which skin redness is a feature include *erythema multiforme*, *erythema nodosum*, *erythema ab igne*, *lupus erythematosus*, and *erythema infectiosum* (also known as *fifth disease*).

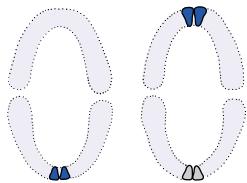

Erythema can have many causes, such as *blushing*, *hot flushes*, *sunburn*, and inflammatory, infective, or allergic skin disorders such as *acne*, *dermatitis*, *eczema*, *erysipelas*, *rosacea*, and *urticaria*.

erythema ab igne

Red, mottled skin that may also be dry and itchy. Erythema ab igne is caused by exposure to strong direct heat, such as

ERUPTION OF TEETH

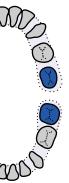

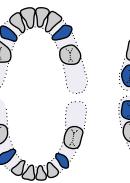

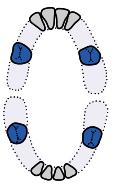

The top diagrams show the approximate ages at which particular deciduous teeth usually appear. The ages at which specific types of permanent teeth usually appear are shown

6 to 10 months:
lower central
incisors

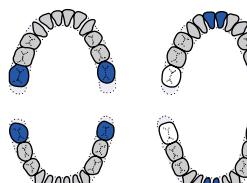

8 to 12 months:
upper central
incisors

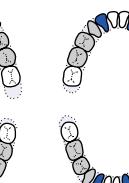

Deciduous teeth

The full deciduous set (left) consists of eight incisors, four canines, and eight molars. They usually start erupting at six months.

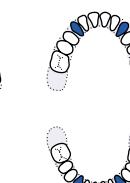

6 to 7 years:
first molars

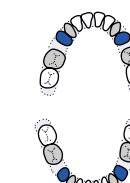

6 to 8 years:

molars

17 to 21 plus:
third
molars

in the lower diagrams. Blue denotes erupting teeth; grey denotes erupted deciduous teeth; white denotes erupted permanent teeth.

Permanent teeth

The full set of permanent teeth (below) consists of eight incisors, four canines, eight premolars, and twelve molars. They usually start erupting at six years.

when an individual has been sitting too close to a fire. The condition is most common in elderly women.

Dryness and itching can often be relieved by use of an *emollient* (soothing cream). The redness fades in time but may not disappear entirely.

erythema infectiosum

See *fifth disease*.

erythema marginatum

A pink rash that appears and disappears spontaneously and that may affect any area of the body except the face. Erythema marginatum is a characteristic sign of *rheumatic fever*.

erythema migrans

A red, circular rash that occurs as a result of infection with *Lyme disease*. Erythema migrans first appears at the site of a bite from an infected tick. The rash then expands, over a period of days or weeks, to form a large, round patch. Erythema migrans is most commonly found on the thighs, groin, or trunk, or in the armpit.

erythema multiforme

Acute *inflammation* of the skin, and sometimes of the *mucous membranes* (the thin, moist tissue that lines body cavities), that is sometimes accompanied by generalized illness. Erythema multiforme means "skin redness of many varieties".

CAUSES

Erythema multiforme can develop as an adverse reaction to certain drugs or it may accompany certain viral infections (for example, *herpes simplex*) or bacterial infections (such as *streptococcal infections*). Other possible causes of erythema multiforme are pregnancy, *vaccination*, and *radiotherapy*. However, about half of all cases occur for no apparent reason.

SYMPTOMS

A symmetrical rash of red, frequently itchy, spots erupts on the skin of the limbs and, occasionally, on the face and the rest of the body. The spots may blis-

The rash of erythema multiforme

The spots of this rash are usually itchy. They may form into target lesions (concentric rings of different shades of red around a pale centre).

ter or form raised, pale-centred weals known as target lesions. People suffering from erythema multiforme may have a fever, sore throat, headache, and/or diarrhoea.

In a more severe form of erythema multiforme, known as *Stevens-Johnson syndrome*, the mucous membranes of the mouth, eyes, and genitals are all affected and become ulcerated.

TREATMENT

Treatment for erythema multiforme depends on the underlying cause. Any causative drug treatment will be withdrawn and any underlying condition will be treated if possible. *Corticosteroid drugs* may be given to reduce the inflammation. People suffering from Stevens-Johnson syndrome are also given *analgesic drugs* (painkillers) and may need intensive care.

erythema nodosum

A condition characterized by reddish-purple, tender swellings on the legs. Erythema nodosum is usually associated with another illness.

CAUSES

The most common cause of erythema nodosum is a *streptococcal infection* of the throat. However, the condition is also associated with other diseases, mainly *tuberculosis* and *sarcoidosis*, and

may occur as a reaction to some drugs, particularly *sulphonamide drugs*, *penicillin drugs*, and *salicylate drugs*. Sometimes there is no apparent cause.

SYMPOTMS

The swellings, which may range from 1 to 10 cm in diameter, are shiny and tender and occur on the fronts of the shins, the thighs, and, less commonly, the arms. Joint and muscle pains and fever also usually occur.

TREATMENT

Successful treatment of any underlying condition clears the swellings. Bed rest, *analgesic drugs* (painkillers), and, occasionally, *corticosteroid drugs* may also be necessary. The condition usually subsides within about a month.

erythematous

Characterized by *erythema* (redness of the skin).

erythrasma

A bacterial skin infection, caused by the organism *CORYNEBACTERIUM*, that affects the groin, armpits, and skin between the toes. Raised, irregularly shaped, discoloured patches appear in the affected areas. Erythrasma is most common in people who have *diabetes mellitus*. The condition generally clears up following a course of treatment with the antibiotic drug *erythromycin*.

erythrocyte

Another name for a *red blood cell*.

erythroderma

See *exfoliative dermatitis*.

erythrogenic toxin

A poisonous protein produced by streptococcal bacteria that causes the red rash in *scarlet fever*.

erythromelalgia

A rare condition, also known as Gerhardt–Mitchell disease, that principally affects the extremities of the body, most commonly the feet. Erythromelalgia usually first appears in middle age. It may be associated with *polycythaemia* (an increase in the total red cell mass of the blood), *thrombocytosis* (an increase in the number of platelets in the blood), *gout* (a metabolic disorder that causes attacks of arthritis), and neurological disease.

Erythromelalgia is characterized by severe attacks of burning pain and mottled redness of the skin; it may be

triggered by heat. Attacks of the condition can be relieved by elevating the affected limb and applying something cold, such as an ice pack, to it. No specific treatment is available, but *aspirin* may relieve the condition in some cases.

erythromelia

Diffuse *erythema* (redness) and *atrophy* (wasting) of the skin of the lower limbs. The cause of erythromelia is unknown.

erythromycin

An *antibiotic drug* used in the treatment of skin, chest, throat, and ear infections. Erythromycin is given to people with these conditions who are allergic to *penicillin drugs*. In addition, it is particularly useful in the treatment of *pertussis* (whooping cough) and *legionnaires' disease*. The drug may be taken in tablet form, liquid form, or intravenously. Possible adverse effects include nausea, diarrhoea, and an itchy rash.

erythrovirus

A *virus* formerly known as parvovirus. Infection with a strain of erythrovirus causes *fifth disease* in humans.

escape beat

An automatic *heartbeat* that occurs after an abnormally long pause in the heart rhythm. An escape beat is therefore a delayed beat that terminates a longer cycle than normal.

eschar

A *scab* that forms on the surface of skin that has been subject to damage, for example by a *burn*.

Escherichia coli (*E.coli*)

A bacterium (see *bacteria*) that is normally found in the intestines but can cause illness under some circumstances.

Types of *E. coli* are often the cause of traveller's diarrhoea, which is usually a mild illness. Bacteria that enter the bladder through the urethra are a common cause of *urinary tract infections*. Some strains of *E.coli*, however, can cause serious food-borne infections that may result in *haemolytic–uraemic syndrome* (a condition in which red blood cells are destroyed and kidney function becomes impaired).

Esmarch's bandage

A broad rubber bandage that is wrapped around the elevated limb of a patient to force blood out of the blood

vessels towards the heart. This action creates a blood-free area, so surgery on the limb can be performed more easily.

The patient is anaesthetized (see *anaesthesia*), then the Esmarch's bandage is wrapped from the fingers or toes upwards. An inflatable tourniquet (a device used to compress blood vessels) is then applied to the upper arm or thigh to stop blood from returning to the limb. The Esmarch's bandage is removed, leaving the inflated tourniquet in position during surgery.

esotropia

An alternative term for a convergent *squint*, in which one eye looks directly at an object while the other eye turns inwards. (See also *exotropia*.)

ESR

The abbreviation for *erythrocyte sedimentation rate*, which is the rate at which erythrocytes (*red blood cells*) sink to the bottom of a test tube.

WHY IT IS DONE

The ESR is increased if the level of *fibrinogen* (a type of protein) in the blood is raised. Fibrinogen is raised in response to a range of illnesses, including *inflammation*, especially when this is caused by infection or by an *autoimmune disease*. The ESR is also increased if levels of *antibodies* (proteins manufactured by the immune system) are very high, as occurs in *multiple myeloma*. ESR is therefore useful for helping to diagnose these conditions as well as in monitoring their treatment.

HOW IT IS DONE

Whole blood collected from the patient is mixed with anticoagulant (a chemical that prevents the blood from clotting) in a test tube. In one method, the blood is left undisturbed at a constant temperature for one hour. The red blood cells, which can be seen as a dark red clump, settle to the bottom of the tube, leaving the clear, straw-coloured plasma at the top. The ESR is the number of millimetres the red cells fall in one hour.

essential amino acids

The nine *amino acids* required for protein synthesis, growth, and development, that cannot be made by the body and must be obtained in the diet.

essential fatty acids

The *fatty acids* that cannot be synthesized by the body and must therefore be obtained in the diet.

essential food factors

Any substances that are essential for normal functioning of the body but cannot be synthesized by the body itself, so must be obtained through the diet. Examples of essential food factors are most *vitamins* and *minerals* and *essential amino acids*.

essential hypertension

Hypertension (high blood pressure) that occurs without known cause.

estradiol

The most important *oestrogen hormone*, which is essential for the healthy functioning of the female reproductive system and for breast development. In its synthetic form, estradiol is used to treat the symptoms and complications of the menopause (see *hormone replacement therapy*) and to stimulate sexual development in female *hypogonadism* (underactivity of the ovaries).

estriol

One of the *oestrogen hormones*. Estriol is the predominant oestrogen produced during pregnancy. Synthetic estriol is prescribed to treat the symptoms and complications of the menopause (see *hormone replacement therapy*) as well as to stimulate sexual development in female *hypogonadism* (underactivity of the ovaries).

estrone

An *oestrogen hormone*. Synthetic estrone is used to treat the symptoms and complications of the menopause (see *hormone replacement therapy*).

ESWL

The abbreviation for extracorporeal shock wave *lithotripsy*.

ethambutol

A drug used in conjunction with other drugs to treat *tuberculosis*. Ethambutol rarely causes side effects, but it may sometimes result in inflammation of the *optic nerve*, leading to blurred vision.

ethanol

The chemical name for the *alcohol* that is present in alcoholic drinks.

ether

A colourless liquid that produces unconsciousness when inhaled. Ether was the first general anaesthetic (see *anaesthesia, general*) to be introduced.

ethics, medical

See *medical ethics*.

ethinylestradiol

A synthetic form of the female sex hormone *estradiol*. Ethinylestradiol is most often used in *oral contraceptives*, in which it is combined with a *progestogen drug*. Rarely, it is used in *hormone replacement therapy*.

ethmoidal sinus

One of the air-containing spaces in the *ethmoid bone* behind the nose (see *sinus, facial*).

ethmoid bone

A *bone* that forms part of the floor of the cranium (skull) and contributes to the roof of the nasal cavity and to the orbits (eye sockets). The *olfactory nerves*, which are responsible for smell, pass through holes in part of the ethmoid bone called the cribriform plate.

ethosuximide

An *anticonvulsant drug* used in the treatment of absence (petit mal) seizures (see *epilepsy*). Ethosuximide may cause nausea and vomiting and, in rare cases, affects the production of blood cells in bone marrow (see *anaemia, aplastic*).

ethyl alcohol

Another name for ethanol, the alcohol in alcoholic drinks.

ethyl chloride

A colourless liquid that is used as an *analgesic drug* (painkiller). Ethyl chloride is applied to the skin as a spray to numb an area before minor surgery is carried out or to relieve muscle pain. The substance is also used in the treatment of *larva migrans*, a hookworm infestation.

etidronate, disodium

A *bisphosphonate drug* used to treat bone disorders (see *bone, disorders of*), such as *Paget's disease* and *osteoporosis*. Disodium etidronate works by reducing the activity of bone cells, thereby halting the progress of the disease. Side effects of the drug are generally mild.

etretinate

A *retinoid drug*, chemically related to *vitamin A*, that is used mainly in the treatment of severe *psoriasis* (a skin disease characterized by thickened patches of red, inflamed skin). Also known as

acitretin, etretinate is also occasionally used in the treatment of other disorders that cause excessive skin thickening, such as *ichthyosis*. It reduces the production of keratin, the protein that forms the hard, outer layers of the skin.

Etretinate can cause liver damage and a rise in blood fats. The drug must not be taken during pregnancy because it can cause damage to the fetus.

eucalyptus oil

A substance distilled from the leaves of eucalyptus trees. Because of its aromatic smell and refreshing taste, it is used as a flavouring. It is also used in cough and cold remedies, when it may be applied as a rub, inhaled as vapour, or incorporated in tablets.

There is little evidence that eucalyptus oil has any curative properties, although it may relieve symptoms.

eugenics

The science that is based on the improvement of the human race and the quality of human life through the principles of *genetics*. Modern eugenics is primarily concerned with the study (and, where possible, the elimination) of genetic disease (see *genetic disorders*).

Eulenburg's disease

A rare, nonprogressive, inherited disorder, also called congenital paramyotonia, in which there is prolonged contraction of muscle fibres (see *myotonia*) when the patient is exposed to the cold. The muscles of the limbs, eyelids, and tongue may be affected. Eulenburg's disease shows an autosomal dominant pattern of inheritance (see *genetic disorders*) and may be caused by a disorder of potassium *metabolism*.

eunuch

A man whose testes (see *testis*) have been removed or destroyed so that he is sterile and lacks male hormones. A male who has been castrated before *puberty* will have broad hips, narrow shoulders, and undeveloped male secondary *sexual characteristics* (such as a small penis, a feminine distribution of body hair, and a high-pitched voice).

euphoria

A state of confident wellbeing. Euphoria is a normal reaction to personal success, but it can also be induced by certain drugs, including prolonged use of *corticosteroid drugs*. Euphoria that has

EUSTACHIAN TUBE

no rational cause may be a sign of *mania* or of brain disease, or damage from *head injury* (particularly damage to the frontal lobes), *dementia*, *brain tumours*, or *multiple sclerosis*.

eustachian tube

The passage that runs from the middle ear into the back of the nose, just above the soft palate (part of the roof of the mouth). The eustachian tube is lined with a smooth, moist, mucous membrane.

FUNCTION

The eustachian tube acts as a drainage channel from the middle ear and maintains hearing by opening periodically to regulate air pressure. The lower end of the tube opens during swallowing and yawning, allowing air to flow up to the middle ear, equalizing the air pressure on both sides of the *eardrum*.

DISORDERS

When a viral infection, such as a cold, causes blockage of the eustachian tube, equalization cannot occur, resulting in severe pain and temporary impairment of hearing. A person with a blocked eustachian tube who is subjected to rapid pressure changes may suffer from *barotrauma* (pressure damage to the eardrum and other structures). *Glue ear* (the accumulation of secretions in the middle ear) or chronic *otitis media* (middle-ear infection) may occur if the tube is blocked, preventing adequate drainage from the middle ear.

These conditions, which often result in partial hearing loss, are much more common in children. This is partly

because their *adenoids* are larger and more likely to cause a blockage if they become infected and partly because children's eustachian tubes are shorter than those of adults.

euthanasia

The use of medical knowledge to end a life painlessly in order to relieve suffering. Voluntary euthanasia refers to action taken to end life at the patient's own request. In the UK, it is illegal to take active measures to end a person's life; however, the withdrawal of treatment that would prolong life may be considered under some circumstances.

euthyroid

A term used to describe a person whose *thyroid gland* is functioning normally. The term "euthyroid" is used especially to refer to someone who has been successfully treated for either *hypothyroidism* (underactivity of the thyroid) or *hyperthyroidism* (overactivity of the thyroid).

Evans's syndrome

An uncommon *autoimmune disorder* in which the body wrongly makes two *antibodies* (immune system proteins): one that attacks healthy red blood cells (see *anaemia, haemolytic*) and one that destroys platelets (tiny cells in the blood that play a vital role in blood clotting). The spleen is usually the main site of cell destruction.

The anaemia can cause tiredness and pallor, and the deficiency of platelets may lead to bruising and a tendency to

bleed easily. The haemolysis (red cell destruction) causes *jaundice* (yellowing of the skin and the whites of the eyes).

A blood transfusion may be needed in the early stages of the condition. *Corticosteroid drugs* may be prescribed to control haemolysis and platelet destruction. In severe cases, the spleen may be removed (see *splenectomy*). The antibodies may eventually disappear after several months or years.

evening primrose oil

An oil extracted from the seeds of the plant *OENOTHERA BIENNIS*, commonly called evening primrose. The oil contains an anti-inflammatory substance known as *gammolenic acid* and is believed by some to be of benefit in treating *eczema* and *premenstrual syndrome*.

eversion

Turning outwards. The term is used medically to describe a type of *ankle* injury or deformity in which the foot is turned outwards.

evidence-based medicine

The use of medical or surgical treatments that have been evaluated for effectiveness and safety by clinical research. The research involves *randomized controlled trials* and often includes *meta-analysis*, in which the results from several trials are combined.

Evista

A brand name for *raloxifene*, a drug that is prescribed for the prevention and treatment of *osteoporosis* in post-menopausal women.

evoked potential

The electrical signal generated when a sensory area, such as a *nerve*, a *muscle*, or the *retina* (the light-sensitive inner layer at the back of the eye), is stimulated. Tests to record evoked potentials are used to diagnose problems affecting the conduction of signals along sensory nerves. (See also *evoked responses*.)

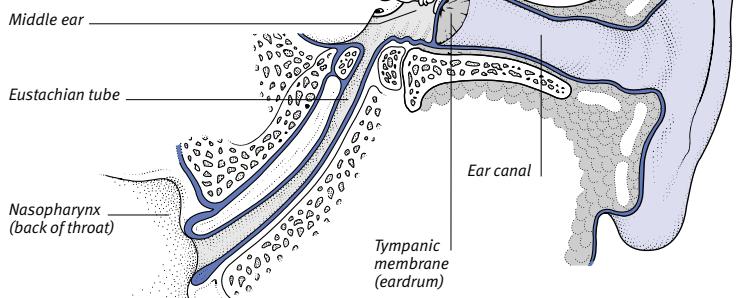

evoked responses

The tracing of electrical activity in the brain in response to a specific external stimulus. The evoked responses procedure is similar to that for an *EEG* (electroencephalography).

The technique is used to check the functioning of various sensory systems (such as sight, hearing, or touch). The information obtained can be used to

ANATOMY OF THE EUSTACHIAN TUBE

The eustachian tube connects the middle ear with the back of the nose. The tube is divided into two separate parts: the uppermost part runs through a bony canal and the lower part is lined with cartilage.

reveal abnormalities caused by inflammation, pressure from a tumour, or other disorders, and to help confirm a diagnosis of *multiple sclerosis*.

Ewing's sarcoma

A rare malignant form of *bone cancer*. Ewing's sarcoma arises in a large bone, usually the *femur* (thigh bone), *tibia* (shin), *humerus* (upper-arm bone), or a pelvic bone, and spreads to other areas at an early stage. The condition is most common in children between ten and 15 years of age.

SYMPOTMS

A bone affected by Ewing's sarcoma is painful and tender. It may also become weakened and fracture easily. Other symptoms include weight loss, fever, and *anaemia* (a reduced level of the oxygen-carrying pigment haemoglobin in the blood).

DIAGNOSIS AND TREATMENT

The sarcoma can be diagnosed by *X-rays* and *biopsy* (removal of a small sample of tissue for microscopic analysis). If cancer is found, the whole skeleton is examined by *X-rays* and *radionuclide scanning*, and the lungs viewed by *CT scanning*, to determine if, and how far, the cancer has spread.

Treatment of Ewing's sarcoma is with *radiotherapy* and *anticancer drugs*. The outlook depends on how far the cancer has spread.

examination, physical

The part of a medical consultation in which the doctor looks at, feels, and listens to various parts of the patient's body. A physical examination is used to assess the patient's condition or to gather information to help the doctor make a *diagnosis*.

Most physical examinations include *palpation* (feeling with the hands), by which the doctor examines relevant areas of the body for signs such as swelling, tenderness, or enlargement of organs. In some cases, *percussion* of the chest, or other parts of the body, may be performed by tapping with the fingers and then listening to the sound produced. *Auscultation* (listening with a stethoscope) may be used to listen to blood flow through the arteries and sounds made by the heart and lungs. Other aspects of the examination may involve taking the patient's pulse or *blood pressure*, examining his or her eyes and ears, and assessing the strength and coordination of the muscles.

exanthema

A skin eruption or rash, or a disease in which a skin eruption or rash is a prominent feature, such as *measles*, *scarlet fever*, or *roseola infantum*.

exchange transfusion

A treatment for *haemolytic disease of the newborn*, a severe disorder resulting from *rhesus incompatibility* between a pregnant mother and her baby and causing destruction of red blood cells in the baby. This condition leads to dangerously high levels of the pigment *bilirubin* in the baby's blood as well as severe *anaemia* (a reduced level of the oxygen-carrying pigment haemoglobin in the blood). Exchange transfusion is used to treat both these symptoms by replacing the infant's blood with rhesus-negative donor blood.

excimer laser

A computer-controlled *laser* used to reshape the *cornea* (the transparent dome that forms the front of the eyeball). The laser removes very thin layers of tissue from the corneal surface (see *LASIK; PRK*). The technique is used to correct *myopia* (shortsightedness), *hypermetropia* (longsightedness), and some other vision disorders.

excision

The surgical cutting out of diseased tissue, such as a breast lump or gangrenous skin, from surrounding healthy tissue. (See also *excisional biopsy*.)

excisional biopsy

A type of *biopsy* that involves the removal of an entire area of affected tissue, together with a margin of adjacent healthy tissue, for microscopic analysis in a laboratory.

exclusion diet

A dietary programme that is used to identify a particular *food allergy* or *food intolerance*. Food is initially limited to a very restricted choice until symptoms improve; test foods, such as milk, are then reintroduced one at a time, at intervals of several days, to see if there is an adverse reaction. The reintroduction of such a test food is known as a food challenge.

Individuals on an exclusion diet are asked to keep a daily record of their symptoms from at least a week before starting the diet until the end of the programme. An exclusion diet should

never be attempted without the advice of a doctor, dietitian, or nutritionist because it can result in serious nutritional deficiencies.

excoriation

Injury to the surface of the skin or to a *mucous membrane* (the thin, moist tissue that lines body cavities) caused by physical *abrasion*, such as scratching.

excrecence

Any abnormal raised growth on the surface of the body, such as a *wart*.

excretion

The discharge of any waste material from the body. Examples of such waste material are the by-products of digestion, waste products from the repair of tissues, and excess water.

ORGANS OF EXCRETION

The *kidneys* excrete urine, which contains excess nitrogen (as urea), together with excess water, salts, some acids, and most drugs. The *liver* excretes bile, which contains waste products and bile pigments formed from the breakdown of red blood cells. Some of the bile is passed from the body in the *faeces*. The large *intestine* excretes undigested food, some salts, and excess water in the form of faeces. The *lungs* discharge carbon dioxide and water vapour into the air. *Sweat glands* excrete salt and water onto the surface of the skin as a method of regulating the body's temperature.

exencephaly

A developmental defect of the cranium (skull) in which part of the bone is absent, leaving the brain exposed or allowing it to protrude. This defect is incompatible with survival.

exenteration

The surgical removal of all organs and soft tissue in a body cavity, usually to arrest the growth of a *cancer*. Exenteration is sometimes used in *ophthalmology* when the eye and the contents of the eye socket are removed.

exercise

Any physical activity performed to improve health. Exercise may be taken for recreation or to correct a physical injury or deformity (see *physiotherapy*).

TYPES OF EXERCISE

Different types of exercise have different effects on the body. Some forms (aerobic exercises) improve the fitness

of the cardiovascular and respiratory systems; some forms improve flexibility; some increase muscular strength; and some improve physical endurance.

During aerobic exercise, such as jogging or swimming, the heart and lungs work faster and more efficiently to meet the muscles' increased demand for oxygen. Regular aerobic exercise improves the condition of both the cardiovascular and respiratory systems.

Exercises such as weight training increase muscle strength and endurance. Activities such as yoga and pilates

improve flexibility. For further information on the effects of exercise, see the illustrated box below.

BENEFITS OF EXERCISE

There is an association between high levels of aerobic exercise and a low incidence of *coronary artery disease*. Regular aerobic exercise usually leads to reduced blood pressure. It also increases levels of *high density lipoprotein* (HDL) in the blood, which is thought to help protect against *atherosclerosis* (the accumulation of fatty deposits on artery walls) and *myocardial infarction* (heart attack).

Exercise can help to relieve the symptoms of *peripheral vascular disease* as well as of some psychological disorders, particularly *depression*. Regular weight-bearing exercise (such as running) increases bone density, making the bones stronger; hence *osteoporosis* is less common in people who have exercised throughout their adult lives. Such exercise also increases muscle mass and strengthens the muscles and ligaments. It can therefore help to prevent or ease lower back pain and can make the ligaments less susceptible to strains.

E

THE EFFECTS OF EXERCISE

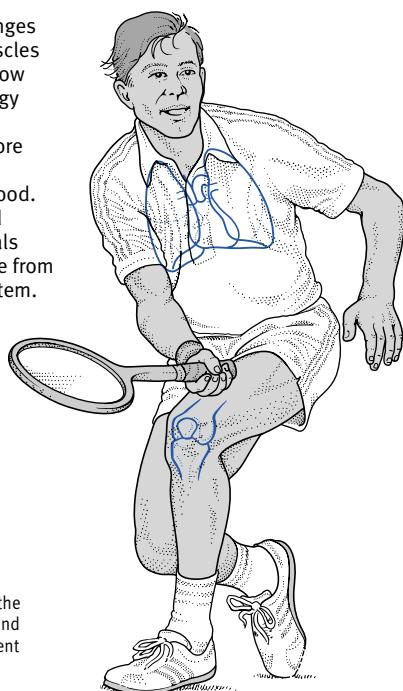

Exercise produces many changes in different body organs. Muscles receive an increased blood flow because of their greater energy requirements, and the heart and lungs work faster and more efficiently to keep the body tissues well supplied with blood. These changes are controlled by the release of the chemicals adrenaline and noradrenaline from the sympathetic nervous system.

The lungs

The rate and depth of breathing increase to ensure a sufficient flow of oxygen from the lungs into the blood. This increase in breathing also helps to remove additional carbon dioxide produced by the muscle cells during exercise.

Bones

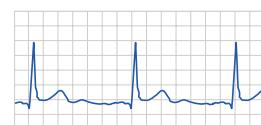

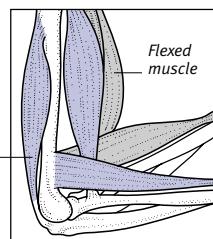

Regular exercise helps to maintain the strength and density of the bones and so prevents or slows the development of the bone disease osteoporosis.

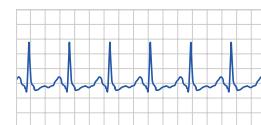

The muscles

As the muscles flex and relax, there is a rise in the chemical activity within muscle cells. The rate at which the cells consume oxygen and glucose increases.

Relaxed muscle

ECG printout showing heart rate at rest

Heart rate during exercise

The heart and circulation

The heart beats faster and more powerfully to increase the blood flow to the working muscles. Blood vessels in the intestines, liver, stomach, and kidneys narrow so that more blood is directed away from these areas and to the muscles.

COMMON TYPES OF EXERCISE

Aerobic	Isometric	Isotonic	Isokinetic
Aerobic  Aerobic exercise is activity in which the body continuously needs to take in additional oxygen to meet the muscles' increased demands. Regular aerobic exercise improves the performance of the cardiovascular and respiratory systems. Jogging, swimming, and cycling are examples of aerobic exercise.	Isometric  Isometric exercise is exercise without movement, in which one group of muscles exerts steady pressure against either an immovable object or an opposing group of muscles. It is an effective means of increasing muscle strength, but does not exercise the cardiovascular system or help in muscular endurance.	Isotonic  Isotonic exercise is exercise with movement, in which muscle tension is more or less constant and the body works against its own weight or external weights. Isotonic exercise includes weight training and calisthenics (repetitious movements with little or no equipment). It increases muscle strength, size, and endurance.	Isokinetic  Isokinetic exercise involves both isotonic and isometric exercise. The muscles move reasonably heavy loads, but are also put through their full range of movement. Isokinetics combines strength training with some aerobic exercise, but requires specialist equipment.

RISKS

In some circumstances, vigorous exercise may pose a number of health risks. For example, people who are out of condition but attempt strenuous activity may suffer injury and put themselves at increased risk of a heart attack. Professional sportsmen, such as footballers, may have an increased risk of *osteoarthritis* in later life because of the repeated minor damage to structures such as the knee and the cervical area of the spine.

exercise ECG

The use of electrocardiography (see *ECG*) to assess the function of the heart when it is put under the stress of exercise. Exercise ECG is usually carried out when a patient is suspected of having *coronary artery disease*. The procedure involves raising the heart rate by exercising, usually on a treadmill with an adjustable gradient or on an exercise bicycle. The heart's electrical activity is then recorded for analysis.

exercise tests

Any of a variety of tests in which exercise is used as a means of deliberately stressing the heart and the lungs. The use of exercise tests enables doctors to assess an individual's level of health and fitness. (See also *cardiac stress test*; *exercise ECG*.)

exfoliation

Flaking off, shedding, or peeling from a surface in scales or thin layers, as in *exfoliative dermatitis*.

exfoliative dermatitis

A skin disorder characterized by severe inflammation, redness, and scaling of the skin over most of the body. Exfoliative dermatitis may be the result of an allergic response to a drug (see *allergy*) or it may be due to worsening of a pre-existing skin condition such as *psoriasis* or *eczema*. The condition sometimes occurs in *lymphoma* and *leukaemia*.

In exfoliative dermatitis, there is a widespread rash, accompanied by severe flaking of the skin, which results in increased loss of water and protein from the surface of the body. Protein loss may cause *oedema* (the accumulation of fluid in tissues) and muscle wasting. Further possible complications include *heart failure* and infection. The treatment of exfoliative dermatitis, and the outlook, depend on the cause.

exhalation

The medical term for the process of breathing out (see *breathing*).

exhaustion

Extreme mental or physical *tiredness* in which a person lacks energy. The state of exhaustion may come about as a result of overactivity or prolonged *insomnia* (difficulty in falling or staying asleep) or it may be a symptom of a mental or physical disorder, such as *anxiety*, stress, severe *anaemia*, or prolonged *labour*. (See also *heat exhaustion*.)

exhibitionism

The habit of deliberately exposing the *genitalia* as a deviant sexual act. This type of behaviour is almost always confined to men. *Psychotherapy* or *behaviour therapy* may help to treat persistent offenders.

existential psychotherapy

An uncommon form of *psychotherapy* in which emphasis is placed on spontaneous interactions and feelings rather than on rational thinking. The psychotherapist is involved in the therapy to the same extent as the patient.

exocrine gland

A gland that secretes substances through a duct (a tube or passage) either onto the inner surface of an organ or the outer surface of the body. Examples of exocrine glands include the *salivary glands* and the *sweat glands*. The release of exocrine secretions can be triggered by a *hormone* or a *neurotransmitter*. (See also *endocrine gland*.)

exogenous

A term referring to a disease or disorder that has a cause external to the body. Examples are infection, poisoning, or injury. (See also *endogenous*.)

exomphalos

A rare *birth defect* in which a membranous sac containing part of the intestines protrudes through the *navel*. In mild cases of exomphalos, only one or two loops of intestine protrude; in severe cases, most of the abdominal organs are exposed. An affected infant may also have intestinal malformation.

Exomphalos is sometimes diagnosed before birth by *ultrasound* examination. The condition is treated using surgery, the success of which depends on the extent of the defect.

exophthalmic goitre

An alternative name for the thyroid gland disorder *Graves' disease*.

exophthalmos

Protrusion of one or both eyeballs caused by a swelling of the soft tissues within the eye socket.

**Appearance of exophthalmos**

The staring appearance in exophthalmos is caused by swelling of the soft tissue in the eye socket, which pushes the eyeball forwards.

CAUSES

Exophthalmos is most commonly associated with Graves' disease, which also causes *thyrotoxicosis* (overactivity of the thyroid gland). Other causes include an *eye tumour*, an *aneurysm* (ballooning of an artery), or inflammation behind the eye.

SYMPTOMS

Exophthalmos may restrict eye movement and cause *double vision*. In severe cases, increased pressure in the socket may restrict blood supply to the *optic nerve*, causing blindness. The eyelids may be unable to close, and vision may become blurred due to drying of the *cornea* (the transparent dome that forms the front of the eyeball).

TREATMENT AND OUTLOOK

In exophthalmos due to thyroid disease, treatment of the thyroid disorder may relieve the exophthalmos; however, exophthalmos may persist even if thyroid function returns to normal.

With early treatment, normal vision is usually restored. Occasionally, surgery may be required to relieve pressure on the eyeball and optic nerve.

exostosis

The most common type of noncancerous *bone tumour*, in which there is an outgrowth of bone tissue. Exostosis develops most commonly at one end of the *femur* (thigh bone) or the *tibia* (shin). The condition may be due to hereditary factors or to prolonged pressure on a particular bone.

SYMPOTMS

In most cases, exostosis produces no symptoms. Often it is recognized only after an injury, when it appears as a hard swelling. Occasionally, the tumour presses on a nerve, causing pain or weakness in the affected area.

DIAGNOSIS AND TREATMENT

Diagnosis can be confirmed by *X-rays*. The tumour may be surgically removed if it is causing symptoms or for cosmetic reasons.

exotoxin

A poison, released by certain types of *bacteria* (including *tetanus* bacilli and *diphtheria* bacilli), that enters the blood-stream and causes widespread effects around the body. Exotoxins are among the most poisonous substances known.

Infections by tetanus, diphtheria, and some other bacteria that release life-threatening exotoxins can be prevented by *immunization* with vaccines consisting of detoxified exotoxins. Treatment of such infections usually includes administration of *antibiotic drugs* and an *antitoxin* to neutralize the exotoxin. (See also *endotoxin*; *enterotoxin*.)

exotropia

An alternative term for a divergent *squint*, in which one eye is used for detailed vision and the other is directed outwards. (See also *esotropia*.)

expectorants

Cough remedies that encourage expectoration (the coughing up of *sputum*).

expectoration

The coughing up and spitting out of *sputum* (phlegm). (See also *cough*.)

expiratory reserve volume

The extra volume of air expired in the fullest possible exhalation; this amount is in addition to the volume that is normally expelled when a person is at rest. The expiratory reserve volume may be measured in pulmonary function tests.

expiratory stridor

An abnormal noise that is heard when a person exhales. Expiratory stridor may occur if the *vocal cords* are partially obstructing the flow of air or if there is an obstruction in the *trachea* (the windpipe) or bronchi (see *bronchus*), which are the main airways to the lungs. Expiratory stridor may occur either alone or with *inspiratory stridor*.

expire

To exhale (breathe out air from the lungs). The term also means "to die".

expired gas

Any gas that has been expelled from the lungs. Expired gas usually contains a high proportion of *carbon dioxide*. It may also contain other substances, such as *alcohol* and *carbon monoxide*, that are carried in the circulation.

exploratory surgery

Any operation carried out to investigate or examine part of the body to discover the extent of known disease or to establish a diagnosis. Advances in imaging, such as *MRI* (a technique that produces cross-sectional or three-dimensional images of body structures), have reduced the need for exploratory surgery.

exposure

A term used to describe the effects on the body of being subjected to very low temperatures, or to a combination of low temperatures, wetness, and high winds. The primary danger in these conditions is *hypothermia* (a sharp fall in body temperature).

The term is also used to describe subjection to *radiation*, to environmental pollutants, or to infectious diseases.

expressing milk

A technique sometimes used by women who are *breast-feeding*, for removing milk from the breasts. The technique may be needed if the woman's breasts are overfull (see *engorgement*). A woman may also want to express milk so that it can be given to the baby in her absence or so that an infant who is unable to feed at the breast (due to prematurity, for example) can still benefit from breast milk. Milk can either be expressed by hand or using a *breast pump*. The milk may also be frozen for later use.

expressive dysphasia

A type of *dysphasia* (disturbance in the ability to use and/or understand words) in which the person can understand others and knows what he or she wishes to say, but has difficulty putting thoughts into words. (See also *aphasia*; *speech*; *speech disorders*; *speech therapy*.)

exsanguinate

To remove, withdraw, or deprive the body of circulating *blood*. Exsanguination usually results from severe internal

or external bleeding. It can also be performed during surgery to create a blood-free area for the procedure. (See also *Esmarch's bandage*.)

extrostomy of the bladder

A rare *birth defect* in which the *bladder* is inside-out and is open to the outside of the body through a space in the lower abdominal wall. There are also, usually, other defects, such as *epispadias* in males (in which the opening of the urethra is on the upper surface of the penis) and failure of the pubic bones to join at the front. Untreated, an affected child constantly leaks urine.

Surgical treatment involves reconstructing the bladder and closing the abdominal wall. If the bladder is very small, it is removed and the urine diverted (see *urinary diversion*).

extensor

Any *muscle* that moves a *joint* in order to straighten a limb. An example of an extensor muscle is the *triceps muscle* in the arm, which straightens the elbow.

external cardiac massage

Rhythmic pressure applied to the chest in order to maintain circulation if a person's heart has stopped beating. The lower breastbone is squeezed repeatedly with the heels of the hands, in order to compress the heart (see *cardiac massage*). External cardiac massage may be used in first aid, as part of *cardiopulmonary resuscitation*.

external fixation

The insertion of pins through the skin to hold together parts of a broken bone (see *fracture*). The pins are held in place by an external metal frame. Usually, the affected limb can be used within a few days; the frame and pins are removed under anaesthesia when the bone has healed. (See also *internal fixation*.)

external haemorrhoids

Haemorrhoids (dilated veins) that form around the outside of the *anus*. Haemorrhoids are commonly known as piles. The condition is sometimes associated with *internal haemorrhoids*, those that develop higher up inside the anal canal. If the blood in an external haemorrhoid clots, the resulting swelling is termed a *perianal haematoma*. This condition is very painful but usually disappears within about five days. (See also *haemorrhoidectomy*; *internal haemorrhoids*.)

extracorporeal circulation

Circulation of blood outside the body through a machine that temporarily assumes an organ's functions. Examples of extracorporeal circulation include the use of a *heart-lung machine*, during open heart surgery, to keep blood moving around the body and carry out carbon dioxide–oxygen exchange, and *extracorporeal dialysis*.

extracorporeal dialysis

Haemodialysis performed through an artificial kidney to remove the substances that are normally excreted in the urine (see *dialysis*).

extracorporeal gas exchange

A technique in which blood is diverted out of the body and through an “artificial lung” to aid *respiration*. It involves a procedure called extracorporeal membrane oxygenation (ECMO), in which blood is passed over an artificial membrane and takes up oxygen, and the removal of waste carbon dioxide. Extracorporeal gas exchange is used to treat severe *respiratory failure*, in addition to mechanical *ventilation*.

extracorporeal

A term meaning “situated or occurring outside the *corpuscles* (minute bodies or cells)”. Extracorporeal refers particularly to the environment outside the *blood cells* (for example, it may be used for agents that attack red blood cells from outside; see *anaemia, haemolytic*).

extraction, dental

The removal of one or more *teeth* by a dentist.

WHY IT IS DONE

Dental extraction may be performed when a tooth is severely decayed or too badly broken to be repaired or when an abscess (see *abscess, dental*) has formed. Teeth may also be removed if there is dental crowding or *malocclusion* (an incorrect bite); if they are loose due to severe gum disease; or if they are preventing another tooth from erupting through the gum (see *eruption of teeth*).

HOW IT IS DONE

For most extractions, local anaesthesia is used (see *anaesthesia, dental*). A general anaesthetic (see *anaesthesia, general*) may be used to extract badly impacted wisdom teeth (see *impaction, dental*), to extract several teeth at once, or for extremely anxious or disabled patients or young children.

Teeth are usually extracted with dental forceps, which are designed to grasp the root of the tooth. When gentle but firm pressure is applied, the blades cut through the periodontal ligaments (the tough, fibrous membranes supporting the tooth in its socket), the socket is gradually expanded, and the tooth is removed. Occasionally the root fractures during this procedure and may need to be removed separately.

In difficult extractions, for example if the tooth is impacted, if the crown is missing, or if the roots are very curved, some gum and bone may need to be removed from around the tooth before the tooth is extracted and the gum is sutured (stitched).

COMPLICATIONS

Most extractions take place without complications. If bleeding does not stop after extraction of a tooth, suturing of the tissue around the socket may be necessary.

Occasionally, if a blood clot (see *blood clotting*) fails to form in the empty tooth socket, or if the blood clot is dislodged, *dry socket* (infection in the tooth socket) develops.

extradural haemorrhage

Bleeding into the space between the inner surface of the skull and the external surface of the *dura mater* (the outer layer of the *meninges*, the protective covering of the brain).

CAUSE

Extradural haemorrhage most commonly occurs as a result of a heavy blow to the side of the head that fractures the skull (see *skull, fracture of*) and ruptures an artery running over the surface of the dura mater.

SYMPOTMS

A *haematoma* (a collection of clotted blood) forms and enlarges, increasing pressure inside the skull. Symptoms result several hours or sometimes even days after the injury. These symptoms may include headache, drowsiness, vomiting, paralysis affecting one side of the body, and *seizures*.

If left untreated, extradural haemorrhage may be life-threatening.

DIAGNOSIS AND TREATMENT

CT scanning or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures) are used to confirm the diagnosis. Treatment may consist of *craniotomy* (drilling holes in the skull), draining the blood clot, and clipping shut the ruptured blood vessel.

extrapyramidal disease

Any of a group of disorders that are the result of damage to, or degeneration of, parts of the *extrapyramidal system* (nerve pathways that link motor nerve nuclei within the brain). Extrapiramidal diseases disrupt the execution of voluntary movements; these diseases are characterized by uncontrollable movements, changes in muscle tone, and postural disturbances. Examples of extrapyramidal disease include *Huntington's disease*, *Parkinson's disease*, and some types of *cerebral palsy*.

extrapyramidal system

A network of *nerve* pathways that links the surface of the *cerebrum* (main mass of the brain) with motor nerve nuclei in the *basal ganglia*, and parts of the *brainstem*. This system influences and modifies electrical impulses sent from the brain to initiate movement in skeletal muscles.

Damage or degeneration of components in the extrapyramidal system may be caused by *extrapyramidal disease*. It may also occur as a side effect of taking *phenothiazine drugs*.

extrasystole

A contraction of the heart that is independent of the heart's normal rhythm. Extrasystole arises in response to an electrical impulse in a part of the heart other than the sinoatrial node (see *ectopic heartbeat*).

extrauterine pregnancy

An alternative term for an *ectopic pregnancy*.

extravasation

The leakage and spread of fluid, usually from blood vessels or *lymph* vessels, into the surrounding tissues. Extravasation has a variety of causes, including injury, burns, and inflammation.

extravascular

Situated or occurring outside the vessels. The term refers particularly to the blood vessels (see *circulatory system*) and lymph vessels (see *lymphatic system*). Extravascular fluid is fluid that exists outside the circulation, in the body tissues.

extrinsic allergic alveolitis

Inflammation and thickening of the tiny air sacs in the lungs that is caused by an allergy to inhaled organic dusts (see *alveolitis*).

extrinsic asthma

Any form of *asthma* precipitated by an environmental factor. Extrinsic asthma is usually due to an *allergy* to a foreign substance, such as inhaled particles, certain foods, or a particular drug.

extrinsic factor

An alternative name for *vitamin B₁₂*.

E

extrovert

A person whose main interest is in other people and the outside world. Extroverts are active, sociable, and have many interests. (See also *introvert; personality*.)

exudation

The discharge of fluid from *blood vessels* into surrounding tissues. Exuded fluid (exudate) contains *cells* and *protein*.

Most exudates are a result of inflammation. In inflamed tissue, the small blood vessels widen and tiny pores in the vessel walls enlarge, allowing fluid and cells (mainly *white blood cells*) to escape.

exudation cyst

A *cyst* (a fluid-filled lump or swelling) formed when an existing body cavity fills with fluid due to *exudation*. A *hydrocele* (fluid-filled swelling in the scrotum) is an example of an exudation cyst.

exudative retinitis

See *Coat's disease*.

eye

The organ of sight. The eye is a complex organ, consisting of a series of structures that focus an image on to the *retina* (the

light-sensitive inner layer at the back of the eye) and nerve cells that convert this image into electrical impulses. These impulses are carried by the *optic nerve* to the visual cortex (an area on the back surface of the brain concerned with *vision*) for interpretation.

The eyes work in conjunction with one another, under the control of the brain. They align themselves on a particular object so that a clear image of the object is formed on each retina. If necessary, the eyes may sharpen the image by altering focus using an automatic process called *accommodation*, which changes the shape of the *lens*.

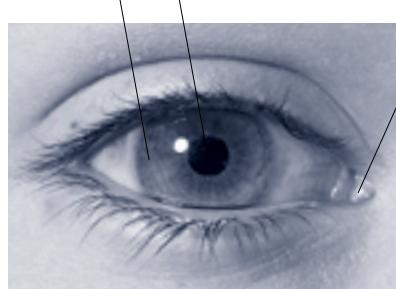

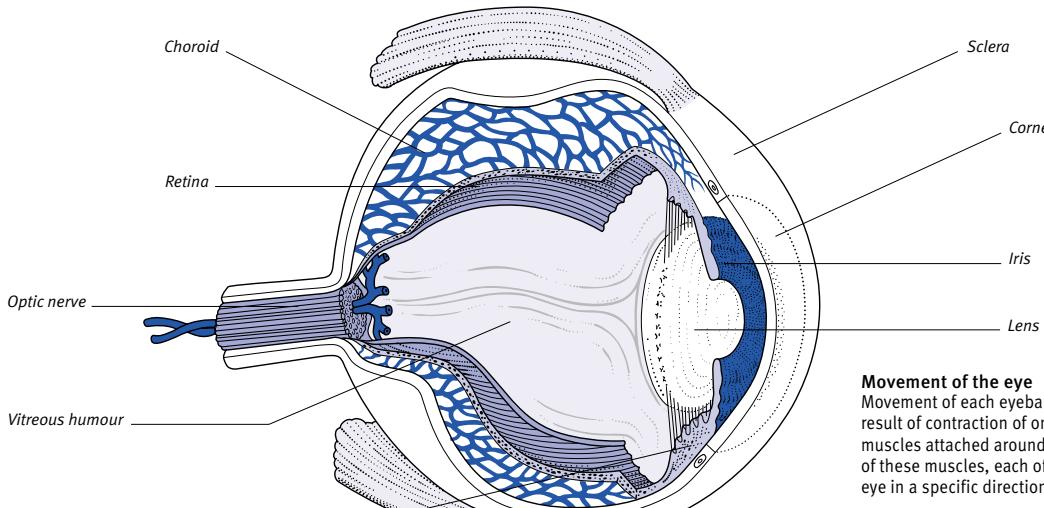

EYEBALL

The eyeballs lie in pads of fat within the bony *orbits* (eye sockets) that provide protection from injury. Each eyeball is

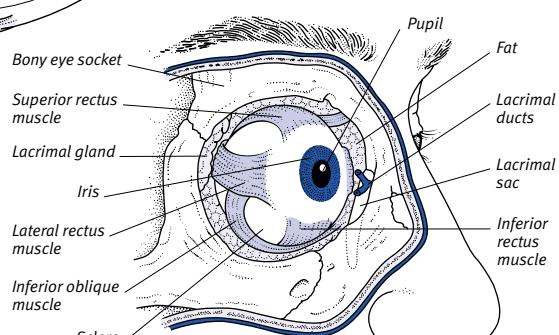

ANATOMY OF THE EYE

The eye is a complex organ that focuses light rays to form an image on the *retina*, the light-sensitive inner layer at the back of the eyeball. The cornea and lens focus the rays. The pupil controls the amount of light entering the eye and the ciliary

body alters the shape of the lens to adjust the focus. The retina has millions of nerve cells that respond to light; they convert the image into a pattern of nerve impulses, which are transmitted to the brain via the *optic nerve*.

The external eye
Behind the transparent cornea is the fluid-filled front chamber of the eye. At the back of this is the iris, with the round pupil in the centre.

**Movement of the eye**

Movement of each eyeball occurs as the result of contraction of one or more of the muscles attached around it. There are six of these muscles, each of which pulls the eye in a specific direction.

moved by six delicate muscles. The eye has a tough, white outer layer known as the *sclera*. At the front of the sclera, the *cornea* (a transparent, thin-walled dome) serves as the main "lens" of the eye and does most of the focusing.

Behind the cornea is a shallow chamber filled with watery fluid (called the aqueous humour), at the back of which is the *iris* (the coloured part of the eye) with its *pupil* (circular opening), which appears black. Tiny muscles alter the size of the pupil in response to changes in light intensity in order to control the amount of light entering the eye.

Behind the iris, and in contact with it, is the crystalline lens, which is suspended by fibres from a circular ring of muscle: the *ciliary body*. Contraction of the ciliary body changes the shape of the lens, enabling fine focusing.

The main cavity of the eye contains a clear gel (the vitreous humour) and is located directly behind the lens. On the inside of the back of the eye is the retina, a complex structure of nerve tissue that is extremely sensitive to light. The retina requires a constant supply of oxygen and glucose. To meet this need, a thin

network of blood vessels, the choroid plexus, lies immediately under it. The *choroid* is continuous at the front with the ciliary body and the iris; these three parts constitute the uveal tract.

CONJUNCTIVA AND EYELID

The eyeball is sealed off by a transparent, flexible membrane called the *conjunctiva*, which is attached to the skin at the corners of the eye and forms the inner lining of the eyelids. The conjunctiva contains mucus-secreting glands. These, together with the meibomian glands in the eyelids (which secrete an oily fluid), provide the tear film that protects the cornea and conjunctiva. Blinking, a protective *reflex*, helps to spread the tear film evenly over the cornea to enable clear vision.

eye, artificial

A *prosthesis* used to replace an *eye* that has been surgically removed. An artificial eye is worn purely for cosmetic and psychological reasons and fits neatly behind the eyelids into the cavity from which the natural eye was removed. Some movement of the artificial eye may be achieved by attaching

the muscles that normally move the eye to the remaining conjunctival membrane (see *conjunctiva*) or to a plastic implant placed in the eye socket.

Often called "glass eyes", artificial eyes were once made of glass; now an easily mouldable plastic material is used.

eye-drops

Medication in solution that is used in the treatment of eye disorders or to aid in their diagnosis. Examples of drugs given in this form are *antibiotic drugs*, *antihistamine drugs*, drugs used either to dilate (widen) or constrict (narrow) the pupil, the circular opening in the centre of the iris, and *corticosteroid drugs*.

A specified number of eye-drops are applied to the inside of the lower eyelid after the lid has been drawn down using the tip of a clean finger. Blinking helps to spread the medicated solution evenly around the eyeball.

eye, examination of

An inspection of the structures of the *eyes*, either as part of a *vision test* or to make a diagnosis when an eye disorder is suspected.

DISORDERS OF THE EYE

Many *eye* disorders are minor, but some can cause loss of vision unless treated. (See also *disorders of the cornea* box; *disorders of the retina* box.)

Congenital defects

Squint (misalignment of the eyes) may be congenital (present at birth). Other examples of congenital defects are *nystagmus* (uncontrollable, jerky eye movements), *albinism* (absence of pigment in the iris), and developmental defects affecting the cornea and retina. A rare birth defect is *microphthalmos* (abnormally small size of one or both eyes). *Cataract* (opacity of the lens) can sometimes be seen in newborn infants.

Infection

Conjunctivitis (inflammation of the conjunctiva) is the most common eye infection. *Trachoma* (a persistent disease of the cornea or conjunctiva) or severe bacterial conjunctivitis can impair vision. Corneal infections can lead to blurred vision or corneal *perforation* if not treated early. *Endophthalmitis* (infection within the eye) can occur as

a result of injury to the eye or infection elsewhere in the body.

Impaired blood supply

Narrowing, blockage, or *inflammation* of retinal blood vessels may cause visual loss.

Tumours

Malignant melanoma of the *choroid* is the most common cancerous tumour of the eye. *Retinoblastoma* (a cancer of the retina) most commonly affects children. *Basal cell carcinoma* affects the eyelid and may result from excessive exposure to sunlight.

Nutritional disorders

Various *vitamin* deficiencies affect the eyes. Vitamin A deficiency may lead to *xerophthalmia* (corneal and conjunctival dryness), *night blindness*, or, eventually, *keratomalacia* (corneal softening and disintegration).

Autoimmune disorders

Uveitis (inflammation of the iris, choroid, and/or ciliary body) may be caused by infection or an *autoimmune disorder* (in which the body's immune system attacks

its own tissues), such as *ankylosing spondylitis* and *sarcoidosis*.

Degeneration

Macular degeneration of the retina is common in elderly people, as is *cataract*.

Focusing disorders

Myopia (shortsightedness), *hypermetropia* (longsightedness), and *astigmatism* are relatively common. *Presbyopia* is a progressive, age-related loss of the ability to focus at close range. *Amblyopia* (poor vision in one eye unrelated to structural abnormality) is often due to squint.

Other disorders

Glaucoma (increased pressure within the eyeball), can lead to permanent visual loss. In *retinal detachment*, the retina lifts away from the eye's underlying layer.

INVESTIGATION

An *ophthalmoscope* and *slit-lamp* are used to view the eye. Vision is evaluated using *Snellen charts* and *refraction* tests.

WHY IT IS DONE

Eye examinations are used to determine the cause of visual disturbance or of other symptoms relating to the eye. They are also used to assess whether corrective devices, such as glasses or contact lenses, are necessary. Eye tests are essential to discover certain serious eye disorders, such as *glaucoma* (in which the fluid in the eye is at abnormally high pressure), because such disorders may be symptomless in the early stages and only detectable during an eye examination.

HOW IT IS DONE

An eye examination usually begins with a physical inspection of the eyes, the eyelids, and the surrounding skin. Eye movements are usually checked and the examiner looks for *squint* (misalignment of the eyes).

Visual acuity (sharpness of vision) in each eye is investigated using a *Snellen chart*, the standard eye test wall chart. *Refraction* testing (using lenses of different strengths) may then be performed to determine precisely what glasses or contact lenses, if any, are required.

An investigation of the *visual fields* (the extent of peripheral vision) may also be carried out, especially in suspected cases of glaucoma or a variety of neurological conditions.

Colour vision is occasionally checked because loss of colour perception is a sign of certain disorders of the *retina* (the light-sensitive inner layer at the back of the eye) or of the *optic nerve* (which transmits impulses from the retina to the brain). In order to check for abrasions or ulcers, the *conjunctiva* (the transparent membrane covering the white of the eye and inside of the eyelids) and the *cornea* (the transparent dome that forms the front of the eyeball) may be stained with *fluorescein* (an orange dye).

Applanation tonometry (measurement of the pressure within the eye) is an essential test for glaucoma.

EQUIPMENT

The *ophthalmoscope* is an instrument used to examine the inside of the eye, particularly the retina.

The slit-lamp microscope, with its illumination and lens magnification, allows for examination of the conjunctiva, the cornea, the front chamber of the eye, the *iris* (the coloured part of the eye) and the *lens* (the component that is responsible for focusing).

To obtain a full view of the lens and the structures behind it, the *pupil* (the circular opening in the centre of the iris) must be widely dilated by using special *eye-drops*.

eye, foreign body in

Any material on the surface of the *eye* or under the eyelid, or an object that penetrates the eyeball.

CAUSES

Particles of dust are the most common type of foreign body to enter the eye. Occasionally, a fragment of metal, plastic, or wood may be deflected into the eye. Rarely, an object travelling at high speed may penetrate the eyeball.

SYMPTOMS AND COMPLICATIONS

A foreign body may cause irritation, redness, increased tear production, and *blepharospasm* (uncontrollable closure and squeezing of the eyelid). Some foreign bodies left within the eyeball may release damaging substances into the eye, resulting in blindness. Other foreign bodies may remain intact but cause infection that can lead to loss of sight. *Sympathetic ophthalmitis* is a rare condition that may threaten sight even in the uninjured eye.

TREATMENT

Foreign bodies on or in the *conjunctiva* (the transparent membrane covering the white of the eye and lining the inside of the eyelids) can usually be flushed out with water. However, medical attention is needed if the object has penetrated the eyeball. The doctor may drop *fluorescein* (an orange dye) into the eye to reveal the presence of any *corneal abrasions* or sites of penetration. *Ultrasound scanning* or an *X-ray* of the eye may also be performed.

Anaesthetic *eye-drops* may be applied and a spatula used to remove an object from the *cornea* (the transparent dome that forms the front of the eyeball). The eye may then be covered with a patch. *Antibiotic drugs* may be prescribed to fight infection.

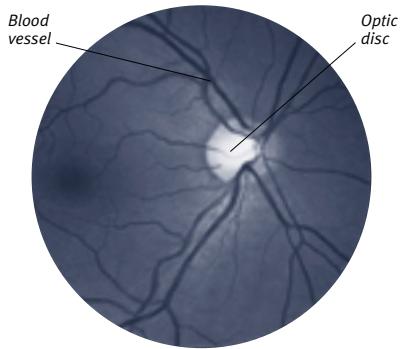

eye injuries

Eye injuries may be caused by a blow to the eye or penetration of a foreign body (see *eye, foreign body in*). However, the eye often escapes serious injury because it is protected by the surrounding bone and the rapid blink reflex.

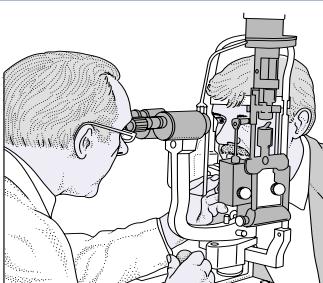

A blow to the eye may cause tearing of the *iris* (the coloured part of the eye) or the *sclera* (the white of the eye), with collapse of the eyeball and potential blindness. Minor injuries may lead to a *vitreous haemorrhage* (bleeding into the gel-filled cavity behind the lens); *hyphaema* (bleeding into the front chamber of the eye); *retinal detachment*; or injury to the *trabeculum* (the chan-

CONDUCTING AN EYE EXAMINATION

In an eye examination, the ophthalmologist checks the external appearance, eye movement, visual acuity, visual field, and colour vision. The eyes are checked for the presence of a squint, abrasions, and ulcers. *Applanation tonometry* and a refraction test may also be carried out.

View of retina through ophthalmoscope
The retina (the inner back surface of the eye) is examined to assess its health and to detect the presence of disorders such as retinopathy.

Applanation tonometry
Measurement of the pressure within the eye is a test for glaucoma.

Snellen chart
This chart is used to check the visual acuity of each eye; the patient's ability to read letters of different sizes from the same distance is assessed.

nel, which drains fluid from the eye), which can lead to *glaucoma* (a sudden increase in fluid pressure in the eyeball).

Injuries to the centre of the *cornea* (the transparent dome that forms the front of the eyeball) impair vision by causing scarring. Damage to the *lens* (the component of the eye responsible for focusing) may cause a *cataract* (loss of transparency) to form.

eyelashes

Hairs that are arranged in rows at the edge of each eyelid and normally curve outwards. The purpose of the eyelashes is to prevent dust and debris from entering the eye. The lashes become finer and fewer as a person ages.

Growth in an abnormal direction may be due to injury to the eyelid or, more commonly, to an infection. Severe *blepharitis* (inflammation of the lid margins) may destroy the roots of the lashes. *Trachoma*, an infection in which the lid can be distorted by scarring, may lead to *trichiasis*, in which the lashes turn inwards and rub against the *cornea* (the transparent dome that forms the front of the eyeball).

eye, lazy

A popular term for *amblyopia* (in which normal vision has failed to develop in an otherwise healthy eye). The term "lazy eye" also refers to a convergent *squint* (in which one eye turns inwards).

eyelid

A fold of tissue at the upper or lower edge of an orbit (eye socket). The eyelids are held in place by *ligaments* attached to the socket's bony edges. They consist of thin plates of fibrous tissue (called *tarsal plates*) covered by muscle and a thin layer of skin. The inner layer is covered by an extension of the *conjunctiva* (the transparent membrane that covers the white of the eye). Along the edge of each lid is a row of *eyelashes*. Immediately behind the eyelashes are the openings of ducts that lead from the meibomian glands, which secrete the oily fluid in tears.

The eyelids act as protective shutters, closing almost instantly as a *reflex* action if anything approaches the eye. They also spread the tear film across the *cornea* (the transparent dome that forms the front of the eyeball).

DISORDERS

Disorders affecting the eyelids include a *chalazion* (a swelling of a meibomian

gland), *blepharitis* (inflammation of the edge of the eyelid), and a stye (a small abscess at the root of one of the lashes).

Certain disorders affect the shape and position of the eyelids. These include *entropion* (in which the eyelid margin turns inwards), *ectropion* (in which the eyelid margin turns outwards), and *ptosis* (in which the eyelid droops down, covering all or part of the eye).

Myokymia (twitching of the eyelid) is common, and usually caused by fatigue.

Blepharospasm (prolonged contraction of the eyelid) is usually due to a condition such as *photophobia* (abnormal sensitivity of the eyes to sunlight) or a foreign body. The skin of the eyelid is a common site for a *basal cell carcinoma*.

eyelid, drooping

See *ptosis*.

eyelid surgery

See *blepharoplasty*.

eye, painful red

A common combination of eye symptoms that may be due to any of various eye disorders.

Conjunctivitis (inflammation of the conjunctiva, the transparent membrane covering the white of the eye) is the most common cause of redness and irritation in the eye. *Uveitis* (inflammation of the iris, choroid, and/or ciliary body) is a common cause of dull, aching pain; this may be due to swelling in the front part of the eye and spasm in muscles around the iris (the coloured part of the eye). The redness is caused by widening of blood vessels around the iris.

Another cause of pain and redness in one eye is acute closed-angle *glaucoma* (a sudden increase in pressure within the eyeball). The pain is severe and may be accompanied by nausea, vomiting, and blurred vision. Increased blood flow in the surrounding blood vessels causes redness in the white of the eye.

There are additional causes of painful red eye including *keratitis* (inflammation of the cornea, the outer protective layer of the eye), which usually occurs as a result of a *corneal ulcer*, and a foreign body in the eye (see *eye, foreign body in*).

eye-strain

A common term used to describe aching or discomfort in or around the eye. Eye-strain is usually due to a headache caused by fatigue, tiredness of muscles around the eye, *sinusitis*, *blepharitis*

(inflammation of the eyelid margins), or *conjunctivitis* (inflammation of the conjunctiva, the transparent membrane that covers the whites of the eye).

eye teeth

A common name for the canine *teeth*.

eye tumours

Tumours of the eye are rare. However, when eye tumours do occur, they are usually painless and cancerous.

TYPES AND TREATMENT

Retinoblastoma This is a cancerous tumour of the *retina* (the light-sensitive inner layer at the back of the eye) that may occur in one or both eyes and most often affects children. Retinoblastoma may be treated by *radiotherapy*, *laser treatment*, or *cryosurgery* (freezing), but the eye may have to be removed to prevent spread of the tumour.

Malignant melanoma This form of cancer occurs in the *choroid* (the layer of tissue between the retina and the sclera, the white of the eye) and usually affects middle-aged or elderly people. There are no symptoms in the early stages, but the tumour eventually causes *retinal detachment* and distortion of vision. Small malignant melanomas can be destroyed by laser treatment, but the eye may need to be removed to prevent spread of the tumour.

Secondary eye tumours If cancer elsewhere in the body spreads to the eye, secondary tumours develop. Symptoms depend on a tumour's location and growth rate. Secondary eye tumours may be controlled by radiotherapy; however, the primary tumour will need to be treated separately.

Basal cell carcinoma This is the most common type of tumour of the eyelid. It may be caused by excessive exposure to sunlight. The tumour usually has a crusty central crater and a hard rolled edge. In the early stages, a basal cell carcinoma of the eyelid may be treated by surgery, radiotherapy, or cryosurgery. If the tumour becomes large, the eyelid may need to be removed.

F

Fabry's disease

F

A rare inherited disorder caused by a deficiency of alpha-galactosidase A, an *enzyme* (a protein that acts as a catalyst) necessary for the metabolism of certain *lipids* (fats) in the body. Without the enzyme, lipid molecules accumulate in the tissues, especially in the nerves, heart, and kidneys.

Fabry's disease is inherited as an X-linked recessive trait (see *genetic disorders*) and therefore affects males more commonly than females.

SYMPOTMS

Among the first symptoms to develop, often in childhood, are pain and discomfort in the hands and feet as a result of damage to the peripheral nerves. As the condition progresses, heart and kidney function may become impaired. Female carriers usually show only mild symptoms.

TREATMENT AND OUTLOOK

Hand and feet pain is treated with *carbamazepine*. Sufferers usually survive into adulthood but are at risk from strokes, heart attacks, and kidney damage.

face-lift

A cosmetic operation to smooth out wrinkles and lift sagging skin on the face to make it look younger. The effect is achieved by making an incision near or along the hairline on each side of the face, lifting the skin off the face, and then removing the excess skin. The edges of skin are then stitched back together within the hairline.

Some bruising of the face is common following the procedure, and there may be some discomfort. Stitches are removed three to five days after the operation. In most cases, the scars, which fade within about a year, are hidden by natural crease lines or by the hair. The effect of a face-lift usually lasts about five years.

In a few cases, satisfactory healing does not occur because blood accumulates under the skin or because of infection that leads to severe scarring.

facet joint

A type of joint found in the *spine*, formed by the process (bony projection) of one vertebra fitting into a hollow in the vertebra above. Facet joints allow a degree of movement between vertebrae, which gives the spine its flexibility.

facial nerve

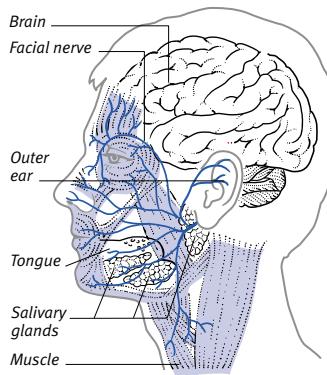

The seventh *cranial nerve*, which arises from structures in the *brainstem* and sends branches to the face, neck, salivary glands, and outer ear.

The facial nerve performs both motor and sensory functions. It controls the neck muscles and those of facial expression; it stimulates the secretion of saliva; and it conveys sensory information from the tongue and from the outer ear.

Damage to the facial nerve results in weakness of the facial muscles (see *facial palsy*) and, in some cases, loss of

LOCATION OF THE FACIAL NERVE

Arising from the brainstem, the facial nerve has branches that connect to the outer ear, tongue, salivary glands, and muscles of facial expression in the neck and face.

taste. Such damage is probably most often due to a viral infection but may also occur in *stroke*.

facial pain

Pain in the face may be due to any one of a variety of causes or may occur for no known reason.

CAUSES

Injury to the face, such as by blows or cuts, is a common cause of facial pain. Facial pain is also commonly due to

infection. *Sinusitis* (inflammation of the air spaces in the facial bones) can cause pain around the eyes and in the cheek bones. The onset of *mumps* can cause pain in the cheeks before swelling is apparent; the pain is in front of and/or below the ears. Pain from a *boil* in the nose or ear may also be felt in the face.

Problems with the teeth and jaws are another common cause of facial pain. Such problems include severe tooth decay (see *caries, dental*), an abscess (see *abscess, dental*), impacted wisdom teeth (see *impaction, dental*), or partial dislocation of the jaw (see *jaw, dislocated*).

Damage to one of the nerves that supply the face can also produce severe pain. Conditions resulting from nerve damage include the stabbing pain that precedes the rash of *herpes zoster* (shingles) and the intermittent shooting pain of *trigeminal neuralgia*, which usually affects the cheek, lip, gum, or chin on one side and is often brought on by touching the face or chewing.

A disorder elsewhere in the body may cause *referred pain* in the face. For example, in *angina pectoris* (chest pain due to impaired blood supply to the heart muscle), pain may also be felt in the jaw. During a *migraine* headache, pain may also occur on one side of the face. Facial pain that occurs for no apparent reason may occasionally be a symptom of *depression*.

TREATMENT

Analgesic drugs (painkillers) can provide temporary relief from pain, but severe or persistent facial pain requires medical attention.

facial palsy

Weakness of the facial muscles as a result of damage to, or inflammation of, the *facial nerve*. The condition is usually temporary and affects only one side of the face.

CAUSES

Facial palsy is most often due to Bell's palsy, which occurs for no known reason. Less commonly, the condition is associated with *herpes zoster* (shingles) affecting the ear and facial nerve. Facial palsy may also result from surgical damage to this nerve, or compression of the nerve by a tumour.

SYMPTOMS

Facial palsy usually develops suddenly. The eyelid and the corner of the mouth on one side of the face droop, and there may be pain in the ear on that side. The ability to wrinkle the brow or to close

the eye may be lost, and smiling is distorted. Depending on which nerve branches are affected, the sense of taste may be impaired or sounds may seem to be unnaturally loud.

TREATMENT

In many cases, facial palsy clears up without treatment. Pain can be relieved by taking *analgesics* (painkillers), and exercising the facial muscles may aid recovery. It may be necessary to tape the eyelid shut at bedtime in order to avoid the risk of *corneal abrasion*.

Bell's palsy may be treated with *corticosteroid drugs* to reduce inflammation and speed recovery. Re-routing or *grafting* of nerve tissue may help people suffering from palsy caused by an injury or a tumour.

facial spasm

An uncommon disorder in which the muscles that are supplied by the *facial nerve* twitch frequently. Facial spasm, which predominantly affects middle-aged women, is of unknown cause.

facial tic

See *facial spasm*.

facies

A term used to denote facial expression, which is often used as a guide to a person's health. For example, the typical facies seen in a child with enlarged adenoids is open-mouthed because of difficulty breathing through the nose.

The term "facies" may also be used to refer to a particular surface of a body structure, part, or organ.

facioscapulohumeral dystrophy

An autosomal dominant *genetic disorder* that causes muscle weakness and wasting. The condition first appears in childhood or adolescence. The muscle wasting chiefly affects the face, shoulder girdle, arms, and later the pelvis and legs.

factitious disorders

A group of disorders in which a patient's symptoms mimic those of a true illness but which have been invented by, and are under the control of, the patient. There is no apparent cause other than a wish for attention; the desire to assume the role of a patient may be an escape from everyday life in order to be cared for and protected.

The most common disorder of this type is *Munchausen's syndrome*, which is characterized by physical symptoms.

The sufferer may aggravate existing physical problems or even inflict self-injury. In *Ganser's syndrome*, symptoms are psychological. Factitious disorders differ from *malingering*, in which a person claims to be ill for a particular purpose (for example, in order to obtain time off work).

factor V

One of the blood proteins that maintains the balance between the blood clotting too easily or too slowly after an injury. About 5 per cent of the population have an inherited *mutation* in the gene controlling factor V production, known as factor V Leiden. They are at increased risk of deep-vein thrombosis (see *thrombophilia*), particularly if taking the oral contraceptive pill or going on long aircraft journeys.

factor VIII

One of the blood proteins involved in *blood clotting*. People with *haemophilia* have a reduced level of factor VIII in their blood and, consequently, have a tendency to abnormal bleeding and to prolonged bleeding when injured.

People with severe haemophilia require regular treatment with concentrates of factor VIII. This treatment reduces the bleeding tendency and allows the affected person a normal quality of life.

factor IX

A protein in blood that plays an important role in the clotting mechanism. A deficiency of factor IX causes a rare genetic *bleeding disorder* known as *Christmas disease*.

fad

See *food fad*.

faecal fistula

See *fistula*.

faecal impaction

A condition in which a large mass of hard *faeces* cannot be evacuated from the rectum. It is usually associated with long-standing *constipation*. Faecal impaction is most common in very young children and in elderly people, especially those who are bedridden.

The main symptoms are an intense desire to pass a bowel movement; pain in the rectum, anus, and centre of the abdomen; and, in some cases, watery faeces that are passed around the mass (and may be confused with diarrhoea).

Treatment of faecal impaction is with *enemas* or, in cases where these are ineffective, by manual removal of the faecal mass.

faecal incontinence

See *incontinence, faecal*.

faecalith

A small, hard piece of impacted faeces that forms in a diverticulum (a sac in the wall of the intestine). A faecalith is harmless unless it forms a blockage at the entrance to the sac, which causes *diverticulitis*, or to the appendix, which causes *appendicitis*.

faecal occult blood test (FOBT)

A test, also known as a stool *guaiac* test, that is used to check for the presence of hidden blood in the faeces (see *occult blood, faecal*). FOBT is a screening test that may be carried out because such bleeding may be one of the earliest indications of colorectal cancer (see *colon, cancer of; rectum, cancer of*). One example of a commonly used brand of FOBT is Hemoccult.

faecal vomiting

The vomiting of matter that resembles faeces, either in appearance or odour or both. Faecal vomiting is a symptom of serious intestinal obstruction (see *intestine, disorders of*).

faeces

Waste material from the digestive tract that is solidified in the large intestine and expelled through the *anus*. Faeces are composed of indigestible food residue (dietary *fibre*), dead bacteria, dead cells shed from the intestinal lining, intestinal secretions such as mucus, *bile* from the liver (which is the substance that gives faeces their brown colour), and water.

Examination of the faeces plays an important part in the diagnosis of disorders of the digestive tract, such as *malabsorption*. Samples of faeces may be examined physically for their colour, odour, consistency, or for the presence of blood. A special test, known as a *faecal occult blood test (FOBT)*, is used to detect concealed blood in the faeces (see *occult blood, faecal*). Microscopic examination may be carried out to detect pus, parasites, or microorganisms. Chemical tests may be performed to assess the excretion of fat. (See also *faeces, abnormal*.)

faeces, abnormal

Faeces that differ from normal in their colour, odour, consistency, or content. Abnormal faeces may be an indication of a disorder of the *digestive system* or a related organ, such as the *liver*. A change in the character of faeces, however, is most often the result of a change in diet.

Diarrhoea (frequent passage of liquid or very loose faeces) may simply be due to anxiety. However, it may be the result of an intestinal infection (see *gastro-enteritis*), an intestinal disorder (such as *ulcerative colitis* or *Crohn's disease*), or *irritable bowel syndrome*. Loose stools may also be an indication of *malabsorption* (impaired absorption of nutrients by the small intestine).

Constipation (infrequent passage of very hard faeces) is generally harmless. Constipation that develops unexpectedly, however, may be caused by a disorder of the large intestine, such as cancer (see *colon, cancer of*).

Pale faeces may be caused by diarrhoea, a lack of bile in the intestine as a result of *bile duct obstruction*, or a disease that causes malabsorption (such as *coeliac disease*). In malabsorption, the paleness is caused by the high fat content of the faeces. This type of faeces may be oily, foul-smelling, and difficult to flush away.

Dark faeces may result from taking iron tablets. If the faeces are black, however, there may be bleeding in the upper digestive tract.

Faeces that contain excessive mucus are sometimes associated with constipation or with irritable bowel syndrome. *Enteritis, dysentery*, or a tumour of the intestine (see *intestine, tumours of*) may also lead to the passage of excess mucus, often accompanied by blood.

Blood in the faeces differs in appearance depending on the site of bleeding. Bleeding from the stomach or duodenum is usually passed in the form of black, tarry faeces (see *melaena*). Blood from the colon is red and is usually passed at the same time as the faeces. Bleeding from the rectum or anus, which may be due to tumours or to *haemorrhoids* (piles), is usually bright red. Occasionally, however, it may not even be visible (see *occult blood, faecal*). (See also *rectal bleeding*.)

faeces, blood in the

See faeces, abnormal; occult blood, faecal; rectal bleeding.

Fahrenheit scale

A temperature scale in which the melting point of ice is 32° and the boiling point of water is 212°. On this scale, normal body temperature is 98.6°F, which is equivalent to 37°C (C). To convert a temperature in Fahrenheit to its Celsius equivalent, subtract 32 and multiply by 0.56 (or 5/9). To convert a Celsius temperature to Fahrenheit, multiply by 1.8 (or 9/5) then add 32. (See also *Celsius scale*.)

Fahr's disease

A rare, degenerative neurological disorder that is characterized by the appearance of abnormal calcium deposits and is associated with cell loss in certain areas of the brain. Fahr's disease may be *familial*, in which it shows either an autosomal recessive or autosomal dominant pattern of inheritance (see *genetic disorders*). In many cases, however, the cause of the disorder is unknown.

Symptoms of Fahr's disease include progressive *dementia* (deterioration in brain function) and the loss of acquired motor skills. Increased muscle stiffness and restricted movements may also develop. Possible complications include *athetosis*, characterized by slow, involuntary, writhing movements, or *chorea*, characterized by irregular, rapid, jerky movements. There may also be gradual deterioration of eyesight.

Individual symptoms of Fahr's disease are treated where possible, but there is no cure.

failure to thrive

Failure of expected growth in an infant or toddler, usually assessed by comparing the rate at which a baby gains weight with measurements on a standardized *growth chart*.

An undiagnosed minor illness such as a urinary infection may be the cause; in some cases, failure to thrive suggests a more serious disorder such as congenital *heart disease* or *kidney failure*. Emotional or physical deprivation can result in failure to thrive, especially if the child is undernourished or neglected. A child who fails to grow at the appropriate rate needs to undergo tests to determine the cause. (See also *growth, childhood; child development*.)

fainting

Temporary loss of consciousness due to reduced blood flow to the brain. The medical term is "syncope".

CAUSES

Episodes of fainting are often due to a *vasovagal attack* – an episode in which overstimulation of the *vagus nerve* (which controls vital organs such as the lungs and heart) causes slowing of the heartbeat and a fall in blood pressure, thereby reducing the flow of blood to the brain. Attacks are usually preceded by sweating, nausea, dizziness, and weakness, and are commonly the result of pain, stress, shock, a stuffy atmosphere, or prolonged coughing. Fainting may also result from postural *hypotension* (low blood pressure), which may occur when a person stands still for a long time or stands up suddenly. This problem is common in elderly people, in those with *diabetes mellitus*, and in those taking *antihypertensive drugs* or *vasodilator drugs*.

TREATMENT

In most cases, recovery from fainting occurs when normal blood flow to the brain is restored. This restoration usually happens within minutes because the loss of consciousness results in the person falling into a lying position, which restores the flow of blood to the brain. Medical attention is required in cases of prolonged *unconsciousness* or repeated attacks of fainting.

faith-healing

The supposed ability of certain people to cure disease by a healing force inexplicable to science.

falciparum malaria

The most severe form of *malaria*, which is caused by the parasitic protozoan *PLASMODIUM FALCIPARUM*.

fallen arches

One of the causes of *flat-feet*. Fallen arches can develop as a result of weakness of the muscles that support the arches of the foot.

fallopian tube

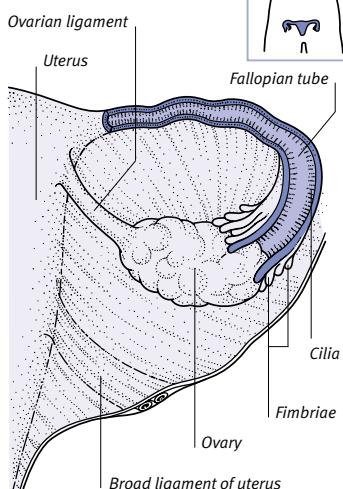

One of the two tubes that extend from the *uterus* to each *ovary*. The fallopian tube transports eggs and sperm and is where *fertilization* takes place.

STRUCTURE

The funnel-shaped fallopian tube is about 10 cm long. It opens into the uterus at one end. The other end, which is divided into *fimbriae* (fingerlike projections), lies close to the ovary. The tube has muscular walls lined by cells with cilia (hairlike projections).

LOCATION OF THE FALLOPIAN TUBES

Situated in the pelvis, each tube extends from the upper part of the cavity of the uterus to an ovary.

FUNCTION

The fimbriae take up the egg after it is expelled from the ovary. The beating cilia and muscular contractions propel the egg towards the uterus. After sexual intercourse, sperm swim up the fallopian tube from the uterus. The lining of the tube and its secretions sustain the egg and sperm, encouraging fertilization to take place, and nourish the egg until it reaches the uterus.

DISORDERS

The fallopian tube may become inflamed, usually as a result of a bacterial sexually transmitted infection (see *pelvic inflammatory disease*); this can, in some cases, lead to *infertility*. *Ectopic pregnancy* (the development of an embryo outside the uterus) is another serious disorder that most commonly occurs in a fallopian tube. This arises when there is a delay in the passage of the fertilized egg along the tube, usually as a result of scarring or blockage. Implantation occurs in the fallopian tube wall, but it is too thin to sustain growth, and as the pregnancy progresses, the tube may rupture and cause internal bleeding. The pregnancy must be terminated.

Fallot's tetralogy

See *tetralogy of Fallot*.

fallout

See *radiation hazards*.

falls in the elderly

The tendency to fall over increases steadily with age. This increased probability of falling is due to a gradual slowing down of *reflex* actions; an elderly person who trips is frequently too slow to prevent a fall.

CAUSES

Falls may simply be accidents, which are commonly the result of obstructions on the ground (such as loose floor coverings), or they may be caused by medical problems. Various medical conditions that are common in elderly people increase the risk of falls. Examples of such conditions are poor sight, *walking disorders*, cardiac *arrhythmia* (an irregular heartbeat), *hypotension* (low blood pressure), and *Parkinson's disease* (a movement disorder). Taking *sleeping drugs* or *tranquillizer drugs* may also increase the risk of falls. Falls sometimes herald the onset of a serious illness, such as *pneumonia*.

COMPLICATIONS

Broken bones (see *fracture*) are a common complication of falls, especially in women. Not only do women have more falls, but they are also more likely to suffer fractures because the strength of their bones may be reduced through *osteoporosis* (loss of bone density).

Falls may sometimes have serious indirect consequences in elderly people. Anyone who falls and lies on the floor for more than an hour, especially if it is cold, may develop *hypothermia* (low body temperature). A fall, or the fear of falling, can also have adverse psychological effects, causing a once active person to become demoralized and housebound.

PREVENTION

Falls may be prevented by taking common-sense measures such as ensuring that floors are free of clutter, good lighting is available, suitable footwear is worn, floor coverings and wiring are safe, and handrails are secure. For elderly people who live alone, personal alarms are available that can be worn round the neck at all times; in the event of a fall the alarm button can be pressed to summon help.

false negative

A test result that wrongly suggests that a particular disease or condition is not present. For example, a false negative

mammography result is one that suggests breast tissue is healthy when, in fact, a breast cancer is present.

false positive

A test result that wrongly suggests that a certain disease or condition is present. For example, a false positive *mammography* result appears to reveal a breast cancer, but subsequent tests do not find any evidence of disease.

false pregnancy

See *pregnancy, false*.

false teeth

See *denture*.

false vocal cord

One of two folds of tissue in the *larynx* (voice-box) that are situated above the true *vocal cords* but which are not involved in the production of speech.

famciclovir

An *antiviral drug* used to treat viral infections such as *herpes zoster* (shingles) and genital *herpes simplex*. Minor side effects can include nausea, vomiting, and headache.

familial

A term applied to a characteristic or disorder that runs in families, that is, it occurs in more members of a particular family than would be expected from the occurrence in the population as a whole. An example of a familial characteristic is male-pattern baldness (see *alopecia*); an example of a familial disorder is *hyperlipidaemia* (abnormally high levels of fats in the blood).

familial adenomatous polyposis (FAP)

See *polyposis, familial adenomatous*.

familial cystinuria

See *cystinuria*.

familial goitre

See *goitre*.

familial hypercholesterolaemia

An inherited disorder of lipoprotein metabolism (see *fats and oils*) that is characterized by a high level of the fatty substance *cholesterol* in the blood. An individual suffering from familial hypercholesterolaemia lacks the *low density lipoprotein* receptors in the liver that remove excess cholesterol from the

blood. The condition shows an autosomal dominant pattern of inheritance (see *genetic disorders*).

Raised levels of cholesterol in the blood lead to the early development of *atherosclerosis* (an accumulation of fatty deposits on the inner walls of the arteries), *coronary artery disease*, and other *vascular* diseases. Treatment, which must continue long term, is with *lipid-lowering drugs*, including *statins*, along with a diet that is low in cholesterol and a weight-reduction regime.

F

familial Mediterranean fever

An inherited condition that affects certain Sephardic Jewish, Armenian, and Arab families. The cause of familial Mediterranean fever is unknown. Symptoms usually begin between the ages of five and 15 years, and include recurrent episodes of fever, abdominal and chest pain, and arthritis. Red skin swellings sometimes occur, and affected people may also suffer from psychiatric problems. Attacks usually last from 24 to 48 hours but may be longer. Between attacks there are usually no symptoms.

Although there is no specific treatment for familial Mediterranean fever, those known to suffer from the condition can reduce the incidence of attacks by taking *colchicine*, a drug that is usually used to treat gout. Death may eventually occur from *amyloidosis*, a complication of the condition.

familial screening

Screening of a family in which one member is affected by an inherited disorder. Looking for evidence of increased susceptibility to a disorder may involve testing for a specific gene defect (as is the case for *cystic fibrosis*), which will also help specialists determine the chances of family members having an affected child.

Alternatively, tests may be carried out to detect a risk factor for a disorder; for example, if a person has a heart attack at an early age, his or her relatives may be tested for *hyperlipidaemia* (high levels of fats in the blood), a condition that increases the risk of *coronary artery disease*.

In addition to being tested for a particular disorder, the relatives of an affected person may be offered regular check-ups so that any abnormal signs may be detected as early as possible and the necessary treatment started without any delay.

family planning

The deliberate limitation or spacing of births. Strategies for family planning include the different methods of *contraception*. (See also *birth control*.)

family therapy

A form of *psychotherapy*, designed to help someone with mental health problems, that is aimed at the whole family rather than just the individual sufferer. The therapist arranges regular meetings with the family to encourage discussion and understanding and to find out what feelings lie behind the way family members deal with each other in everyday life. The main theory behind family therapy is that improving the functioning of the family unit will benefit the individual's health.

famotidine

An *H₂ receptor antagonist* drug that promotes healing of *peptic ulcers* and reduces inflammation of the oesophagus (see *oesophagitis*). Famotidine acts by suppressing production of stomach acid. Side effects are uncommon, but may include headaches and dizziness.

Fanconi's anaemia

A rare type of aplastic anaemia (see *anaemia*, *aplastic*) in which the bone marrow, which normally makes all of the types of blood cells, produces abnormally low numbers of the cells.

Fanconi's syndrome

A rare kidney disorder that usually occurs in childhood. In Fanconi's syndrome, various important chemicals, such as *amino acids*, *phosphate*, *calcium*, and *potassium*, are lost in the urine. The results of these losses include failure to thrive, stunting of growth, and bone disorders such as *rickets*.

Possible causes include several rare inherited abnormalities of body chemistry and an adverse reaction to certain drugs, such as *tetracycline* that has passed its "use-by" date.

If an underlying chemical abnormality is detected and can be corrected, the affected child may resume normal growth. Alternatively, a *kidney transplant* may be possible.

fantasy

The process of imagining events or objects that are not actually occurring or present. The term also refers to the mental image itself.

Fantasy can give the illusion that wishes have been met. In this sense, it provides satisfaction and can be a means of helping people to cope when reality becomes too unpleasant. Fantasy can also stimulate creativity.

Psychoanalysts believe that certain fantasies are unconscious and represent primitive instincts; these fantasies are presented to the conscious mind in the form of symbols.

farmer's lung

An occupational disease affecting the lungs of farm workers. Farmer's lung is a type of allergic *alveolitis*, in which affected people develop *hypersensitivity* (an excessive reaction of the immune system) to certain moulds or fungi that grow on hay, grain, or straw. The causative organisms thrive in warm, damp conditions, and outbreaks are most common in areas of high rainfall.

SYMPTOMS

Symptoms typically develop about six hours after exposure to dust containing fungal spores. They include shortness of breath, headache, fever, and muscle aches. In acute attacks, the symptoms last for about a day. Repeated exposure to spores may lead to a chronic form of the disease, causing permanent scarring of lung tissues.

DIAGNOSIS AND TREATMENT

Diagnosis of farmer's lung may involve a *chest X-ray*; *pulmonary function tests*; and blood tests for a specific *antibody* to the fungus.

Corticosteroid drugs relieve the symptoms of the condition. Further exposure to the spores of the fungus should be avoided. Complete recovery is likely if the disease is diagnosed before permanent lung damage has occurred. (See also *fibrosing alveolitis*.)

farmer's skin

Premature aging of the skin caused by prolonged exposure to sunlight. Features of farmer's skin include a lack of elasticity, wrinkling, dryness, thinning (sometimes with thicker areas), and excessive skin pigmentation.

fascia

Fibrous *connective tissue* that surrounds many structures in the body. One layer of the tissue, known as the superficial fascia, envelops the entire body just beneath the skin. Another layer, the deep fascia, encloses muscles, forming a sheath for individual muscles and

separating them into groups; it also holds in place soft organs such as the kidneys. Thick fascia in the palm of the hand and sole of the foot have a cushioning, protective function.

fasciculation

Spontaneous, irregular, and usually continual contractions of a muscle that is apparently at rest. Unlike the contractions of *fibrillation*, fasciculation is visible through the skin.

Minor fasciculation, such as that occurring in the eyelids, is common and is no cause for concern. However, persistent fasciculation with weakness in the affected muscle indicates damage to the nerve cells in the spine that control the muscle, or to the nerve fibres that connect the spinal nerves to the muscle; *motor neuron disease* is one such disorder.

fasciitis

Inflammation of a layer of *fascia* (fibrous connective tissue), causing pain and tenderness. Fasciitis is usually the result of straining or injuring the fascia surrounding a muscle; it most commonly affects the sole of the foot. The condition may occur in people who suffer from *ankylosing spondylitis* (a rheumatic disorder affecting the spine) or those with *Reiter's syndrome* (inflammation of the urethra, conjunctivitis, and arthritis).

Treatment of fasciitis involves resting the affected area and protecting it from pressure. A local injection of a *corticosteroid drug* may be given. If fasciitis is part of a widespread disorder of the joints, treatment of this condition will generally improve symptoms. (See also *necrotizing fasciitis*.)

fascioliasis

A disease affecting the liver and bile ducts that is caused by infestation with the *liver fluke* species *FASCIOLA HEPATICA*. Fascioliasis is acquired through eating plant food (such as watercress) contaminated with the larvae of the fluke. Treatment is with *anthelmintic drugs*.

fasciotomy

An operation to relieve pressure on muscles by making an incision in the *fascia* (fibrous connective tissue) that surrounds them.

Fasciotomy is usually performed to treat *compartment syndrome*, a painful condition in which constriction of a

group of muscles causes obstruction of blood flow; it gives the muscles space in which to expand. The procedure is also sometimes performed as a surgical emergency after an injury has resulted in muscle swelling or bleeding within a muscle compartment.

fasting

Abstaining from all food and drinking only water. In temperate conditions and at moderate levels of physical activity, a person can survive on water alone for more than two months; however, without consuming either food or drink, death usually occurs within about ten days.

EFFECTS ON THE BODY

In the absence of food, the energy that is needed in order to maintain essential body processes is supplied by substances stored in the body tissues. About six hours after the last meal, the body starts to use *glycogen* (a carbohydrate stored in the liver and muscles). This process continues for about 24 hours, after which time the body obtains energy from stored fat and by breaking down protein in the muscles. If fasting continues, the body's *metabolism* slows down in an attempt to conserve energy, and the fat and protein stores are consumed more slowly.

In the initial stages of fasting, weight loss is rapid. It then slows down, not only due to the slowing of the metabolism, but also because the body begins to conserve its salt supply, resulting in the retention of water in the tissues. This accumulated fluid causes *oedema* (swelling), which principally affects the legs and abdomen.

In prolonged fasting, the ability to digest food may be impaired because the stomach stops secreting digestive juices. Prolonged fasting also halts the production of sex hormones, causing *amenorrhoea* (the absence of menstruation) in women.

fat

A substance that is composed of one or more *fatty acids*. Fat is the main form in which energy is stored by the body. A layer of fat, known as *adipose tissue*, lies directly beneath the skin and surrounds various internal organs. Excess amounts of fat are deposited under the skin in *obesity*. (See also *fats and oils*.)

fatal

Causing, or ending in, *death*.

fat atrophy

Localized loss of fatty tissue beneath the skin. Fat atrophy can occur at injection sites in people with type 1 (insulin-dependent) *diabetes mellitus*. A particular pattern of fat atrophy also develops in some people being treated with *antiretroviral drugs* for *HIV* infection or *AIDS* (see *lipodystrophy*).

fatigue

See *tiredness*.

fat pad

A localized collection of fatty tissue. Fat pads are normally found in parts of the body that need cushioning and protection, such as behind the eyeballs, around the kidneys, behind the knees, under the heel bone, and in the cheeks (especially in infants). Abnormal fat pads may be noncancerous tumours (see *lipoma*) or may develop in certain disorders, such as *lipodystrophy*.

fats and oils

Nutrients that provide the body with its most concentrated form of *energy*. Fats are the largest group of *lipids*, and are compounds containing chains of carbon and hydrogen atoms with very little oxygen. Chemically, they consist mostly of *fatty acids* combined with *glycerol*. Fats are usually solid at room temperature, while oils are liquid.

TYPES

Fats and oils are divided into two main groups – saturated and unsaturated – depending on the proportion of hydrogen atoms they contain. If the fatty acids contain the maximum possible quantity of hydrogen, the fats are saturated. If some sites on the carbon chain are unoccupied by hydrogen, they are unsaturated. Monounsaturated fats are unsaturated fats with only one site that could take an extra hydrogen atom; if many sites are vacant, the fats are polyunsaturated. Animal fats, such as those in meat and dairy products, are largely saturated; vegetable fats tend to be unsaturated.

FAT AND HEALTH

The amount and types of fat in the diet have important implications for health. A diet containing a large amount of fat, particularly saturated fat, is linked to obesity and an increased risk of *atherosclerosis* (deposition of fat on the walls of arteries) and of subsequent *coronary artery disease* and *stroke*. Other serious disorders related to the consumption

of excess fat include cancers of the breast, colon, and prostate and type 2 *diabetes mellitus*.

USES IN THE BODY

Some dietary fats, mainly triglycerides (combinations of glycerol and three fatty acids), are sources of the fat-soluble vitamins A, D, E, and K and also of essential fatty acids.

Triglycerides are the main form of fat stored in the body. These stores act as an energy reserve; they also provide insulation and a protective layer for delicate organs such as the heart and kidneys. *Phospholipids* are structural fats found in cell membranes. Sterols, such as *cholesterol*, are found in animal and plant tissues; they have a variety of functions, and are essential for making hormones or vitamins. Phospholipids and sterols are made in the body from nutrients provided in the diet.

FAT METABOLISM

Dietary fats are first emulsified (reduced to microscopic particles) by *bile* salts before being broken down by lipase, a pancreatic *enzyme*. They are absorbed via the *lymphatic system* before entering the bloodstream.

To be carried in the blood, the lipids become bound to proteins; in this state, they are known as lipoproteins. There are four classes of lipoprotein: chylomicrons; high-density lipoproteins (HDLs); low-density lipoproteins (LDLs); and very low-density lipoproteins (VLDLs). LDLs and VLDLs contain large amounts of cholesterol, which they carry through the bloodstream and deposit in tissues; they are sometimes referred to as bad fats. HDLs, known as good fats, pick up cholesterol and carry it back to the liver for processing and excretion. High levels of LDLs are associated with atherosclerosis, whereas HDLs have a protective effect. (See also *nutrition*.)

fatty acids

Organic acids, containing carbon, oxygen, and hydrogen, that are constituents of *fats and oils*. There are more than 40 fatty acids found in nature; they are distinguished from one another by their constituent numbers of carbon and hydrogen atoms.

Certain fatty acids cannot be synthesized by the body and must be provided by the diet. These substances, sometimes collectively termed essential fatty acids, are linoleic, linolenic, and arachidonic acids. Strictly speak-

ing, only linoleic acid is truly essential, because the body can make the other two from linoleic acid obtained from food. (See also *nutrition*.)

fatty degeneration

A general term describing the accumulation of fat within the cells of tissues damaged by disease.

fatty diarrhoea

See *steatorrhoea*.

fatty liver

A condition in which fat accumulates within the liver cells. The most common cause of fatty liver is excessive consumption of alcohol which, if continued, eventually leads to *cirrhosis*. However, if the drinking of alcohol stops, the fat clears from the liver. Fatty liver can also occur in association with *obesity*, *diabetes mellitus*, starvation, and in some cases of chronic ill-health.

favism

A disorder that is characterized by an extreme sensitivity to the broad bean *VICIA FABA* (fava bean). If an affected person eats these beans, a chemical in the bean causes rapid destruction of red blood cells, leading to a severe type of anaemia (see *anaemia, haemolytic*).

Favism is uncommon except in some areas of the Mediterranean. It is a sex-linked *genetic disorder*. Affected people have *G6PD deficiency*, a defect in a certain chemical pathway in their red blood cells that normally helps protect the cells from injury.

Children with a family history of favism can be screened for the disorder at an early age. If the condition is found, they must avoid fava beans as well as certain drugs, including some *antimalarial drugs* and *antibiotic drugs*, that can have a similar effect on their red blood cells.

febrile

Feverish or related to *fever*. Febrile convulsions, for example, occur mainly in young children with high temperatures (see *convulsion, febrile*).

febrile convolution

See *convulsion, febrile*.

feedback

A self-regulating mechanism that controls certain body processes, such as hormone and enzyme production.

If, for example, levels of a hormone are too high, output of any substance that stimulates the hormone's release is inhibited; the result is reduced hormone production (negative feedback). The reverse process (positive feedback) restores the balance if the levels of a hormone become too low. (See also *endocrine system*.)

feeding, artificial

The administration of nutrients other than by mouth, usually by way of a tube passed through the nose into the stomach or small intestine. If long-term artificial feeding is anticipated, a tube is inserted directly into the stomach or upper small intestine during endoscopic surgery (see *gastroscopy*). This is called *enteral feeding*. If the gastrointestinal tract is not functioning, nutrients must be introduced directly into the bloodstream (see *infusion, intravenous*). This type of feeding is known as *parenteral nutrition*.

TUBE FEEDING

Tube feeding may be necessary for people who have difficulty swallowing, or gastrointestinal disorders (for example, conditions resulting in *malabsorption*), or disorders affecting the nervous system or kidneys. Premature babies often require tube feeding if their *suckling reflexes* are undeveloped, as do critically ill patients due to their increased nutritional requirements.

Food mixtures, or preparations of nutrients, are given through a tube that is passed through the patient's nostril and down to the stomach or duodenum. There are two methods of feeding: continuous drip feeding, and bolus feeding (in which set amounts of nutrients are given at regular intervals throughout the day). In both methods, the rate of delivery of the food can be controlled by a pump.

INTRAVENOUS FEEDING

Intravenous feeding is usually given when large areas of the small intestine have been damaged by disease or have been surgically removed. Nutrient preparations are given and are inserted into a large central vein near the heart, via a *catheter* (a thin, flexible tube) that is buried under the skin.

feeding, infant

A person grows more rapidly in his or her first year than at any other time in life. A good diet is essential for healthy growth and development.

BREAST- OR BOTTLE-FEEDING

During the first four to six months, most of the nutritional requirements of babies are satisfied by *milk* alone, whether by *breast-feeding* or by *bottle-feeding*. Both human milk and artificial milk contain carbohydrate, protein, fat, vitamins, and minerals in similar proportions; however, human milk also

contains *antibodies* and *white blood cells* that protect the baby against infection. From six months of age, supplementary *vitamins A, C, and D* should be given to breast-fed babies. (Formula milk already contains vitamin supplements.)

Cows' milk should not be given in the first year of life. From one year, it is safe to feed with full-fat cows' milk.

FEEDING AN INFANT: INTRODUCING SOLIDS

The age at which an infant should be weaned on to solids depends entirely on the individual. There is no real need to feed solid foods to an infant below the age of six months unless he or she is consistently hungry. The following is a flexible guide:

Age	Time	Food
4 months	At second breast- or bottle-feed	Breast milk/formula. Offer one or two teaspoons of pureed fruit or vegetables or rice cereal.
4½ months	At second breast- or bottle-feed	Breast milk/formula. Offer two teaspoons of rice cereal.
	At third breast- or bottle-feed	Breast milk/formula. At third breast- or bottle-feed offer two teaspoons of vegetable or fruit puree.
5 to 6 months	Early morning	Breast- or bottle-feed.
	Breakfast	Two teaspoons of rice cereal, followed by breast- or bottle-feed.
	Lunch	One teaspoon of meat puree with three teaspoons of vegetables. Offer water instead of milk.
	Mid-afternoon	Mashed banana or other soft fruit, followed by usual milk feed.
	Dinner	Breast- or bottle-feed if the baby is still hungry.
6 to 7 months	Early morning	Breast- or bottle-feed.
	Breakfast	Two teaspoons of cereal with well-cooked scrambled egg. Offer breast- or bottle-milk from a cup.
	Lunch	Offer minced or mashed food instead of pureed. Give meat or fish with some vegetables, then offer yoghurt and fruit. Give a drink of water or well-diluted fruit juice.
	Late afternoon/dinner	Meat or cheese sandwich. Milk from a cup.
7 to 8 months	Early morning	Offer a drink of water or well-diluted fruit juice instead of milk.
	Breakfast	Cereal and hard-boiled egg with wholemeal bread and butter. A drink of milk.
	Lunch	Cheese, fish, or minced meat with some vegetables. Pudding or fresh fruit. A drink of water or well-diluted fruit juice.
	Late afternoon/dinner	Meat or cheese sandwich. A drink of milk.
9 to 12 months	Early morning	A drink of water or well-diluted fruit juice.
	Breakfast	Cereal, then well-cooked egg or fish with wholemeal toast and butter. A drink of milk.
	Lunch	Chopped meat, fish, or cheese, with vegetables. Pudding or fresh fruit. A drink of water or well-diluted fruit juice.
	Late afternoon/dinner	Meat or cheese sandwich. A drink of milk.

WARNING Avoid eggs, fish, and citrus fruit (including juice) before six months. Nuts should not be given to babies under six months, and whole nuts should not be given under five years. Avoid gluten before six months. Parents should be especially careful about feeding their children foods containing gluten or peanuts because serious allergies to these products are common.

INTRODUCING SOLIDS

Solids, initially as fruit or vegetable purees and wheat-free cereals, should be introduced between four and six months of age, depending on the baby's birth weight, rate of growth, and contentment with feeding. From six months, the baby should be eating true solids, such as chopped-up meat and vegetables, and at this stage can start eating well-cooked eggs. A baby under one year should not be given honey or products containing nuts. Salt and sugar used in home-prepared meals should be kept to a minimum to prevent kidney problems and dental decay, respectively.

FEEDING PROBLEMS

A few babies have an intolerance to certain foods, such as lactose or cows' milk protein (see *food intolerance; nutritional disorders*). Reactions can include vomiting, diarrhoea, or rashes. Difficulties associated with milk usually appear within the first month; solids should be introduced one by one so that any foods that cause problems can be identified.

Prolonged crying after feeds may mean that the baby needs help bringing up wind, that artificial milk is not being digested properly, or that the baby has colic (see *colic, infantile*).

felbinac

A *nonsteroidal anti-inflammatory drug* (NSAID) that is used for the relief of pain and inflammation in injuries such as sprains or bruising. Felbinac is applied topically as a gel or aerosol foam. Rarely, it may cause localized skin irritation. As some of the drug is absorbed in the bloodstream, felbinac should not be taken by anyone with an adverse reaction to oral (taken by mouth) NSAIDs, such as worsening of asthma.

Felty's syndrome

A disorder that is characterized by an enlarged *spleen* and an abnormally low white *blood cell* count. Felty's syndrome occurs in some people with *rheumatoid arthritis*, but the exact cause is unknown.

Symptoms of Felty's syndrome may include general malaise, fatigue, loss of appetite, weight loss, *anaemia*, joint swelling and stiffness, and recurrent infections. Possible signs of the condition include an enlarged spleen and, in some cases, swollen *lymph nodes*.

Treatment is the same as for *rheumatoid arthritis*. *Splenectomy* (surgical removal of the spleen) may be needed in some cases.

female

An individual with two X *sex chromosomes*. Females are also characterized by the presence of a vagina and vulva (see *sexual characteristics, primary*).

female catheter

A short *catheter* (flexible tube) that can be inserted into a woman's bladder through the *urethra* for the purpose of withdrawing *urine*.

feminization

The development of female secondary sexual characteristics in a male (such as breast enlargement and fat deposits beneath the skin and loss of facial hair). The condition is due either to a hormonal disorder or to *hormone therapy*. (See also *demasculinization; intersex; masculinization; sex determination; sexual characteristics, secondary; testicular feminization syndrome*.)

femoral artery

A major blood vessel that supplies oxygenated blood to the leg. The femoral artery is formed in the pelvis from the iliac artery, which is the terminal branch of the *aorta*. It then runs from the groin down the front of the thigh, and passes behind the knee to become the popliteal artery, which branches again to supply the lower leg.

femoral epiphysis, slipped

Displacement of the upper *epiphysis* (growing end) of the *femur* (thigh bone). Such displacement is rare; it usually affects children between the ages of 11 and 13, and occurs more often in boys and obese children. There is a tendency for the condition to run in families.

During normal growth, the epiphysis is separated from the shaft of the bone by a plate of *cartilage*. This area is relatively weak, so a fall or any other type of injury can cause the epiphysis to slip out of position. If this happens, a limp develops, and pain is felt in the knee or groin. The leg tends to turn outwards, and movements of the hip are restricted.

Surgery is needed to fix the epiphysis into its correct position; the procedure is usually completely successful. In some cases, however, the other hip may also need to be stabilized. However, following the injury and repair, the hip tends to be more susceptible than normal to *osteoarthritis*.

femoral hernia

A type of *hernia* that occurs in the groin area, at the point where the *femoral artery* and femoral vein pass from the lower abdomen to the thigh. Women who are overweight or who have had several pregnancies are at risk of femoral hernia because their abdominal muscles are weakened.

femoral nerve

One of the main nerves of the leg. The nerve fibres that form the femoral nerve emerge from the lower spine and run down into the thigh, where they branch to supply the skin and front muscles of the thigh. The nerve branches supplying the skin convey sensation; the branches supplying the muscles stimulate contraction of the *quadriceps muscle*, thereby straightening the knee.

Damage to the femoral nerve (which impairs the ability to straighten the knee) is usually the result of a slipped disc in the lumbar region of the spine (see *disc prolapse*). Damage may also result from a dislocation of the hip or from a *neuropathy*.

femur

The medical name for the thigh bone, which is the longest bone in the body. The lower end of the femur hinges

with the tibia (shin) to form the knee joint. The upper end is rounded into a ball (the head of the femur) that fits exactly into a socket in the pelvis to form the hip joint.

The head of the femur is joined to the bone shaft by a narrow piece of bone called the neck of the femur, which is a common fracture site (see *femur, fracture of*). At the lower end, the bone is enlarged to form two lumps (the condyles) that distribute the weight-bearing load through the knee joint. On the outer side of the upper femur is a protuberance called the greater trochanter.

The shaft of the femur is surrounded by muscles that move the hip and knee joints. The shaft is also well supplied with blood vessels; therefore, a fracture can result in considerable blood loss.

femur, fracture of

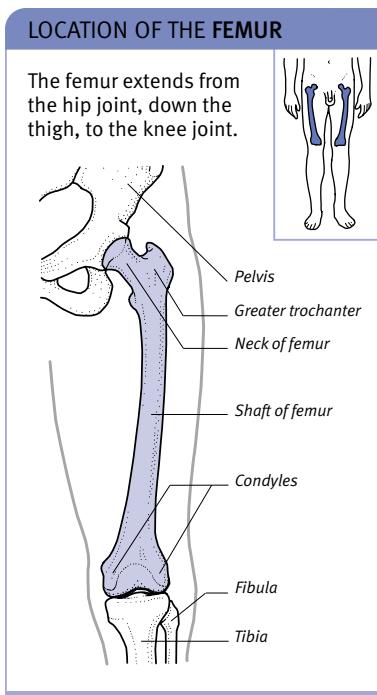

A break in the femur (the thigh bone). The symptoms, treatment, and possible complications of a fracture depend on whether the bone has broken across its neck (the short section between the top of the shaft and the hip joint) or across the shaft.

FRACTURE OF NECK OF FEMUR

This type of fracture, which is often called a broken hip, is very common in elderly people, especially in women with the bone disorder *osteoporosis* (loss of bone density). It is usually associated with a fall. In a fracture of the neck of the femur, the broken bone ends are often considerably displaced; in such cases there is usually severe pain in the hip and groin, making standing impossible. Occasionally, the broken bone ends become impacted (pushed together). In this case, there is less pain, and walking may be possible.

The diagnosis is confirmed by *X-ray*. If the ends of the bone are displaced, an operation is necessary, either to realign the bone ends and fasten them together, or to replace the entire head and neck of the femur with an artificial substitute (see *hip replacement*). If the bone ends are impacted, the fracture may heal naturally, but surgery may still be recommended.

A possible complication is damage to the blood supply to the head of the femur, resulting in the disintegration of the bone in that area (see *avascular necrosis*). *Osteoarthritis* may develop in the hip joint after fracture of the femur neck. In elderly people, immobility

and surgery may result in complications, such as *pneumonia*, that are not directly related to the fracture site.

FRACTURE OF SHAFT OF FEMUR

Fracture of the bone shaft usually occurs when the femur is subjected to extreme force, such as that occurring in a traffic accident. In most cases, the bone ends are considerably displaced, causing severe pain, tenderness, and swelling. With a fractured femoral shaft there is often substantial blood loss from the bone.

The diagnosis is confirmed by X-ray. The fracture is usually repaired by surgery in which the fractured ends of the bone are realigned and fastened together with a metal pin. Sometimes, however, the bone ends can be realigned by manipulation and surgery is unnecessary. After realignment, the leg is supported with a *splint* and put in *traction* to hold the bone while it heals.

Complications include failure of the bone ends to unite or fusion of the broken ends at the wrong angle; infection of the bone; or damage to a nerve or artery. A fracture of the lower shaft can cause permanent knee stiffness.

fenbufen

A *nonsteroidal anti-inflammatory drug* (NSAID) that is used to relieve pain and stiffness caused, for example, by *rheumatoid arthritis*, *osteoarthritis*, and *gout*. Fenbufen is also used to reduce pain and to help speed recovery following muscle and ligament sprains.

In common with many NSAIDs, fenbufen can cause irritation of the stomach lining (see *gastritis*) and may also cause a rash.

fenestration

A surgical procedure in which an artificial opening, or window, is created in a sheath or a membrane. For example, fenestration may involve removal of part of the wall of a *cyst* to prevent fluid reaccumulating.

fenoprofen

A *nonsteroidal anti-inflammatory drug* (NSAID) that is used to relieve pain and stiffness caused, for example, by *rheumatoid arthritis*, *osteoarthritis*, and *gout*. Fenoprofen is also used to treat muscle and ligament sprains; it reduces pain and helps to speed recovery.

In common with many NSAIDs, fenoprofen may cause irritation of the stomach lining (see *gastritis*).

fentanyl

An *opioid analgesic* drug that is given by injection to provide pain relief during surgery and to enhance general anaesthesia (see *anaesthesia, general*). Fentanyl is also used in the form of a skin patch to control the severe chronic pain of conditions such as cancer.

In common with other opioid drugs, fentanyl has side effects that include depressed breathing, constipation, nausea, and vomiting. The use of patches containing fentanyl may be associated with local irritation of the skin.

ferritin

A complex of *iron* and protein, found mainly in the liver and spleen. Ferritin is the principal form in which iron is stored in the body.

ferrous fumarate

A form of *iron* given in an oral preparation to treat iron-deficiency *anaemia*. Ferrous fumarate can cause diarrhoea, constipation, and abdominal pain.

ferrous sulphate

Another name for *iron sulphate*.

fertile period

The period during a woman's *menstrual cycle* when *conception* is most likely to occur. The fertile period is usually between three and five days in duration, beginning just before *ovulation*. Ovulation occurs about 14 days before a new menstrual cycle begins.

fertility

The ability to produce children without undue difficulty. Fertility depends on both male and female partners.

MALE FERTILITY

A man's fertility depends on the production of normal quantities of healthy *sperm* in the testes (see *testis*). This ability depends on adequate production of *gonadotrophin hormones* by the pituitary gland, situated at the base of the brain. Fertility in males is also dependent on the ability to achieve an *erection* and to ejaculate *semen* into the vagina during *sexual intercourse*.

Males become fertile at puberty and usually remain so, although to a lessening degree, well into old age.

FEMALE FERTILITY

A woman's ability to conceive depends on normal *ovulation* (the monthly production of a healthy *ovum*, or egg, by an *ovary*) and the ovum's unimpeded

passage down a *fallopian tube* towards the *uterus*; on thinning of the mucus surrounding the mouth of the *cervix*, to enable sperm to penetrate; and on changes in the lining of the uterus that prepare it for the implantation of a fertilized ovum.

These processes, in turn, depend on normal production of *gonadotrophins* by the pituitary gland, and of the sex hormones *oestrogen* and *progesterone* by the ovaries.

Women become fertile at puberty and remain so (although to a lessening degree as they become older) until the *menopause*, which usually occurs between 45 and 55 years of age. (See also *fertility drugs; infertility*.)

fertility drugs

COMMON DRUGS

- Bromocriptine • Cabergoline • Clomifene
- Follicle-stimulating hormone • Gonadorelin analogues • Human chorionic gonadotrophin • Luteinizing hormone • Tamoxifen

A group of hormonal or hormone-related drugs that are used to treat some types of *infertility*.

In women, fertility drugs may be given when the abnormal production of hormones by the *pituitary gland* or ovaries (see *ovary*) disrupts *ovulation* (the release of an ovum, or egg, from an ovary) or causes mucus around the *cervix* to become so thick that sperm cannot penetrate it. Treatment with the drug *clomifene*, which may continue over a number of months, can help to bring about ovulation in women whose pituitary glands do not produce sufficient hormones for ovulation to occur naturally. If this treatment fails to produce ovulation, treatment with follicle-stimulating hormone (FSH), followed by an injection of human chorionic gonadotrophin (HCG), may be given in order to stimulate ripening of the ovum and ovulation. (See also *gonadotrophin hormones*.)

Treatment with fertility drugs must be monitored carefully in order to avoid overstimulation of the ovaries. Symptoms of overstimulation may include nausea, vomiting, abdominal swelling, and the development of massive ovarian cysts. The condition is potentially life-threatening.

Fertility drugs are generally less effective in men but may be used when abnormal hormone production by the pituitary gland or testes interferes with

THE PROCESS OF FERTILIZATION

Fertilization occurs when the head of a sperm penetrates a mature ovum. After penetration, the nuclei (which contain the genetic material) of the sperm and ovum fuse and the body and tail of the sperm drop off. The newly fertilized ovum, called a zygote, then forms an outer layer that is impenetrable to other sperm. The zygote undergoes repeated cell divisions as it passes down the fallopian tube. By the time it reaches the uterus, it has grown into a solid ball of cells called a morula. It then develops an inner cavity with a small cluster of cells to one side; this is called a blastocyst.

Sperm and ovum

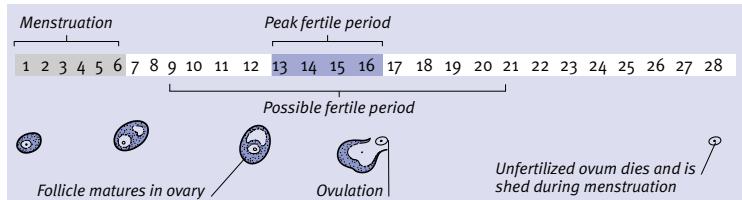

A single sperm penetrates the ovum, thereby fertilizing it. To achieve this, the sperm releases enzymes that dissolve a path through the ovum's outer layers.

JOURNEY OF THE SPERM

When semen is ejaculated into the vagina, as many as 500 million sperm are released, most of which are capable of fertilizing an ovum. But, as they travel upwards (propelled by their whiplike tails), more than half are killed by acidic vaginal secretions; many more die during the journey up through the cervix and uterus and into the fallopian tubes. The journey can take from less than half-an-hour to five hours and, in the end, only a few thousand sperm have survived.

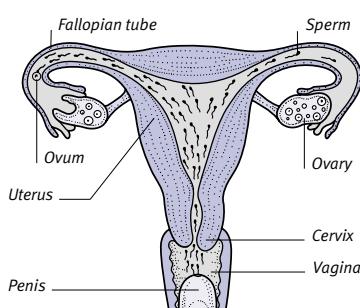

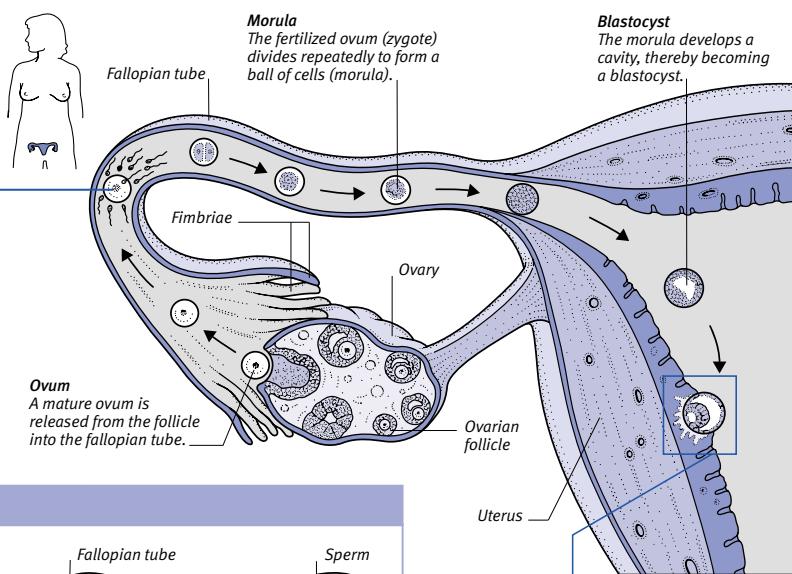

FERTILE PERIOD

Ovulation occurs halfway through the menstrual cycle (13 to 16 days before the start of a period), after which the released ovum is available for fertilization for about two days. Sperm can also live for about two days, so the peak fertile period is about four days (two pre- and two post-ovulation).

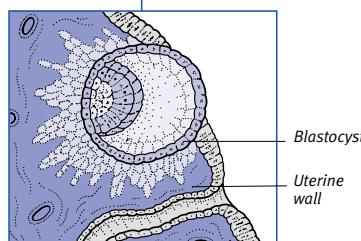

Peak and possible fertile periods

Although the peak fertile period is about four days, the possible fertile period may last seven to 12 days, due to variations in how long the ovum and sperm can survive and the timing of ovulation. The illustration shows the peak and maximum possible fertile periods in a 28-day cycle.

Lifespan of sperm

A sperm can live in a fallopian tube for up to 48 hours, during which time it is capable of fertilizing an ovum.

Blastocyst

The blastocyst embeds in the uterine wall (implantation), where it develops into an embryo and also forms the placenta.

the production of sperm. Low sperm production may be treated with gonadotrophins (FSH or HCG). (See also *testosterone*.)

fertilization

The union of a *sperm* and an *ovum* (egg cell). In natural fertilization (see the illustrated box), the sperm and ovum unite in the woman's *fallopian tube* following *sexual intercourse*.

Fertilization may also occur as a result of semen being artificially introduced into the cervix (see *artificial insemination*) or it may take place in a laboratory (see *in vitro fertilization*).

festinating gait

An involuntary style of *walking* in which a person moves, often on tiptoe, with progressively shortening and accelerating steps. A festinating gait is a feature of an individual suffering from the movement disorder *parkinsonism*.

fetal alcohol syndrome

A rare combination of birth defects that occur as a result of continued, excessive *alcohol* consumption by the baby's mother during *pregnancy*.

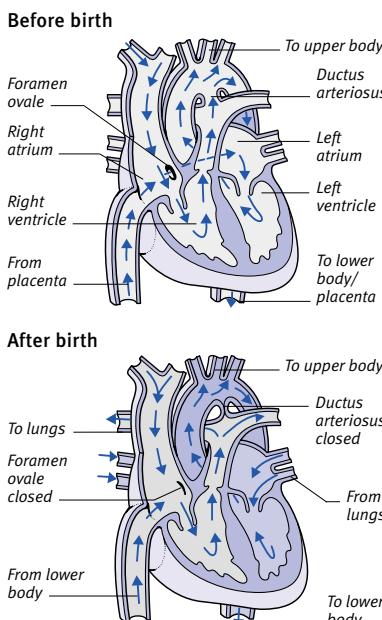

The affected baby has diminished growth, a small head and brain, and small eyes. He or she may also have a cleft palate, a small jaw, heart defects, and joint abnormalities. As a newborn, the baby sucks poorly, sleeps badly, and is irritable due to alcohol *withdrawal*.

Some affected babies die during the first few weeks of life. Those who survive may experience delayed mental development and are, to some degree, mentally and physically handicapped.

fetal circulation

Blood circulation in the fetus is different from the normal circulation after birth (see *circulatory system*). The fetus neither breathes nor eats, so oxygen and nutrients are obtained, via the *placenta* and *umbilical cord*, from the mother's blood. The other fundamental difference in circulation is that blood bypasses the lungs in the fetus.

Oxygen and nutrients enter the fetal blood through the placenta, an organ embedded in the inner lining and wall of the uterus and connected to the fetus by the umbilical cord. The maternal and fetal circulations are separated by a thin membrane in the placenta, which allows the exchange of nutrients and waste products.

Fetal heart circulation

In the fetus, blood passes directly from the right atrium of the heart to the left atrium through the foramen ovale. Another channel, the ductus arteriosus, allows blood to pass from the pulmonary artery to the aorta. After birth, both channels close redirecting blood through the lungs.

Oxygenated and nutrient-rich blood flows from the mother to the fetus along a vein in the umbilical cord before entering the right atrium (upper chamber) of the heart. Then, instead of flowing to the lungs, it bypasses them by flowing into the left atrium via an opening known as the foramen ovale. From there, the blood passes to the left ventricle (lower chamber), where it is pumped to the upper parts of the body to provide the tissues with oxygen.

Blood returning to the heart flows into the right atrium and from there into the right ventricle. In the fetus, the blood is only partly deoxygenated at this stage and has more tissues to supply with oxygen. Bypassing the lungs again, it flows from the pulmonary artery into the aorta, through a channel called the ductus arteriosus. The aorta carries the blood to the lower parts of the body. From there, completely deoxygenated blood is carried via the umbilical cord to the placenta, where carbon dioxide and other waste diffuses into the mother's blood.

After birth, the foramen and the ductus arteriosus normally close. Blood pumped from the right ventricle passes via the pulmonary artery to the lungs

for reoxygenation and elimination of carbon dioxide and other wastes. In rare cases, the foramen ovale or ductus arteriosus fails to close after birth, causing a congenital heart disorder (see *heart disease, congenital*).

fetal death

See *stillbirth*.

fetal distress

The physical stress experienced by a fetus during *labour* as a result of not receiving enough oxygen. During each contraction, the uterus tightens and thus reduces the oxygen supply from the placenta to the fetus. If there are also problems, such as pressure on the *umbilical cord* or the mother losing blood, there may be an inadequate amount of oxygen reaching the fetus.

MONITORING

Various monitoring techniques may be used during childbirth to detect signs of fetal distress. A cardiotocograph (see *fetal heart monitoring*) will record whether the baby's heart rate is slow or if it is failing to show normal variability. *Acidosis* (high acidity in the body), which indicates that the oxygen supply to the fetus is inadequate, can be detected in a sample of blood taken from the baby's scalp. Signs of *meconium* (fetal faeces) in the amniotic fluid can also be an indication of fetal distress.

DELIVERY

Fetal distress sometimes occurs as a temporary episode, but, if acidosis is severe, the distressed fetus may need to be delivered promptly by *caesarean section*, *forceps delivery*, or *vacuum extraction*. (See also *childbirth*.)

fetal heart monitoring

The use of an instrument to record and/or listen to an unborn baby's heartbeat during *pregnancy* and *labour*.

WHY IT IS DONE

The fetal heart is checked routinely during pregnancy with a fetal stethoscope or *Doppler ultrasound* scanning. Additional monitoring is carried out if tests indicate that the placenta is not functioning normally or if the baby's growth is slow. Uterine contractions or other stimuli, such as reflex kicking, increase the heart rate in a healthy fetus; the midwife or obstetrician can detect this using a fetal heart monitor. During labour, monitoring can detect *fetal distress*, in which oxygen deprivation causes abnormalities in the fetal heart rate.

HOW IT IS DONE

The most simple form of fetal heart monitoring involves using a special fetal stethoscope. Cardiotocography, a more sophisticated electronic version, is a procedure that produces a continuous paper recording of the heartbeat and a recording of the uterine contractions. The heartbeat is picked up either externally by an *ultrasound* transducer strapped to the mother's abdomen or, as an alternative during labour, internally by an electrode attached to the baby's scalp that passes through the vagina and cervix. The mother's uterine contractions are measured and recorded by an external pressure gauge strapped to the mother's abdomen, or by an internal plastic tube inserted through the vagina into the amniotic fluid.

fetal movement

Movements made by a developing fetus in the uterus, which can usually be detected by the mother from between about the 16th and 20th weeks of pregnancy. Fetal movement at this stage may feel like a gentle "flutter" to the mother; later in pregnancy the fetus becomes more robust in its movements and may kick as it moves around in the amniotic sac. Some fetuses are more active than others. In late pregnancy, to monitor fetal well-being, the number of movements may be recorded on a "kick chart".

fetishism

Reliance on special objects in order to achieve sexual arousal. The objects need not have an obvious sexual mean-

ing; they may include shoes, rubber or leather garments, and parts of the body such as the feet or ears.

Fetishism usually has no obvious cause. According to psychoanalysts, the origin may be a childhood *fixation* of sexual interest upon some aspect of the mother's appearance. Treatment is necessary only if the behaviour leads to distress or is causing persistent criminal acts.

fetoscopy

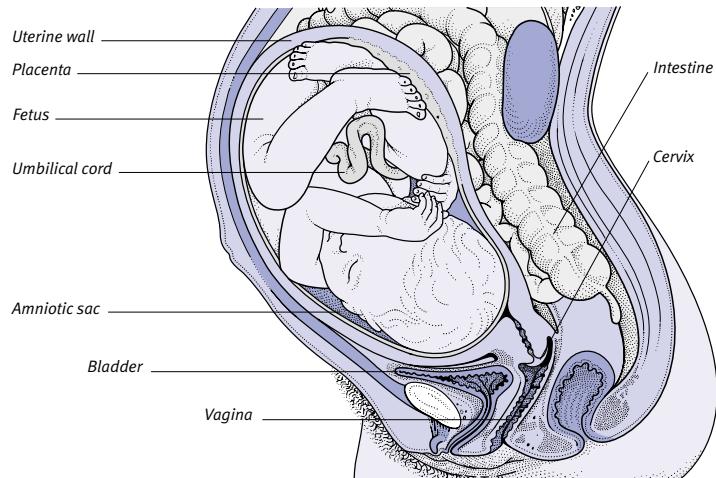

A procedure for directly observing a fetus inside the uterus using a fetoscope, which is a type of *endoscope* (a tubelike viewing instrument). Fetoscopy allows a close-up look at the fetus, particularly the face, limbs, genitals, and spine, and is used to diagnose various *congenital* abnormalities before birth.

DEVELOPMENT OF THE FETUS

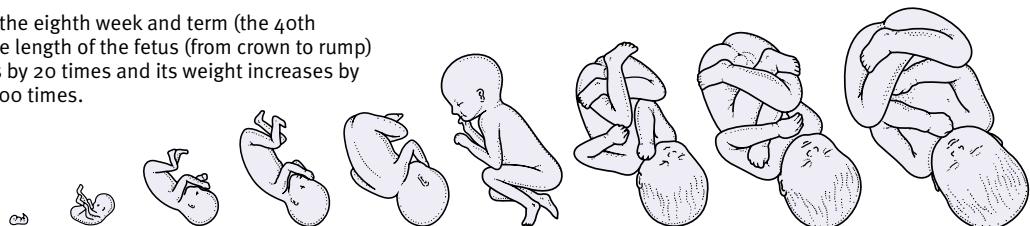

By the 32nd week of pregnancy, the internal organs of the fetus are almost fully mature and it is perfectly formed. In most cases, the fetus has turned to lie head-down in the pelvis.

**Fetus in sac**

This MRI scan shows the developing fetus head-down in the mother's uterus during the 36th week of pregnancy. Internal organs (such as the brain) are fully formed.

**GROWTH OF THE FETUS FROM 8 TO 40 WEEKS**

Between the eighth week and term (the 40th week), the length of the fetus (from crown to rump) increases by 20 times and its weight increases by about 1,700 times.

Week	8	12	16	20	24	28	32	36	40
Length	2.5 cm	7.5 cm	16 cm	25 cm	33 cm	37 cm	40.5 cm	46 cm	51 cm
Weight	2 g	18 g	135 g	340 g	570 g	900 g	1.6 kg	2.5 kg	3.4 kg

The technique carries some risks, so it is performed only when other tests, such as *ultrasound scanning*, detect an abnormality. By attaching additional instruments, doctors can use the fetoscope to take samples of fetal blood or tissue for analysis and to perform surgical procedures, such as insertion of a catheter into the fetal bladder. (See also *amniocentesis*; *chorionic villus sampling*.)

fetus

The unborn child from the end of the eighth week after conception until birth. For the first eight weeks, the unborn child is called an *embryo*.

The fetus develops in the mother's *uterus* in a sac filled with *amniotic fluid*, which cushions it against injury. The oxygen and nutrients required by the fetus are supplied via the *placenta*, an organ embedded in the inner wall of the uterus that is attached to the fetus by the *umbilical cord*.

FEV

See *forced expiratory volume*.

fever

Known medically as *pyrexia*, elevation of body temperature above the normal level of 37°C in the mouth and 0.6°C lower in the axilla (armpit). A fever may be accompanied by symptoms such as shivering, sweating, a headache, thirst, unusually rapid breathing, and a flushed face. *Confusion* or *delirium* sometimes occur with a fever, especially in elderly people. A high fever may cause seizures in a child under five years (see *convulsion, febrile*) or *coma*.

CAUSES

Most fevers are caused either by bacterial infections, such as *tonsillitis*, or by viral infections, such as *influenza*. In such cases, proteins called pyrogens are released when the white blood cells fight the microorganisms that are responsible for the infection (see *immune system*). Pyrogens act on the temperature-controlling centre in the brain, causing it to raise the temperature of the body in an attempt to destroy the invading microorganisms.

Fever may also occur in other conditions where infection is not present. Such conditions include *dehydration*, *thyrotoxicosis* (a condition that results from overactivity of the thyroid gland), *lymphoma* (a tumour of the lymphatic system), and *myocardial infarction* (heart attack).

TREATMENT

Drugs such as *aspirin*, other *nonsteroidal anti-inflammatory drugs*, or *paracetamol* may be given to reduce fevers that are due to infections. Otherwise, treatment is directed at the underlying cause; for example, *antibiotic drugs* are given to treat a bacterial infection.

feverfew

The common name for the plant *TANACETUM PARTHENIUM*, which is used in herbal medicine for the treatment of headache and migraine.

fibrates

A type of *lipid-lowering drug* that is used to treat high blood levels of *triglycerides* or *cholesterol*.

fibre, dietary

The indigestible plant material in food. Dietary fibre includes certain types of polysaccharide, cellulose, hemicellulose, lignin, and gums and pectins (see *carbohydrates*). Humans do not have the enzymes necessary to digest these substances, so the material passes through the digestive system virtually unchanged and cannot be used as a source of energy.

Some components of dietary fibre hold water, thereby adding bulk to the faeces and aiding bowel function. For this reason, dietary fibre can be effective in treating *constipation*, *diverticular disease*, and *irritable bowel syndrome*. A high-fibre diet can help to reduce blood cholesterol levels. Certain high-fibre foods, such as fruit and vegetables, are also beneficial in protecting against

cancers. Unrefined carbohydrate foods, including wholemeal bread, cereals, and root vegetables, are very rich in dietary fibre. (See also *nutrition*.)

fibre-optics

The transmission of images through bundles of thin, flexible glass or plastic threads. Light from a powerful external source is conducted along the length of the fibre, without losing its intensity, by a process known as total internal reflection. Fibre-optics have led to the development of *endoscopes*, instruments that enable structures deep within the body to be viewed directly.

fibrillation

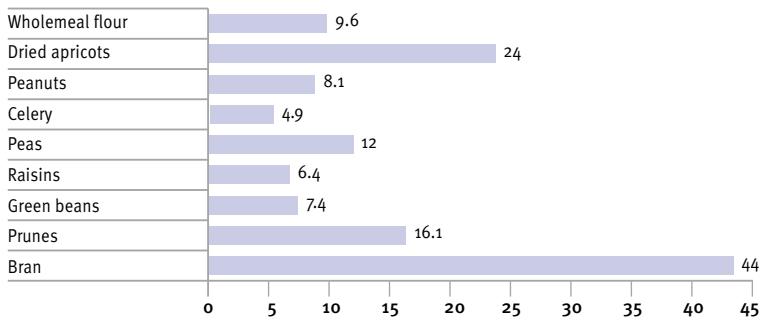

Localized, spontaneous, rapid contractions of muscle fibres that can affect both skeletal and heart muscle.

In skeletal muscle, fibrillation generally occurs when a nerve supplying a muscle is destroyed, causing the muscle to become weak and waste away. Unlike *fasciculation* (muscular quivering), fibrillation in skeletal muscle is not visible through the skin; instead, the contractions can be detected using an *EMG* (electromyogram).

Fibrillation in the heart muscle is caused by disruption to the spread of nerve impulses through the wall of one of the chambers of the heart. Either the upper chambers (see *atrial fibrillation*) or the lower chambers (see *ventricular fibrillation*) of the heart may be affected. The condition can be detected by the use of an *ECG* (electrocardiogram). Fibrillation in heart muscle has the

GOOD SOURCES OF FIBRE (per 100g portion)

Essential for the efficient working of the digestive system, fibre is usually eaten as fruit or grains. Among the best sources are bran, apricots, prunes, and wholemeal bread. Eating sufficient fibre in food can reduce constipation. The recommended daily intake is 25 to 30 grams.

potential to be serious because it impairs the ability of the chambers to contract efficiently.

fibrin

A substance that is produced in the blood during the process of *blood clotting*. Fibrin is formed from a dissolved protein called *fibrinogen*. It forms long filaments that bind clumps of *platelets* and other blood cells into a mass that plugs the bleeding point, thereby preventing further blood loss.

F

fibrinogen

A protein that is present in blood and which is converted into *fibrin* during the *blood clotting* process.

fibrinolysis

The breakdown of *fibrin*, the principal component of any blood clot. Fibrin is a stringy protein that is formed in blood as the end product of coagulation (see *blood clotting*).

Blood also contains a fibrinolytic system, which is activated in parallel with the coagulation system when a blood vessel is damaged. The fibrinolytic system prevents the formation of clots in undamaged blood vessels, thereby preventing a blockage in these vessels, and it acts to dissolve a clot once healing of a broken blood vessel wall has taken place.

Thrombosis (abnormal formation of blood clots) occurs in situations in which there is a disturbance in the normal balance between the coagulation and fibrinolytic mechanisms.

Drugs that achieve the effect of fibrinolysis (see *thrombolytic drugs*) can be used to treat certain disorders, such as *pulmonary embolism* and *myocardial infarction*, in which blood clots block the circulation.

fibrinolytic drugs

Another name for *thrombolytic drugs*, which are used to dissolve blood clots.

fibroadenoma

A noncancerous fibrous tumour most commonly found in the breast. Fibroadenomas occur most often in women under the age of 30 and in black women. Multiple tumours may develop in one or both breasts.

Fibroadenomas of the breast are painless, firm, round lumps that are usually between 1 and 5 cm in diameter and movable. Although the cause of

fibroadenomas is not fully understood, their development in the breast is believed to be linked to the sensitivity of breast tissue to female sex hormones. The lumps tend to grow more quickly during pregnancy, probably due to the increased levels of female sex hormones.

A sample of tissue from the lump is removed and examined to confirm the diagnosis (see *biopsy*). Fibroadenomas are harmless and do not require treatment unless they become very large or cause discomfort.

fibroadenosis

An outdated term for the general lumpiness that is a normal feature of some women's breasts. Cyclical changes in hormone levels often lead to the appearance of lumps in the breasts, and the lumpiness is more obvious before a menstrual period.

Lumpy breasts do not increase the risk of developing breast cancer. However, a new solitary, discrete *breast lump* should be assessed by a doctor to rule out the possibility of breast cancer. (See also *mammary dysplasia*.)

fibrocystic disease

A term that is used to refer either to the inherited disorder *cystic fibrosis* or to general lumpiness of the breasts (see *fibroadenosis*).

fibroid

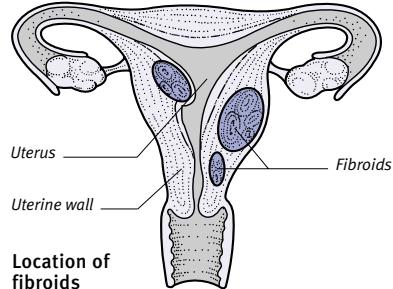

A slow-growing and noncancerous tumour that is found in the wall of the *uterus*. A fibroid is composed of smooth muscle and *connective tissue*. There may be one or more fibroids, and they may range in size from as small as a pea to as large as a grapefruit. Fibroids are common, appearing most often in women between the ages of 35 and 45.

CAUSE

The cause of a fibroid is thought to be related to an abnormal response to *oestrogen hormones*. Oral contraceptives that contain oestrogen can cause enlargement of fibroids, as can *pregnancy*. Decreased production of oestrogen after the *menopause* usually causes any fibroids to shrink.

SYMPTOMS

In many cases, there are no symptoms. If a fibroid enlarges and projects into the cavity of the uterus, it may cause heavy or prolonged periods. A large fibroid may exert pressure on the blad-

der, causing frequent passing of urine, or on the bowel, causing backache or constipation. Fibroids that distort the uterine cavity may cause recurrent *miscarriage* or *infertility*. Rarely, a fibroid may become twisted, resulting in sudden pain in the lower abdomen.

DIAGNOSIS AND TREATMENT

Fibroids that do not cause symptoms are often discovered during a routine pelvic examination. *Ultrasound scanning* can confirm the diagnosis.

Small, symptomless fibroids generally require no treatment, but regular examination may be needed to assess growth. Surgery or microwave *endometrial ablation* (MEA) is required for fibroids causing serious symptoms. In some cases, they can be removed with a *hysteroscope* (a tubelike viewing instrument with surgical attachments) under general anaesthesia (see *anaesthesia, general*), leaving the uterus intact. Removal of fibroids usually results in regained fertility. Sometimes, however, a *hysterectomy* (removal of the uterus) is required.

fibroma

A noncancerous tumour of the cells that form *connective tissue*. For example, a neurofibroma is a tumour of the cells that surround nerve fibres (see *neurofibromatosis*). Treatment is only needed if there are symptoms.

fibromyalgia

Pain and stiffness in the muscles, which is often associated with disturbance of sleep. Fibromyalgia is most common in women aged between 40 and 60 years. The condition is also known as chronic widespread pain (CWP) and was formerly referred to as fibrositis. Medical investigation usually fails to reveal any underlying cause and, for this reason, some doctors do not recognize fibromyalgia as a medical condition. However, the lives of affected people are often severely disrupted.

The muscles most commonly affected are those in the neck, shoulders, chest, back, buttocks, and knees. There is usually no restriction of movement. Attacks are generally worse in cold, damp weather. Exhaustion and disturbed sleep are common.

Use of *analgesic drugs* (painkillers), hot baths, and massage usually relieves pain and stiffness. *Antidepressant drugs*, such as amitriptyline, are often effective in improving sleep and relieving pain.

fibroplasia

The formation of fibrous tissue, which is a process that occurs normally during the healing of a wound, that may occur abnormally in some tissues. In one form of the condition, known as *retrolental fibroplasia*, fibrous tissue develops behind the lens of the eye and causes blindness. This type of fibroplasia is usually seen only in newborn premature babies and is the result of excessive treatment with oxygen.

fibrosarcoma

A rare, cancerous tumour of the cells that make up *connective tissue* (the material that surrounds body structures and holds them together). A fibrosarcoma may develop from a non-cancerous *fibroma* or may be cancerous from the start.

Treatment of a fibrosarcoma is by surgical removal and/or *radiotherapy*. However, this may be only temporarily successful if cells from the tumour have already spread through the bloodstream to initiate growths elsewhere in the body.

fibrosing alveolitis

Inflammation and thickening of the walls of the alveoli (the tiny air sacs in the lungs; see *alveolus, pulmonary*) that results in scarring of lung tissue (see *interstitial pulmonary fibrosis*). Fibrosing alveolitis most frequently occurs in people over the age of 60.

Usually, fibrosing alveolitis is a long-term disorder, that develops over months or years. Rarely, an acute form occurs that develops rapidly over a few days or weeks. Both forms tend to become progressively worse and are difficult to treat.

CAUSES

In some cases, fibrosing alveolitis is the result of an *autoimmune disorder* (in which the immune system attacks the body's own tissues) and may be associ-

ated with such conditions, particularly *rheumatoid arthritis* and systemic *lupus erythematosus*. Other causes of the condition may include *radiotherapy* of the organs in the chest and treatment with *anticancer drugs*. In many cases, however, the cause is unknown; the condition is then known as idiopathic pulmonary fibrosis.

SYMPTOMS

Symptoms of fibrosing alveolitis include shortness of breath, a persistent dry cough, and joint pains. As the condition progresses, breathing becomes increasingly difficult, especially during vigorous exercise. In severe cases, there is increased risk of *respiratory failure* and *chronic heart failure*. Some people with the disorder are more susceptible to *lung cancer*.

TREATMENT

Treatment of the condition involves *corticosteroid drugs* combined with other *immunosuppressant drugs* to slow the progress of lung damage. Home oxygen therapy may be used to assist breathing. For some people, a lung transplant may be life-saving.

fibrosis

An overgrowth of scar tissue or *connective tissue*. Fibrous tissue may be formed as an exaggerated healing response to infection, inflammation, or injury. Fibrosis may also result from a lack of oxygen in a tissue, usually due to inadequate blood flow through it (in heart muscle damaged by a *myocardial infarction*, for example).

In fibrosis, specialized structures (for example, kidney or muscle cells) are replaced by fibrous tissue, which results in impaired function of the organ concerned. An overgrowth of fibrous tissue can compress hollow structures, a situation that occurs in *retroperitoneal fibrosis*, in which the ureters (tubes draining urine from the kidneys into the bladder) become blocked. Fibrous tissue formed within a muscle after a tear causes shortening of the muscle and disruption of the normal contraction of its fibres. The likelihood of further tears occurring is increased unless the muscle is stretched and exercised.

fibrositis

A former term for *fibromyalgia*.

fibrous adhesion

See *adhesion*.

fibula

The outer and thinner of the two long bones of the lower leg. The fibula is much narrower than the other lower-leg bone, the *tibia* (shin), to which it runs parallel and to which it is attached at both ends by *ligaments*. The top end of the fibula does not reach the knee, but the lower end extends below the tibia and forms part of the *ankle joint*.

The main function of the fibula is to provide an attachment for the muscles. It provides little supportive strength to the lower leg.

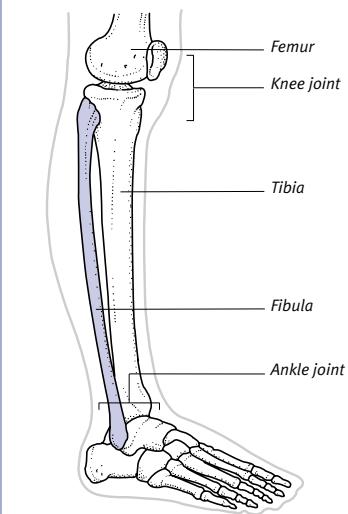

FRACTURE

The fibula is one of the most commonly broken bones. A fracture of the fibula just above the ankle may occur with a severe ankle sprain as a result of a violent twisting movement. *Pott's fracture* is a fracture at this location combined with dislocation of the ankle and sometimes with fracture of the tibia.

To confirm a fracture of the fibula, *X-rays* are taken. In some cases, the lower leg is immobilized in a plaster *cast* to allow the bone to heal. If a fracture occurs in the middle portion of the fibula, however, immobilization may not be needed. If the fracture is severe (especially if it is accompanied by dislocation of the ankle), surgery may be necessary to fasten the broken pieces of bone with pins.

LOCATION OF THE FIBULA

The fibula lies beside the tibia on the outside of each lower leg.

A fractured fibula may take up to six weeks to heal, depending on its severity and the age of the patient.

fifth disease

An infectious disease that often causes a widespread rash. Fifth disease, which is also known as slapped cheek disease or erythema infectiosum, principally affects children and is caused by a strain of *erythrovirus*. Erythrovirus is transmitted in airborne droplets from the coughs and sneezes of individuals who are carrying the infection, but it may occasionally be transmitted through a blood transfusion.

Many children do not develop symptoms; in other children, the rash appears seven to 14 days after infection. The rash of fifth disease starts on the cheeks as separate, rose-red, raised spots, which subsequently converge to give the characteristic appearance of the condition. Within a few days, the rash spreads in a lacy pattern over the limbs, but only sparsely on the trunk. The rash is frequently accompanied by mild fever and generally clears up after approximately ten days.

Adults, who contract the disease only rarely, tend to be more severely affected than children. They may have joint pain and swelling that lasts for up to two years. Infection may bring a temporary halt to the production of red blood cells in the bone marrow (known as an aplastic crisis); it can therefore have serious implications for people with *anaemia*.

The only treatment for the infection is with drugs to reduce the fever. In most cases, the condition clears up within two weeks. However, people at risk of anaemia may need hospital treatment. One attack of erythrovirus confers lifelong immunity.

fight-or-flight response

The arousal of the sympathetic part of the *autonomic nervous system*, generally in response to fear. *Adrenaline* (epinephrine), *noradrenaline* (norepinephrine), and other hormones are released from the adrenal glands and nervous system, leading to a raised heart rate, pupil dilation, and increased blood flow to the muscles. These responses make the body more efficient in either fighting or fleeing the apparent danger. Prolonged or excessive fight-or-flight responses occur as part of *anxiety disorders*.

figure-of-eight bandage

A *bandage* that is wrapped over itself a number of times to resemble the figure eight. A figure-of-eight bandage is often used in first aid to support the elbows, wrists, knees, and ankles, particularly if the joint is to be kept in a flexed position.

filariasis

A group of tropical diseases, caused by various parasitic worms or their larvae, which are transmitted to humans by insect bites. Adult female worms, which may measure anything between 2 and 50 cm, produce many thousands of larvae, which are carried through the body in the bloodstream. Blood-sucking insects (primarily certain species of mosquito) ingest the larvae while feeding on blood from infected people and transmit them by biting others.

Filariasis is prevalent in tropical Africa, Indonesia, the South Pacific, coastal Asia, southern Arabia, Mexico, and Guatemala.

TYPES AND SYMPTOMS

Some species of worm live in the lymphatic vessels (see *lymphatic system*). Swollen *lymph nodes* and recurring fever are early symptoms of the disease. Inflammation of lymph vessels results in localized *oedema* (the accumulation of fluid in the tissues, causing swelling). After repeated infections, the affected area, which is commonly a limb or the

scrotum, becomes very enlarged; in addition, the skin becomes thick, coarse, and fissured, resulting in a condition known as *elephantiasis*.

The larvae of another type of worm invade the eye, causing blindness (see *onchocerciasis*). A third type of larva, which may sometimes be seen and felt moving beneath the skin, causes *loiasis*, characterized by irritating and sometimes painful areas of oedema called calabar swellings.

DIAGNOSIS AND TREATMENT

A diagnosis of filariasis is confirmed by microscopic examination of the blood (see *blood tests*). The *anthelmintic drugs* diethylcarbamazine or ivermectin generally cure the infection, but they may also cause certain side effects, however, such as fever, sickness, muscle pains, and increased itching.

PREVENTION

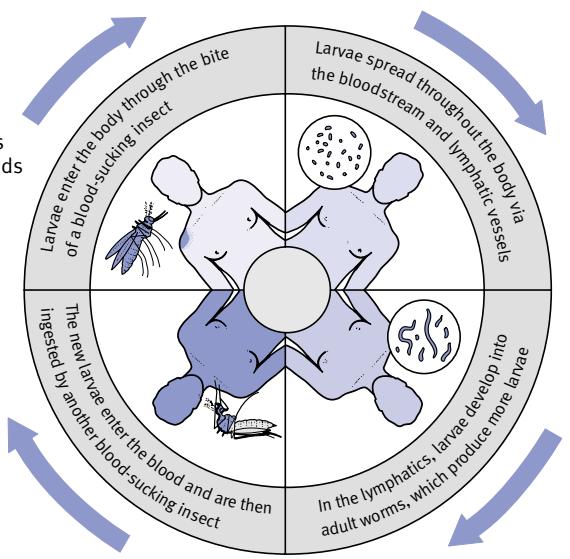

The drug diethylcarbamazine can be given as a preventative measure; and the use of insecticides and protective clothing are useful protection against insect bites. (See also *roundworms; insects and disease*.)

filling defect

An abnormal finding on *contrast X-rays* due to a lesion occupying space within a hollow organ. Normally, in contrast X-rays, a radio-opaque dye (a contrast medium) is introduced into a hollow body structure, such as the intestine,

THE CYCLE OF FILARIASIS

Filariasis is caused by parasitic worms and/or their larvae. There are several stages in the development of this infection as it spreads through the body.

and X-rays are taken; the dye outlines the shape of the structure. Anything that protrudes into the cavity of a body structure, such as *polyps* in the large intestine or a tumour in the bladder, will prevent the area from filling with the contrast medium, and will produce a distorted shape on the X-ray.

filling, dental

The process of replacing a chipped or decayed area of tooth with an inactive material. The term may also be used to describe the restorative material itself.

Amalgam, a hard-wearing mixture of silver, mercury, and other metals, is often used for back teeth. Tiny amounts of mercury released from such fillings are believed by some to cause health problems. However, a link has yet to be scientifically established.

If a front tooth is chipped, bonding (see *bonding, dental*), in which plastic or porcelain tooth-coloured material is attached to the surface of the tooth, may be used.

WHY IT IS DONE

When enamel is damaged, bacteria can invade the dentine beneath and eventually attack the pulp (inner tissue containing blood vessels and nerves), causing the tooth to die. Teeth are therefore repaired, where possible, at the first signs of damage to prevent decay. Filling also restores a tooth's original shape, which is important for appearance and also for a correct bite.

HOW IT IS DONE

If the filling required is large or in a sensitive area, the dentist numbs the surrounding gum with a local anaesthetic (see *anaesthesia, dental*). Any soft, decayed material is removed with sharp instruments. A high-speed drill is used to remove harder material and to shape a hole that will hold the filling securely. While the dentist works, a suction tube placed in the patient's mouth draws away saliva and produces water to cool the end of the drill.

If the pulp is almost exposed, the bottom of the cavity is lined with a sedative paste to protect the sensitive pulp from pressure and temperature changes. If one or more of the walls of the tooth is missing through extensive decay, a steel band may be placed around the tooth to support the filling. The dentist then mixes the amalgam or other filling material, and packs it into the cavity, smoothing the surface. The material hardens over 24 hours.

OUTLOOK

Amalgam fillings have a limited life and may need to be replaced after about ten years. Occasionally, a filling needs to be replaced sooner if decay has spread under the filling or the filling has become dislodged or fractured.

film

A thin, transparent sheet of cellulose acetate or similar material, coated with a light- or *radiation*-sensitive emulsion, on which images such as *X-rays* are produced. The term is also used to describe any thin layer or coating, such as the covering of *tears* on the eyeball. (See also *blood film*.)

film badge

A device that enables hospital staff to monitor their exposure to *radiation*. Film badges are worn by people working in *X-ray* and *radiotherapy* departments. The badge consists of a piece of photographic film in a holder, which is worn on the clothing. The film has a fast (sensitive) emulsion on one side and a slow emulsion on the other. Small doses of radiation blacken only the fast emulsion; higher doses start to blacken the slow emulsion and make the fast emulsion turn opaque.

fimbriae

A fringe of threadlike or fingerlike filaments, such as those that make up the ends of the *fallopian tubes* that open on to the ovaries (see *ovary*). During *ovulation*, the fimbriae guide the egg (see *ovum*) into the tube.

finasteride

A specific *enzyme* inhibitor drug that prevents the conversion of *testosterone* into the more potent male hormone dihydrotestosterone. Finasteride is used in the treatment of noncancerous enlargement of the prostate (see *prostate, enlarged*); it shrinks the gland, thereby improving urine flow. It is also used to treat male pattern baldness in men. Side effects include *impotence* and reductions in *libido* and *semen volume*.

fine tremor

A *tremor* (an involuntary trembling or oscillating movement) characterized by very small and rapid vibrations.

finger

One of the digits of the *hand*. Each finger has three phalanges (finger bones), and the thumb has two. The phalanges

join at hinge joints moved by muscle tendons that flex (bend) and extend (straighten) the finger. The tendons are covered by synovial sheaths that contain fluid, enabling the muscles to work without friction. A small artery, vein, and nerve run down each side of the finger. The entire structure is enclosed in skin with a *nail* at the tip.

DISORDERS

Finger injuries are common, especially *lacerations*, *fractures*, and ruptures of the tendons. *Mallet finger* is a condition that occurs when the extensor tendon along the back of the finger is pulled away from its attachment after a blow to the fingertip.

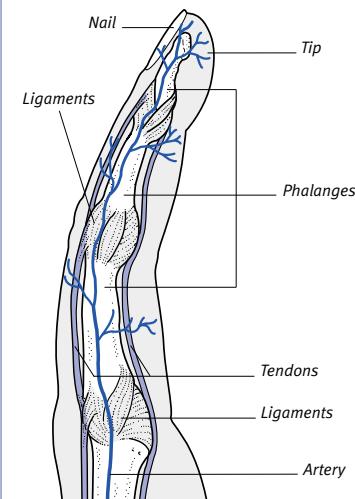

Infections may occur in the finger pulp at the tip; *paronychia* (infection of the tissue around a nail) sometimes follows a minor cut.

Inflammation that is due to *rheumatoid arthritis* or *osteoarthritis* may affect the joints of the fingers, causing stiffness, pain, swelling, and deformity. In addition, the flexor tendons, which run along the front of the fingers, may become inflamed and stuck in the tendon sheath, causing a condition known as *trigger finger*.

Altered control of the muscles in the walls of the blood vessels and impaired blood supply to the hands and fingers may cause *Raynaud's disease*. Dactylitis is a spindle-shaped swelling of the fingers

STRUCTURE OF A FINGER

The phalanges (finger bones) are joined at hinge joints and moved by tendons.

that is found in *sickle-cell anaemia*. Swelling of the fingers is also a rare feature of tuberculosis and syphilis.

Clubbing of the fingers is a sign of chronic lung disease or of certain forms of congenital heart disease. Tumours of the finger are rare, but they may occur in *chondromatosis*, a condition that is characterized by multiple noncancerous tumours of the *cartilage*.

Congenital finger disorders include *syndactyly* (fused fingers), *polydactyly* (extra fingers), missing fingers, or a webbed appearance of the hand that is caused by a deep membrane between the fingers.

finger-joint replacement

A surgical procedure in which one or more artificial joints (made of metal, plastic, or silicone rubber) are used to replace finger joints that have been destroyed by disease, usually by *rheumatoid arthritis* or *osteoarthritis*.

HOW IT IS DONE

Usually, several finger joints are treated at the same time. An incision is made to expose the joint; the ends of the two diseased bones in the joint are cut away, along with diseased cartilage. An artificial joint is then inserted into the bone ends. The finger is immobilized in a splint until the wound has healed. After about ten days, the dressings are removed and the patient is encouraged to exercise the fingers and resume normal activities.

RESULTS

Finger-joint replacement is usually successful in relieving arthritic pain and enabling the patient to use his or her hands again. However, it rarely restores normal movement.

fingerprint

An impression that is left on a surface by the pattern of fine curved ridges on the skin of the fingertip. These ridges occur in four patterns: loops, arches, whorls, and compounds (which are combinations of the other three). No two people (not even identical twins) have the same fingerprints.

first aid

The immediate treatment of any injury or sudden illness before professional medical care can be provided. Most first aid consists of treating minor injuries and *burns*, and *fractures*. Sometimes, however, emergency life-saving first aid treatment may be needed.

The aims of first-aid treatment in an emergency are to preserve life; to protect the individual from further harm; to provide reassurance; to make the victim comfortable; to arrange for medical help; and to find out as much as possible about the circumstances of the accident or injury.

Various techniques can be used to achieve these aims. For example, the *recovery position* helps to maintain an open airway in an unconscious person who is breathing; *artificial respiration* is necessary if a person is not breathing. *Cardiopulmonary resuscitation* is essential if a person is not breathing and has no heartbeat. Heavy bleeding, which can result in *shock*, may be controlled by applying pressure at appropriate *pressure points*.

fish oil

A product occurring naturally in some species of oily fish, such as mackerel. Fish-oil preparations, which are rich in *omega-3 fatty acids*, are used as *lipid-lowering drugs*.

fissure

A cleft or groove, which can be either normal or abnormal. A dental fissure is a naturally occurring defect in the enamel of a tooth in which tooth decay (see *caries, dental*) commonly arises. The sylvian fissure is one of the deep folds that separate the temporal lobe of the *brain* from the frontal and parietal lobes. An *anal fissure* is a tear occurring in the anal canal.

fissure sealant

A substance that is bonded to the biting surface of a tooth to seal any naturally occurring *fissures* (clefts or grooves) in the enamel and to help prevent tooth decay (see *dental caries*). Treatment with fissure sealant may be offered as a preventive measure to children whose molar teeth have recently emerged (see *eruption of teeth*).

fistula

An abnormal passage leading from an internal organ to the body surface or connecting two organs. Fistulas may rarely be congenital (present from birth), or they may be acquired as a result of tissue damage.

Congenital types include *tracheoesophageal fistulas*, branchial fistulas (see *branchial disorders*), and thyroglossal fistulas (see *thyroglossal disorders*).

Acquired fistulas may result from infection, injury, or cancer. Fistulas between the *intestine* and the skin may occur in the inflammatory bowel condition *Crohn's disease*; these fistulas may allow the intestinal contents to escape to the skin through an opening, in which case they are known as faecal fistulas. Fistulas of the urinary tract, which open from the *urethra* or *bladder* to the perineum (the area between the anus and genitals), may be the result of *radiotherapy* to the pelvis, or they may be caused by a difficult childbirth. Such fistulas may cause leakage of urine (see *incontinence, urinary*) or *urinary tract infection*.

Certain types of *arteriovenous fistula* (between an artery and a vein) are surgically constructed to provide ready access to the circulation in people who are having *dialysis*.

TREATMENT

Identifying the cause of a fistula, and treating it if possible, is the first line of action. Some types of fistula close spontaneously but most need surgery. In faecal fistulas, a temporary colostomy may be necessary to divert faeces away from the affected area.

fit

See *seizure*.

fitness

The capacity for performing physical activities without exhaustion. Fitness depends on strength (the ability to exert force for pushing, pulling, lifting), flexibility (the ability to bend, stretch, and twist through a full range of movements), and endurance (the ability to maintain a certain amount of effort for a certain period of time).

HOW FITNESS IS ACHIEVED

Cardiovascular fitness is the precondition for all other forms of fitness; for this reason, regular aerobic exercise (see *aerobics*), which makes the body's use of oxygen more efficient, is the basis of any fitness programme. Specific activities, such as weight training or *yoga*, can help to develop strength and flexibility when included in a programme (see *exercise*). Although fitness training has cumulative effects that build up over many months (provided that there is a sustained increase in activity levels), the effects are specific to the muscles used and the ways in which they are used. A variety of activities is therefore necessary to achieve overall fitness.

BENEFITS OF FITNESS

When the body is fit, the maximum work capacity and endurance are increased. A fit person has a better chance of avoiding *coronary artery disease* as well as of preventing the effects of aging and chronic disease.

The strength, endurance, and efficiency of the heart is also increased by exercise. A fit heart pumps 25 per cent more blood per minute when at rest, and over 50 per cent more blood per minute during physical exertion, than an unfit heart. A fit person's heart normally beats 60 or 70 times a minute; an unfit person's heart beats 80 to 100 times per minute.

fitness testing

A series of exercises designed to determine an individual's level of *fitness*, primarily his or her cardiovascular fitness and muscle performance. Fitness testing is often carried out before a person starts an exercise programme to evaluate its safety and suitability or to monitor progress thereafter.

A physical examination is usually performed, including measurement of body fat, height, and weight. Blood and urine tests may be done, including an analysis of blood *cholesterol*. The performance of the heart is measured by taking the pulse before, during, and after aerobic exercise such as step climbing, riding a stationary bicycle, or running on a treadmill. The more efficient the heart, the slower it works during exercise and the quicker it returns to normal afterwards.

Another test involves measuring a person's overall performance in a standard exercise. This is most suitable for monitoring progress through an exercise programme and for setting goals. The test may be based either on measuring the distance covered in a fixed time or the time needed to cover a fixed distance. (See also *aerobics; exercise*.)

fixation

In *psychoanalytic theory*, the process by which an individual becomes, or remains, emotionally attached to real or imagined objects or events that occurred during early childhood. If the fixations are powerful, resulting from traumatic events, they may lead to immature and inappropriate behaviour. Regression to these events is regarded by some analysts as the basis of certain emotional disorders.

The word "fixation" also describes the alignment and stabilization of fractured bones. Fixation may be external, as with a plaster *cast*, or internal, using pins, plates, or nails introduced surgically into the injured area.

fixative

A chemical agent, such as *formaldehyde*, that is used for the hardening and preservation of tissue specimens prior to microscopic analysis (see *histology*).

fixed pupil

An abnormal *pupil* (the circular opening in the centre of the *iris*) that does not react to light or adjust on *accommodation* (the process by which the eye focuses on objects). A fixed pupil may be symptomatic of various eye disorders (see *eye, disorders of*), such as acute *glaucoma* and *uveitis*, or, rarely, of a *brain tumour* in which *brainstem* structures that control eye reflexes are compressed. Both pupils being fixed and dilated is a sign of brain death.

fixed-rate pacemaker

An artificial cardiac *pacemaker* (a device that sends electrical impulses to the *heart* to maintain a regular *heartbeat*) that is set to pace at a single rate regardless of the patient's own *heart rate*. Fixed-rate pacemakers are still used in some clinical and diagnostic settings, and may be appropriate for the elderly. For active people, rate-responsive pacemakers (see *demand pacemaker*) are often a better choice; these devices deliver electrical stimuli as required and at a rate to match the patient's level of activity.

flaccid

Lacking in firmness or characterized by a loss of *muscle tone*.

flail chest

A type of chest injury that usually results from a traffic accident or from violence. In flail chest, several adjacent ribs are broken in more than one place, producing a piece of chest wall that moves in the opposite way to normal as the victim breathes: when the victim inhales, and the rib cage expands, the flail segment moves inwards, and during exhalation it moves outwards.

The injury may severely impair the efficiency of breathing and may lead to *respiratory failure* and *shock*. It makes

breathing and coughing very painful, which can increase the risk of chest infection and lung collapse (see *atelectasis*).

Emergency treatment involves turning the person on to the affected side or firmly strapping the flail segment. In severe cases, artificial *ventilation* is needed until the chest wall has become stable and the ribs have healed.

flat-feet

A condition, usually affecting both feet, in which the arch of the foot is absent and the sole rests flat on the ground. The arches normally form gradually as the supportive ligaments and muscles in the soles develop; they are not usually fully formed until about the age of six. In some people, however, the ligaments are lax, or the muscles in the feet are weak, and the feet therefore remain flat. Less commonly, the arches of the feet may not form because of a hereditary defect in bone structure.

Flat-feet can be acquired in adult life because of fallen arches, sometimes as the result of a rapid increase in weight. Weakening of the supporting muscles and ligaments of the feet may occur in certain neurological or muscular diseases, such as *poliomyelitis*.

In most cases, flat-feet are painless and require no treatment, although in some cases the feet may ache on walking or standing. Arch supports can be worn in the shoes for comfort and special exercises can be used to help strengthen weakened ligaments and muscles. A small number of affected children require an operation to correct the bones in the feet.

flatulence

Abdominal discomfort or fullness that is relieved by belching or by passing wind through the anus. Flatulence is a feature of many gastrointestinal conditions, such as *irritable bowel syndrome* and *gallbladder* disorders.

When an individual is in an upright position, most swallowed air passes back up the *oesophagus* to be expelled through the mouth. When a person is in a prone position, the air may pass through the intestine and anus instead. Gas formed in the intestine is passed only through the anus.

flatus

Gas, commonly known as "wind", that is passed via the anus. Gas is formed in the large intestine by the action of

bacteria on *carbohydrates* and *amino acids* in food. The gas consists of hydrogen, carbon dioxide, and methane. Air may be swallowed while eating and enter the stomach or intestine.

Large amounts of gas may cause *flatulence* (abdominal discomfort), which may be relieved by the passage of wind or by *defaecation* (passing faeces).

flatworm

Any species of worm that has a flattened shape. Two types of flatworm are parasites of humans: cestodes (*tapeworms*) and trematodes (schistosomes, flukes; see *liver fluke; schistosomiasis*).

flea bites

See *insect bites*.

flecainide

An *antiarrhythmic drug* used in the treatment of *tachycardia*, *atrial fibrillation*, and *arrhythmias* associated with conditions such as Wolff–Parkinson–White syndrome (an abnormality of heart rhythm). Flecainide is given, in the form of tablets or injection, to people who are physically resistant to or intolerant of other treatments. The treatment is always started in hospital.

Side effects include dizziness, visual disturbances, and worsening of the existing arrhythmia or development of a new type. In rare cases, nausea, vomiting, *urticaria* (nettle rash), *vertigo*, and *jaundice* occur.

flexor

Any *muscle* that acts to flex a *joint*. An example of a flexor muscle is the *biceps muscle*, in the upper arm, which contracts to bend the elbow.

flies

See *insects and disease*.

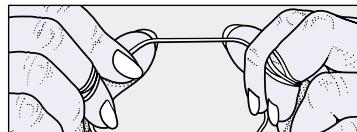

floaters

Small fragments that are perceived to be floating in the field of vision. Floaters move rapidly with eye movement but drift slightly when the eyes are still. They do not usually affect vision.

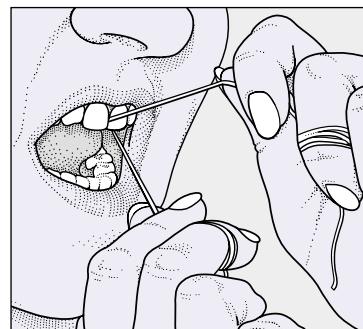

The majority of floaters are the result of shadows cast on the *retina* by microscopic structures in the *vitreous humour* (the jellylike substance behind the lens of the eye). In older people, the vitreous humour tends to shrink slightly and detach from the retina, often resulting in conspicuous floaters, which usually decrease over time.

HOW TO USE DENTAL FLOSS

Floss should be used as an adjunct to toothbrushing to remove plaque and food particles from gaps between teeth and around gums. Care should be taken to avoid damaging the gum margins, and floss should never be reused.

1 Break off a generous length of floss (about 50 cm) and wrap the ends around one finger of each hand.

2 Holding the floss taut, guide it gently into the gap between the teeth until it reaches the gum line. Then rub the sides of each tooth with the floss using an up-and-down motion.

flossing, dental

The removal of plaque (see *plaque, dental*) and food particles from between the teeth using soft nylon or silk thread or tape. Dental floss may be waxed or unwaxed. Flossing should be carried out as an adjunct to toothbrushing.

flu

See *influenza*.

flucloxacillin

A *penicillin drug* usually used to treat *staphylococcal infections*.

fluconazole

An *antifungal drug* used in the treatment of *candidiasis* (thrush), a fungal infection that commonly affects the vagina or the mouth. Although generally well tolerated, fluconazole may sometimes cause nausea and diarrhoea.

fluctuant

A term used to describe the movement within a swelling when it is examined by touch. It is a sign that the swelling contains fluid. The term is often used to describe an *abscess*.

fluid retention

The excessive accumulation of fluid in body tissues. Mild fluid retention is a common feature of *premenstrual syndrome*, but it disappears with the onset of menstruation. A more severe case of fluid retention may be associated with an underlying heart, liver, or kidney disorder (see *ascites; nephrotic syndrome; oedema*). *Diuretic drugs* may be used to treat fluid retention.

fluke

A type of flattened worm, also known as a trematode, that may infest humans or animals. The two main diseases caused by flukes are *liver fluke* infestation, which occurs worldwide, and *schistosomiasis*, a debilitating disease that is common in tropical countries.

flunitrazepam

A type of *benzodiazepine drug* that is used as a sleeping drug in the treatment of *insomnia*. The effects of flunitrazepam may persist into the following day. Prolonged use of this drug may result in dependence (see *drug dependence*). Also known as Rohypnol, or the “date-rape” drug, flunitrazepam is a *controlled drug*.

fluorescein

A harmless orange dye (that glows green in contact with defective cells when blue light is shone on it) used in *ophthalmology* to aid the diagnosis of certain eye disorders. Fluorescein can be applied to the front of the eye to detect abrasions of the *conjunctiva* or *cornea*. It is also given intravenously during fluorescein *angiography* in order to detect abnormalities of the blood vessels in the *retina* (the light-sensitive inner layer at the back of the eye), which occur in such conditions as *macular degeneration* and *diabetic retinopathy*.

fluoridation

The addition of *fluoride* to the water supply as a means of reducing the incidence of dental *caries* (tooth decay). Some areas have naturally high levels of fluoride in the drinking water; in other areas, however, fluoride is added to bring the concentration up to the recommended level. In the UK, decisions to add fluoride to drinking water are made by the local authorities.

fluoride

A mineral that helps to prevent dental *caries* (tooth decay) by strengthening tooth enamel (see *teeth*), making it more resistant to acid attacks. Fluoride may also reduce the acid-producing ability of microorganisms in *plaque*.

Fluoride that is ingested during the formation of teeth has a lifelong beneficial effect because it is incorporated into the developing tooth substance. In the UK, fluoride is added to the water supply, and fluoridation has led to a decrease in the incidence of tooth decay among children.

Fluoride is also beneficial to both children and adults when it is applied directly to the teeth as part of dental treatment or used in the form of a mouthwash or toothpaste. However, the ingestion of excess fluoride as the teeth are forming can lead to fluorosis (staining of the tooth enamel).

fluorosis

Mottling or staining of the tooth enamel (see *teeth*) that is caused by the ingestion of excess *fluoride* as the teeth are formed. In severe cases of fluorosis the enamel develops brown stains. This occurs principally in areas in which the fluoride level in water exceeds the recommended level or if additional supplements are taken.

fluorouracil

An *anticancer drug* used in the treatment of cancers of the breast, bladder, ovaries, and intestine.

fluoxetine

An *antidepressant drug* that belongs to a drug group called *selective serotonin reuptake inhibitors* (SSRIs). SSRIs work by increasing the amount of *serotonin* available in the brain and thus stimulating brain cells. The most common adverse effects include restlessness, insomnia, headache, and diarrhoea.

flupentixol

An *antipsychotic drug* used to treat *schizophrenia* and similar illnesses. It is also sometimes prescribed for *depression*. Side effects of the drug most commonly include blurred vision, nausea, a rapid heartbeat, dizziness, and *parkinsonism*.

flurazepam

A type of *benzodiazepine drug* that is used as a sleeping drug in the treatment of *insomnia*. The drug's effects may persist the following day. Prolonged use may result in dependence (see *drug dependence*).

flurbiprofen

A *nonsteroidal anti-inflammatory drug* that is used particularly to ease the symptoms of musculoskeletal disorders, such as *rheumatoid arthritis*.

flush

Reddening of the face, and sometimes of the neck, caused by dilation of the blood vessels near the skin surface.

Flushing may occur during *fever* or as a result of embarrassment. *Hot flushes* are common at the *menopause*.

fluticasone

A *corticosteroid drug* taken in the form of an inhaler to control *asthma*, as a nasal spray to relieve the symptoms of *allergic rhinitis* (see *rhinitis allergic*), and as an ointment or cream to treat *dermatitis* and *eczema*.

Side effects are rare, but may include nosebleeds when the drug is taken as a nasal spray, *candidiasis* (thrush) of the mouth and throat when taken as an inhaler, and skin irritation when taken as an ointment or cream.

Flynn–Aird syndrome

A rare, inherited disorder that is characterized by *atrophy* (wasting away) of the muscles and skin, *ataxia* (incoordination and clumsiness), and dementia. Other symptoms of Flynn–Aird syndrome include tooth decay (see *caries, dental*), stiffness in the joints, *retinitis pigmentosa* (degeneration of the rods and cones of the *retina*), peripheral *neuropathy* (a peripheral nerve disorder), *cataracts*, and progressive loss of hearing. Flynn–Aird syndrome shows an autosomal dominant pattern of inheritance (see *genetic disorders*).

foam, contraceptive

See *spermicides*.

focal point

The point at which light rays converge after passing through a *lens*. In people with normal vision, light rays from a viewed object converge on the light-sensitive *retina* after passing through the cornea and lens, producing a clear image. In shortsightedness, the focal point occurs in front of the retina and the image is blurred; in longsightedness, it occurs beyond the retina, with the same result.

foetus

An alternative spelling for *fetus*.

Foley catheter

A type of *catheter* (flexible tube) that is fed through the *urethra* into the *bladder* and used for the continuous drainage of *urine* (see *catheterization, urinary*). A Foley catheter is kept in place within the *bladder* by means of a balloon at its tip that is inflated with either air or liquid.

folic acid

A *vitamin* that is essential for the production of red *blood cells* by the *bone marrow*. Folic acid is contained in a variety of foods, particularly liver and raw vegetables; adequate amounts are usually included in a normal diet.

During pregnancy, folic acid is very important for fetal growth, the development of the nervous system, and the formation of blood cells. The incidence of *neural tube defects* is reduced if a woman takes folic acid supplements before conception and during the first 12 weeks of pregnancy.

Folic acid deficiency is a cause of megaloblastic *anaemia*, which produces symptoms such as headaches, fatigue, and pallor. Deficiency can occur during any serious illness or can be the result of a nutritionally poor diet, especially in people who consume large amounts of alcohol.

folie à deux

A French term that is used to describe the unusual occurrence of two people sharing the same psychotic illness (see *psychosis*). Often the two people are closely related and share one or more paranoid *delusions*. If the sufferers become separated, one of them usually rapidly loses the symptoms, which have been imposed by the dominant, and genuinely psychotic, partner.

folk medicine

Any form of medical treatment that is based on popular tradition, such as the charming of warts or the use of copper bracelets to treat rheumatism.

follicle

A small cavity in the body. For example, a *hair follicle* is a pit in the skin from which a single strand of hair emerges. Another example is an ovarian follicle, which is a fluid-filled cavity in the *ovary* in which an *ovum* (egg) develops.

follicle-stimulating hormone

A *gonadotrophin hormone* that is produced by the *pituitary gland* and acts on the *ovary* or *testis*. In women, follicle-stimulating hormone (FSH) causes an egg follicle to start maturing in the ovary in the first week of the menstrual cycle, ready for *ovulation*. In men, FSH stimulates *sperm* production in the testes. FSH is given medically to treat certain types of *infertility*.

folliculitis

Inflammation of one or more hair follicles as a result of a *staphylococcal infection*. Folliculitis can occur almost anywhere on the skin, but the condition most commonly affects the neck, armpits, thighs, or buttocks, causing a *boil*; it may also affect the bearded area of the face, producing pustules (see *sycosis barbae*). Treatment of folliculitis is with *antibiotic drugs*. Because the infection is easily spread, careful hygiene is important, and an affected individual should wash any clothes worn next to the skin daily in boiling water until the condition has cleared up.

fomites

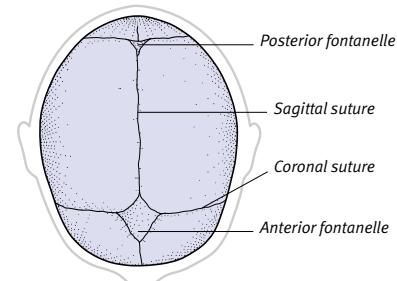

Inanimate objects (for example, bed linen, clothing, books, or telephone receivers) that are not in themselves harmful but which may be capable of harbouring harmful microorganisms or parasites and, therefore, of conveying an infection from one person to another. Fomites principally transmit respiratory infections, such as *influenza*. The singular form of the word fomites is "fomes".

fontanelle

Either one of two membrane-covered spaces between the bones of a baby's skull. At birth, the skull bones are not yet fully fused, and two soft areas can be felt through the scalp. These are the anterior fontanelle, which is diamond-shaped and usually closes up by age 18 months, and the posterior fontanelle, which is triangular and closes up within the first two months.

It is normal for the fontanelles to become tense and bulge out when a baby cries. Persistent tension at other times, however, may indicate an abnormality, particularly *hydrocephalus* (the accumulation of fluid in the skull). A sunken fontanelle may be a sign of *dehydration*. If a fontanelle is abnormally large or takes a long time to close, the cause may be a brain abnormality or a disorder, such as *rickets*, affecting the skull bones. Early closure of the fontanelles results in a deformity called *craniosynostosis*.

Occasionally, a third fontanelle is present between the other two; this is a feature of *Down's syndrome*. Sometimes a baby may have extra bones in the anterior fontanelle, but this is not abnormal. These extra bones fuse into the skull when the gap between them closes.

**Location of the fontanelles**

There are two soft areas on the baby's skull – the anterior fontanelle is diamond-shaped, the posterior fontanelle is triangular.

food additives

Any substance that is added to food for the purposes of preservation or to improve its acceptability in terms of taste, colour, or consistency.

TYPES AND USES

Additives fall into five main groups: those that preserve food; those that affect texture; those that affect appearance and taste; added nutrients, such as vitamins; and miscellaneous additives, such as rising and glazing agents, flour improvers, and anti-foaming agents. For further information on the many different types of food additives, see the table opposite.

Preservatives, such as sodium nitrate, are added to food to control the growth of bacteria, moulds, and yeasts. Other additives, such as antioxidants, can improve the keeping quality of food by preventing any undesirable chemical changes within it; for example, antioxidants prevent rancidity in some foods containing fat.

Additives that improve the texture of food include thickeners, emulsifiers, stabilizers, and gelling agents. Lecithin, which occurs naturally in all animal and plant cells, is an emulsifier that is added to margarine to prevent separation.

The appearance and taste of many foods and drinks may be improved through the use of colourings, flavourings, sweeteners, and flavour enhancers. Artificial sweeteners, such as saccharin and aspartame, may be used instead of sugar, especially in products that are aimed at people trying to lose weight. Many colourings are natural (for example, beetroot red).

RISKS

Certain additives may produce an allergic reaction in some individuals, although this is relatively rare. Some substances, particularly food colourings

FOOD ADDITIVES

Most additives approved by the EU have been given an E number, which must be listed by type and name and/or by number on food labels. Some examples of food additives and foods in which they are used are shown below. Antioxidants improve the keeping qualities of certain foods by preventing undesirable chemical changes. Preservatives also improve keeping quality, but by inhibiting growth of microorganisms. Emulsifiers and stabilizers improve the texture of foods. Sweeteners improve palatability and reduce dental problems associated with excess sugar intake.

Additive	Comments	Often used in
Antioxidants		
E300–302	L-ascorbic acid/ascorbates (vitamin C)	Fruit drinks
E307	Synthetic alpha-tocopherol	Cereal-based baby foods
E322	Lecithins	Low-fat spreads
Colours		
*E102	Tartrazine (yellow/orange)	Soft drinks
*E104	Quinoline yellow (greenish/yellow)	Smoked fish
E160	Carotenes/Annatto (orange)	Cheese
Emulsifiers and stabilizers		
E406	Agar (extracted from seaweed)	Ice cream
E412	Guar gum (extracted from cluster beans)	Packet soups
E440	Pectin (occurs naturally in fruits and plants)	Jams, preserves
Preservatives		
*E210–219	Benzoic acid/benzoates	Fruit products
*E220–227	Sulphur dioxide/sulphites	Meat products
*E249–252	Nitrites/nitrates	Cooked and cured meats
Sweeteners		
*E950	Acesulfame-K	Baked goods, dairy products, confectionery
*E951	Aspartame	Carbonated drinks, sugar substitutes
*E954	Saccharin	Sugar substitutes, chewing gum

*Warning: may produce reactions in susceptible people

such as tartrazine, may be a contributory factor in *behavioural problems in children*, but this is difficult to confirm.

food allergy

An inappropriate or exaggerated reaction of the *immune system* to a food. Sensitivity to cows' milk protein is a

fairly common food allergy in young children. Other foods that are commonly implicated in food allergy are nuts (particularly peanuts), wheat, fish, shellfish, and eggs. Food allergy is more common in those who suffer from other forms of *allergy* or *hypersensitivity*, such as *asthma*, *allergic rhinitis*, and *eczema*.

Immediate reactions, which occur within an hour (or sometimes only minutes) of eating the trigger foods, include swelling of the lips, tingling in the mouth or throat, vomiting, abdominal distension, abnormally loud bowel sounds, and diarrhoea. Serious food allergies can cause *anaphylactic shock*, which requires immediate self-injection with *adrenaline* (epinephrine). The only effective treatment for food allergy is avoidance of the offending food. (See also *food intolerance*.)

food-borne infection

Any infectious illness caused by eating food contaminated with viruses, bacteria, worms, or other organisms.

There are two mechanisms by which food can become infected. Firstly, many animals that are kept or caught for food may harbour disease organisms in their tissues or organs; if meat or milk from such an animal is eaten without being thoroughly cooked or pasteurized, the organisms may cause illness in their human host. In the UK, the only common infection of this type is *food poisoning*. Secondly, food may be contaminated with organisms spread from an infected person or animal, usually by flies moving from faeces to food (see *Food poisoning* box overleaf).

Immunization is available against certain food- and *water-borne infections*, such as *typhoid fever*.

food challenge

The controlled reintroduction into the diet of a food suspected of causing symptoms. Food challenges are usually attempted after a person has already been following an *exclusion diet*.

food fad

A like or dislike of a particular food or foods that is taken to extremes. A food fad may lead to undue reliance on, or avoidance of, a particular food. Fads are common in toddlers, adolescents, and people who are under *stress*. When a food fad becomes obsessive or persistent, however, it may indicate a serious eating disorder. (See also *anorexia nervosa*; *bulimia*.)

food intolerance

An adverse reaction to a food or an ingredient of food that occurs each time an individual eats the substance. Food intolerance does not have a psychological cause; it is not the result of

FOOD POISONING

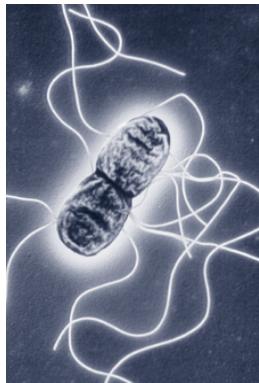

Some animals, including cows, pigs, poultry, and shellfish, harbour disease organisms (such as bacteria, viruses, worms, and parasites) in their tissues; these organisms may cause infection if meat, fish, or dairy products are consumed raw or are improperly cooked. Beef, pork, and fish tapeworm infestations, salmonella poisoning, and (rarely) brucellosis

can be transmitted in this way. Adequate pasteurization of milk and the inspection of meat and fish before they go on sale prevent most infections and infestations of this type from occurring. Thorough preparation and cooking of meat, fish, shellfish, poultry, and eggs further reduce the risk of infection.

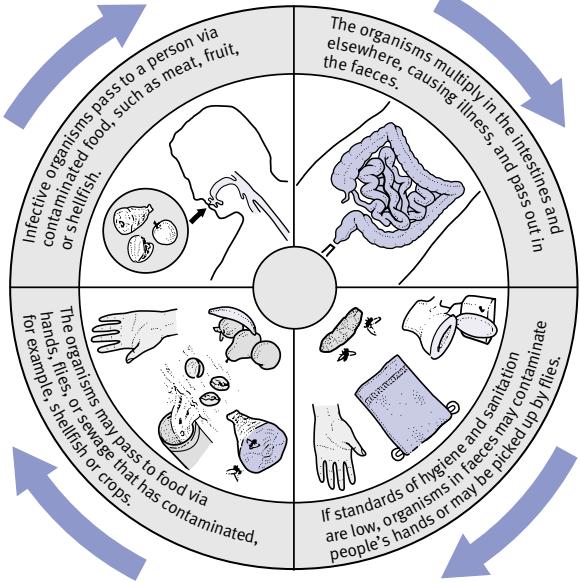

F

FOOD CONTAMINATION

Intestinal infections may be spread from person to person if organisms in faeces contaminate food, either directly or indirectly. Contamination can occur if vegetable crops are sprayed with sewage, if flies settle on faeces and then on food, or if food is handled by a person who has not washed his or her hands.

Contaminating organism
The photograph (left), taken through an electron microscope, shows a typical *Salmonella* bacterium. The organism uses its many flagellae (whiplike structures) to move. *Salmonella* is a common contaminant of poultry, eggs, and egg products and may cause severe food poisoning.

food poisoning: and it does not involve the immune system.

Food intolerance is commonly of unknown cause. Certain foods may be poorly tolerated as a result of impaired digestion and absorption, which may be associated with disorders of the *pancreas* or of the *biliary system* (which produce digestive juices to break down food). Some individuals have a genetic deficiency of a specific *enzyme*, such as *lactase* (which is required for the digestion of lactose, the sugar that occurs in milk); on drinking milk, those people with lactose intolerance develop abdominal cramps, flatulence, and loose stools.

food poisoning

A term used to describe any gastrointestinal illness of sudden onset that is likely to have been caused by contaminated food or water. Most cases of food poisoning are caused by contamination of food or water by bacteria, viruses,

or parasites. The illness is more common in hot weather.

Food poisoning is usually suspected when, for example, several members of a household (or customers at a particular restaurant) become ill after eating the same food.

BACTERIAL CAUSES

The bacteria commonly responsible for food poisoning belong to the groups *SALMONELLA*, *CAMPYLOBACTER*, and *E. COLI*, certain strains of which are capable of multiplying rapidly in the intestines to cause widespread inflammation. Food poisoning may also be caused by *LISTERIA* (see *listeriosis*).

Certain farm animals, especially poultry, commonly harbour the bacteria that are responsible for food poisoning. If frozen poultry is incompletely thawed before being cooked, or if it is not cooked thoroughly, it is liable to cause food poisoning. Eggs laid by affected poultry may also contain disease-causing bacteria. Fresh eggs are

unlikely to be heavily contaminated. However, but eggs that are kept for more than a couple of weeks should be thoroughly cooked before being eaten. Bacteria may also be transferred to food from the excrement of infected animals or people; the bacteria can be transmitted either by flies or through poor personal hygiene.

Some types of bacteria cause the formation of toxins, which may be difficult to destroy even after thorough cooking. For example, the organism *CLOSTRIDIUM PERFRINGENS* is resistant to heat, and it may survive in precooked foods, such as pies, that have been incorrectly stored. *Botulism* is an uncommon, life-threatening form of food poisoning that is caused by a bacterial toxin. The foods most likely to cause botulism are home-preserved fruit, vegetables, and fish.

VIRAL CAUSES

The viruses that are most commonly responsible for food poisoning are

astrovirus, rotavirus, and a small round-structured virus (SRSV), which affects shellfish. This form of poisoning can occur when raw or partly cooked foods have been in contact with water that has been contaminated by human excrement.

OTHER INFECTIVE CAUSES

The protozoan parasite CRYPTOSPORIDIUM (see *cryptosporidiosis*), which principally affects farm animals, can be passed on to humans through drinking water supplies, swimming pools, or by direct contact with infected animals. People with *HIV* infection or *AIDS* are particularly susceptible to contracting this type of food poisoning.

NONINFECTIVE CAUSES

There are a number of noninfective causes of food poisoning including poisonous mushrooms and toadstools (see *mushroom poisoning*), fresh fruit and vegetables contaminated with high doses of insecticide, and chemical poisoning from some foods, such as fruit juice, that are stored in containers made partly from zinc.

Certain foods, such as puffer fish, considered a delicacy in Japan, or cassava, a staple food in many tropical countries, can also cause moderate to lethal poisoning if improperly cooked or prepared.

SYMPTOMS

The onset of symptoms depends on the cause of poisoning. Symptoms usually develop within 30 minutes in cases of chemical poisoning, between one and 12 hours in cases of bacterial toxins, and between 12 and 48 hours with most bacterial and viral infections.

Symptoms of food poisoning usually include diarrhoea, nausea and vomiting, stomach pain, and, in severe cases, shock and collapse. Botulism affects the nervous system, causing visual disturbances, difficulty with speech, paralysis, and vomiting.

DIAGNOSIS

The diagnosis of bacterial food poisoning can usually be confirmed from examination of a sample of faeces. Chemical poisoning can often be diagnosed from a description of what the person has eaten, and from analysis of a sample of the suspect food.

TREATMENT

Mild cases can be treated at home by replacement of lost fluids (see *rehydration therapy*). In severe cases, or when the very young or elderly are affected, hospital treatment may be necessary.

poisoning by a chemical or bacterial toxin is suspected, the stomach may be washed out (see *lavage, gastric*).

Except for botulism and some cases of mushroom poisoning, most food poisoning is not serious; recovery usually occurs within about three days. Some strains of *E. coli* can seriously damage red blood cells, causing *kidney failure* (see *haemolytic-uraemic syndrome*). (See also *cholera*; *dysentery*; *seafood poisoning*; *typhoid fever*.)

PREVENTION

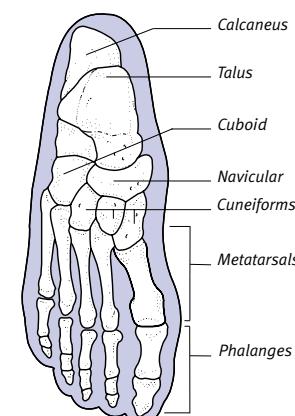

Some simple measures can virtually eliminate the risk of food poisoning. Hands should always be washed before food is handled, and fresh fruit and vegetables should be rinsed in clean water. Cutting boards and implements that have been used for raw meat should be washed with hot water before being used for other foods. Meat, poultry, and eggs must be cooked thoroughly. Raw and cooked foods should be stored well apart in the refrigerator, and raw meat should be kept in the coldest part. Advice should be sought when preparing unfamiliar foods.

foot

The foot has two vital functions. The first of these functions is to support the weight of the body in standing or

ANATOMY OF THE FOOT

An adult has 26 bones (about one eighth of the total number in the entire skeleton) in each foot. The calcaneus is attached to the talus above. In front are the navicular, cuboid, and cuneiform bones, which are attached to the metatarsals. The phalanges form the toes.

walking; the second function of the foot is to act as a lever that propels the body forwards.

STRUCTURE

The largest bone of the foot, the heel-bone (see *calcaneus*), is jointed with the ankle bone (the talus). The tarsal bones are located in front of the talus and calcaneus and they are jointed to the five *metatarsal bones*. The bones of the toes are called the *phalanges*; the big toe has two phalanges and all the remaining toes have three.

Tendons passing around the ankle connect the muscles that act on the various bones of the foot and toe. The main blood vessels and nerves pass in front of and behind the inside of the ankle to supply the foot. The under-surface of a normal foot forms a natural arch that is supported by ligaments and muscles. Fascia (fibrous tissue) and fat form the sole of the foot, which is covered by a layer of tough skin.

DISORDERS

Injuries to the foot often result in *fracture* of the foot bones (the metatarsals and phalanges). The calcaneus may fracture following a fall from a height on to a hard surface.

Congenital foot abnormalities are fairly common and include club-foot (see *talipes*), flat-feet, and claw-foot. A *bunion* is a common deformity of the foot in which a thickened *bursa* (fluid-filled pad) lies over the joint at the base of the big toe.

Corns are small areas of thickened skin that are usually caused by tightly fitting shoes. *Verrucas* (see *plantar warts*) develop on the soles of the feet. *Athlete's foot* is a fungal infection that affects the skin between the toes, causing it to become very itchy, sore, and cracked.

Gout is a relatively common type of arthritis that often affects the joint at the base of the big toe or one of the joints in the foot. An ingrowing toenail (see *toenail, ingrowing*) commonly occurs on the big toe and may lead to inflammation and infection of the surrounding tissues (see *paronychia*).

Foot-drop is the inability to raise the foot properly causing it to drag along the ground when the person is walking. The condition may occur as a result of damage to the muscles in the leg that are responsible for performing this movement or, alternatively, to the nerves that supply these muscles.

foot-drop

A condition in which the foot cannot be raised properly and hangs limp from the ankle, causing it to catch on the ground when the affected person is walking along.

Neuritis (inflammation of a nerve) affecting the nerves that supply the foot muscles is a common cause. This condition may be due to *diabetes mellitus*, *multiple sclerosis*, or a *neuropathy* (nerve disease). Weakness in the foot muscles can also result from pressure on a nerve at the point where it leaves the spinal cord, due to a *disc prolapse* or a *tumour*. Damage to the muscles in the leg from an injury may also be a cause of foot-drop.

The underlying cause is treated, but in many people the weakness persists. A lightweight plastic *caliper splint* may be used to keep the foot in place when the person is walking.

foramen

A natural opening in a bone or other body structure, usually to allow the passage of nerves or blood vessels. For example, the *foramen magnum* is a hole in the base of the skull through which the *spinal cord* passes.

Forbes–Albright syndrome

A condition that is characterized by *amenorrhoea* (the absence of menstruation) and *galactorrhoea* (the production of breast milk) that is not associated with pregnancy. Forbes–Albright syndrome is usually the result of a *pituitary tumour* that secretes excessive amounts of the hormone *prolactin*. Treatment with the drug *bromocriptine* may suppress prolactin production. However, surgical removal of the tumour may be necessary.

forced expiratory volume

The maximum volume of air that can, over a given period of time, be forcibly exhaled from the lungs, usually over one second. Forced expiratory volume (FEV) tests are often carried out in conjunction with *forced vital capacity* (FVC) tests to check for a variety of lung disorders. (See also *pulmonary function tests*.)

A low result may indicate one of a variety of disorders, including chronic obstructive pulmonary disease (see *pulmonary disease*, *chronic obstructive*) and diminished lung volume, such as that found in *emphysema*.

forced vital capacity

The largest volume of air that can be expired following a deep inhalation. Forced vital capacity (FVC) is one of the variables measured in a lung function test (see *pulmonary function tests*), which is carried out to check for a variety of lung disorders.

forceps

A tweezerlike instrument that is used for handling tissues or equipment during surgical procedures. Various types of forceps have been designed for specific purposes. For example, forceps that are used for holding and removing wound dressings have scissor handles to make manipulation easier; tissue forceps have fine teeth at the tip of each blade so that body tissues can be handled delicately during surgery. (See also *forceps delivery*.)

forceps delivery

The use of specially designed forceps (see *forceps, obstetric*) to ease out the baby's head during a difficult birth (see *childbirth*).

WHY IT IS DONE

Forceps delivery is used if the mother is overtired or unable to push out her baby unaided, or if the baby is showing signs of *fetal distress*. Forceps are also used to control the baby's head once the body has been delivered in *breech delivery* to prevent an overly rapid birth. They may also be used if the baby's head is stuck in the middle of the mother's pelvis and needs to be rotated to make delivery possible.

HOW IT IS DONE

The mother is given a painkiller and either local or epidural *anaesthesia*. She lies on her back, with her legs raised in stirrups. Forceps can be applied only if the cervix (neck of the uterus) is fully dilated and the baby's head is engaged in the pelvis. An *episiotomy* (making a cut in the perineum) is usually needed for a forceps delivery. The forceps blades are placed on either side of the baby's head, just in front of the ears, and gentle traction is applied to bring about delivery of the baby.

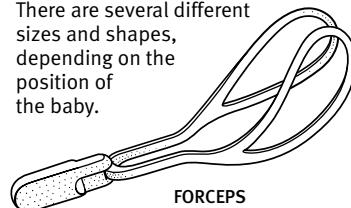

Recovery and care for mother and child is usually the same as after a vaginal delivery.

forceps, obstetric

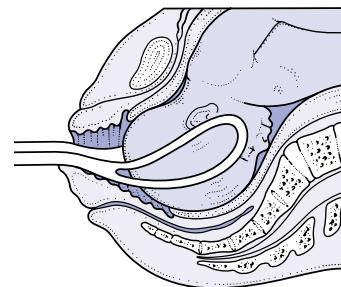

Surgical instruments that are used in *forceps delivery* to deliver the head of a baby in a difficult labour and birth.

OBSTETRIC FORCEPS

The two wide, blunt blades are designed to fit around the baby's head. The handles are inserted separately and lock together so that the blades are held apart. There are several different sizes and shapes, depending on the position of the baby.

FORCEPS

**Positioning**

The forceps blades lie along the sides of the baby's head just in front of the ears.

Obstetric forceps are of various types but basically consist of two blades that cup around the baby's head.

Fordyce's disease

A fairly common condition consisting of raised yellow patches on the lips and gums and in the lining of the mouth. The patches are composed of misplaced *sebaceous glands*. The disease is also known as Fordyce's granules. The condition is not serious and does not usually need treatment.

forebrain

The foremost, and largest, of the main divisions of the *brain*. The forebrain is responsible for controlling many of the brain's higher functions, including conscious thought.

foreign body

An object that is present in an organ or passage of the body but should not be there. A foreign body may enter the body accidentally (for example, by inhalation or swallowing), or it may be introduced deliberately (for example, a child pushing a bead into a nostril). The most common sites for

foreign bodies include the airways (see *choking*), ears (see *ear, foreign body in*), eyes (see *eye, foreign body in*), rectum, and vagina.

foremilk

The breast milk that is produced at the beginning of a feed (see *breast-feeding*). Foremilk is bluish in appearance; it contains lactose and proteins, but little fat. (See also *hindmilk*.)

forensic medicine

The branch of medicine that is concerned with the law, especially criminal law. A forensic pathologist is a doctor who specializes in the examination of bodies when it appears that death was the result of unnatural causes. Forensic specialists may examine victims of alleged sexual assault.

Forensic scientists use laboratory methods to study body fluids (such as blood and semen) found on or near the victim and compare them with samples obtained from suspects. Forensic scientists are also trained in ballistics and in the identification of fibres from materials such as clothing. In addition, forensic scientists may advise on *blood groups* and *genetic fingerprinting* in certain legal investigations.

forensic psychiatry

A branch of *psychiatry* specializing in the diagnosis of mental illness related to criminal behaviour.

foreplay

A sexually stimulating activity that commonly precedes *sexual intercourse* but may also occur independently. Foreplay can involve any of a range of activities, including kissing, caressing, and oral sex.

foreskin

The popular name for the prepuce, which is the loose fold of skin that covers the glans (head) of the *penis* when it is flaccid and which retracts during erection.

At birth, the foreskin is attached to the glans and is not retractable. It separates from the glans during the first three to four years of life. The foreskin may be removed (see *circumcision*) for religious or medical reasons.

DISORDERS

In *phimosis*, the foreskin remains persistently tight after the age of five, causing difficulty in passing urine and

ballooning of the foreskin. There may also be recurrent *balanitis* (infection of the glans). Erection is frequently painful, which is why the condition is often discovered only at puberty. In *paraphimosis*, the foreskin becomes stuck in the retracted position, causing painful swelling of the glans that requires emergency treatment.

forewaters

A term that is commonly used to refer to the *amniotic fluid* (the "waters") that is discharged from the uterus when the part of the *amniotic sac* in front of the presenting part of the fetus ruptures just before childbirth. This may happen before or after the onset of labour. (See also *hindwaters*.)

forgetfulness

The inability to remember (see *memory*). (See also *amnesia*.)

formaldehyde

A colourless, pungent, irritant gas. In medicine, a solution of formaldehyde and a small amount of alcohol in water, a preparation known as formalin, is used as a preserving medium for tissue specimens or to harden them before they are stained and examined. Formalin is also used as a *disinfectant*.

forme fruste

The term that is used to describe any disease that does not follow its usual course. One example of forme fruste is when certain characteristic symptoms of the disease fail to appear; another example is when the progression of the disorder terminates at an earlier stage than expected.

formication

An unpleasant sensation, as though ants were crawling over the skin. This feeling may occur following abuse of certain drugs, such as *alcohol* or *morphine*. Scratching of the skin in an attempt to relieve the sensation can sometimes cause a rash to develop, which may result in an incorrect diagnosis of skin disease.

formula, chemical

A way of expressing the constituents of a chemical in symbols and numbers. Water, for example, has the formula H₂O, indicating that each molecule is composed of two atoms of hydrogen (H₂) and one of oxygen (O).

formulary

A book of formulae. The term "formulary" is commonly used to refer to a publication that lists drug preparations and their components and effects. The contents of a formulary may be decided by a group of medical professionals who are working together to ensure similar patterns of drug usage.

fornix

An archlike structure or the space encompassed by such a structure. The term is used to describe the fornix cerebri, a triangular structure of *white matter* in the *brain*, and also the recesses of the *vagina* around the *cervix*.

Fosamax

A brand name for alendronate sodium (see *alendronic acid*), a drug for certain bone disorders (see *bone, disorders of*).

fossa

A depression or hollow area. Examples include the posterior fossa, which is an area at the back of the base of the brain occupied by the *cerebellum*, and the cubital fossa, which is the hollow at the front of the elbow joint.

Fothergill's disease

An alternative name for *trigeminal neuralgia*, a disorder of the *trigeminal nerve* (the fifth cranial nerve, which supplies the facial muscles).

fovea

An area situated near the centre of the *retina* that has the highest concentration of light-sensitive cells. The fovea allows detailed vision. (See also *colour vision*.)

Foville's syndrome

A neurological condition that results from damage to tissue (usually *infarction* or a tumour) in the centre of the *brainstem*. The damage causes numbness and paralysis on one side of the face, together with impaired eye movement. There is also damage to the motor nerve fibres to the opposite side of the body, causing paralysis or weakness (see *hemiplegia*).

Fox-Fordyce disease

A chronic pruritic (itching) condition, found most commonly in women, that is characterized by small pimples in areas where apocrine glands (see *sweat glands*) are located.

The pimples of Fox–Fordyce disease are caused by the obstruction and rupture of apocrine ducts in the *epidermis* (the outermost layer of the skin). Treatment with topical retinoids (derivatives of *vitamin A*) and *antibiotic drugs* may help to relieve symptoms in patients who have suffered from the disease in the long term.

fracture

A break in a bone. Fractures most often occur across the width of a bone, but can be lengthwise, oblique, or spiral.

TYPES

There are two main types of fracture: closed (simple) or open (compound). In a closed fracture, the broken bone ends remain beneath the skin and little of the surrounding tissue is damaged; in an open fracture, one or both of the bone ends project through the skin. If the ends of the bone have moved out of alignment, which can occur in either a closed or an open fracture, the fracture is termed “displaced”.

Fractures may be further divided according to the pattern of the break: for example, transverse or spiral fractures of long bones. In a greenstick fracture, the break is not through the full width of the bone. This type of fracture occurs only in children because their bones are more pliable. In an avulsion fracture, a small piece of bone is pulled off by a tendon.

CAUSES

Most fractures are the result of a sudden injury that exerts more force on the bone than it can withstand. The force may be direct, for example when a finger is hit by a hammer, or indirect, for example when twisting the foot exerts severe stress on the shin.

In some diseases, such as *osteoporosis* and certain cancers, the bone is weakened to such an extent that even a minor injury, or occasionally no injury at all, can cause the bone to break; this is known as a pathological fracture. Compression fractures of the vertebrae are common in people suffering from osteoporosis. Elderly people are most prone to fractures because they are more likely to fall and their bones are very fragile.

SYMPOTMS AND SIGNS

Common sites of fracture include the hand, wrist (see *Colles' fracture*), ankle joint, clavicle (collarbone), and the neck of the femur (see *femur, fracture of*). There is usually swelling and tender-

ness at the fracture site. The pain is often severe and is usually made worse by movement.

DIAGNOSIS AND TREATMENT

X-rays can confirm the presence of a fracture. Bone begins to heal soon after it has broken, so the first aim of treatment is to ensure that the bone ends are aligned. Displaced bone ends are moved back into position, under general anaesthesia, by manipulation either through the skin or through an incision. The bone is then immobilized. In some cases, the ends of the bone may be fixed with metal pins or plates.

RECOVERY AND COMPLICATIONS

Most fractures heal without any problems. Healing is sometimes delayed because the blood supply to the affected bone is inadequate (as a result of damaged blood vessels) or because the bone ends are not sufficiently close together. If the fracture fails to unite, internal fixation or a *bone graft* may be needed. *Osteomyelitis* (infection of bone tissue) is a possible complication of open fractures.

Physiotherapy plays an important part in rehabilitation following a fracture because complete immobility of a bone for a prolonged period can result in loss of muscle bulk in that area and stiffness in nearby joints.

(See also *fracture, dental; humerus, fracture of; jaw, fractured; march fracture; Pott's fracture; radius, fracture of; rib, fracture of; skull, fracture of; Smith's fracture; stress fracture; ulna, fracture of.*)

fracture, dental

A break in a tooth (see *teeth*) most commonly caused by falling onto a hard surface or by being hit in the mouth with a hard object. Fractures may involve the crown or the root of a tooth, or both.

Fractures of the enamel can usually be repaired by bonding (see *bonding, dental*); in some cases, a replacement crown may be fitted (see *crown, dental*). *Pulpotomy* (removal of part of the pulp of the tooth) may be performed in cases where the pulp is damaged. Root fractures may be treated by splinting (see *splinting, dental*), *root-canal treatment*, or removal of the tooth (see *extraction, dental*).

fragile X syndrome

An inherited defect of the *X chromosome* that causes learning difficulties. The disorder occurs within families according

to an unusual X-linked recessive pattern of inheritance (see *genetic disorders*). Although fragile X syndrome principally affects males, females can also inherit the disorder. Both men and women can be carriers without having any signs of the disorder.

In addition to having learning difficulties, affected people may have a prominent nose and jaw, and increased ear length; they are also prone to epileptic seizures and behavioural difficulties. Males tend to have large testes. Some carriers may also show intellectual impairment.

The condition cannot be treated, but affected children may benefit from speech therapy, specialist education, and help from a psychologist for any accompanying behavioural problems. Life expectancy is normal, but affected boys usually need lifelong care. Couples who have a family history of fragile X syndrome may wish to seek genetic counselling when planning to have a child.

Fragmin

A brand name for dalteparin, which is a low molecular weight *heparin* (an *anticoagulant drug* that is used in the prevention and treatment of abnormal *blood clotting*).

Fraley's syndrome

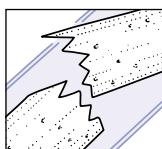

A rare condition in which the uppermost renal calyces in the *kidney* (part of the central region where urine collects before passing out of the kidney) are compressed; this is usually caused by some of the blood vessels that supply the area. Abdominal pain, back pain in the area of the kidney, and blood in the urine are usually the main symptoms. Possible complications of this syndrome include recurrent urinary tract infections and kidney stones formation (see *calculus, urinary tract*).

Franceschetti's syndrome

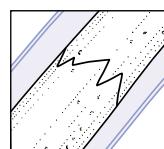

A rare genetic disorder, also known as Treacher–Collins syndrome, that causes severe facial malformations. The condition is congenital (present from birth). The nose, cheek bones, lower jaw, and chin are deformed, and the child may have a receding chin (see *micrognathia*). There is a pronounced droop to the outer corners of the eyes. Surgery to reconstruct abnormal features results in significant improvement in appearance and function.

FRACTURES: TYPES AND TREATMENT

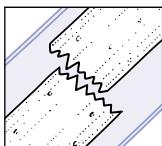

There are two main types of fracture: simple (closed) and compound (open). Within these two categories are several other types, three of which are illustrated to the right.

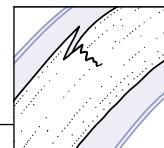

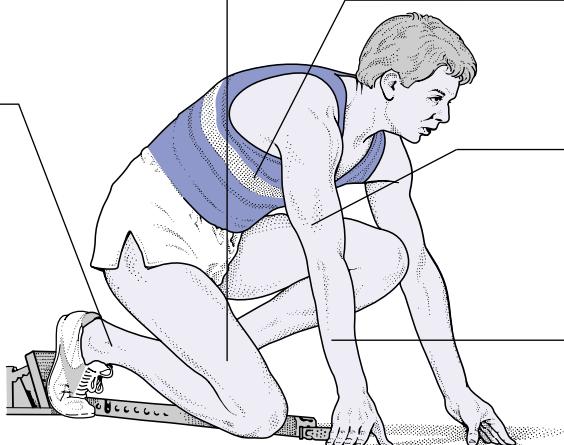

Compound fracture
A sharp piece of bone punctures the skin and is therefore exposed to organisms. There is a high risk of infection.

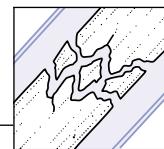

Simple fracture
The broken bone does not break the skin. Because organisms do not come into contact with the fracture, infection is rare.

Transverse fracture
This may result from a sharp, direct blow or be a stress fracture caused, for example, by prolonged running.

Greenstick fracture
This type usually occurs in children. Sudden force causes only the outer side of the bent bone to break.

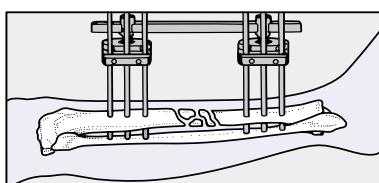

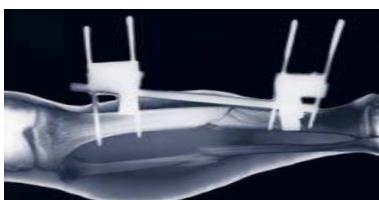

Comminuted fracture
The bone shatters into more than two pieces. This fracture is usually caused by severe force, such as in a car accident.

REPAIR OF FRACTURES

There are various ways of repairing fractures depending on the particular bone, the severity of the fracture, and the age of the patient.

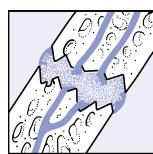

Internal fixation
The photograph (left) shows the repair of a fracture in the hip. A metal pin has been inserted through the neck of the femur and is held in place by a plate screwed to the shaft.

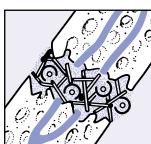

External fixation
Immobilization may be achieved by means of a plaster cast (above) or, in cases such as an unstable fracture of the tibia (left and above left), through the use of metal pins inserted into bone on either side of the break and locked into position on an external metal frame.

THE BONE HEALING PROCESS

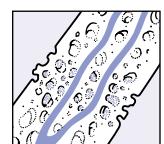

After a fracture, the bone starts to heal immediately. Any displacement of the bone ends must therefore be corrected without delay to minimize deformity.

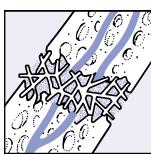

1 A blood clot forms between the bone ends, sealing off the ends of the damaged vessels.

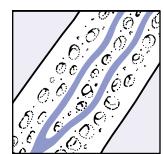

2 Macrophages (immune system cells) invade the fracture site to remove wound debris. Fibroblasts then create a mesh to form a base for new tissue.

3 New bone (callus) is laid down between the ends of the bones and over the fracture line.

4 Remodelling takes place, with denser, stronger bone being laid down. New blood vessels have formed.

5 Over a period of weeks, the bone returns to its former shape.

Fraser's syndrome

An inherited condition in which there is cryptophthalmos (absence of the opening between the upper and lower *eyelids*) together with malformations of the ear; cleft palate (see *cleft lip and palate*); narrowing of the *larynx* (the voice-box); *syndactyly* (fusion of two or more fingers or toes); imperforate anus (see *anus, imperforate*); cardiac defects; kidney malformation; and genital *masculinization* in females. Fraser's syndrome is inherited as an autosomal recessive genetic trait (see *genetic disorders*).

Many babies born with Fraser's syndrome die within the first year of life. For those who survive, surgery to the eyelids and corneas may provide some degree of vision and eyelid movement.

fraternal twins

An alternative term for dizygotic *twins*.

freckle

A tiny patch of *pigmentation* that occurs on sun-exposed skin. Freckles tend to become more numerous with continued exposure to sunlight. A tendency to freckling is inherited and occurs most often in fair and red-haired people. Freckles are harmless.

free-floating anxiety

An all-pervasive feeling of apprehension or tension with no apparent cause. Free-floating anxiety is often associated with *generalized anxiety disorder*.

Freeman–Sheldon syndrome

A rare *congenital* disorder with the following characteristics: sunken eyes; under-development of the cartilage of the nose; pursed lips; various skeletal malformations; and muscle weakness. Intelligence and life expectancy are normal. Freeman–Sheldon syndrome is usually inherited as an autosomal dominant genetic trait (see *genetic disorders*). Affected children may need corrective surgery to improve deformities of the face, hands, or feet.

free radicals

Highly active molecules that bind to and destroy body cells. Free radicals can be formed as a result of the effects of external sources such as smoke, sunlight, and food. They are produced in the body principally as a result of the chemical reactions involved in metabolism. They are thought to contribute to the cumulative damage to body cells

that occurs with aging and to the development of cancers and possibly heart disease. Free radicals and their effects may be neutralized by antioxidants, such as *vitamin C* and *vitamin E*.

frenulum

Any fold of tissue or *mucous membrane* that limits the movement of an organ or part of the body. One example of a frenulum is the fold of mucous membrane on the inside of the upper lip that connects the lip to the gum; another example is the attachment of the *foreskin* to the glans (head) of the penis.

frequency

See *urination, frequent*.

Freudian slip

A slip of the tongue or a minor error of action that could betray what the person really wanted to say or do.

Freudian theory

A discipline that was developed by Sigmund Freud (1856–1939), a Viennese neurologist. The theory developed out of Freud's treatment of neurotic patients using *hypnosis* and, later, the interpretation of their dreams. The Freudian theory formed the basis of the technique of *psychoanalysis*.

Freud believed that an individual's feelings, thoughts, and behaviour were controlled by unconscious wishes and conflicts originating in childhood. Problems are said to occur when the desires are not fulfilled or if conflicts remain unresolved into adulthood.

The essence of Freud's theory concerns early psychological development, particularly sexual development. Freud defined three developmental stages: oral, anal, and genital (representing the areas of the body on which the infant's attention becomes fixed at different ages). He also identified three components of personality: the *id*, the *ego*, and the *superego* (based respectively on pleasure, reality, and moral and social constraints). (See also *psychoanalytic theory; psychotherapy*.)

friar's balsam

A brand name for the aromatic liquid tincture of benzoin. Friar's balsam is used with hot water as a *steam inhalation* to help relieve nasal congestion, acute rhinitis, and sinusitis, as well as to loosen coughs. Friar's balsam is available over the counter.

Friedreich's ataxia

A rare inherited disease in which degeneration of nerve fibres in the spinal cord causes loss of coordinated movement and balance.

SYMPTOMS

Symptoms tend to appear between the ages of five and 15 years. Early signs of the condition include difficulty in walking and deformities of the lower legs and feet, such as *claw-foot*. The difficulty in movement then extends to the arms and trunk. Once symptoms have developed, the disease becomes progressively more severe; the muscles then weaken and waste away. A gradual loss of sensation occurs in the extremities, which may eventually spread to other parts of the body; speech becomes slow and slurred; and *nystagmus* (involuntary, jerky eye movements) is common.

Other symptoms include chest pain, shortness of breath, and palpitations. Many people with Friedreich's ataxia develop heart problems, such as *cardiomyopathy* (disease of the heart muscle) and abnormalities of the heart rhythm (see *arrhythmia, cardiac*).

TREATMENT AND OUTLOOK

Treatment can help with the symptoms but cannot alter the course of the disease. Braces or surgery may be used to correct deformities, physiotherapy may help to maintain movement for as long as possible, and drugs can be given for heart conditions. However, most affected people die in early adulthood.

frigidity

A lack of desire for sexual contact or an inability to become aroused during stimulation (see *sexual desire, inhibited*). (See also *orgasm, lack of*.)

frontal

A term referring to the front part of an organ (for example, the frontal lobe of the *brain*).

frostbite

Damage to body tissues caused by extremely cold temperatures. Frostbite can develop at any temperature below freezing; the lower the temperature, the more rapidly the frostbite will develop. The risk of frostbite is increased by windy conditions.

Frostbite can affect any part of the body, but the extremities (the nose, ears, fingers, and toes) are most susceptible and tend to be affected first.

People who have impaired circulation, such as those with *diabetic vascular disease*, are at increased risk.

SYMPTOMS

The first symptom of frostbite is a *pins-and-needles* sensation, followed by complete numbness in the affected region. The affected skin appears white, cold, and hard; it may then become red and swollen.

TREATMENT AND OUTLOOK

Treatment of frostbite involves rewarming the affected areas by immersion in warm water (ensuring that it is not too hot to touch), then applying bandages. When warmed, mildly affected tissues become red, swollen, and sore. If frostbite is more severe, blisters appear, and the area becomes very painful.

If the damage is restricted to the skin and the tissues that immediately underlie it, rewarming may result in complete recovery of the tissues. Recovery from frostbite damage usually occurs within about six months, but some lasting sensitivity to extreme temperatures is common. However, following severe frostbite, symptoms including stiffness, pain, and numbness may persist indefinitely.

If blood vessels are affected by frostbite, *gangrene* (tissue death) may follow. In such circumstances, amputation may be necessary.

frottage

A sexual *deviation* in which an individual rubs his or her body against another person in order to achieve sexual arousal. Typically, this activity is carried out within a crowd of people (such as on a crowded train) where a man rubs his (clothed) genitals against a woman's buttocks or thigh.

frozen section

A method of preparing a *biopsy* specimen (a sample of tissue removed for microscopic analysis) that can provide a rapid indication of whether or not a tissue is cancerous.

WHY IT IS DONE

Frozen section may be used for the purpose of determining whether *breast lumps* are cancerous. The technique can also be used to check whether thyroid or intestinal tumours are cancerous and to diagnose *lymphomas* (cancerous tumours of lymphoid tissue).

HOW IT IS DONE

Frozen section may be undertaken during an operation in order that the

results can be used to determine the appropriate surgical treatment. The surgeon removes a sample of tissue and sends it to the pathology laboratory for analysis. The sample is quickly frozen in liquid nitrogen, cut into very thin sections, placed on a glass slide, and stained so that the cells can be examined under the microscope. The entire process takes about 20 minutes. Information about the sample is then conveyed to the operating theatre.

frozen shoulder

Stiffness and pain in the *shoulder* that limits normal movement of the joint. In severe cases of frozen shoulder, the shoulder may be completely rigid, and pain may be intense.

CAUSES

Frozen shoulder is caused by inflammation and thickening of the lining of the joint capsule. In some cases, it occurs following a minor injury to the shoulder. Frozen shoulder can also occur if the shoulder is kept immobilized for a long period of time, such as following a *stroke*. In many cases, however, the disorder develops for no apparent reason.

The condition is more common in people over the age of 40. People with *diabetes mellitus* are also more susceptible to developing frozen shoulder.

TREATMENT

Moderate symptoms of frozen shoulder can be eased by exercise, by taking *analgesic drugs* (painkillers) and *non-steroidal anti-inflammatory drugs* for the relief of pain and inflammation, and by applying *ice-packs*. However, in severe cases of frozen shoulder, *corticosteroid drugs* may need to be injected into the affected joint.

Manipulation of the joint under general anaesthesia can restore mobility. However, this treatment carries the risk of increasing pain initially.

OUTLOOK

Recovery is often slow, and the shoulder may remain stiff for some months, but it is usually back to normal and pain-free within two years.

fructose

A simple sugar (monosaccharide) that is naturally present in honey and certain fruits. Fructose and *glucose* are the two components of *sucrose* (table sugar).

Fructose can be converted into energy as easily as glucose but, unlike glucose, fructose metabolism is not

dependent on *insulin*. For this reason, fructose can prove an important element in the diet of people suffering from *diabetes mellitus*.

frusemide

An alternative name for *furosemide*, a *diuretic drug*.

frustration

A deep feeling of discontent and tension as a result of unresolved problems or unfulfilled needs, or because the individual's path to a goal is blocked. In some people, frustration can lead to *regression* (childlike behaviour), *aggression*, or *depression*.

FSH

An abbreviation for *follicle-stimulating hormone*, a *gonadotrophin hormone* produced by the *pituitary gland*.

FTT

The abbreviation for *failure to thrive* in infants and children. A child who fails to grow at the appropriate rate needs tests to determine the cause.

Fuchs' spots

Pigmented spots that develop on the *retina* (the light-sensitive inner layer at the back of the eye). The condition sometimes occurs in people who suffer from a severe degree of *myopia* (shortsightedness).

Fuchs' syndrome

A slowly progressing disease that usually affects both eyes and which may be hereditary. The condition is also known as Fuchs' corneal dystrophy. Fuchs' syndrome occurs when cells in the innermost layer of the *cornea* (the transparent front part of the eyeball) gradually deteriorate. Fuchs' syndrome may result in pain and severe visual impairment.

There is no preventive treatment for the disease. In some cases, a corneal transplant may eventually be necessary to restore sight.

Fucithalmic eye drops

A brand of eye drops containing *fusidic acid*, an *antibiotic drug*. The drops are used for bacterial conjunctivitis.

fugue

An episode of altered consciousness in which a person purposefully wanders away from home or work and,

in some cases, adopts a new identity. Afterwards, the person has no recollection of what has occurred.

Fugues may last for hours or days. During a short fugue, the sufferer may be confused and agitated. During a fugue lasting for days, behaviour may appear normal but there may be accompanying symptoms, such as hallucinations, feelings of unreality, and unstable mood.

Fugues are rare. Possible causes include *dissociative disorders*, *temporal lobe epilepsy*, *depression*, *head injury*, and *dementia*. (See also *amnesia*.)

fulminant

A term used to describe a disorder that develops and progresses suddenly and with great severity. A virulent infection, a severe form of arthritis, or a cancer that has spread rapidly is often described as being fulminant.

fumes

See *pollution*.

functional disorders

Illnesses in which there is no evidence of organic disturbance even though physical performance is impaired.

functional endoscopic sinus surgery (FESS)

Surgery that is carried out in order to improve the drainage of the facial sinuses or to clear a blockage in them. The procedure, which involves the use of an endoscope, enlarges the drainage holes leading to the nose.

fundus

The bottom or base of an organ, or the part that is farthest away from the organ's opening. The optic fundus is the back of the retina as viewed through an ophthalmoscope.

fungal infections

A wide range of diseases that are caused by the multiplication and spread of *fungi*. Fungal infections, also known as mycoses, range from mild and barely noticed to severe and sometimes even fatal. (In addition to infections, fungi are also responsible for some allergic disorders, such as *allergic alveolitis* and *asthma*.)

CAUSES

Some fungi are harmlessly present all of the time in areas of the body such as the mouth, skin, intestines, and vagina.

Usually, however, they are prevented from multiplying by competition from bacteria. Other fungi are kept from multiplying to a harmful degree by the body's *immune system*.

Fungal infections are therefore more common in people who are taking *antibiotic drugs* (which destroy the bacterial competition) and in those whose immune systems are suppressed by *immunosuppressant drugs*, *corticosteroid drugs*, by a disorder such as *AIDS*, or by chemotherapy. Such serious fungal infections are described as *opportunistic infections* because they take advantage of the body's lowered defences. Some fungal infections are more common in people with *diabetes mellitus*.

Fungi that cause skin infections thrive in warm, moist conditions, such as those that occur between the toes and in the genital area.

TYPES

Fungal infections can be broadly classified into three categories: superficial (affecting the skin, hair, nails, inside of the mouth, and genital organs); subcutaneous (beneath the skin); and deep (affecting internal organs).

The main superficial infections are *tinea* (including ringworm and athlete's foot) and *candidiasis* (thrush), both of which are common. Tinea affects external areas of the body. Candidiasis is caused by the yeast *CANDIDA ALBICANS* and usually affects the genitals or inside of the mouth.

Subcutaneous infections are rare. The most common is *sporotrichosis*, which may follow contamination of a scratch. Most other conditions of this type, the most important of which is *mycetoma*, occur mainly in tropical countries.

Deep fungal infections are uncommon, but they can present a serious threat to people who have an immune deficiency disorder or those who are taking immunosuppressant drugs. Fungal infections of this sort include *aspergillosis*, *histoplasmosis*, *cryptococcosis*, and *blastomycosis*, all of which are caused by different species of fungi. The fungal spores enter the body through inhalation into the lungs. Candidiasis can also spread from its usual sites of infection to affect the oesophagus, the urinary tract, and other internal tissues.

TREATMENT

Treatment of fungal infections is with *antifungal drugs*, either used topically

on the infected area or given by mouth for generalized infections. (For further information, see *Fungal diseases* box, opposite.)

fungi

Simple parasitic life-forms that include yeasts, moulds, mushrooms, and toadstools. The fungi that are responsible for causing disease can be divided into two groups: filamentous fungi and yeasts. Filamentous fungi are made up of branching threads known as hyphae, which form a network called a mycelium. Mushrooms and toadstools are the reproductive structures (known as fruiting bodies) of a filamentous fungus that has spread in dead matter or soil. Yeasts are single-celled organisms.

FUNGI AND DISEASE

The majority of fungi are either completely harmless or actually beneficial to human health. However, there are a number of fungi that can cause illness and disease.

The fruiting bodies of some fungi contain toxins that may cause poisoning if they are eaten (see *mushroom poisoning*). Certain other fungi infect food crops and also produce toxins that may cause food poisoning. The best known of these fungi is a species that infects cereals and produces *ergot*, a toxin that constricts blood vessels. Another fungus that sometimes grows on peanuts and produces *aflatoxin*, a poison and *carcinogen*.

The inhaled spores of some fungi can cause allergic *alveolitis*, a persistent allergic reaction in the lungs. Farmer's lung, which is caused by spores from mouldy hay, is an example of such a reaction. Fungal spores are sometimes responsible for various other allergic disorders, such as *allergic rhinitis* (hay-fever) and *asthma*.

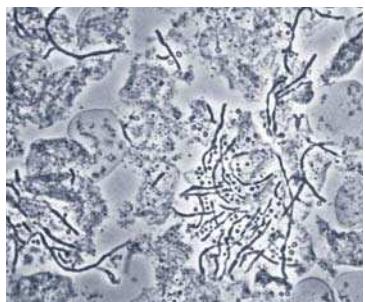

Some fungi are capable of invading the body and forming colonies in various parts of the body such as the lungs, the skin, or sometimes in a variety of tissues throughout the body, leading to conditions that range from mild irritation to severe, even fatal, widespread infection (see *fungal infections*) and illness. For further information, see *Fungal diseases* box, opposite. (See also *candidiasis*.)

fungicidal

A term used to describe the ability to kill fungi (see *antifungal drugs*).

FUNGAL DISEASES

The skin, genitals, and nails are common sites of fungal infection. Examples include *tinea* (ringworm) and *candidiasis* (thrush). Fungi may rarely infect the lungs and other internal organs, causing a more serious disease. They may also cause allergic lung disease, such as farmer's lung.

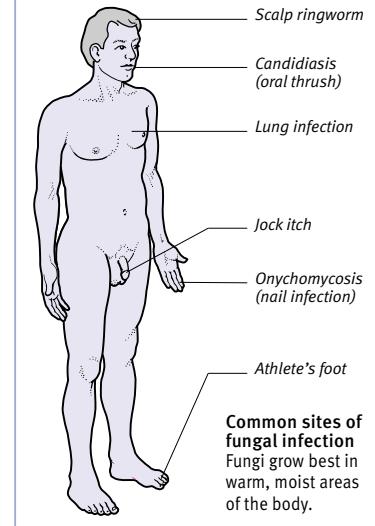

Fungal nail infection

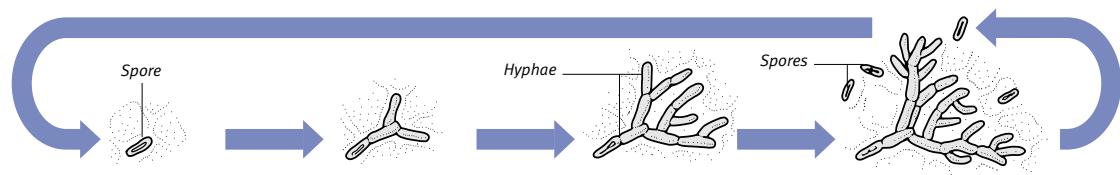

This condition can affect toenails or finger nails. It is liable to last for years. Antifungal medications are of benefit to some people.

Colony of fungal cells

The microscope photograph (left) shows a colony of yeast cells in a skin fragment.

FUNGAL GROWTH

funny-bone

A popular term for the small area at the back of the *elbow* where the ulnar nerve passes over a prominence of the *humerus* (upper-arm bone).

A blow to the nerve causes acute pain, numbness, and a tingling sensation in the forearm and hand.

furosemide

A *diuretic drug* used in the treatment of *oedema* (the accumulation of fluid in body tissues) and *heart failure*. Furosemide belongs to a group of drugs known as loop diuretics, which cause a rapid, temporary increase in the output of urine. When given by injection, furosemide has a very rapid effect; it may therefore be used in emergencies to relieve *pulmonary oedema* (a buildup of fluid around the lungs).

Furosemide increases the rate at which potassium is excreted from the body, which may cause headaches, dizziness, and muscle cramps. In order to prevent excessive potassium loss, doctors frequently give potassium supplements, or alternatively potassium-sparing diuretics, in combination with the drug.

furuncle

An alternative term for a *boil*.

fusidic acid

A type of *antibiotic drug* that is used in the treatment of a variety of bacterial infections that are resistant to *penicillin drugs*. Fusidic acid is commonly used in preparations applied to localized areas of skin in conditions such as impetigo. The drug is also used in eye and ear preparations.

FVC

The abbreviation for *forced vital capacity*. (See also *forced expiratory volume*.)

Fybogel

A brand name for a bulk-forming *laxative drug*.

G

G6PD deficiency

An *X-linked disorder* in which an abnormal gene causes a deficiency of G6PD (the *enzyme* glucose 6 phosphate dehydrogenase) in red blood cells. In a healthy person, this enzyme contributes to a chemical process that protects the cells from damage. G6PD deficiency makes the red cells prone to damage or destruction by infectious illness or by certain drugs or foods.

The disorder most commonly affects southern European and black men. Women are unaffected but they can carry the abnormal gene and are at risk of passing it on to their sons.

Some drugs, such as certain *antimalarial drugs* and *antibiotics*, may precipitate haemolysis (destruction of red cells) in people with the abnormal gene; see the table below for drugs that may pose this risk. In one form of G6PD deficiency, called *favism*, haemolysis may be triggered by a chemical in broad beans, and affected people must avoid eating them.

After taking a precipitating drug or food, or during an infectious illness, an affected person develops symptoms of anaemia (see *anaemia, haemolytic*), such as *jaundice*, fatigue, headaches, and shortness of breath (which may occur even after mild exertion).

G6PD deficiency is diagnosed with a blood test. There is no specific treatment available, but symptoms provoked by a drug or food can, however, be prevented by avoiding that substance.

GABA

The abbreviation for gamma-aminobutyric acid. This chemical is a *neurotransmitter* (a chemical released from nerve endings that relays messages within the *nervous system*). GABA controls the flow of nerve impulses by blocking the release of other neurotransmitters, such as *noradrenaline* and *dopamine*, that stimulate electrical activity in the nerve cells; as a result, this activity is inhibited.

The action of GABA is enhanced by *benzodiazepine drugs*, *anticonvulsant drugs*, and possibly *alcohol*. In contrast, it has been suggested that people with *Huntington's disease* (an inherited disorder that causes a loss of brain function and abnormal movements) suffer degeneration of GABA-secreting brain cells, leading to overstimulation of the *basal ganglia* (an area of the brain that helps coordinate movement) and producing the typical symptoms.

gabapentin

An *anticonvulsant drug* used either alone or with other anticonvulsants to treat some types of *epilepsy*. Common side effects include drowsiness, dizziness, unsteadiness, and fatigue.

gag reflex

An automatic impulse to retch, brought about by the *autonomic nervous system* in response to a particular stimulus, such as a foreign object touching the back of

the throat. The reflex protects the airway from becoming blocked by debris. If a person becomes unconscious, however, the gag reflex may be lost, and the person may be at risk of choking.

gait

A term used to describe the manner or style of *walking*. Gait varies from one person to another. An abnormal gait, or an unusual change in the gait, may indicate a neuromuscular or brain disorder (such as *Parkinson's disease*). (See also *festinating gait*.)

galactocele

A *breast cyst* that contains milk or a milky substance. A galactocele can be caused by obstruction of a milk duct in the *breast* during *breast-feeding*. In most cases, it occurs at the end of breast-feeding when milk is allowed to stagnate in the breast. The swelling may occasionally become infected, leading to a *breast abscess*. Usually, no treatment is needed; the fluid is reabsorbed, or can be expelled by massaging the breast towards the nipple.

galactokinase deficiency

A rare, inherited condition in which there is a deficiency of galactokinase, an *enzyme* involved in the breakdown of galactose (a simple sugar that is derived from the milk sugar *lactose*). Galactokinase deficiency is an autosomal recessive *genetic disorder*. The condition leads to a form of *galactosaemia* (the inability of the body to convert galactose into *glucose*, another simple sugar). The only manifestation of galactokinase deficiency galactosaemia is *cataracts*, which usually become apparent in affected babies within the first few weeks of life.

galactorrhoea

The spontaneous, persistent production of breast milk by a woman who is not pregnant or *breast-feeding*, or, very rarely, by a man. Lactation (milk production) is initiated by a rise in the level of *prolactin*, a hormone produced by the *pituitary gland*. Galactorrhoea is caused by excessive secretion of prolactin due either to a *pituitary tumour* or to another endocrine disorder, such as *hypothyroidism*. It may also be caused by some *antipsychotic drugs*.

As well as triggering breast milk production, excess prolactin may adversely affect the *ovaries*, causing *amenorrhoea* (absence of menstrual periods) or

DRUGS TO BE AVOIDED BY PEOPLE WITH G6PD DEFICIENCY

Class	Drugs to avoid
Antimalarial drugs	Primaquine, chloroquine*, quinine*, quinidine*, dapsone
Antibacterial and antibiotic drugs	Nitrofurantoin, sulphonamides (such as co-trimoxazole), quinolone drugs (such as ciprofloxacin and nalidixic acid)
Analgesics (painkillers)	Aspirin*
Miscellaneous	Vitamin K (water-soluble form), probenecid

*These drugs do not usually cause problems in the type of G6PD deficiency that affects black people.

infertility. If the underlying cause is a pituitary tumour, there may be symptoms associated with the tumour, such as headaches and visual disturbances.

Treatment with *bromocriptine* suppresses prolactin production, but the underlying cause of the disorder may also require treatment.

galactosaemia

A rare, inherited condition in which the body is unable to convert galactose (a simple sugar that is derived from the milk sugar *lactose*) into *glucose* (another simple sugar) due to the absence of a particular *enzyme* (a protein that acts as a catalyst to speed up a reaction) in the liver and in red blood cells.

Galactosaemia causes no symptoms at birth, but *jaundice*, diarrhoea, and vomiting may develop after a few days, and the baby fails to gain weight. If untreated, the disorder may result in liver disease, *cataracts* (opacities in the lenses of the eyes), and *learning difficulties*.

The diagnosis is confirmed by urine and blood tests. An affected person must avoid milk products, and use lactose-free milk, throughout life.

gallbladder

A small, muscular, pear-shaped sac, situated just beneath the *liver*, in which *bile* is stored and concentrated.

Bile, which is produced by the liver, enters the gallbladder via the hepatic and cystic ducts. When food passes from the *stomach* into the *duodenum* (the first part of the small intestine), gastrointestinal hormones make the gallbladder contract. This causes it to release the bile, via the common bile duct, into the duodenum, where it aids the breakdown of fats contained in the food. (See also *biliary system*.)

gallbladder cancer

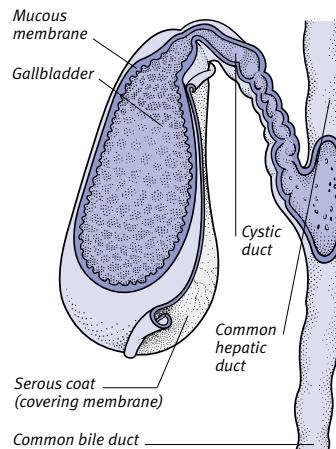

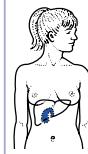

A rare cancer that occurs mainly in the elderly. It is usually associated with *gallstones*, but affects only a tiny proportion of those people with gallstones.

Gallbladder cancer may cause *jaundice* and tenderness in the abdomen, but it is sometimes symptomless.

The cancer is usually diagnosed by *ultrasound scanning*. Treatment is by surgical removal of the tumour, but if the cancer has spread to the liver by the time it is detected, the outlook is poor.

ANATOMY OF THE GALLBLADDER

The gallbladder receives bile from the liver via the common hepatic duct. It expels bile into the small intestine via the cystic duct and the common bile duct.

DISORDERS OF THE GALLBLADDER

The gallbladder rarely causes problems in childhood or early adulthood but, from middle age onwards, an increasing occurrence of *gallstones* may sometimes give rise to symptoms.

The digestive system can function normally without a gallbladder, and its removal has few known long-term adverse effects.

Metabolic disorders

The principal disorder, with which most other gallbladder problems are associated, is the formation of gallstones. Every year thousands of people develop gallstones. Women are affected up to four times as often as men, depending on their age and ethnicity.

The formation of gallstones results from a metabolic problem in which the chemical composition of bile (the digestive juice stored in the gallbladder) is altered. There are three main types of gallstone: stones formed from the fatty substance *cholesterol*; stones made from *bile* pigments; and mixed gallstones, which contain both cholesterol and pigments. The great majority are mixed.

Only about 20 per cent of affected people experience symptoms or complications; many carry "silent" gallstones, producing no symptoms. Attempts by the gallbladder to expel the stone or stones, however, can cause severe *biliary colic* (abdominal pain).

Infection and inflammation

If a gallstone lodges in the gallbladder outlet, trapped bile may irritate and inflame the lining, and bile may become infected. This disorder is called acute *cholecystitis*. The first symptom may be biliary colic, followed by fever and abdominal tenderness.

Repeated attacks of biliary colic and acute cholecystitis can lead to chronic cholecystitis, in which the gallbladder becomes shrunken and thick-walled and ceases to function. Rarely, it may become inflamed when no gallstones are present: a condition called acalculous cholecystitis.

Cholecystitis can proceed to *empyema*, in which the gallbladder fills with pus; a high fever and severe abdominal pain may result.

Congenital and genetic defects

Abnormalities that may be present from birth include absence of the gallbladder, an

oversized gallbladder, or two gallbladders. These defects, however, rarely cause problems.

Tumours

Gallbladder cancer usually occurs in a gallbladder that contains gallstones. This cancer is, however, extremely uncommon compared to the high prevalence of gallstones.

Other disorders

In rare cases where the gallbladder is empty and a stone obstructs its outlet, the gallbladder may become distended and filled with mucus secreted by its lining. A gallbladder with this problem is known as a *mucocoele*.

INVESTIGATION

Gallbladder problems are investigated by physical examination and imaging techniques such as *ultrasound scanning*, *radionuclide scanning*, or *cholecystography*. Blood tests may also be carried out.

gallium

A metallic element whose radioactive form is used in *radionuclide scanning* (a technique using a tiny amount of a radioactive substance to obtain images of internal organs). Gallium is injected into the bloodstream before a scan in order to reveal areas of inflammation, such as those that occur in cancers, *abscesses*, *osteomyelitis*, and *sarcoidosis*.

gallstone ileus

See *ileus, gallstone*.

gallstones

Lumps of solid matter found in the *gallbladder* (the sac under the liver where bile is stored) or in the *bile ducts* (which connect the gallbladder and liver to the duodenum). Most gallstones are made of *cholesterol* and bile pigments from the breakdown of red blood cells.

CAUSES AND INCIDENCE

Gallstones develop due to a disturbance in the chemical composition of *bile*. They are rare in childhood and become increasingly common with age. Women are affected more than men. Risk factors for developing gallstones include a high-fat diet and being overweight.

SYMPOTMS

Most gallstones cause no symptoms. Any symptoms often begin when a stone lodges in the gallbladder outlet. This problem causes *biliary colic* (intense pain in the upper right area of the abdomen or between the shoulderblades), nausea, and sometimes indigestion and flatulence. Possible complications include *cholecystitis* (inflammation of the gallbladder) and *bile duct obstruction*.

DIAGNOSIS AND TREATMENT

Gallstones are usually diagnosed by *ultrasound scanning*, X-ray oral *cholecystography*, or *cholangiography*.

Stones that are not causing symptoms are usually left alone. In other cases, the gallbladder and stones may be surgically removed by *cholecystectomy*. Ultrasonic shock waves (see *lithotripsy*) are sometimes used to shatter gallstones; the fragments pass into the intestines and cause no further problems. Drugs such as *ursodeoxycholic acid* can dissolve some gallstones if taken over several months, but further stones may form once the treatment is stopped.

gambling, pathological

A chronic inability to resist impulses to gamble, resulting in personal, social, and/or financial problems.

gamete

A sex cell. Gametes are found in the reproductive systems of adults: *sperm* are formed in the *testes* in males, and an *ovum* (egg cell) is released approximately every month from the *ovaries* in females. Sperm and ova come together during *fertilization* to create offspring. (See also *meiosis*.)

gamete intrafallopian transfer (GIFT)

A technique for assisting *conception* (see *infertility*) in women. It can only be used if a woman has functioning *fallopian tubes*. In GIFT, ova (eggs) are removed from the woman's *ovary* during *laparoscopy* (viewing of the interior of the abdomen) and mixed with *sperm* in the laboratory. The mixed eggs and sperm are introduced into one of the fallopian tubes, where *fertilization* takes place. A fertilized egg may then become implanted in the *uterus*.

Gamgee tissue

The brand name for a material consisting of a thick layer of highly absorbent cotton wool enclosed in gauze. Gamgee tissue may be used for padding and compression of soft-tissue injuries, but may also be used on open wounds, such as *ulcers*, to aid the healing process by applying compression and soaking up body fluids.

gamma aminobutyric acid

See *GABA*.

gamma camera

A piece of equipment used to generate diagnostic images in *radionuclide scanning*. A tiny amount of a radioactive substance is introduced into the body (usually by injection) and taken up by the tissues to be examined. The gamma camera detects radiation emitted by the material and displays its pattern of distribution as an image on a monitor.

gamma-globulin

A substance that contains *antibodies* against a specific infection. Injections of gamma-globulins provide temporary protection against diseases such as *chickenpox* and *tetanus*. (See *immunization; immunoglobulin injections*.)

gamolenic acid

An essential *fatty acid* found in evening primrose oil and starflower (borage) oil. Gamolenic acid may be taken for

premenstrual syndrome and *eczema*. Very large doses may cause abdominal pain and loose stools.

ganciclovir

An *antiviral drug* that is used to treat severe *cytomegalovirus* infection. Such a condition occurs in those people whose *immune system* is impaired or suppressed because they have *AIDS*, they are taking *immunosuppressant drugs*, or have had an organ *transplantation*.

Ganciclovir is toxic and produces a range of side effects, including nausea; diarrhoea; abdominal pain; weakness; and suppression of blood cell formation in the bone marrow. For this reason, it is used only when the benefits are likely to outweigh the risks.

ganglia

The plural form of *ganglion*.

ganglion

A group of *nerve* cells that have a common function; for example, the *basal ganglia* in the brain are concerned with the control of muscular movements.

The term is also used to describe a fluid-filled swelling associated with the sheath of a *tendon*. A ganglion may disappear spontaneously; if necessary, it may be drained or removed surgically.

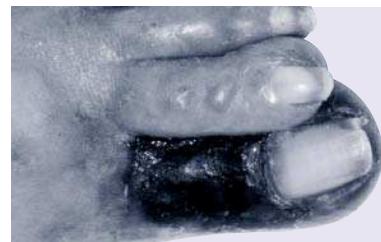

gangrene

Death of tissue, usually caused by loss of the blood supply. Gangrene may affect a small area of skin or a large portion of a limb.

SYMPTOMS AND TYPES

Pain is felt as the tissues are dying, but once dead they become numb. The affected tissue turns black. There are two types of gangrene: dry and wet.

In dry gangrene, the tissue dies as it has no blood supply. The gangrene does not spread. Dry gangrene may be caused by *arteriosclerosis*, *diabetes mellitus*, *thrombosis*, frostbite, or an *embolism*.

Gangrene of the foot

This shows a gangrenous foot, with areas of dead tissue and blackening of the skin on the big toe.

Wet gangrene develops when an area of dry gangrene, or a wound, becomes infected by *bacteria*. Redness, swelling, and oozing pus may occur around the blackened tissues. The gangrene spreads, and the area gives off an unpleasant smell. A virulent type called *gas gangrene* is due to a bacterium that destroys muscles and produces a foul-smelling gas.

TREATMENT

Treatment of dry gangrene involves attempting to improve the circulation to the affected area before the tissues die. *Antibiotic drugs* can prevent wet gangrene from setting in.

To treat wet gangrene, *amputation* of the affected part and the surrounding tissue may be necessary.

Ganser's syndrome

A rare *factitious disorder* in which an individual seeks, either consciously or unconsciously, to mislead others about his or her mental state and may simulate symptoms of *psychosis*.

Gardnerella vaginalis

A *bacterium* that is often found in the vaginal discharge of women with *bacterial vaginosis*.

gargle

A liquid preparation to wash and freshen the mouth and throat. Some gargles contain *antiseptics* or local *anaesthetics* to relieve sore throats.

gargoylism

Another name for *Hurler's syndrome*, in which the facial features are coarsened.

gas-and-air

A mixture of *nitrous oxide* and *oxygen* that is mainly used for temporary pain relief in emergencies or during *labour*.

gas gangrene

A rare but life-threatening form of *gangrene* (tissue death), usually due to infection by the bacterium *CLOSTRIDIUM PERFRINGENS*. This organism thrives in *anaerobic* environments, where there is little or no oxygen, such as dying tissue.

Gas gangrene develops suddenly and normally occurs at the site of a recent, serious wound. The bacteria multiply in the damaged tissue, producing toxins that release a gas, and spread incredibly rapidly to healthy tissue.

The affected area is swollen and painful, and pale or reddish-brown in colour. Gas collects in the tissues,

causing a crackling sensation if the area is pressed. Other symptoms that develop early in the infection include sweating, fever, and anxiety. If left untreated, the condition may lead to *shock* (failure of blood circulation), *kidney failure*, *coma*, and even death.

Penicillin drugs destroy the bacteria at the edges of the gangrene, but all of the diseased tissue needs to be surgically removed. *Amputation* of an affected limb may be required, in some cases, to control the spread of infection. *Hyperbaric oxygen treatment*, in which the patient is exposed to oxygen at high pressure, may help to kill the bacteria.

gastrectomy

Removal of the whole *stomach* (total gastrectomy) or of part of the stomach (partial gastrectomy). Total gastrectomy is used to treat some *stomach cancers*. Partial gastrectomy used to be a treatment for *peptic ulcers* (ulcers of the stomach or duodenum) but has largely been replaced by drug treatment.

A person who has had a gastrectomy may experience fullness and discomfort after meals. Possible postoperative complications include the regurgitation or vomiting of *bile*, which may lead to inflammation of the stomach or the oesophagus; diarrhoea; and *dumping syndrome* (sweating, nausea, dizziness, and weakness after meals, due to food leaving the stomach too quickly). Other complications include *malabsorption* (a reduced ability to absorb nutrients), which may lead to *anaemia* or *osteoporosis* (loss of bone density). After a total gastrectomy, patients cannot absorb vitamin B_{12} and need injections of the vitamin for the rest of their lives.

gastric erosion

A break in the surface layer of the membrane that lines the *stomach*. Gastric erosions occur in some cases of *gastritis* (inflammation of the stomach lining). Many result from ingestion of irritants such as *alcohol*, *iron tablets*, or *aspirin*. The physical stress of serious illness, injuries such as *burns*, or major surgery may also cause erosions to develop.

Often there are no symptoms, but erosions may bleed, causing *vomiting of blood* or blood in the faeces. Persistent loss of blood may lead to *anaemia*.

Gastric erosions are diagnosed by *gastroscopy* (inspection and examination of the stomach via a flexible viewing instrument; an endoscope).

They usually heal in a few days when treated with antacid drugs, H_2 -receptor antagonists, or proton pump inhibitors (see *ulcer-healing drugs*). Drugs that block the production of stomach acid are often given to people who are at high risk of developing erosions, such as those receiving *intensive care*.

gastric lavage

See *lavage*, *gastric*.

gastric ulcer

A raw area in the *stomach* wall caused by a breach of the lining (see *gastric erosion*) that penetrates into the tissues. A gastric ulcer is a type of *peptic ulcer* (ulcer of the stomach or duodenum).

gastrin

A *hormone* produced by cells in the *stomach* lining. Gastrin causes the stomach to produce more acid and helps to propel food through the digestive tract. (See also *gastrointestinal hormones*.)

gastritis

Inflammation of the *stomach* lining due to irritation of the tissues. The condition may be *acute* or *chronic*.

Acute gastritis may be due to infection with the *HELICOBACTER PYLORI* bacterium. It may also be caused by drugs, usually *nonsteroidal anti-inflammatory drugs* such as *aspirin*; *alcohol*; or severe physical stress, such as *burns* or major surgery.

Chronic gastritis is most often due to *H. PYLORI* infection but may be due to prolonged irritation by *smoking*, *alcohol*, or *bile*; by an *autoimmune disorder* that damages the stomach lining (see *anaemia*, *megaloblastic*); or by degeneration of the lining with age.

Symptoms include discomfort in the upper abdomen, nausea, and vomiting. In acute gastritis, the faeces may be blackened by blood lost from the stomach (see *melaena*); in chronic gastritis, slow blood loss may lead to *anaemia* (see *anaemia*, *iron-deficiency*), resulting in symptoms such as pallor, tiredness and breathlessness.

Diagnosis of gastritis is made through *gastroscopy* (examination of the stomach lining with a flexible viewing instrument), during which a *biopsy* (removal of a tissue sample for analysis) may be performed. *Ulcer-healing drugs* and *antibiotics* may be prescribed to treat *H. PYLORI* infection. *Anaemia* will be treated. There is no treatment for gastritis due to an *autoimmune disorder*, however.

gastroenteritis

Inflammation of the *stomach* and intestines, usually causing sudden upsets that last for two or three days. *Dysentery*, *typhoid fever*, *cholera*, *food poisoning*, and *travellers' diarrhoea* are all forms of gastroenteritis. Gastroenteritis may be caused by a variety of *bacteria*, bacterial *toxins*, *viruses*, and other organisms in food or water. There are also a number of non-infectious causes, such as *food intolerance* and certain irritant drugs.

The usual symptoms are appetite loss, nausea, vomiting, cramps, and diarrhoea. Their onset and severity depend on the cause; symptoms may be mild, or may be so severe that *dehydration*, *shock*, and collapse occur.

Mild cases usually require rest and *rehydration therapy* only. For severe illness, treatment in hospital may be necessary, with fluids given by *intravenous infusion*. *Antibiotic drugs* may be given for some bacterial infections, but others need no specific treatment.

gastroenterology

The study of the *digestive system* and the diseases and disorders that affect it.

gastroenterostomy

Surgery that is performed to create a connection between the *stomach* and the *jejunum* (the middle two thirds of the small intestine), sometimes combined with a partial *gastrectomy* (the removal of the lower part of the stomach). The operation, formerly carried out to treat duodenal ulcer (see *peptic ulcer*), is now rarely performed.

gastrointestinal hormones

A group of *hormones* released from specialized cells in the *stomach*, *pancreas*, and small intestine that control various functions of the digestive organs. *Gastrin*, *secretin*, *cholecystokinin*, and *vasoactive intestinal polypeptide* are the best known of these hormones (see *Hormones in the digestive tract*), but new hormones are still being discovered.

gastrointestinal tract

The part of the *digestive system* consisting of the *mouth*, *oesophagus*, *stomach*, and *intestines*. These structures together form a long tube through which food passes as it is digested.

gastro-oesophageal reflux disease (GORD)

The medical term for *acid reflux*.

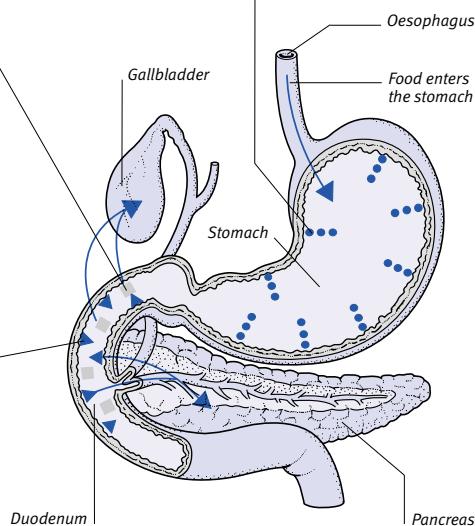

HORMONES IN THE DIGESTIVE TRACT

Hormones released from endocrine cells in the stomach, pancreas, and intestine aid digestion by stimulating the release of bile from the gallbladder and enzymes from the pancreas into the duodenum.

Cholecystokinin
Released by the duodenum in response to fats and acid, cholecystokinin causes the gallbladder to squeeze bile into the duodenum and stimulates the production of pancreatic enzymes, which pass into the duodenum through the pancreatic duct.

Secretin
Secreted by the lining of the duodenum in response to acid entering from the stomach, secretin acts on the pancreas to increase the output of bicarbonate, which neutralizes acid from the stomach. It also increases the release of enzymes from the pancreas.

Gastrin
Secreted mainly by cells in the stomach in response to eating food (especially protein), gastrin causes the stomach to produce more acid and stimulates contraction of muscle in the wall of part of the stomach, ileum, and colon. This contraction propels food through the digestive tract.

gastroscopy

Examination of the *stomach* via a flexible *endoscope* (a viewing instrument) inserted through the mouth. The *oesophagus* and *duodenum* (the first part of the small intestine) are also inspected; for this reason, the procedure is more accurately called an *oesophagogastroduodenoscopy*. The patient is often sedated throughout.

Gastroscopy is used to investigate bleeding, or other disorders, of the oesophagus, stomach, or duodenum. Attachments to the gastroscope enable a *biopsy* (removal of a tissue sample for analysis) to be carried out, as well as treatments such as *laser treatment*. A gastroscope may also be used to ease the passage of a gastric feeding tube through the skin (see *gastrostomy*).

gastrostomy

A surgically created opening in the *stomach*. It is usually made to connect the stomach to the outside of the body, so that a feeding tube can be passed into the stomach or small intestine.

Gastrostomy may be performed on people who cannot eat properly due to oesophageal cancer (see *oesophagus, cancer of*) or who are unable to chew and swallow due to a *stroke*.

Gaucher's disease

A *genetic disorder* in which the lack of the enzyme glucocerebrosidase leads to accumulation of a fatty substance, glucosylceramide, in the liver, spleen, bone marrow, and, sometimes, in the brain. The condition is treated by regular injections of the missing enzyme.

gauze

An absorbent, open-weave fabric, usually made of cotton. Sterilized gauze is often used to clean wounds, or applied as a *dressing* to soak up fluids from wounds. It is not used on areas of damaged tissue such as burns or ulcers, because it may stick to the surface and dislodge new tissue when it is removed.

gavage

Feeding of liquids through a *nasogastric tube*, which is passed into the stomach through the nose (see *feeding, artificial*).

The term "gavage" can also refer to *hyperalimentation* (treating a patient by feeding beyond appetite requirements).

gel

A jelly-like suspension consisting of small, insoluble particles that are dispersed through a liquid. Gels are often

used as bases for *topical* skin treatments, particularly those that are used on the face and scalp.

gemfibrozil

A drug that lowers the level of fats in the blood. Gemfibrozil is usually given to people with *hyperlipidaemia* after dietary measures have failed to reduce blood fat levels. It may cause nausea and diarrhoea, and should not be taken by people with liver disease.

gender identity

An individual's inner feeling of maleness or femaleness. Gender identity is not necessarily the same as biological sex. It is fixed within the first two to three years of life and is reinforced during puberty; once established, it cannot usually be changed.

A minority of people have persistent feelings of discomfort about their sexual identity. This condition is called gender dysphoria; in the most severe cases, a person may feel that he or she is the wrong sex (see *transsexualism*).

gene

A particular area of *DNA*, the material within cells that governs the physical characteristics, development, and functioning of an individual. DNA is a very long, chain-like structure that exists in

the *nucleus* of a cell. Each strand has about 30,000 pairs of genes, arranged on 23 pairs of *chromosomes*. All body cells (except egg and sperm cells) contain identical sets of genes because they are all derived, by a process of division, from a single fertilized egg.

During growth and cell repair, cells divide to form two identical new cells, each containing a full set of genes (see *mitosis*). *Gametes* (cells involved in reproduction), however, undergo a different form of division, called *meiosis*; as a result, they contain just one gene from each pair, so that each parent contributes half of the genetic material used to form an offspring.

GENE FUNCTION

Each gene controls or influences a specific feature or process in the body. Genes act by directing the manufacture of specific *proteins* (see *What genes are and what they do*, overleaf). Many proteins are involved in forming body structures, or in regulating particular chemical processes (see *enzyme*). Certain proteins, however, are made solely to influence other genes by switching them "on" or "off". The genes that make these regulatory proteins are called control genes.

The whole complex process of development and growth is regulated by the sequential switching "on" and "off" of particular genes. The activities of control

genes also determine the specialization of cells. Within any cell, some genes are active and others are idle, according to the cell's particular function; for example, nerve cells and liver cells will have different sets of active and idle genes. If the control genes are disrupted, however, cells lose their specialist abilities and multiply out of control; this is the probable mechanism by which cancers develop (see *carcinogenesis*; *oncogenes*).

GENE MUTATION

Occasionally, when new cells are formed, a fault occurs in the copying process, leading to a *mutation* (change). The mutant gene is then passed on each time the cell subsequently divides. Disorders that result from such mutant genes are known as *genetic disorders*.

ALLELES

The gene at any particular location on a chromosome can exist in any of various forms, called *alleles*. If the effects of a specific allele mask those of the allele at the same location on its partner chromosome, that allele is described as *dominant*; the masked allele is *recessive*. (See also *genetic code*; *inheritance*.)

gene mapping

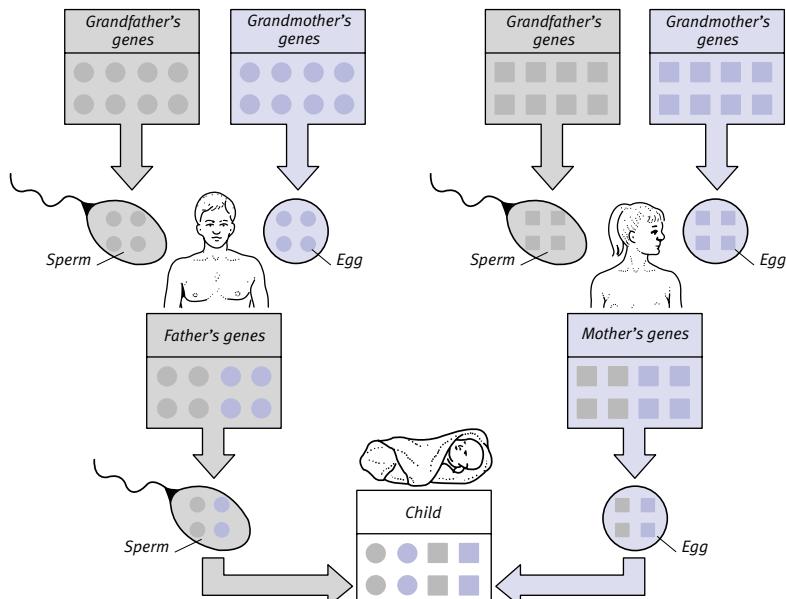

A process by which the location of particular *genes* on each *chromosome* is determined. In some cases, gene location gene can be found by certain tests.

WHERE DO YOUR GENES COME FROM?

A person's genes are inherited from his or her parents. Half come from the mother and half from the father via the egg and sperm cells. Each parent provides a different selection, or "mix", of his or her genes to each child; this accounts for the marked differences in appearance, health, and personality among most brothers and sisters. Everyone holds a copy of his or her genes within each body cell.

Gene transmission

In this diagram, only eight genes are shown – in reality, each cell in the body contains about 30,000 genes. Half of them come from the mother and half from the father – thus a quarter of the genes originate from each of the four grandparents.

WHAT GENES ARE AND WHAT THEY DO

Genes are units of DNA (the material that controls the body's growth, structure, and functions) contained in every cell. They exert their effects by directing the manufacture of proteins. All of a person's genes come from his or her parents. The physical differences between people, such as in eye, hair, and skin colour, arise from slight differences in gene structure.

G

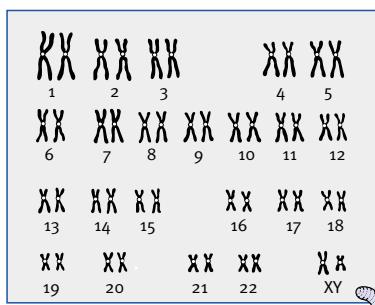

DNA PRINTOUT

Through painstaking laboratory research, the exact structure of many genes is now known.

DNA base sequence

This printout shows a small part of the sequence in the gene that codes for the protein trypsin, a digestive enzyme.

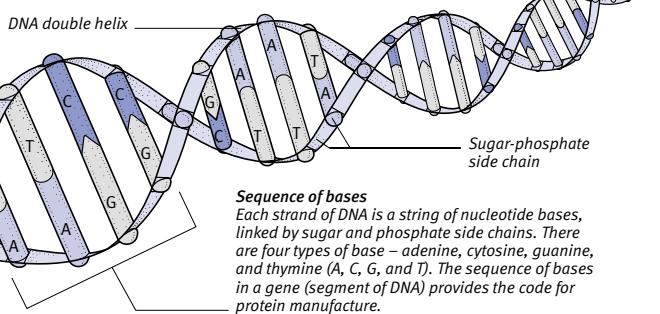

Chromosomes

Genes are contained in the chromosomes within the nuclei of a person's cells. Each chromosome contains a long strand of DNA (deoxyribonucleic acid).

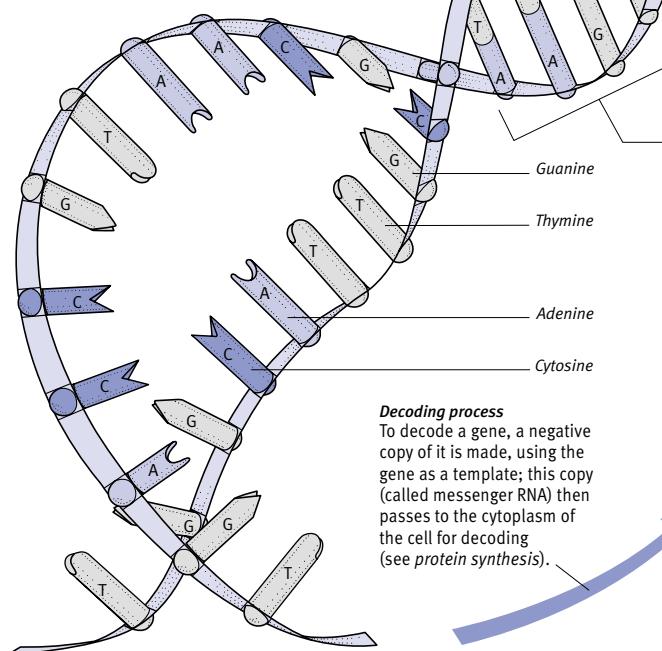

DNA and genes

DNA has a long, thread-like molecule made up of two intertwined strands: the double helix. Genes are segments of DNA contained within chromosomes. Each individual gene directs the manufacture of one particular type of protein; the instructions for this function are encoded within the structure of its segment of DNA.

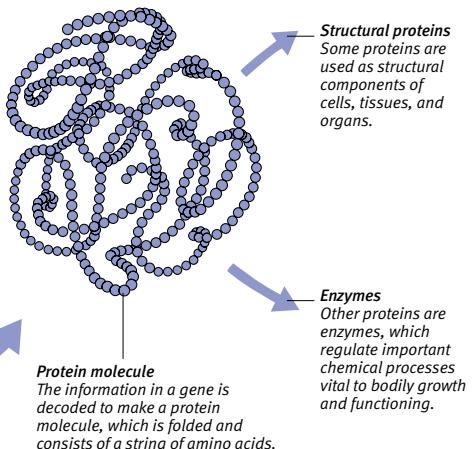

Sequence of bases

Each strand of DNA is a string of nucleotide bases, linked by sugar and phosphate side chains. There are four types of base – adenine, cytosine, guanine, and thymine (A, C, G, and T). The sequence of bases in a gene (segment of DNA) provides the code for protein manufacture.

Decoding process

To decode a gene, a negative copy of it is made, using the gene as a template; this copy (called messenger RNA) then passes to the cytoplasm of the cell for decoding (see protein synthesis).

Protein molecule

The information in a gene is decoded to make a protein molecule, which is folded and consists of a string of amino acids.

Enzymes

Other proteins are enzymes, which regulate important chemical processes vital to bodily growth and functioning.

DISORDERS DUE TO SINGLE GENE DEFECTS

Autosomal dominant

In these disorders, only one copy of the defective gene needs to be present in order to cause an abnormality. Each child of an affected person usually has a 1 in 2 chance of inheriting the defective gene and being affected, and a 1 in 2 chance of being unaffected.

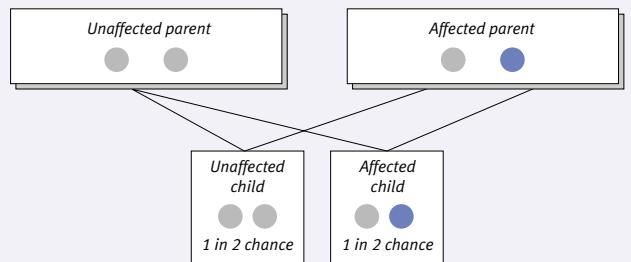

Examples

- Achondroplasia
- Familial polyposis
- Hereditary spherocytosis
- Huntington's disease
- Marfan syndrome
- Neurofibromatosis
- Polycystic kidney disease (adult type)
- Tuberous sclerosis

Key

Defective gene

Normal gene

Autosomal recessive

In this group, the disorder occurs when a pair of abnormal genes is inherited. Usually, both parents of an affected person are unaffected carriers of the defective gene. Each of their children has a 1 in 4 chance of being affected and a 2 in 4 chance of being a carrier.

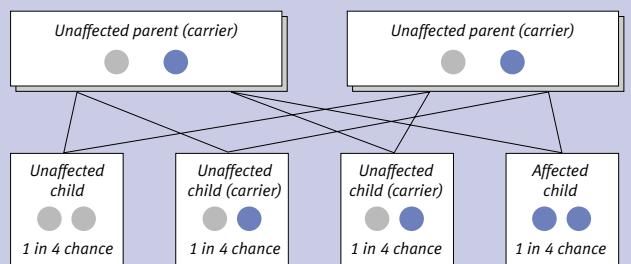

Examples

- Albinism (oculocutaneous)
- Cystic fibrosis
- Friedreich's ataxia
- Galactosaemia
- Hurler's syndrome
- Phenylketonuria
- Sickle cell anaemia
- Tay-Sachs disease

Key

Defective gene

Normal gene

X-linked recessive

These conditions are caused by defects on the X chromosome. They usually cause abnormalities only in males, in whom the defect cannot be masked by the equivalent gene on a second, normal X chromosome. Women may be carriers of the defect. There is a 1 in 2 chance of their sons having the disorder and a 1 in 2 chance that their daughters will be carriers.

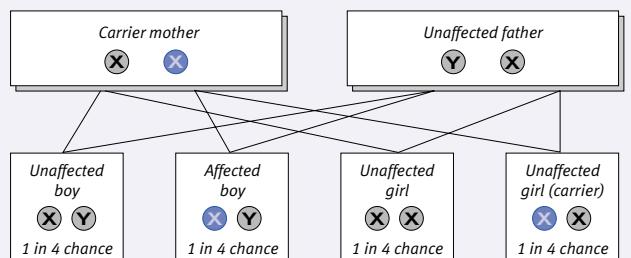

Examples

- Christmas disease
- Colour blindness (most types)
- Fragile X syndrome
- G6PD deficiency
- Haemophilia
- Muscular dystrophy (Duchenne)

Key

Defective X chromosome

Normal X chromosome

Alternatively, the positions of genes that are close to one another on one chromosome (and so are usually passed on together) may be found by a process called linkage analysis. The information is shown as a diagram of a chromosome with the gene locations marked on it.

general anaesthetic

See *anaesthesia, general*.

generalized anxiety disorder

A psychiatric illness characterized by chronic and persistent apprehension and tension that has no particular focus. There may also be various physical symptoms such as trembling, sweating, lightheadedness, and irritability.

The condition can be treated with *psychotherapy*, *antidepressants*, or with drugs such as *beta blockers* or *sedatives*.

that relieve symptoms but do not treat the underlying condition. (See *anxiety*; *anxiety disorders*.)

general paralysis of the insane

An outdated term describing the mental and physical deterioration of untreated or unsuccessfully treated *syphilis*.

general practice

The term used in the UK for the provision of personal medical care outside a hospital setting. Doctors who provide it are called general practitioners (GPs). This form of health-care is now more commonly known as *primary care*.

generic drug

A medicinal drug that is marketed under its official medical name (its generic name) rather than under a

patented name (its brand name). Most drugs are now prescribed under their generic names.

gene therapy

A treatment in which copies of a normal gene are inserted into the DNA of a person's cells to help fight cancer or to counter the effects of a faulty gene.

Gene therapy is most likely to be successful in the treatment of autosomal recessive diseases (see *Disorders due to single gene defects*), such as cystic fibrosis, which are caused by a pair of defective genes. When a normal copy of the gene is introduced into the body, it overrides the abnormal ones and corrects the condition. It is less successful, however, in treating autosomal dominant disorders, such as Huntington's disease, in which a faulty gene

overrides a normal one. In these cases, the abnormal gene must be removed and is then replaced by a normal copy.

The copies of the normal gene can be introduced into the body in various ways. In one technique, a person's white blood cells are grown in a *culture* with a *retrovirus* containing the normal gene and then reintroduced into the body, where they multiply. An alternative method, currently being tried to treat cystic fibrosis, involves packaging normal DNA in tiny liposomes, which are added to an aerosol spray. The spray is inhaled and the liposomes bind to the walls of cells in the lung tissue and the normal gene is activated.

Research is also being carried out to assess the potential of gene therapy in treating cancer. In certain forms of cancer, a gene called p53 (which controls programmed cell death) is faulty, allowing cells to multiply uncontrollably to form a tumour. The introduction of a normal p53 gene may prompt the death of these abnormal cells.

genetically modified foods

Food or food constituents that are derived from plants whose genetic material has been deliberately altered in order to modify certain characteristics. In genetic modification, *DNA* is isolated from one organism and inserted into the DNA of another (the recipient).

The procedure is intended to be beneficial; for example, transferred DNA may enable recipient plants to be more resistant to pests, which is likely to increase crop yields. There may also be disadvantages, however. Ecological and health concerns about GM foods are the subjects of ongoing debate.

genetic code

The inherited instructions, contained in *genes*, that specify the activities of cells and thereby the development and functioning of the body. Each gene in a *chromosome* contains the coded instructions for a cell to make a *protein* that has a specific function in the body.

The DNA that makes up genes consists of two long, intertwined strands, each comprising a sequence made up of four chemicals called nucleotide bases (see *nucleic acids*). These four bases are adenine, thymine, cytosine, and guanine (often abbreviated to A, T, C, and G). They are joined in pairs (base-pairs), thus linking the two strands of the DNA molecule. The sequence of these bases

along the DNA strands makes up the genetic code. During *protein synthesis*, *RNA* (ribonucleic acid) is used to help read this code and create the protein.

genetic counselling

Medical guidance offered to people who have a known risk of having a child with a *genetic disorder*, such as cystic fibrosis, or who are at increased risk of developing a genetic disorder themselves. The counsellor will examine individual and family medical histories and, in some cases, arrange for tests such as *chromosome analysis* and *genetic probes*.

Genetic counselling enables people to make informed decisions about their future, particularly parenthood. If there is a significant risk of a couple having an affected child, doctors may be able to offer pre-implantation genetic testing with *in vitro fertilization* (see *embryo diagnosis*), or antenatal diagnosis, to optimize the chances of their having a healthy child. If parents already have an affected child, genetic counselling will provide information on the outlook for that child.

genetic disorders

Any disorder caused, wholly or partly, by one or more faults in a person's *DNA*. Genetic disorders may be *congenital* (present at birth) or may become apparent later in life. Many of them are *familial* (shared by various people in the same family). A child may, however, be born with a genetic disorder when there is no previous family history.

A genetic disorder can occur in two different ways: one or both parents have a defect in their own genetic material that is then inherited by the child, or a *mutation* occurs during the formation of the *ovum* or *sperm* cell.

The disorders fall into three broad categories: *chromosomal abnormalities*, single gene defects, and multifactorial defects. Chromosomal abnormalities involve a child having an abnormal number of whole *chromosomes* (as in *Down's syndrome*), or extra or missing bits of chromosomes. Single gene defects are rare, and are caused by one abnormal gene or pair of genes. Multifactorial disorders are thought to be due to the effects of several genes combined with environmental influences.

SINGLE GENE DEFECTS

There are two main forms of single gene defect. In sex-linked disorders, the defective gene is carried on one of the sex chromosomes – almost always the X

chromosome. In autosomal disorders, the defective gene is carried on one of the other 44 chromosomes. These disorders are subdivided into autosomal dominant and autosomal recessive disorders. See *Disorders due to single gene defects* (previous page) for examples.

Another, rare group of single gene defects involves the *mitochondrial DNA*, which exists outside the nuclei.

X-linked recessive disorders The most common type of sex-linked disorder, X-linked recessive disorders are caused by a defective gene on an X chromosome. *Haemophilia* and colour blindness (see *colour vision deficiency*) are this type.

Women have two X chromosomes; men have only one, inherited from their mothers. When a woman inherits one defective gene, its effect is masked by the normal gene on her other X chromosome and she has no abnormality. She is, however, capable of passing the gene on to her children, and is called a carrier. On average, carriers transmit the defective gene to half their sons, who are affected, and to half their daughters, who become carriers in turn. When a male inherits the defective gene from his mother, he has no normal gene on a second X chromosome to mask it, so he displays the abnormality. Affected males therefore greatly outnumber affected females. The males pass the defective gene to none of their sons but to all of their daughters, who become carriers.

autosomal dominant disorders In these conditions, the defective gene is *dominant* in relation to the equivalent normal gene, so only one copy needs to be present in order to cause an abnormality. People who have an autosomal dominant disorder carry one normal copy and one defective copy of the affected gene, and are termed *heterozygotes*. Affected people have a 50 per cent chance of passing the defective gene on to their children.

autosomal recessive disorders The defective gene that causes an autosomal recessive disorder is *recessive* in relation to the normal gene, so two faulty copies of the gene are required to cause an abnormality. People who have the disorder carry two identical defective copies of the gene, and are called *homozygotes*. In most cases, both parents of an affected individual are heterozygotes: they carry one copy of the defective gene and one copy of the normal gene.

MITOCHONDRIAL DISORDERS

In rare cases, a defect in a specific area of mitochondrial DNA causes diseases.

Such disorders include certain myopathies (muscle disorders), neuropathies (nerve disorders), and some cases of degeneration of the retina, and *deafness*. These disorders are always passed on from the mother, because sperm cells have very few or no mitochondria.

MULTIFACTORIAL DISORDERS

A wide range of disorders, including *asthma*, *diabetes mellitus*, and most forms of *hyperlipidaemia* are thought to result from the cumulative effects of several faulty genes, together with environmental factors. The pattern of inheritance in these disorders is less straightforward than that in chromosomal abnormalities or single gene defects.

genetic drift

Chance fluctuation in *gene* frequency within a finite, isolated sample of a population over a number of generations. The chance of random variation increases as the population size decreases because, in a large population, the random nature of the transmission of *alleles* (various forms of a gene at a particular location) will tend to average out.

genetic engineering

A branch of *genetics* concerned with the alteration of genetic material in an organism in order to produce a desired change in the organism's characteristics. Genetic engineering has mainly been used to mass-produce a variety of substances that are useful in medicine.

A *gene* responsible for making a useful protein is identified and isolated. It is then inserted into "host" cells (most commonly bacteria or yeast); this altered DNA is called recombinant DNA. The host cells reproduce rapidly to form a colony of cells containing the gene. This colony produces the protein in large amounts. The human hormones *insulin* and *growth hormone* and proteins, such as *factor VIII* (used to treat *haemophilia*), are made in this way. Genetic engineering is also used in *gene therapy*.

genetic fingerprinting

A technique that can be used to demonstrate relationships between people (for example in *paternity testing*) or, in forensic investigations, to identify a suspect.

DNA contains a *genetic code* ("genetic fingerprint") that is unique to each individual, except in the case of identical twins. DNA can be extracted from any material containing body cells, such as blood or semen. Its code can then be

analysed in comparison with that of a sample from another person, or from the scene of a crime.

genetic probe

A specific fragment of DNA used in laboratory tests to determine whether a particular genetic defect is present in a person's DNA. The probe contains the same structure as the abnormal gene and, when added to a sample of the person's DNA, will bind to that gene if it is present. A radioactive or fluorescent marker may be added to the probe so that it can easily be detected.

Genetic probes are mainly used in antenatal diagnosis of *genetic disorders*, and in determining whether people with a family history of a genetic disorder carry the defective gene themselves (see *familial screening*).

genetics

The study of *inheritance* (the transmission of characteristics from one generation of an organism to the next). Genetics involves determination of the chemical basis for inheritance of particular characteristics, and investigating the causes of similarities and differences between individuals of a particular species or between different species.

Branches of human genetics include population genetics, which studies the relative frequency of various *genes* in different human races; molecular genetics, which is concerned with the structure, function, and copying of DNA; and clinical genetics, which is concerned with the study and prevention of *genetic disorders*.

genetic screening

See *familial screening*.

genital herpes

See *herpes, genital*.

genitalia

The reproductive organs, especially those that are external. The male genitalia include the *penis*, *testes* (situated within the *scrotum*), *prostate gland*, *seminal vesicles*, and associated ducts, such as the *epididymis* and *vas deferens*. The female genitalia include the *ovaries*, *fallopian tubes*, *uterus*, *vagina*, *clitoris*, *vulva*, and *Bartholin's glands*.

genitalia, ambiguous

A group of conditions, also known as intersex, in which an individual's external sex organs are not clearly male or

female, or in which the organs appear to be those of the opposite chromosomal sex. Cases of ambiguous genitalia may result from an abnormality of the *sex chromosomes* or a *hormonal disorder* (see *hermaphroditism*; *sex determination*; *adrenal hyperplasia, congenital*).

genital phase

A term used in *psychoanalytic theory* to refer to a stage of a person's psychosexual development. The genital phase begins at around the ages of 3–5 years. (See also *anal phase*; *oral phase*.)

genital ulcer

An eroded area of skin on the *genitalia*. There are various possible causes. The most common cause of genital ulcers is a *sexually transmitted infection*, particularly *genital herpes* (see *herpes, genital*) or *syphilis*. *Chancroid* and *granuloma inguinale* are tropical bacterial infections that cause genital ulcers. *Lymphogranuloma venereum* is a bacterial infection (*CHLAMYDIA*) producing genital blisters. *Behcet's syndrome* is a rare condition that causes tender, recurrent ulcers in the mouth and on the genitals. Cancer of the penis or vulva may first appear as a painless ulcer with raised edges.

genital warts

See *warts, genital*.

genito-urinary medicine

The branch of medicine concerned with *sexually transmitted infections* and their effects on the body.

genome, human

The complete set of human genetic material. The human genome consists of 23 *chromosomes*, which, together, contain about 30,000 *genes*. All cells (except for egg and sperm cells) contain two sets of the 23 chromosomes, one inherited from the father and the other from the mother.

The Human Genome Project, an international research programme, was launched in 1990 with the aim of identifying all the genes in the human body. The project was finally completed in the year 2003.

genotype

The entire genetic makeup of an individual, or group of related individuals, as opposed to the individual's observable characteristics (see *phenotype*). The term is also used to describe the set of

alleles (any of various forms of a *gene*) at a specific location within a *chromosome*; the genetic information carried by alleles determines a particular characteristic of that organism.

gentamicin

An *antibacterial drug* given by injection to treat serious infections such as *meningitis* and *septicaemia* (blood poisoning). Gentamicin can result in damage to the kidneys or the inner ear if the dosage is not carefully controlled.

The drug is also used in various eye and ear-drops but is unlikely to cause serious side effects when taken in these types of preparation.

gentian violet

A purple dye used to make *bacteria* visible under a microscope. Gentian violet was also formerly used as an *antiseptic*.

genu valgum

The medical term for *knock-knee*.

genu varum

The medical term for *bowleg*.

geriatric medicine

The medical speciality concerned with the care of elderly people, also known as "care for the elderly". This group require specialist medical care because they respond to illness and treatment in a different way from younger people. Physical and mental decline due to *aging* can mean that illnesses are more severe in older people, and people may have two or more diseases at once. In addition, the liver and kidneys become less efficient at breaking down and excreting drugs, so drug dosages for elderly people must be carefully controlled to avoid dangerous side effects.

Geriatric medicine relies on an integrated team of health-care workers, including a doctor (or a specialist called a geriatrician), nurse, physiotherapist, and occupational therapist. This team helps older people to maintain independence and health, and to cope after illness or injury. (See also *rehabilitation*.)

germ

The popular term used to describe any microorganism that causes disease, such as *viruses* and *bacteria*.

German measles

The common name for the viral infection *rubella*.

germ cell

An embryonic *cell* with the potential to develop into a *spermatozoon* or *ovum*. The term also describes a *gamete* (mature sex cell) or any cell that is undergoing gametogenesis (the process by which gametes are formed).

germ cell tumour

A growth comprised of immature *sperm* cells in the male *testis* or of immature egg cells (see *ovum*) in the female *ovary*. A *seminoma* is one type of germ cell tumour (see *testis, cancer of*).

gerontology

The study of developmental, biological, medical, psychological, and sociological *aging*. (See also *geriatric medicine*.)

Gerstmann's syndrome

A neurological disorder involving a writing disability such as *agraphia*, together with the inability to understand mathematical calculations, to distinguish right from left, and to identify the fingers (a type of *agnosia*). Many sufferers also experience *aphasia* (complete loss of language skills). The syndrome may occur after a *stroke* or damage to the left parietal lobe of the *brain*, but the precise cause is unknown.

Gerstmann–Straussler syndrome

A rare, inherited type of human *spongiform encephalopathy*, the group of degenerative brain disorders to which Creutzfeldt–Jakob disease belongs. Gerstmann–Straussler syndrome is believed to be caused by infection with a *prion* (slow virus).

The disease is characterized by *ataxia* (loss of balance) and *dementia* and is not usually evident before early adulthood. It progresses more slowly than Creutzfeldt–Jakob disease, but there is no cure, and death usually occurs within three to five years.

Gestalt theory

A school of *psychology* that emphasizes the viewing of personal experiences as a whole rather than breaking them down into collections of stimuli and responses. Gestalt therapy aims to increase self-awareness by looking at all aspects of a person in his or her environment.

gestation

The period that lasts approximately nine months between *conception* and the birth of a human baby; it is the time

during which the infant develops in the *uterus*. (See also *embryo*; *fertilization*; *fetus*; *pregnancy*.)

gestational diabetes

Diabetes mellitus that develops during pregnancy, usually clearing up after delivery (see *diabetic pregnancy*).

gestodene

A *progestogen drug* that is used with the oestrogen drug *ethynodiol* in low-strength combined *oral contraceptives*. Gestodene is reported to carry a slightly increased risk of venous *thromboembolism* (the blockage of a blood vessel by a fragment of a blood clot) in comparison with older drugs.

Ghon's tubercle

An abnormal area in the lung, also known as a Ghon's focus, that is produced by infection with *tuberculosis* in a person who has not previously been exposed to the disease. Often, a Ghon's tubercle heals without causing symptoms, but in some cases it may result in tuberculosis that spreads via the *lymphatic system*, in the bloodstream, or in the air sacs of the lungs. A healed tubercle may become calcified, and may be discovered during a routine *chest X-ray*.

Gianotti–Crosti syndrome

A characteristic, harmless response of the skin to certain viral infections, including *hepatitis B* infection, *Epstein Barr virus* (see *mononucleosis, infectious*), and *coxsackievirus*. In this condition, a papular (lumpy) rash develops on the face, buttocks, and limbs and lasts for several weeks. The condition mainly affects children between the ages of six months and twelve years.

SYMPTOMS AND SIGNS

There may be no noticeable symptoms. Alternatively, there may be a mild temperature, and swelling of the *lymph nodes* in the armpits and groin that persists for some months. The liver may become enlarged.

DIAGNOSIS AND TREATMENT

Blood tests and *liver function tests* are carried out to investigate liver function and detect possible causative viruses. There is no specific treatment, but a mild, topical *corticosteroid* cream may be prescribed for itching. The rash usually fades in two to eight weeks.

giant cell arteritis

An alternative name for *temporal arteritis*.

giardiasis

An infection of the small intestine caused by the *protozoan* (single-celled) parasite *GIARDIA LAMBLIA*. Giardiasis is spread by eating or drinking contaminated food or water or through direct contact with an infected person.

SYMPOTMS

Most of those infected have no symptoms. If, however, symptoms do occur, they begin between one and three weeks after infection. They include diarrhoea, and wind, as well as faeces that are foul-smelling, greasy, and tend to float in the toilet. Abdominal discomfort, cramps, and swelling, loss of appetite, and nausea may also occur. In some cases, giardiasis may become *chronic*.

DIAGNOSIS AND TREATMENT

The infection is diagnosed from microscopic examination of a faecal sample or by a *jejunal biopsy* (removal of a small sample of tissue from the middle section of the small intestine for analysis).

Acute giardiasis usually clears up without treatment but the drug *metronidazole* quickly relieves symptoms and helps to prevent the spread of infection. Infection can be prevented in the first place by avoiding food or water that could possibly be contaminated.

gibbous

A term meaning "humped", as in a gibbous spine, which curves outwards (see *kyphosis*). A deformity called a gibbus (an extreme hunch in the back) was once a common condition caused by *tuberculosis* of the spine.

giddiness

See *dizziness*.

GIFT

See *gamete intrafallopian transfer*.

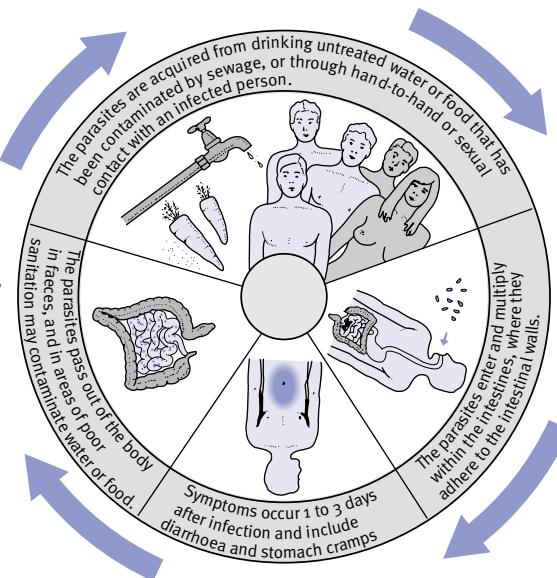

gigantism

Excessive growth (especially in height) during childhood or adolescence that results from overproduction of *growth hormone* by a tumour of the pituitary gland (see *pituitary tumours*). If untreated, the tumour may compress other hormone-producing cells in the gland, causing symptoms of hormone deficiency (see *hypopituitarism*).

People with gigantism may be treated with a drug that blocks the release of growth hormone, such as *bromocriptine*, or they may have to have surgery or *radiotherapy* to remove or destroy the pituitary tumour. (See also *acromegaly*.)

HOW GIARIDIASIS IS SPREAD

Giardiasis is spread by contaminated water or food, or by personal contact. This parasitic infection is most common in the tropics, but it has become a more frequent occurrence in developed countries, especially among groups of preschool children.

Gilbert's disease

A common inherited condition that affects the way in which *bilirubin* is processed by the *liver*. Usually there are no symptoms, but *jaundice* may be brought on by unrelated illnesses. Sufferers are otherwise healthy and no treatment is necessary.

Gilles de la Tourette's syndrome

A rare, inherited neurological disorder that is transmitted by an autosomal dominant gene (see *genetic disorders*).

Gilles de la Tourette's syndrome is more common in males and starts in childhood with repetitive grimaces and tics. Involuntary barks, grunts, or other noises may appear as the disease progresses. In some cases, the sufferer has episodes of compulsively using foul language (a condition called coprolalia).

People with Tourette's syndrome usually have it their whole lives; in some sufferers *antipsychotic drugs* may help to relieve some of the symptoms.

gingiva

The Latin name for the *gums*.

gingival hyperplasia

See *hyperplasia, gingival*.

gingival pocket

A feature of chronic *periodontitis*.

gingivectomy

The surgical removal of part of the *gum* margin. Gingivectomy may be used to treat severe cases of gingival *hyperplasia* (thickening of the gums) or to remove pockets of infected gum in advanced cases of *periodontitis* (gum disease). Gingivectomy is usually performed by a dentist under local anaesthesia.

gingivitis

Inflammation of the *gums*. Gingivitis is usually due to a build-up of *plaque* around the base of the teeth. *Toxins* produced by bacteria in the plaque irritate the gums, causing them to become infected, swollen, tender, and reddish-purple in colour. Gingivitis may also result from injury to the gums, usually through rough toothbrushing or flossing. Pregnant women and people with *diabetes mellitus* are especially susceptible to the disorder.

Gingivitis can be reversed; good *oral hygiene* is the main method of preventing and treating it. If left untreated, however, it may lead to damage of the gum tissue, which may in turn lead to chronic *periodontitis* (an advanced stage of gum disease). Acute ulcerative gingivitis (see *gingivitis, acute ulcerative*) may develop in people who have chronic gingivitis, particularly those with a lowered resistance to infection.

gingivitis, acute ulcerative

Painful infection and ulceration of the **gums**. Acute ulcerative gingivitis is uncommon, primarily affecting people aged between 15 and 35. It is caused by abnormal overgrowth of bacteria that usually exist harmlessly in small numbers in gum crevices. Predisposing factors include poor *oral hygiene*, smoking, throat infections, and *stress*. In many cases, the disorder is preceded by *gingivitis* or *periodontitis*.

The gums become sore and bleed easily. Crater-like ulcers, which bleed spontaneously, develop on the gum tips between teeth. There may be a foul taste in the mouth, bad breath, and swollen lymph nodes (see *glands, swollen*). The infection may spread to the lips and the insides of the cheeks (see *noma*).

A *hydrogen peroxide* mouthwash can relieve the inflammation. *Scaling* is then performed to remove plaque. In severe cases, the antibacterial drug *metronidazole* may be given to control infection.

**Example of gingivitis**

The gums around the bases of the upper teeth are puffy, shiny, and tender and overhang the teeth margins. Affected gums often bleed when brushed.

gingivostomatitis

Inflammation of the gums and mouth. Gingivostomatitis is often due to a viral infection, particularly *herpes simplex*. The condition can also be due to a bacterial infection or an adverse reaction to a prescribed drug. (See also *cold sore*.)

ginkgo

An extract from the maidenhair tree, *GINKGO BILOBA*. Preparations containing ginkgo are claimed to help treat circulatory disorders, reduced circulation in the brain, *senility*, *depression*, and *premenstrual syndrome*. Possible side effects include muscle spasms and cramps.

gland

A group of specialized *cells* that manufacture and release chemical substances, such as *hormones* and *enzymes*.

There are two main types of gland: endocrine and exocrine. *Endocrine glands* do not have ducts and release their secretions directly into the bloodstream; examples include the pituitary, thyroid, and adrenal glands. *Exocrine glands* have ducts and release their secretions to the surface or interior of the body. Examples include the sebaceous glands, which secrete sebum on to the surface of the skin, and the salivary glands, which secrete saliva into the mouth. The pancreas releases endocrine and exocrine secretions (for example *insulin* and *cholecystokinin*, respectively).

Lymph nodes are sometimes called glands, particularly when they are enlarged due to infection (see *glands, swollen*). Strictly speaking, this is incorrect usage because lymph nodes do not secrete chemicals.

glanders

An infection of horses caused by the bacterium *PSEUDOMONAS MALLEI*. It rarely affects humans. Symptoms include fever and general aches and pains. Skin ulcers may develop and, if bacteria enter the lungs, *pneumonia* may occur. In severe cases, *septicaemia* (blood poisoning) may follow. Treatment is with *antibiotics*.

glands, swollen

Enlargement of the *lymph nodes* (which are commonly called "glands"), due to inflammation and/or proliferation of white blood cells within them. Swollen lymph nodes are a common symptom, especially in children. They are usually caused by a minor infection or an allergic reaction (see *allergy*).

Rare causes include cancer affecting the lymph nodes (see *Hodgkin's disease*; *lymphoma*) or cancer of the white blood cells (see *leukaemia*).

glandular fever

See *mononucleosis, infectious*.

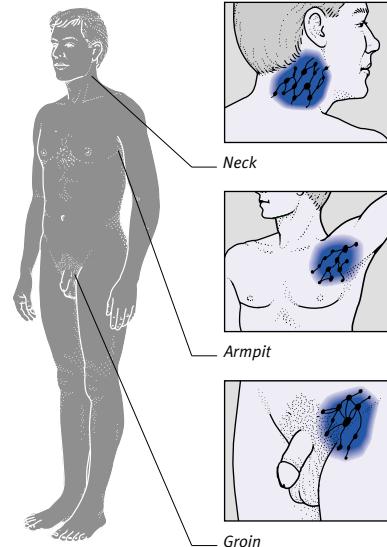

glans

The head of the *penis*. The glans is covered by a loose fold of skin called the *prepuce* (foreskin), which retracts when the penis becomes erect; in some males, this skin is removed by *circumcision*.

The term "glans" may also be applied to the tip of the *clitoris* in females.

Glanzmann–Riniker syndrome

A severe, inherited *immunodeficiency disorder* (failure of the body's *immune system* to fight infection). The condition

**Common sites of swollen glands**

The three most common sites where swollen lymph nodes (glands) can be felt are in the neck, armpit, and groin.

is more common in males. Inheritance is either autosomal recessive or X-linked (see *genetic disorders*).

In Glanzmann–Riniker syndrome, the blood contains virtually no B-lymphocytes (a type of *white blood cell*) and, as a result, *antibodies* (proteins produced by B-lymphocytes to destroy invading microorganisms) fail to form.

The condition is evident from early infancy, when an affected child fails to thrive. It is characterized by absence of the *thymus* (a gland that forms part of the immune system) and susceptibility to bacterial, and viral infections. Symptoms and signs include watery diarrhoea and lung abscesses. Children do not normally survive beyond the first two years of life.

glare

The discomfort that results from bright light entering the field of vision (see *eye*) either directly or by reflection from another surface, such as a computer screen or a stretch of water. The light hits the *retina* and reduces central vision.

glasses

Devices, worn on the face, that contain lenses to correct focusing errors in the eyes and thereby achieve clear vision.

Lenses are made of glass or plastic, and the shape and thickness of a lens are chosen during a *vision test*. Convex lenses (which curve outwards) are needed for *hypermetropia*, or longsightedness, and

concave lenses (which curve inwards) for *myopia*, or shortsightedness (see *Why glasses are used* box, right). Most lenses are single-vision, but bifocal, trifocal, and varifocal lenses are becoming popular. Tinted lenses protect the eyes from sunlight. (See also *bifocal; contact lenses*.)

glass eye

See *eye, artificial*.

glass test

A test for *meningitis* that involves pressing a clear glass against a rash. If the rash remains visible through the glass, it may be a form of *purpura* (leaking of blood beneath the skin), which sometimes occurs in meningitis.

glaucoma

A condition in which the *intraocular pressure* (fluid pressure inside the eyes) causes impaired vision. *Aqueous humour* (watery fluid) is secreted into the front of the eye by the *ciliary body* (a structure behind the *iris*) to maintain the eye's shape and nourish the tissues. Excess fluid drains away at the edge of the iris. In glaucoma, however, this excess fluid may not be able to escape. It causes compression and obstruction of the blood vessels that supply the *retina* and the *optic nerve*. This, in turn, may destroy nerve fibres and cause gradual loss of vision.

TYPES, CAUSES, AND SYMPTOMS

The most common form of glaucoma is chronic simple (open-angle) glaucoma. It rarely occurs before the age of 40, and tends to run in families. In this condition, the outflow of aqueous humour is gradually blocked over a period of years, causing a slow rise in pressure. There are often no symptoms until visual loss is advanced.

In acute (closed-angle) glaucoma, the outflow of aqueous humour is rapidly blocked, and the pressure rises suddenly. This may cause a severe, dull pain in and above the eye, fogginess of vision, and the perception of haloes around lights at night. Nausea and vomiting may occur, and the eye may become red with a dilated pupil.

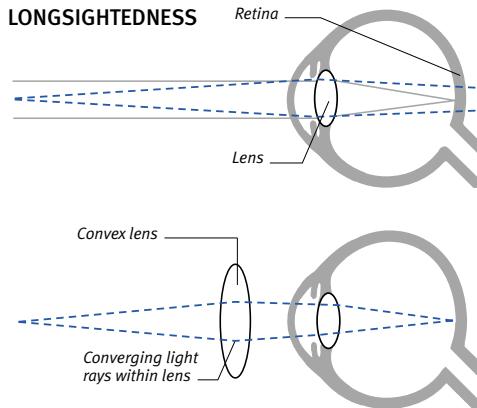

Congenital glaucoma is due to an abnormality in the drainage angles of the eyes that develops before birth. Glaucoma can also be caused by injury or an eye disease such as *uveitis* or *lens dislocation*.

A less common form, called normal-pressure or low-tension glaucoma, occurs in people whose intraocular pressure is normal or only slightly raised but causes

WHY GLASSES ARE USED

Glasses compensate for certain visual defects in which the lens of the eye does not focus light correctly on to the retina, at the back of the eyeball. For *hypermetropia* (longsightedness) or *presbyopia*, convex (or plus) lenses are needed. *Myopia* (shortsightedness) requires concave (or minus) lenses.

LONGSIGHTEDNESS

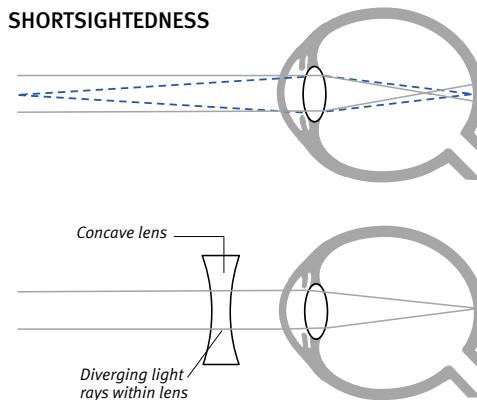

Before correction

Longsightedness occurs when focusing power is inadequate. Light from distant objects is focused on to the retina, but light from close objects is focused behind it.

After correction

Convex magnifying (or plus) lenses cause light rays to converge (bend together). As a result, they focus the light from close objects correctly on to the retina.

SHORTSIGHTEDNESS

Before correction

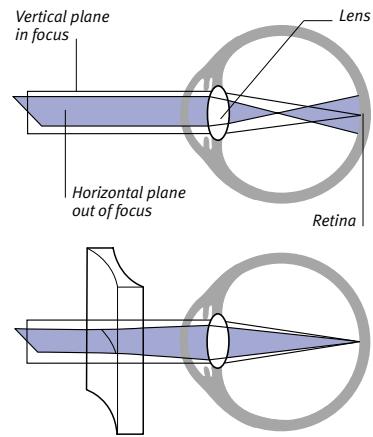

The focusing power of the eye is too great. Light from close objects is focused correctly; however, light from distant objects is focused in front of the retina, and the objects appear blurred.

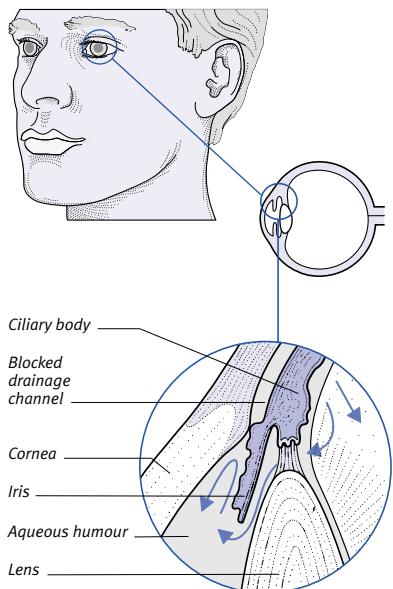

After correction

Concave weakening (or minus) lenses cause light rays to diverge (bend apart). As a result, they focus the light from distant objects correctly on to the retina.

ASTIGMATISM

In astigmatism, the surfaces of the cornea, rather than being a hemisphere as normal, are steeper in one direction than in the others; as a result, the light rays in one meridian (plane) are out of focus. Lenses to correct astigmatism are designed with additional curvature in one meridian, then set accurately in the frame of the glasses so that the steepest curves correspond to the flattest meridian of the cornea. As a result, they cancel out the effects of the distortion in the cornea. Both concave and convex lenses can be designed to correct astigmatism.

**Acute closed-angle glaucoma**

This type of glaucoma is caused by an unduly narrow angle between the iris and the back of the peripheral cornea. Dilatation of the pupil may therefore lead to a sudden complete blockage of the outflow, which, in turn, causes a rapid increase in pressure in the eyeball.

the same damage to the retina and optic nerve as excessively high fluid pressure. This condition is not well understood; and it seems that the pressure, although not considered to be excessive, is too high for the tissues to withstand, and thus causes damage.

DIAGNOSIS AND TREATMENT

Tonometry is used to check for glaucoma by measuring the pressure within the eye. **Ophthalmoscopy** may show depression of the head of the optic nerve due to the increase in pressure. Tests of the **visual field** will be needed to assess whether vision has already been damaged, because longstanding or severe glaucoma can result in loss of peripheral vision (see *tunnel vision*). Prompt treatment is essential to prevent permanent loss of vision.

Chronic simple glaucoma can usually be controlled with eye-drops, such as *timolol*, or tablets that reduce pressure in the eye. Treatment needs to be continued for life. If drugs are ineffective, surgery or *laser treatment* can unblock the drainage channel at the edge of the iris or create an artificial channel.

Acute glaucoma requires emergency drug treatment, often in hospital. Surgery or laser treatment may be needed in order to prevent a further attack. The

usual procedure is *iridectomy*, in which a small opening is made at the edge of the iris so that aqueous humour can drain more easily.

Treatment for normal-pressure glaucoma is the same as for open-angle glaucoma, but is aimed at reducing the intraocular pressure to an even lower level than normal.

Gleason's score

A system of grading prostate cancer cells (see *prostate, cancer of*) to determine the most appropriate treatment and the patient's outlook.

Several tissue samples are taken and are assigned a score between 1 and 5. The lowest and highest scores are added together to give the Gleason's score, which is a number between 1 and 10. A low Gleason's score indicates that the cancer cells are very similar to normal prostate cells; a high score means that the cancer cells are very different. In general, the more the cancerous cells diverge from the normal prostate cells, the more serious the cancer.

The Gleason's score is often used in conjunction with a measure called the TNM classification, which defines the extent to which a cancer has spread.

glenoid

A term meaning "resembling a pit or socket". For example, the glenoid fossa (depression) is the cavity at the top of the scapula (shoulderblade) into which the head of the humerus (the bone of the upper arm) fits.

glibenclamide

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) used to treat type 2 (non-insulin dependent) *diabetes mellitus*. In this form of diabetes, body cells are resistant to the action of the hormone *insulin*, and absorb insufficient glucose. The drug causes the pancreas to increase insulin secretion thereby compensating for the resistance.

gliclazide

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) used to treat type 2 *diabetes mellitus* along with dieting. The drug causes the pancreas to increase insulin secretion. Side effects are mild.

glimepiride

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) used to treat type 2 *diabetes mellitus*. The drug causes the

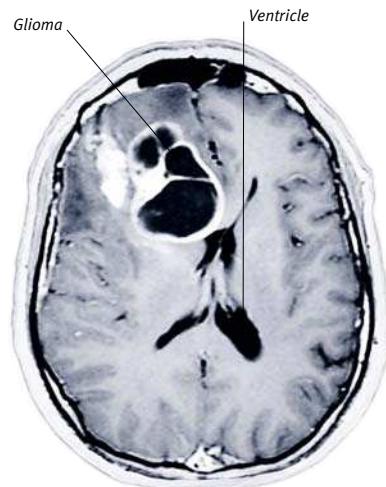

pancreas to increase insulin secretion. Side effects are infrequent but may include mild nausea and diarrhoea. Low blood sugar (see *hypoglycaemia*) may occur if the drug is not taken with sufficient food.

glioblastoma multiforme

A fast-growing and highly cancerous type of primary *brain tumour*. Glioblastoma multiforme is a type of *glioma* that often develops in the *cerebrum* (the main mass of the brain). The cause is unknown. Treatment of glioblastoma multiforme may include surgery, *radiotherapy*, and/or *chemotherapy*.

glioma

A type of *brain tumour* arising from connective tissue (glial cells) in the brain. Types of glioma include *astrocytoma*, *glioblastoma multiforme*, *ependymoma*, *medulloblastoma*, and *oligodendrogioma*. Symptoms, diagnosis, and treatment are as for other types of brain tumour.

**Brain scan of a glioma**

In this scan, taken from below, a glioma (a type of brain tumour) is visible as a dark area in the right hemisphere (on the left of the image).

glipizide

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) used to treat type 2 *diabetes mellitus*. Glipizide acts by stimulating the pancreas into increasing its production of *insulin*. Side effects are usually mild and infrequent, but dizziness and drowsiness may occur. Rarely, glipizide can cause an abnormal reaction of the skin to sunlight and can reduce blood sodium levels. Low blood sugar (see *hypoglycaemia*) may occur if the drug is not taken with sufficient food.

global

A term used of a disorder affecting an entire body function or system. For example, global aphasia (see *aphasia*) is the loss of all ability to speak, write, or understand language; global paralysis is extreme weakness of the muscles in every part of the body, which may result in a complete inability to move.

globin

The protein that combines with certain iron-containing compounds to form the oxygen-carrying pigments *haemoglobin*, which is found in *red blood cells*, and *myoglobin*, which is present in muscle.

globulin

Any of a group of proteins that are insoluble in water but soluble in dilute salt solutions. There are many globulins in the blood, including *immunoglobulins* (also called antibodies).

globus hystericus

A condition in which there is an uncomfortable feeling of a “lump in the throat”. This lump is felt to interfere with swallowing and breathing; however, there is no physical basis for the condition. In severe cases, *hyperventilation* (rapid breathing) and symptoms of a *panic attack* ensue.

Globus hystericus occurs most commonly in people who are anxious or depressed. Treatment is by reassurance, breath-control training, or *psychotherapy*.

glomerulonephritis

Inflammation of the filtering units (see *glomerulus*) in both kidneys. Damage to the glomeruli hampers the removal of waste products, salt, and water from the bloodstream, which may cause serious complications. This condition occurs worldwide; in the US and Europe, it is one of the most common causes of chronic *kidney failure*.

CAUSES

Some types of glomerulonephritis are caused by the *immune system* making *antibodies* to eliminate microorganisms (usually infectious bacteria, such as those that cause *streptococcal infections* of the throat). The antibodies combine with bacterial *antigens* to form particles called immune complexes. These particles circulate in the bloodstream and become trapped in the glomeruli, triggering an inflammatory process that may damage the glomeruli and prevent them from working normally.

Glomerulonephritis also occurs in certain *autoimmune disorders*, such as systemic *lupus erythematosus*. Infectious diseases such as *malaria* and *schistosomiasis* are causes in tropical countries.

SYMPTOMS

Mild glomerulonephritis may cause no symptoms, and it may only be discovered during routine urine testing; alternatively, the condition may remain undetected until the kidney damage has reached an advanced stage and accumulated waste products have started to produce symptoms.

Some people develop symptoms suddenly. They may experience a dull ache over the kidneys. The urine may become bloodstained because when damaged the glomeruli allow red blood cells to escape into the urine. Protein may also be lost into the urine, causing *oedema* (see *nephrotic syndrome*); this is a common condition in affected children. *Hypertension* (high blood pressure) is a potentially serious complication. Long-term glomerulonephritis is a common cause of chronic kidney failure.

DIAGNOSIS AND TREATMENT

Diagnosis involves *kidney function tests*, *urinalysis* (the microscopic and chemical

analysis of urine), and, in most cases, *kidney biopsy* (removal of a small tissue sample for microscopic analysis).

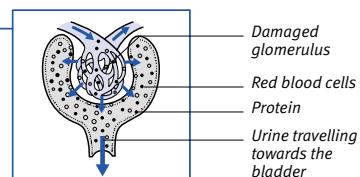

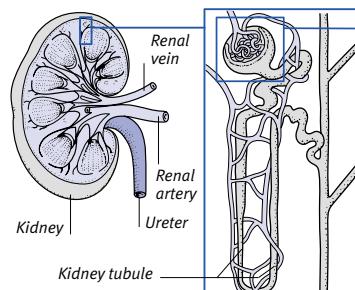

Treatment for glomerulonephritis is usually given in hospital, and depends on the cause and the severity of the disease. Children with nephrotic syndrome usually respond to *corticosteroid drugs*. Glomerulonephritis caused by a streptococcal infection usually clears up after the infection is successfully treated with *antibiotic drugs*.

Adults tend to respond less well to treatment, but kidney failure may sometimes be prevented or delayed. Drugs may be prescribed to control hypertension, and a special diet may be given to reduce the workload on the kidneys. Temporary *dialysis* may be necessary to help remove waste products from the blood, and *diuretic drugs* may be given to help treat any oedema.

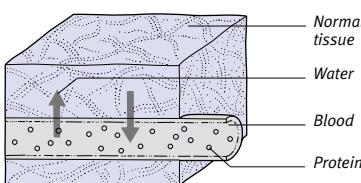

A few people with severe glomerulonephritis respond to treatment with *immunosuppressant drugs* (which reduce the activity of the immune system); others may undergo *plasmapheresis* (a procedure that removes immune complexes and other harmful substances from the bloodstream).

THE EFFECTS OF GLOMERULONEPHRITIS

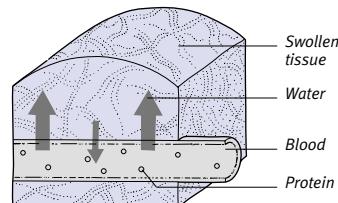

Normally, the glomeruli retain red cells and protein molecules in the blood while filtering out salts and waste. If they are damaged, however, they allow blood cells and protein to leak into the urine, causing characteristic symptoms.

Cross-section of a damaged glomerulus
Damage to the tiny blood vessels of the glomerulus causes red blood cells and protein to pass into the urine. As a result, the urine may be bloodstained.

Healthy tissue
Through osmosis, protein molecules in the blood draw back water that has been lost to surrounding tissues.

Oedema
If protein is lost into the urine, there is a fall in osmotic pressure and more water escapes into surrounding tissues, causing swelling.

glomerulosclerosis

Scarring caused by damage to the glomeruli (see *glomerulus*), the filtering units of the kidney.

Mild glomerulosclerosis occurs as a normal part of the aging process. The condition may also occur in some severe types of *glomerulonephritis*. In addition, it may be associated with *diabetes mellitus*, *hypertension* (high blood pressure), *AIDS*, or intravenous *drug abuse*.

glomerulus

A filtering unit in the *kidney*. Each glomerulus consists of a cluster of capillaries (tiny blood vessels) enclosed in a capsule and supplied with blood from the renal artery; it forms part of a larger filtering unit called a *nephron*. Filtered blood eventually leaves the kidney via the renal vein. (See also *glomerulonephritis*; *glomerulosclerosis*.)

glomus tumour

A small, bluish swelling in the skin, usually on a finger or toe near or under the nail. The swelling feels tender and is more painful if the limb is hot or cold. Glomus tumours are caused by an overgrowth of the nerve structures that normally control blood flow and temperature in the skin. They are harmless but can be surgically removed.

glossectomy

Removal of all or part of the *tongue*. Glossectomy may be performed to treat *tongue cancer*. If a large part of the tongue is removed, speech is impaired and eating is difficult.

glossitis

Inflammation of the *tongue*. The tongue feels sore and swollen and looks red and smooth; adjacent parts of the mouth may also be inflamed.

Glossitis occurs in various forms of *anaemia* and in *vitamin B* deficiency. Other causes include infection of the mouth (especially by *herpes simplex*), irritation by dentures, and excessive use of alcohol, tobacco, or spices.

Treatment is for the underlying cause. Rinsing of the mouth with a salt solution and good *oral hygiene* may help to relieve the soreness.

glossodynia

A painful, burning sensation in the *tongue*, often with no known cause. Glossodynia tends to disappear of its own accord over time.

glossolalia

Speaking in an imaginary language that has no actual meaning or syntax. (See also *neologism*.)

glossopharyngeal nerve

The ninth *cranial nerve*. This nerve supplies the tongue and the throat, and performs both sensory and motor functions. It conveys sensations, especially taste, from the back of the *tongue*, regulates the secretion of saliva by the *parotid gland*, and controls movement of the throat muscles.

glottis

The part of the *larynx* (voice-box) that consists of the *vocal cords* and the slit-like opening between them.

glucagon

A *hormone* that stimulates the breakdown of stored *glycogen* into *glucose* (a simple sugar). Glucagon is released by the *pancreas* when the blood level of glucose is low (see *feedback*).

Glucagon is used as an injected drug in the emergency treatment of people with *diabetes mellitus* who are unconscious as a result of *hypoglycaemia* (low blood glucose). Nausea and vomiting are occasional adverse effects.

glucagonoma

A tumour of the *pancreas* that secretes *glucagon* (the hormone responsible for raising blood sugar levels). Glucagonomas, which can be cancerous or noncancerous, may lead to attacks of *hyperglycaemia* (high blood glucose) due to excess glucagon production.

glucocorticoids

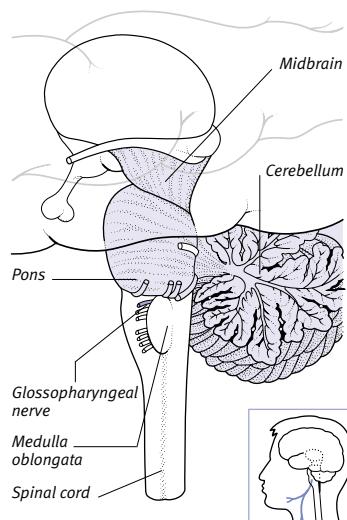

A group of *corticosteroid hormones*, produced by the cortex (outer layer) of the *adrenal glands*, that affect the chemical breakdown of *carbohydrates* by increasing both the blood sugar level and the amount of *glycogen* stored in the liver. Glucocorticoids also enable the body to respond effectively to physical stress. Both natural and synthetic glucocorticoids are used to treat inflammatory conditions (see *corticosteroid drugs*). The main glucocorticoid is *hydrocortisone*, also called cortisol.

gluconeogenesis

A process in which *glucose* (a simple sugar) is synthesized from sources other than *carbohydrates*, such as *amino acids* and *glycerol*. The process, which

LOCATION OF THE GLOSSOPHARYNGEAL NERVE

The nerve arises from the medulla oblongata and branches to the lower jaw and the throat.

occurs mainly in the *liver* and muscles, is an important source of energy when insufficient amounts of carbohydrate are available (for example, between meals or when a person is fasting).

glucosamine

A molecule that occurs naturally as a component of various substances in the body, including *cartilage* and *collagen*. Glucosamine is also sold as a food supplement and is recommended to relieve symptoms of *arthritis*.

glucose

A simple *sugar* (monosaccharide) that is naturally present in fruits and is also a product of the digestion of *starch* and *sucrose*. Glucose is the chief source of energy for the body and is carried to all tissues in the circulation. (The term "blood sugar" refers to levels of glucose in the bloodstream.)

The level of glucose in the blood is normally kept fairly constant by the actions of various *hormones*, notably *insulin*, *glucagon*, *adrenaline*, *corticosteroid hormones*, and *growth hormone*. An abnormally high level of glucose in the blood (known as *hyperglycaemia*) may cause glucose to be lost into the urine. An abnormally low blood glucose level is called *hypoglycaemia*.

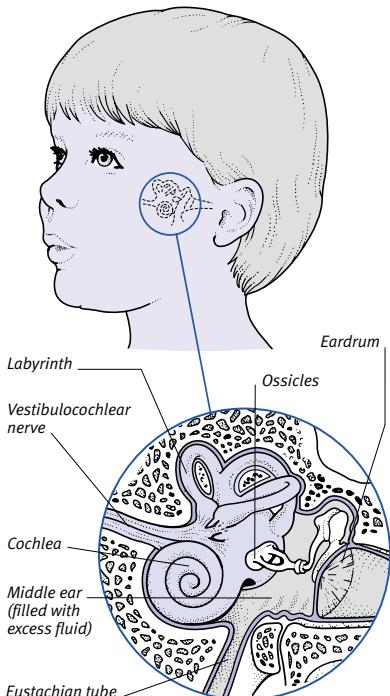

glue ear

Accumulation of fluid in the cavity of the *middle ear*, causing impaired hearing. Persistent glue ear is most common in children. It is often accompanied by enlarged *adenoids* and frequently occurs with viral respiratory tract infections, such as the common *cold*. It is usual for both ears to be affected.

In glue ear, the lining of the middle ear becomes overactive, producing large amounts of a sticky fluid, and the *eustachian tube* (which links the middle ear to the back of the nose and throat) becomes blocked so that the fluid cannot drain away. The accumulated fluid interferes with the movement of the delicate bones of the middle ear.

Glue ear is sometimes first detected by *hearing tests*. Examination with an *otoscope* (viewing instrument) can confirm the diagnosis.

Mild cases of the condition often clear up without specific treatment. If symptoms persist, the insertion of *grommets* (small tubes) may be necessary, which allows air into the middle ear and encourages fluid to drain away. *Adenoidectomy* (removal of the adenoids) may also be required.

Effects of glue ear

In this condition, sticky fluid in the middle ear prevents free movement of the eardrum and ossicles, causing deafness.

glue-sniffing

See *solvent abuse*.

glutaraldehyde

A topical (applied to the skin) preparation for the treatment of *warts*, especially *plantar warts* (*verrucas*). Glutaraldehyde may cause a rash or irritation and may stain the skin brown.

gluteal

A term meaning "relating to the buttocks", as in the gluteal muscles.

gluten

A combination of gliadins and glutenins (types of proteins) present in wheat, rye, and barley. Mixed with water, flours containing gluten become sticky and trap air, thus forming dough. Sensitivity to gluten causes *coeliac disease*.

gluten enteropathy

See *coeliac disease*.

gluten intolerance

See *coeliac disease*.

gluteus maximus

The large, powerful *muscle* in each of the buttocks that gives them their rounded shape. The gluteus maximus is responsible for moving the thigh sideways and backwards.

glycerol

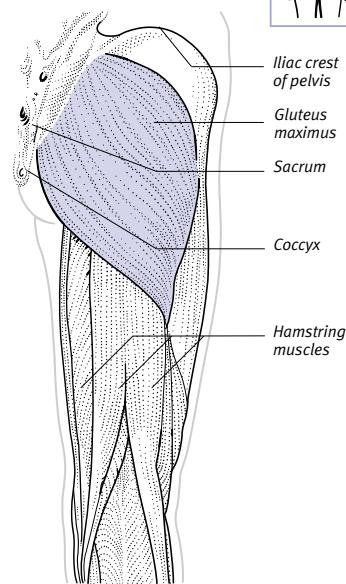

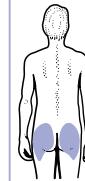

A colourless, syrupy liquid that has a sweet taste. Glycerol is an essential constituent of *triglycerides* (simple fats) in the body. It may also be prepared commercially from *fats and oils*. Glycerol is added to moisturizing creams to help prevent dryness and cracking of the skin. It is also used in eardrops to help soften earwax, and in *cough remedies* to help soothe a dry, irritating cough. Furthermore, glycerol is added to rectal *suppositories*; it relieves *constipation* by softening hard faeces.

glyceryl trinitrate

A *vasodilator drug* used for the treatment and prevention of symptoms of *angina pectoris* (chest pain due to inadequate blood supply to the heart). *Sublingual* or *buccal* sprays and tablets are available for rapid pain relief and slow-release tablets or skin patches for sustained pain relief. The drug is sometimes prescribed to treat anal fissures but is not licenced for this use. High doses may cause headaches, flushing, and dizziness.

LOCATION OF THE GLUTEUS MAXIMUS

The top of the muscle is attached to the sacrum, coccyx, and pelvis. The lower part is attached to the femur (thigh bone).

glycogen

The main form of *carbohydrate* stored in the body. Glycogen is a polysaccharide, consisting of chains of *glucose* molecules, and is found mainly in the liver and in muscles.

When there is excess glucose in the blood, it is converted to glycogen by the action of *insulin* and *glucocorticoids* (a class of *corticosteroid hormones*). When the blood glucose level is low, glycogen is converted back to glucose (regulated by *adrenaline* and *glucagon*) and released into the bloodstream.

glycogen storage diseases

A group of rare *genetic disorders* characterized by an absence or deficiency of certain *enzymes* (proteins that act as catalysts) responsible for the metabolism of *glycogen*. These enzyme defects may lead to abnormal concentrations of glycogen in the tissues, insufficient *glucose* (a simple sugar) in the blood, or the inability of the body to use glucose as energy. Also known as *glycogenoses* or *GSDs*, these diseases may affect the liver, the muscles, or both.

TYPES AND CAUSES

There are several types of GSD. One is glycogen storage disease type I. This condition is caused by a defect in glucose-6-phosphatase, an enzyme that aids *gluconeogenesis* in the liver. The majority of GSDs have an autosomal recessive pattern of inheritance: they occur when a child inherits the affected gene from parents who are carriers.

SYMPOMTS AND SIGNS

These features vary according to the particular type of GSD. Symptoms and signs may include failure to grow normally during childhood; muscle cramps and wasting; an enlarged liver; and low blood glucose levels.

DIAGNOSIS, TREATMENT, AND OUTLOOK

Diagnosis may involve biochemical tests (see *biochemistry*) on tissue samples from a muscle or a liver *biopsy*.

Some types of GSD can be controlled by management of symptoms, including by diet control. In certain cases a *liver transplant* is an option, but in other cases no treatment is possible and death occurs in the first few years of life.

glycosuria

The presence of *glucose* in the urine. Glycosuria results from failure of the kidneys to reabsorb glucose back into the bloodstream after the blood has been filtered to remove waste products.

Failure to reabsorb sufficient glucose may be due to *hyperglycaemia* (an abnormally high blood glucose level), as in *diabetes mellitus*. It may also occur if the kidney tubules have been damaged (for example, through drug poisoning) and thus cannot reabsorb even normal amounts. In addition, glycosuria may occur during pregnancy, but is usually not serious provided that the blood glucose level is normal and there are no other symptoms.

Glycosuria is diagnosed by testing the urine (see *urinalysis*). The treatment depends on the cause.

glycosylated haemoglobin

A form of *haemoglobin* that is bound to the sugar glucose. In most people, between three and eight per cent of haemoglobin is glycosylated. In people with *diabetes mellitus*, the level of glycosylated haemoglobin may be raised if treatment has not kept the blood glucose level within the normal range.

Glycosylated haemoglobin levels indicate blood glucose levels over the preceding three months.

GM foods

See *genetically modified foods*.

gnathic

Pertaining to the *jaw*, as in gnathitis (inflammation of the jaw).

goitre

Enlargement of the *thyroid gland*, visible as a swelling at the base of the neck.

CAUSES

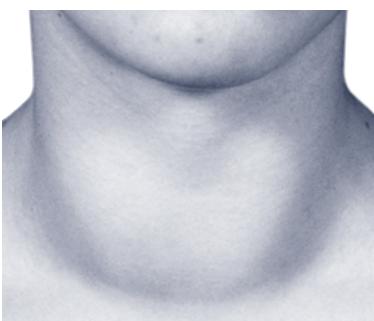

The thyroid gland may enlarge (without any disturbance of its function) at *puberty*, during pregnancy, or in women taking *oral contraceptives*. In many parts of the world the main cause of a goitre is a dietary deficiency of *iodine*, an element that the thyroid needs in order to produce thyroid hormone. This form of the condition is called *endemic goitre*.

A condition called toxic goitre develops as a result of *thyrotoxicosis* in *Graves' disease* and in certain other forms of *hyperthyroidism* (overactivity of the thyroid gland). A goitre is also a feature of different types of *thyroiditis* (inflammation of the thyroid gland), including *Hashimoto's thyroiditis* and *De Quervain's thyroiditis*. Other causes include a tumour or nodule in the gland and, in rare cases, *thyroid cancer*.

There are also various types of familial goitre. This kind of goitre is caused by an inherited thyroid disorder; it appears during childhood and is often associated with signs of *hypothyroidism*, such as learning difficulties.

SYMPOMTS

A goitre can range in size from a barely noticeable lump to a large swelling, depending on the cause. Large goitres may press on the *oesophagus* or the *trachea* and therefore make swallowing or breathing difficult.

Appearance of goitre

The thyroid gland can become enlarged for a variety of reasons, including dietary deficiency of iodine, inflammation, or an autoimmune disorder affecting the gland.

DIAGNOSIS AND TREATMENT

Diagnosis may involve various *thyroid-function tests*, including blood tests and *radionuclide scanning*, to determine the activity of the thyroid gland.

A goitre that is not due to disease may eventually disappear of its own accord. Goitre due to iodine deficiency can be treated by iodine-rich foods. When a goitre is the result of disease, treatment is for the underlying disorder. Large goitres can be surgically removed (see *thyroidectomy*).

gold

A precious metal. Certain compounds containing gold are used to treat severe *rheumatoid arthritis* and, occasionally, arthritis arising as a complication of *psoriasis* (see *disease-modifying antirheumatic drugs*).

Gold is used in a form called sodium aurothiomalate, given as intramuscular injections, or is taken orally (see *auranofin*). A common adverse effect of gold treatment is *dermatitis* (skin inflammation). Gold may result in damage to the kidneys, liver, and bone marrow and may also cause loss of appetite, nausea, and diarrhoea.

Goldberg–Maxwell syndrome

A common form of male pseudohermaphroditism (a biological *intersex* condition in which the external genitalia of a genetic male resemble those of a female). Affected individuals have testes but have a small penis and a divided scrotum that resembles labia. (See also *sex determination*.)

Goldenhar's syndrome

A rare, *congenital* type of *dysplasia* (growth abnormality) in which the head and face fail to develop normally before birth. Common features include missing or abnormally developed ears and malformations of the jaw, mouth, palate, eyes, and vertebrae.

golfer's elbow

A condition caused by overuse of the forearm muscles that bend the wrist and fingers, usually due to activities such as using a screwdriver or playing golf with a faulty grip. The injury leads to inflammation of the *epicondyle* (bony prominence) on the inner part of the elbow, where the affected muscles are attached. Symptoms include pain and tenderness of the elbow and sometimes also the forearm.

Treatment consists of resting the elbow, applying *ice-packs*, and taking *analgesic drugs* (painkillers). Severe or persistent pain may be relieved by local injections of a *corticosteroid drug*.

gonadal dysgenesis

Defective development of the *gonads* (the testes and ovaries). Gonadal dysgenesis is a feature of *Turner's syndrome*.

gonadorelin

A medicinal version of gonadotrophin-releasing hormone (GnRH), which is naturally released by the *hypothalamus*. GnRH stimulates the nearby pituitary gland to secrete the two *gonadotrophin hormones* follicle-stimulating hormone (FSH) and luteinizing hormone (LH).

Gonadorelin can be given by injection. It is used to investigate suspected disease of the hypothalamus.

Gonadorelin analogues are synthesized forms of, and closely resemble, gonadorelin. They cause the hypothalamus to release less GnRH, and this effect leads to a reduction in the levels of FSH and LH. Gonadorelin analogues are used to counter the effects of natural hormones during gonadorelin treatment of *infertility*. The drugs are also used to treat *endometriosis* and hormone-dependent cancers including *breast cancer* and *prostate cancer*.

gonadotrophin hormones

Hormones that stimulate cell activity in the *ovaries* and *testes*. Gonadotrophins are essential for fertility. The most important are follicle-stimulating hormone (FSH) and luteinizing hormone (LH), secreted by the *pituitary gland*. Another gonadotrophin, HCG (see *gonadotrophin, human chorionic*), is produced by the placenta in pregnancy.

Certain gonadotrophins are used as drugs in the treatment of *infertility*.

gonadotrophin, human chorionic

A *hormone* produced by the *placenta* in early *pregnancy*. Human chorionic gonadotrophin (HCG) stimulates the *ovaries* to produce *oestrogen* and *progesterone*, which are necessary for a healthy pregnancy. HCG may also be produced in nonpregnant women by a *choriocarcinoma* (a cancerous tumour of the uterus), and by some testicular tumours (see *testis, cancer of*) in men.

HCG is excreted in the urine; the detection of HCG levels in urine forms

the basis of *pregnancy tests*. HCG extracted from the urine of pregnant women is given by injection to treat certain types of *infertility*. It may help to induce *ovulation* in women who have not been ovulating, and, in men, it may increase *sperm* production. HCG is occasionally given to prevent *miscarriage* in women whose production of progesterone is deficient.

gonads

The sex glands: the testes (see *testis*) in men and the ovaries (see *ovary*) in women. The activities of the gonads, both male and female, are regulated by *gonadotrophin hormones*, which are released by the pituitary gland.

gonorrhoea

One of the most common *sexually transmitted infections*. Gonorrhoea is widespread throughout the world.

CAUSES AND INCIDENCE

Gonorrhoea, which is caused by the bacterium *NEISSERIA GONORRHOEAE*, is most often transmitted during sexual activity, including oral and anal sex. An infected woman may also transmit the disease to her baby during *childbirth*.

SYMPTOMS AND SIGNS

Gonorrhoea has an incubation period of between two and ten days. In men, symptoms include a discharge from the *urethra* and pain on passing urine. Many infected women have no symptoms; if symptoms are present, they usually consist of a vaginal discharge or a burning sensation on passing urine.

Infection acquired through anal sex can cause gonococcal *proctitis* (inflammation of the rectum and anus). Oral sex with an infected person may lead to gonococcal *pharyngitis*, which sometimes causes a sore throat. A baby exposed to the infection during birth may acquire the eye infection gonococcal *ophthalmia*.

COMPLICATIONS

Untreated gonorrhoea may spread to other parts of the body. In men, it may cause *prostatitis* (inflammation of the prostate) or *epididymo-orchitis* (inflammation of a testis and the chamber where sperm mature), affecting fertility. In women, it causes *pelvic inflammatory disease*, which may damage the *fallopian tubes*. This problem increases the risk of later *ectopic pregnancy* and may lead to *infertility*. Gonococcal bacteria in the bloodstream may result in *septicaemia* or *septic arthritis*.

DIAGNOSIS AND TREATMENT

Tests are performed on a sample of discharge or on swabs taken from the *urethra*, *cervix*, or *rectum* in order to confirm the diagnosis.

Gonorrhoea is treated with *antibiotic drugs*. Treatment is effective but does not protect against reinfection; in addition, bacterial resistance to antibiotics is an increasing problem. The patient's recent sexual contacts will need to be tested to establish whether or not they are also infected (see *contact tracing*).

Goodpasture's syndrome

A rare *autoimmune disorder* (in which the body's immune system attacks its own tissues) causing *inflammation* of the *glomeruli* (see *glomerulus*) in the kidneys and the *alveoli* (tiny air sacs) in the lungs, as well as *anaemia*. Goodpasture's syndrome is a serious disease; unless treated early it may lead to life-threatening bleeding into the lungs and progressive *kidney failure*. It is most common in young men, but can develop at any age and in women.

Goodpasture's syndrome may respond to treatment with *immunosuppressant drugs* and *plasmapheresis* (a procedure for removing unwanted antibodies from blood plasma). People who have severe or repeated attacks of the disorder require *dialysis* (a technique for removing waste products from the blood) and, ultimately, a *kidney transplant*.

GORD

The abbreviation for gastro-oesophageal reflux disease (see *acid reflux*).

goserelin

A synthetic drug chemically related to the hypothalamic hormone *gonadorelin*. Goserelein is used to treat *breast cancer*, *prostate cancer*, *fibroids*, infertility, and *endometriosis*. Adverse effects of goserelein include loss of bone density after prolonged application.

gout

A common *metabolic disorder* that causes attacks of *arthritis*, usually in a single joint (often the base of the big toe). Gout is due to high levels of uric acid in the blood (see *hyperuricaemia*); the arthritis is due to the deposition of uric acid crystals in joint tissue.

The affected joint is red, swollen, and extremely tender. Attacks last for a few days and often recur. They are sometimes accompanied by fever. With recurrent

attacks, more joints may be involved, and there may be constant pain due to joint damage from chronic inflammation. In addition, gout may be associated with kidney stones (see *calculus, urinary tract*) or, rarely, with kidney damage due to the deposition of crystals in the kidney tissue.

The diagnosis is confirmed by tests on blood or fluid from the affected joint to measure uric acid levels.

The pain and inflammation of acute (of sudden onset) attacks can be controlled by *nonsteroidal anti-inflammatory drugs* (NSAIDs) or by *colchicine*. If these drugs are ineffective, a *corticosteroid drug* may be injected into the joint. Many people require no further treatment. Long-term treatment with drugs that help to lower urate levels, such as *allopurinol* or *sulfinpyrazone*, can stop or reduce the frequency of recurrent attacks. These drugs, however, may trigger an attack at the start of treatment, so are initially prescribed with NSAIDs.

Graefe's sign

Lagging of the upper eyelid (see *lid lag*) as it follows the downward rotation of the eyeball in *Graves' disease*.

grafting

The process of transplanting healthy tissue from one part of the body to another (autografting) or from one person to another (allografting). Tissue transplantation from an animal to a person (xenografting) is also carried out.

Grafting is used to repair or replace diseased, damaged, or defective tissues or organs. Common operations of this type are *skin graft, bone graft, bone marrow transplant, corneal graft, kidney transplant, heart transplant, liver transplant, heart-lung transplant, heart-valve surgery, and microsurgery* on blood vessels and nerves.

COMPLICATIONS

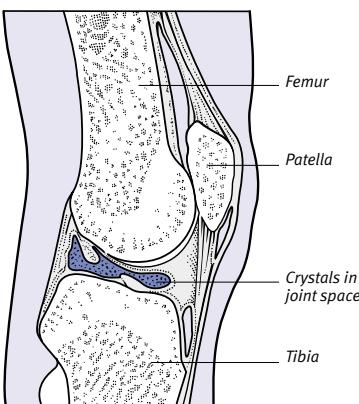

With autografting, the grafted tissue is usually assimilated well into the surrounding tissue at the new site.

There is a risk of tissue rejection following other forms of grafting. The only exceptions are grafts between identical twins, because their tissue matches exactly, and corneal grafting, because the cornea has no blood supply and therefore no white blood cells and antibodies to act as a defence system against the foreign cells.

To overcome rejection, as close a match as possible between the tissues of recipient and the tissues of donor is sought (see *tissue-typing*). The recipient is

GOUT

Gout is a common joint disease, affecting 10 times more men than women. In men it may occur at any time after puberty; in women it usually occurs only after the menopause. There is often a family history of the disorder. Hyperuricaemia (excess uric acid in the blood) leads to the formation of uric acid crystals inside joints. Crystals may also be deposited in the soft tissues in the ears and around tendons.

Crystal precipitation

Crystals of uric acid precipitate (solidify) into the joint space and surrounding tissues of the knee, causing intense inflammation and extreme pain.

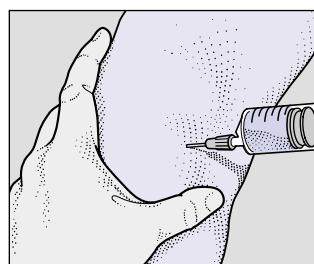

Appearance of gout

Deposition of uric acid crystals in the joint space has caused inflammation and swelling of the patient's affected left knee.

DIAGNOSIS

Gout is suspected if an attack of arthritis affects a single joint. A blood test is usually performed; a high level of uric acid will suggest gout. Examination of fluid from the joint may confirm the diagnosis.

Aspiration

Fluid is aspirated (removed through a needle into a syringe) from the swollen joint and examined under a microscope to detect any uric acid crystals.

Microscopic evidence

The presence of uric acid crystals in the fluid confirms the diagnosis of gout.

given *immunosuppressant drugs* to suppress the body's natural defences. (See also *transplant surgery*.)

graft-versus-host disease

A complication of a *bone marrow transplant* in which certain *immune system* cells, called killer *T-lymphocytes*, in the transplanted marrow attack the tissues of the recipient.

Graft-versus-host (GVH) disease may occur soon after transplantation or may take some months to appear. The first sign is usually a skin rash. This may be

followed by diarrhoea, abdominal pain, *jaundice*, *inflammation* of the eyes and mouth, and breathlessness. Most people with GVH recover within a year, but about one in five may eventually develop fatal complications.

GVH disease can usually be prevented by giving *immunosuppressant drugs* to all transplant patients. If, despite prophylactic treatment, the disease develops, it can be treated with *corticosteroid drugs* and immunosuppressant drugs such as *cyclosporin*. In some cases, however, it can be difficult to control.

Gram's stain

An *iodine*-based stain used to differentiate between types of *bacterium*.

A specimen of bacteria is stained with *gentian violet* and a solution of Gram's stain. It is then treated with a decolorizing agent, such as acetone, before being counterstained with a red dye. Bacteria that retain the dark violet stain are known as Gram-positive; those that lose the violet stain after decolorization and take up the counterstain (so that they appear pink) are known as Gram-negative.

Examples of Gram-positive bacteria include *STREPTOCOCCUS* and *CLOSTRIDIUM*. Gram-negative bacteria include *VIBRIO CHOLERAE*, which causes *cholera*, and various species of *SAFMONELLA*.

grand mal

The former name for tonic-clonic seizures, which occur in *epilepsy*. The episode may start with warning sensations, such as unease or fear. This so-called aura lasts for a few seconds. The person then loses consciousness and collapses, and may briefly stop breathing. During the seizure there are generalized, jerky muscle contractions. As it finishes, the muscles relax and bowel and bladder control may briefly be lost. This type of seizure usually lasts for only a few minutes; the person may have no recall of it on awakening.

grand multipara

A term relating to a pregnant woman who has had five or more previous pregnancies that have resulted in *delivery*. During any subsequent pregnancy, a grand multipara woman is considered to be at increased risk of a variety of conditions including *anaemia*, *hypertension* (high blood pressure), *diabetes mellitus*, *placenta praevia*, *malpresentation*, prolonged labour, delivery by *caesarean section*, ruptured *uterus*, and *postpartum haemorrhage*.

granulation tissue

Red, moist, granular tissue that develops on the surface of an ulcer or an open *wound* during the process of *healing*.

granulocyte

A type of white *blood cell*.

granuloma

A growth comprising cells of a type associated with chronic *inflammation*. Granulomas usually occur as a reaction

to certain infections, such as *tuberculosis*, or to a foreign body, such as a suture (stitch), but they may also develop for unknown reasons in conditions such as *sarcoidosis*.

A pyogenic granuloma is an excess of *granulation tissue* developing at the site of an injury to the skin or mucous membrane. (See also *granuloma annulare*; *granuloma inguinale*.)

granuloma annulare

A harmless skin condition characterized by circular, raised areas of skin that spread outwards, forming rings. It occurs mostly in children and young adults, usually on the backs of the hands and feet. The cause is unknown.

The diagnosis of granuloma annulare is often made simply from its appearance, but may be confirmed by a skin *biopsy* (removal of a tissue sample for analysis). No treatment is necessary. In most cases, the skin heals fully over several months or years.

granuloma inguinale

A *sexually transmitted infection* that causes ulceration of the genitals. The infection is caused by *CALYMMATOBACTERIUM GRANULOMATIS*, also known as Donovan's bodies. It is common in parts of the tropics but rare in temperate countries.

The first symptoms are painless, raised nodules on the penis or labia (external female genitalia) or around the anal area. The nodules gradually ulcerate forming red, raised areas, which may contain pus. Left untreated, the affected areas may eventually heal but there will be extensive scarring.

A *biopsy* (removal of a tissue sample for microscopic analysis) is performed on a sore in order to confirm diagnosis. The antibiotics *tetracycline* or *erythromycin* are effective treatments.

granulomatosis

Any condition marked by the formation of multiple *granulomas* (collections of inflamed tissue), such as *Hodgkin's disease* and *Wegener's granulomatosis*.

granulomatous lung disease

A condition in which one or more *granulomas* (collections of inflamed tissue) develop within the lungs. In certain diseases, such as *Churg-Strauss syndrome* and *Wegener's granulomatosis*, granulomas and vasculitis (an inflammation of the blood vessels) develop at the same time.

Other conditions result from an *immune system* response to a foreign substance or infectious organism. Causes include *tuberculosis*, fungal infections, and inhaled rock or mineral dusts. In some diseases, however, such as *sarcoidosis*, the cause is unknown.

grasp reflex

A primitive reflex (see *reflex, primitive*) in which the fingers or toes curl when the palm or sole is touched or stroked. The grasp reflex is normal in babies, but if it continues into later life or appears in an adult, it may indicate a disorder of the frontal lobe of the brain.

Graves' disease

An *autoimmune disorder* (in which the *immune system* attacks the body's own tissues) that affects the *thyroid gland*. Graves' disease is characterized by toxic *goitre* (an overactive and enlarged thyroid gland); excessive production of thyroid hormones (*hyperthyroidism*), leading to *thyrotoxicosis*; and *exophthalmos* (bulging eyeballs).

gravida

The medical term for a pregnant woman. The term "gravida" is often combined with a prefix to indicate the number of pregnancies that a woman has had (including the current one); for example, a primigravida is a woman who is pregnant for the first time.

gravitational ulcer

A form of skin ulcer that occurs in the lowermost parts of the body. The usual site is the lower leg (see *leg ulcer*), and a common cause is *varicose veins*.

gray

An SI unit (part of the International System of Units) of radiation dosage (see *radiation unit*).

graze

See *abrasion*.

greenstick fracture

A type of *fracture* that occurs when a long bone in the arm or leg bends and cracks on one side only. This type of fracture occurs only in children, whose bones are still growing and flexible.

grey baby syndrome

A rare but potentially fatal condition in newborn, and particularly premature, babies. Grey baby syndrome is caused

by the antibiotic drug *chloramphenicol*, which is not usually prescribed for newborns, but may be passed to a baby via the mother's bloodstream. Newborn babies' bodies cannot process or excrete the drug effectively, so very high levels build up. An affected infant is cold and has grey skin (see *cyanosis*) due to circulatory collapse (see *shock*).

If the condition is detected early, and the drug is discontinued, the infant may recover fully. Treatment with chloramphenicol should be avoided in late pregnancy and during breast-feeding.

G**grey matter**

Regions of the *central nervous system* consisting mainly of closely packed and interconnected *nerve* cell bodies and their branching dendrites. (In contrast, the nerve cells' *axons*, which conduct nerve impulses, make up the *white matter* of the central nervous system.)

Grey matter is found mostly in the outer layers of the *cerebrum* (the main mass of the *brain* that is responsible for advanced mental functions) and in deeper regions of the brain, such as the *basal ganglia*. Grey matter also makes up the core of the *spinal cord*.

grief

A painful emotion, usually caused by loss of a loved one. (See *bereavement*.)

grip

The ability of the *hand* to hold objects firmly. The hand has an opposable thumb (which can touch each of the fingers), specialized skin on the palm and fingers to give adhesion, and a complex system of muscles, tendons, joints, and nerves that enables precise movements of the *digits*. The hand is capable of performing two types of grip: grasping, in which the whole hand is used, and pinching, a precise hold using the thumb and one finger.

Gripping ability is greatly reduced by conditions that cause muscular weakness or impairment of sensation in the hands. Such conditions include *stroke* or *nerve injury*, and disorders that affect the bones or joints of the hand or wrist, such as *arthritis* or a *fracture*.

gripe

Severe abdominal pain (see *colic*).

gripe

An outdated term of French origin for any illness resembling *influenza*.

griseofulvin

An oral *antifungal drug*. Griseofulvin is particularly useful for infections affecting the scalp, beard, palms, soles of the feet, and nails. Common side effects are headache, dry mouth, abdominal pain, and *photosensitivity* (increased sensitivity of the skin to sunlight). Long-term treatment with the drug may cause liver or bone marrow damage

Groenouw's corneal dystrophy

An inherited disorder of the eye. There are two forms of the condition: type I (granular) and type II (macular).

Granular corneal dystrophy is an autosomal dominant disorder (see *genetic disorders*) characterized by small granular opacities in the top layers of the *cornea*. It develops in the first ten years of life. Macular corneal dystrophy is an autosomal recessive disorder typified by a diffuse haze with areas of dense corneal opacity. It develops in young people up to the age of 20.

Treatment for discomfort associated with the disorder may include *antibiotic* eye-drops. Severe cases may require laser surgery or a corneal transplant.

groin

The hollow between the lower abdomen and the top of the thigh.

groin, lump in the

A swelling in the *groin*. The most common cause is enlargement of a lymph node due to an infection (see *glands, swollen*). Another common cause is a *hernia*, in which the abdominal contents protrude through a weak area in the abdominal wall. Rarely, in males, an undescended testis may lead to a lump in the *groin* (see *testis, undescended*). Treatment depends on the cause.

groin strain

Pain and tenderness in the *groin* as a result of overstretching a *muscle*, typically while running or playing sport. The muscles commonly affected are the adductors (on the inside of the thigh) and the rectus femoris (at the front of the thigh). Groin strain is most often treated with *physiotherapy*, but recovery may be slow.

grommet

A small tube that may be inserted through an incision in the *ear drum* during surgery to treat *glue ear*, usually in children (see *myringotomy*). The grommet

equalizes the pressure on both sides of the *ear drum*, permitting mucus to drain down the *eustachian tube* into the back of the throat.

Grommets are usually allowed to fall out as the hole in the *ear drum* closes; this generally occurs six to 12 months after insertion.

group therapy

Any treatment of psychological problems in which a group of patients is given therapy together. The group meets regularly, under the guidance of a therapist, in order to discuss their problems. Interaction between the members of the group is thought to be beneficial.

Group therapy may be useful for people with personality problems and for those who are suffering from *alcohol dependence, drug dependence, anxiety disorders*, and *eating disorders*.

growing pains

Vague aches and pains that occur in the limbs of children aged between six and 12 years old. Pains are usually felt at night, often in the calves. The cause is unknown, but the pains seem to be unrelated to the growing process itself.

Growing pains are of no medical significance and need no treatment. In contrast, pains that occur in the morning, cause a limp, or prevent normal use of a limb are not growing pains and should be assessed by a doctor.

growth

An abnormal proliferation of cells in a localized area (see *tumour*). Growth is also increase in size, usually as a result of increasing age (see *growth, childhood*).

growth, childhood

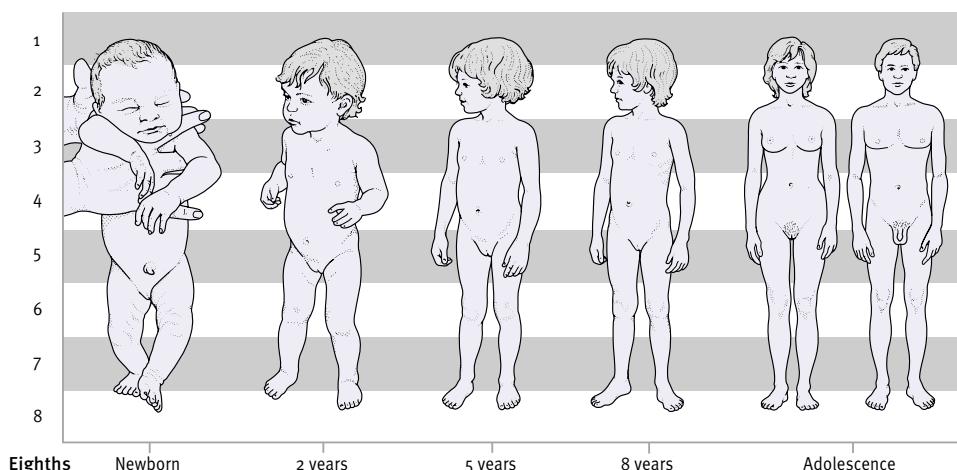

The increase in size that occurs as a child develops. Growth is usually monitored by measuring height, weight, and, in babies, head circumference.

The period of fastest growth occurs before birth. Growth is still rapid in the first few years of life, especially in the first year, but the rate decreases during childhood. *Puberty* marks another major period of growth, which continues until adult height and weight are reached, usually at age 16 to 17 in girls and between 19 and 21 in boys. See *growth charts* (p.352).

The body shape changes during childhood because different areas grow at different rates. For example, at birth, the head is already about three quarters

CHANGES IN BODY PROPORTIONS BETWEEN BIRTH AND ADOLESCENCE

As a child grows, the body proportions change radically in relation to the body's overall length (see right). For example, a newborn baby's legs account for only three eighths of the body length, while before adolescence legs account for one half. A newborn's head accounts for as much as a quarter of the total body length, while an adolescent's head accounts for only one eighth.

of its adult size; it grows to almost full size in the first year. Thereafter, it becomes proportionately smaller because the body grows at a much faster rate than that of the head.

Growth can be influenced by *heredity* and by environmental factors, such as nutrition and general health. *Hormones* also play an important role, particularly *growth hormone*, *thyroid hormones*, and, at puberty, the *sex hormones*.

A chronic illness, such as *cystic fibrosis*, may retard growth. Even a minor illness can slow the growth rate briefly, although the rate usually catches up when the child recovers. In some cases, slow growth is the only sign that a child is ill, malnourished, or emotionally distressed, when it is known as *failure to thrive*. However, *short stature* does not always indicate poor health.

Abnormally rapid growth is rare. Usually, it is a familial trait, but it may occasionally indicate an underlying disorder, such as a pituitary gland tumour causing *gigantism*. (See also *age*; *child development*.)

growth, excessive

See *gigantism*.

growth factor

Any of various chemicals that are involved in stimulating new cell growth and maintenance. Some growth factors, such as vascular endothelial growth factor, which stimulates the formation of new blood vessels, are significant in the growth and spread of cancers.

growth hormone

A substance produced by the *pituitary gland* that stimulates normal body growth. Growth hormone increases the production of protein in muscle cells and the release of energy from the breakdown of fats. Oversecretion of the hormone leads to *gigantism* if it occurs before puberty or *acromegaly* if it occurs afterwards. A deficiency of the hormone may result in *short stature*. Synthetic growth hormone may be given by injection to treat short stature caused by pituitary or genetic disorders.

growth rate

The increase in size of an individual over a given period of time. Growth rate may be expressed in absolute terms or relatively, as a percentage of the average growth rate. (See also *growth*, *childhood*; *height velocity*.)

growth, restricted

See *short stature*.

G syndrome

See *Opitz syndrome*.

GTN

The abbreviation for *glyceryl trinitrate*.

guaiac

A chemical used to detect haemoglobin (the oxygen-carrying pigment in red blood cells) in faeces. Tests using guaiac, known as *faecal occult blood tests*, are performed to detect hidden bleeding in the digestive tract (see *occult blood*, *faecal*).

guar gum

A gum extracted from the cluster bean (*CYAMOPSIS TETRAGONOLABA*). Guar gum is not digested in the body. It is used to help control the blood *glucose* level in people with *diabetes mellitus* because it slows the absorption of glucose from the small intestine. The gum is taken as granules sprinkled on food or dissolved in water. It may cause *flatulence*, nausea, and abdominal discomfort.

Guillain–Barré syndrome

A rare condition affecting the *peripheral nervous system* that causes weakness, usually in the limbs.

CAUSES

The cause of Guillain–Barré syndrome is believed to be an allergic reaction to an infection, usually viral; the nerves are damaged by *antibodies* produced against the virus. Most cases develop two or three weeks after the infection.

SYMPTOMS

Weakness, often accompanied by numbness and tingling, usually starts in the legs and spreads to the arms. It may worsen, resulting in *paralysis*. The muscles of the face and those controlling speech, swallowing, and breathing may also be affected.

DIAGNOSIS AND TREATMENT

Diagnosis is confirmed by electrical tests to measure how fast nerve impulses are conducted, and by a *lumbar puncture*, in which a sample of cerebrospinal fluid is taken from the spinal canal for analysis.

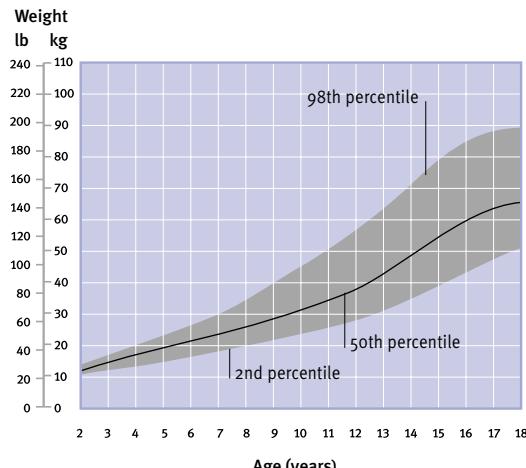

Most people recover fully with only supportive treatment. Severe cases may

GROWTH CHARTS

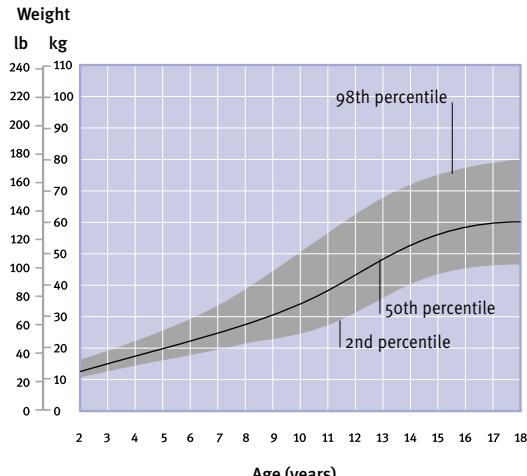

Growth charts are used to record the growth of children from the age of two to 18 years. Recording of a child's weight and height are carried out as part of a routine health check. The doctor or health visitor measures the child's weight and height and plots them against age on a chart. The growth curve is compared with the typical range, represented by the shaded area on the chart, for all children of the same age and gender.

The vertical axis on the charts show the weight, in kilograms and pounds, and the height in centimetres and inches; the horizontal axis shows the age range from two to 18 years. About 98 per cent of children fall below the line of the 98th percentile; the 50th percentile is the average, and 50 per cent fall below this line; only 2 per cent of children fall below the line of the 2nd percentile.

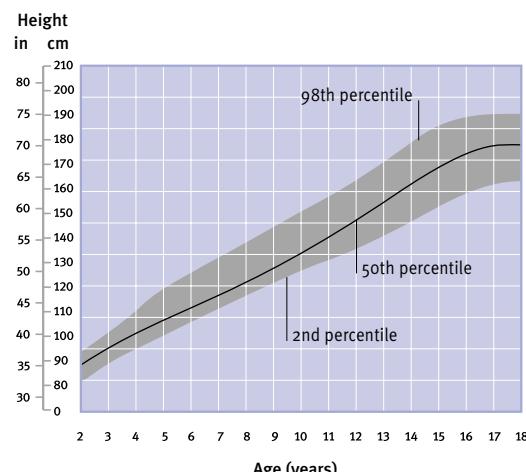

BOYS' WEIGHT (2–18 YEARS)

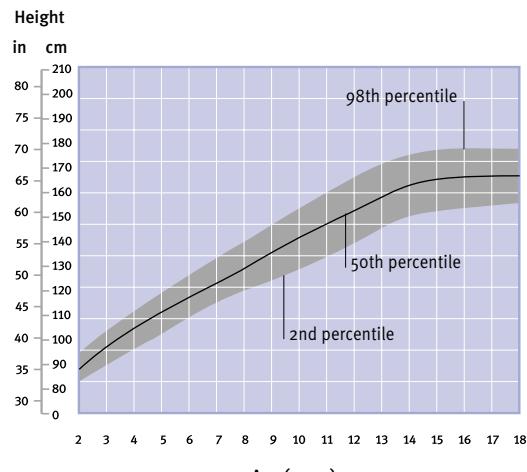

GIRLS' WEIGHT (2–18 YEARS)

BOYS' HEIGHT (2–18 YEARS)

GIRLS' HEIGHT (2–18 YEARS)

Growth in boys

Normally, there is a steady increase in height and weight until the onset of puberty. A sudden spurt in growth occurs during puberty (between the ages of 13 and 16). This chart was constructed using the height and weight of thousands of children; it is used by doctors to check whether growth of a particular boy is significantly above or below average.

Growth in girls

Normally, there is a steady increase in height and weight until the onset of puberty. A sudden spurt in growth occurs during puberty (between the ages of 11 and 14). These charts were constructed using the height and weight of thousands of children; it is used by doctors to check whether growth of a particular girl is significantly above or below average.

need treatment with *plasmapheresis* (in which blood is treated to remove antibodies) or *immunoglobulin*. Mechanical *ventilation* may be used to aid breathing if the chest muscles and *diaphragm* are severely affected. Some people are left with a permanent weakness, others may have further attacks of the disease, and a number may suffer both weakness and further attacks.

guilt

A painful emotion that arises from the awareness of having broken a moral code. Guilt (unlike shame, which depends on how other people view the transgression) is self-inflicted. Some psychoanalysts view it as a result of the prohibitions of the *superego* (conscience) that are instilled in early life, while others see guilt as a conditioned response to actions that on previous occasions have led to punishment.

Feeling guilty for no reason, or for an imagined crime, is one of the main symptoms of *depression*.

Guinea worm disease

A tropical disease caused by a parasitic worm about 1 m long. The disease occurs in Africa, South America, the Middle East, and India.

Infection results from drinking water containing the water flea CYCLOPS, which harbours the worm larvae. Once consumed in a drink, the larvae pass through the intestine and mature in body tissues. After about a year, the adult female worm, now pregnant, reaches the skin surface and creates an inflamed blister that bursts, exposing the end of the worm. *Urticaria* (nettle rash), nausea, vomiting, and diarrhoea often develop during the formation of the blister.

The traditional remedy for the disease is to wind the worm from the skin on to a small stick. The drugs *tiabendazole* and *niridazole* are given to reduce inflammation, *antibiotic drugs* are given to control secondary infection, and the patient is immunized against *tetanus*.

Gulf War syndrome

A group of symptoms affecting armed forces personnel of various nationalities involved in the war in the Persian Gulf in 1991. A wide range of symptoms has been associated with the illness, including severe fatigue, fever, headaches, rashes, chronic *bronchitis*, visual disturbances, impaired short-term memory, and *depression*. The cause is unknown.

gullet

The common name for the *oesophagus*.

gum

The soft tissue surrounding the *teeth* that protects underlying structures and keeps the teeth in position in the *jaw*.

Healthy gums are pink or brown and firm. Careful *oral hygiene* helps to keep the gums clean and prevent disease. *Gingivitis* (an early, reversible stage of gum disease characterized by inflammation of the gums) may occur if *plaque* is allowed to collect around the base of the teeth. If untreated, it may lead to chronic *periodontitis*, advanced gum disease in which infected pockets form between the gums and the teeth.

Bleeding gums are nearly always a symptom of gingivitis; rarely, they are due to *leukaemia* or *scurvy* (vitamin C deficiency). Gingival *hyperplasia* (fleshy thickening of the gums) occurs most commonly as a side effect of treatment with *phenytoin* (an anticonvulsant drug). (See also *receding gums*.)

gumboil

See *abscess*, *dental*.

gumma

A soft tumour that may develop in the late stages of untreated *syphilis*. Gummas are rare in developed countries.

gustatory

Related to the organs or sense of *taste*.

gut

A common name for the *intestine*.

Guthrie test

A blood test performed routinely on blood samples taken from the heels of babies between the eighth and the fourteenth days after birth. The test is used to check for the inherited disorder *phenylketonuria*, which can lead to severe brain damage if left untreated.

guttate psoriasis

A form of *psoriasis* (a skin disease characterized by patches of inflamed skin) that is found mainly in children and young adults, especially following *streptococcal infections*. A particular feature of guttate psoriasis is the formation of multiple small, teardrop-shaped skin blemishes. When it occurs in children following a streptococcal infection, it usually clears up completely. However, affected children are

at a higher risk of developing plaque *psoriasis* (the more common form of psoriasis) in later life.

gynaecology

The medical speciality concerned with the female *reproductive tract*. Gynaecology deals with *contraception*; the investigation and treatment of menstrual problems (see *menstruation*, *disorders of*); *sexual problems*; *infertility*; problems relating to the *menopause*; and disorders such as uterine *fibroids* and ovarian *cysts*. Gynaecologists also deal with disorders in the early stages of pregnancy, such as recurrent *miscarriage*.

gynaecomastia

Enlargement of one or both *breasts* in men or boys. The condition is sometimes due to an excess of the female sex hormone *oestrogen*.

CAUSES AND INCIDENCE

Mild, temporary gynaecomastia can occur in boys at birth due to maternal hormones, and the condition is also common at *puberty*.

Gynaecomastia that develops in later life may be due to a chronic liver disease, such as *cirrhosis*, in which the liver is unable to break down oestrogen. Hormone-secreting tumours, such as pituitary or testicular tumours, may also be responsible for the condition.

Adult gynaecomastia, which sometimes occurs in only one breast, can also occur when synthetic hormones and some drugs, such as *digoxin*, *spironolactone*, and *cimetidine*, cause a change to the balance of sex hormones. Very rarely, a discrete lump that develops on one breast may be caused by a male breast cancer.

DIAGNOSIS AND TREATMENT

Investigation may involve *blood tests*. If cancer is suspected, a *biopsy* (removal of the lump or a piece of tissue for analysis) will be performed.

Treatment depends on the cause. If a drug is responsible, an alternative will be given if possible. If there is no underlying disease, the swelling usually subsides over a period of time. In severe cases, however, cosmetic surgery (see *mammoplasty*) may be considered.

H

H₁-receptor antagonists

A common abbreviation for histamine₁-receptor antagonists, a type of *antihistamine drug*, that are used in the treatment of allergic reactions.

H₂-receptor antagonists

A common abbreviation for histamine₂-receptor antagonist, a type of *ulcer-healing drug*. (See also *cimetidine; ranitidine; famotidine*.)

habit tic

A type of *tic* (repetitive, involuntary movement of a muscle) that has a psychological cause and does not result from damage to or disease of the nervous system.

habitual abortion

An outdated term for the spontaneous abortion (see *miscarriage*) of a fetus in three or more consecutive pregnancies, after less than 24 weeks' gestation. Habitual abortion is now more commonly known as recurrent pregnancy loss or recurrent miscarriage. Habitual abortions may be caused by defects or disorders of the uterus, such as *fibroids*, or of the cervix (see *cervical incompetence*). Certain conditions affecting the mother, such as systemic *lupus erythematosus* or *Hughes' syndrome*, may also cause habitual abortion.

habituation

The process of becoming accustomed to an experience. In general, the more a person is exposed to a stimulus, the less he or she is affected by it. People can become habituated to certain drugs and develop a reduced response to their effects (see *tolerance*).

haem

An iron-bearing pigment that combines with globin (a protein) to form *haemoglobin*, the main component of *red blood cells*. The haem binds with *oxygen* in order to transport it from the lungs to the tissues.

haem-

A prefix that is placed before a variety of words (for example, *haemoglobin*) to indicate *blood*.

haemangioblastoma

A rare type of brain tumour consisting of blood-vessel cells. Haemangioblastomas develop slowly as cysts, often in the *cerebellum*, and are mostly noncancerous. Symptoms include headache, vomiting, *nystagmus* (abnormal jerky eye movements) and, if the tumour is in the cerebellum, *ataxia* (lack of muscle coordination). Most haemangioblastomas can be removed surgically.

haemangioma

A birthmark caused by an abnormal distribution of blood vessels. Haemangiomas may be flat or raised.

TYPES

Port-wine stains are large, flat, purple-red marks, which are permanent and can be unsightly. In rare cases, port-wine stains are associated with abnormalities in the blood vessels of the brain (see *Sturge-Weber syndrome*).

Small, flat marks, often known as stork marks or stork bites, are common in newborn babies, particularly on the back of the neck. Most begin to fade about three weeks after birth.

Raised bright red haemangiomas, often called strawberry marks, usually enlarge rapidly during the first few weeks after birth. They generally disappear without leaving a scar by the time a child is five to seven years old.

COMPLICATIONS AND TREATMENT

Haemangiomas do not usually require treatment. However, a haemangioma that bleeds persistently or that looks unsightly may need to be removed by *laser treatment*, *cryosurgery* (destruction of tissue by extreme cold), *radiotherapy*, *embolization* (obstruction of blood flow to tissue), or *plastic surgery*.

haemarthrosis

Bleeding into a *joint*, causing the capsule that encloses the joint to swell, and resulting in pain and stiffness.

CAUSES

Haemarthrosis is usually the result of severe injury to a joint, such as a torn capsule, torn ligaments, or fracture of a bone forming part of the joint. Often the cause is a sports injury to the knee.

Less common causes are *bleeding disorders*, such as *haemophilia* (in which failure of the blood-clotting mechanism

causes abnormal bleeding). Any joint may be affected and bleeding into the joint may occur spontaneously or be caused by even a minor knock. Overuse of *anticoagulant drugs* can also cause haemarthrosis.

Repeated haemarthrosis may damage joint surfaces, causing *osteoarthritis*.

SYMPTOMS AND SIGNS

Haemarthrosis causes a joint to swell immediately after injury. The joint may gradually stiffen into a fixed position as a result of spasm in surrounding muscles.

TREATMENT

Ice-packs may reduce swelling and pain. Fluid may be withdrawn from the joint in order to relieve pain and for diagnosis. Haemophiliacs are given *factor VIII* to promote blood clotting. Resting the joint in an elevated position can prevent further bleeding.

haematemesis

The medical term for *vomiting blood*.

haematocolpos

The accumulation of menstrual blood in the vagina due to blockage of the vaginal opening. This rare condition occurs either when the *hymen* (the membrane around the vaginal opening) lacks the perforation that would normally allow the blood to leave the body or as a result of developmental abnormalities of the vagina. Haematocolpos requires surgical treatment to drain the blood and, if necessary, to reconstruct the vagina.

haematology

The study of *blood* and its formation, as well as the investigation and treatment of disorders that affect the blood and the *bone marrow*.

Microscopic examination and counting of blood and bone marrow cells are essential procedures in diagnosing types of blood disorder, such as *anaemia* or *leukaemia*. Analysis of blood is used in the diagnosis of a range of disorders as well as specific blood disorders.

haematoma

A localized collection of *blood* (usually clotted) that is caused by bleeding from a ruptured blood vessel. Haematomas can occur almost anywhere in the body and vary from a minor to a potentially fatal condition.

Less serious types of haematoma include those that develop under the nails or in the tissues of the outer ear (*cauli-*

flower ear). Most haematomas disappear without treatment in a few days, but if they are painful they may need to be drained. More serious types include extradural and subdural haematomas, which press on the brain (see *extradural haemorrhage; subdural haemorrhage*).

haematoma auris

The medical term for *cauliflower ear*.

haematospermia

An alternative term for haemospermia, the medical term for blood in the semen (see *semen, blood in the*).

haematuria

Blood in the *urine*, which may or may not be visible to the naked eye. In small amounts, it may give the urine a smoky appearance.

Almost any *urinary tract* disorder can cause haematuria. *Urinary tract infection* is a common cause; *prostatitis* may be a cause in men. *Cysts, kidney tumours, bladder tumours, stones* (see *calculus, urinary tract*), and *glomerulonephritis* (inflammation of the filtering units of the kidney) may cause haematuria. *Bleeding disorders* may also cause the condition.

Blood that is not visible to the naked eye may be detected by a dipstick *urine test* or microscopic examination. *CT scanning, ultrasound scanning, or intravenous urography* can help to determine the cause. If bladder disease is suspected, *cystoscopy* is performed.

haemochromatosis

An inherited disease in which too much dietary iron is absorbed. Excess iron gradually accumulates in the liver, pancreas, heart, testes, and other organs. Men are more frequently affected than women because women regularly lose iron in menstrual blood.

SYMPOTMS AND COMPLICATIONS

Haemochromatosis rarely causes problems until middle age. Loss of sex drive and a reduction in the size of the testes are often the first signs. Excess iron over a period of time causes enlargement of the liver and *cirrhosis* (chronic liver damage) and can lead to *diabetes mellitus*, bronzed skin coloration (due to iron pigment deposition in the skin), cardiac *arrhythmia*, and, eventually, *liver failure* and *liver cancer*.

DIAGNOSIS AND TREATMENT

Diagnosis is based on *blood tests* and a *liver biopsy* (removal of a small sample of tissue for analysis). Treatment is by *ven-*

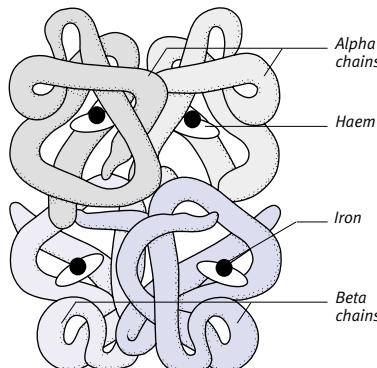

section (withdrawal of blood from a vein). Initially, the procedure is performed every week. After iron levels have returned to normal, however, the process of venesection is required less often. (See also *haemosiderosis*.)

haemodialysis

One of the two means of *dialysis* (artificial filtration of the blood) used to treat *kidney failure*.

haemoglobin

The oxygen-carrying pigment that is present in red *blood cells*. Haemoglobin molecules, which are produced by *bone marrow*, are made up of four protein chains (two alpha- and two beta-globin) and four haem (a red pigment that contains iron).

Structure of haemoglobin

Each molecule contains four globin chains – two alpha and two beta. Each chain carries a haem component capable of binding oxygen.

Oxygen from the lungs enters red blood cells in the bloodstream. The oxygen then combines chemically with the haem in the haemoglobin to form oxyhaemoglobin, which gives blood in the *arteries* its bright red colour. In this medium, oxygen is carried around the body and delivered to the areas that need it. When the oxyhaemoglobin has released its oxygen it reverts to haemoglobin, giving the blood in the *veins* its distinctive darker colour.

DISORDERS

Some defects in haemoglobin production are the result of a *genetic disorder*; defects such as these are subdivided into two types, namely errors of haem production, known as *porphyrias*, and those of globin production, known as *haemoglobinopathies*. Other defects, such as some types of *anaemia*, have a non-genetic cause.

haemoglobinopathy

A term used to describe the *genetic disorders* in which there is a fault in the production of the globin chains of *haemoglobin* (the oxygen-carrying substance in the blood). Examples of haemoglobinopathies include *sickle cell anaemia* and the *thalassaemias*.

haemoglobinuria

The presence of *haemoglobin* in urine. Haemoglobin is an oxygen-carrying substance mainly contained in red blood cells, but a small amount is free in the blood plasma. Excessive breakdown of red blood cells, due to heavy exercise, cold weather, falciparum *malaria*, or *haemolytic anaemia*, increases the concentration of free haemoglobin in the plasma. The body excretes the excess haemoglobin in the urine.

haemolysis

The destruction of red *blood cells*. Haemolysis is the normal process by which old red blood cells are destroyed, mainly in the *spleen*. *Bilirubin*, a waste product of haemolysis, is excreted into the *bile* by the liver. Abnormal haemolysis, in which red blood cells are destroyed prematurely, may cause anaemia and jaundice (see *anaemia, haemolytic*).

haemolytic anaemia

See *anaemia, haemolytic*.

haemolytic disease of the newborn

Excessive *haemolysis* (destruction of red blood cells) in the fetus and newborn by *antibodies* produced by the mother. Haemolytic disease of the newborn is most often caused by *Rhesus incompatibility*. This occurs when a mother with Rh-negative type blood, who has previously been exposed to Rh-positive blood through birth, miscarriage, abortion, or *amniocentesis*, is pregnant with a baby that has Rh-positive blood. Haemolytic disease has become uncommon since the introduction of routine preventive treatment for Rh-negative women during pregnancy (see *anti-D (Rh_o) immunoglobulin*).

SYMPTOMS AND SIGNS

In mild cases of the disease, the newborn baby becomes slightly jaundiced during the first 24 hours of life (due to an excess of the bile pigment *bilirubin* in the blood) and slightly anaemic. In more severe cases, the level of bilirubin in the blood may increase to a dangerous level,

causing a risk of *kernicterus* (a type of brain damage). Severely affected babies have marked anaemia while still in the uterus. They become swollen (*hydrops fetalis*) and are often stillborn.

TREATMENT

In mild cases, no treatment is necessary. In other cases, the aim is to deliver the baby before the anaemia becomes too severe, usually by *induction of labour* at 35–39 weeks' gestation. If the baby is too young to be delivered safely, fetal blood transfusions may be necessary.

After birth, *phototherapy* (light treatment that converts bilirubin in the skin into a water-soluble form that is more easily excreted from the body) can help to reduce *jaundice*. An exchange blood transfusion may be needed.

haemolytic-uraemic syndrome

A rare disease in which red *blood cells* are destroyed prematurely and the *kidneys* are damaged, causing acute *kidney failure*. *Thrombocytopenia* (reduction of *platelets* in the blood) can also occur. haemolytic-uraemic syndrome most commonly affects young children.

CAUSES

The precise cause of haemolytic-uraemic syndrome is uncertain, but the disorder may be triggered by a serious bacterial or viral infection. It is thought that the lining of small blood vessels in the kidneys becomes damaged, causing small clots to form. These clots cause *haemolysis* (breakdown of red cells) as blood flows past them.

SYMPTOMS

The onset of the disease is sudden; symptoms include weakness, lethargy, and a reduction in the volume of urine. Severe *hypertension* (high blood pressure) is common and may cause *seizures*.

DIAGNOSIS AND TREATMENT

Blood and urine tests can determine the degree of kidney damage. *Dialysis* (artificial filtration of the blood) may be needed until the kidneys have recovered. Most patients recover normal renal function.

haemophilia

An inherited *bleeding disorder* caused by deficiency of a blood protein, *factor VIII*, which is essential for blood clotting. Haemophiliacs (who are almost always male) suffer recurrent bleeding, usually into their joints, which may occur spontaneously or after injury.

INCIDENCE AND CAUSES

The lack of factor VIII is due to a defective gene, which shows a pattern of

sex-linked inheritance. Affected males pass on the gene not to their sons but to their daughters, who are carriers of the condition. Some of the sons of carrier females may be affected, and some of the daughters of carriers may themselves be carriers. Many haemophiliacs have an uncle, brother, or grandfather also affected. However, in about one third of cases there is no family history of haemophilia.

SYMPTOMS

The severity of the disorder differs markedly among individuals. However, episodes of bleeding are painful and, unless treated promptly, can lead to deformity of the knees, ankles, and other joints. Injury, and even minor operations such as tooth extraction, may lead to profuse bleeding. Internal bleeding can lead to blood in the urine or extensive bruises.

DIAGNOSIS AND TREATMENT

Haemophilia is diagnosed by *blood-clotting tests* and by *amniocentesis* or *chorionic villus sampling* in a fetus. Bleeding can be controlled by infusions of factor VIII concentrates. People with a severe form of the disorder may need regular intravenous injections of factor VIII as a preventive measure.

OUTLOOK

Most people with haemophilia can lead an active life but should avoid the risk of injury. Contact sports, such as football, are not advisable but other forms of exercise, such as swimming and walking, can be beneficial. The female relatives of anyone with haemophilia should obtain genetic counselling before planning a pregnancy.

Haemophilus influenzae

A bacterium (see *bacteria*) responsible for numerous cases of the infectious diseases *epiglottitis* and *meningitis*.

haemoptysis

The medical term for *coughing up blood*.

haemorrhage

The medical term for *bleeding*. (See also *haematoma*.)

haemorrhagic fever

See *viral haemorrhagic fever*.

haemorrhagic shock

Physiological *shock* (a dangerous reduction of blood flow throughout the body tissues), which is caused by severe blood loss. (See also *hypovolaemia*.)

haemorrhoidectomy

Surgical removal of *haemorrhoids*. The procedure is used to treat large, prolapsing, or bleeding haemorrhoids, if other simpler methods such as *banding* have not been successful.

Complete healing after a haemorrhoidectomy takes three to six weeks. *Laxative drugs* are usually given during this period to soften faeces and make them easier to pass.

haemorrhoids

Swollen veins in the lining of the *anus*. Haemorrhoids may occur close to the anal opening, when they are called external haemorrhoids, or higher in the anal canal, in which case they are called internal haemorrhoids. Sometimes these veins protrude outside the anal canal, in which case they are called prolapsing haemorrhoids.

CAUSES

Haemorrhoids are caused by increased pressure in the veins of the anus, most commonly through straining repeatedly to pass hard faeces. Such faeces may result from a diet that is too high in refined foods and too low in fibre (see *constipation*). Haemorrhoids are also common during pregnancy, when the weight of the fetus exerts pressure on blood vessels.

SYMPTOMS

Rectal bleeding and discomfort on defaecation are the most common features. Prolapsing haemorrhoids often produce a mucous discharge and itching around the anus. A complication of prolapse is *thrombosis* and *strangulation*. This occurs when a blood clot forms in the vein, preventing it from returning to its position in the anus and restricting its blood supply. The condition can cause extreme pain.

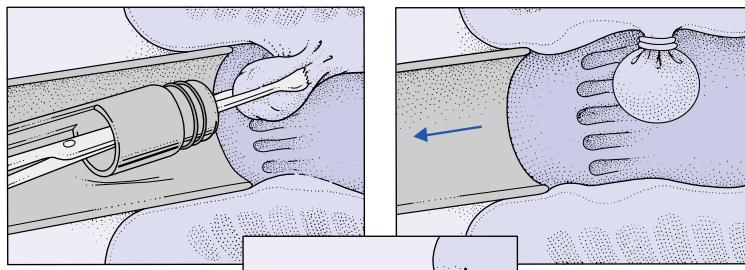

DIAGNOSIS AND TREATMENT

Diagnosis is usually by *proctoscopy* (inspection of the rectum with a viewing instrument). Mild cases are controlled by drinking plenty of fluids, eating a high-fibre diet, and establishing regular bowel movements. Rectal suppositories and creams that contain *corticosteroid drugs* and local *anaesthetics* reduce pain and swelling. More troublesome haemorrhoids may be treated by *sclerotherapy* (injection of an irritant liquid), *cryosurgery* (application of extreme cold), or by banding, in which a band is tied around the haemorrhoid, causing it to wither and drop off. A *haemorrhoidectomy* (the surgical removal of haemorrhoids) is generally required for prolapsing haemorrhoids.

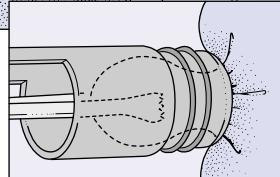

TREATING HAEMORRHOIDS

In the procedures shown below, the patient will usually have been given a laxative so that the lower bowel is clear of faeces. Banding requires no anaesthesia; either general or epidural anaesthesia is given before a haemorrhoidectomy is performed.

BANDING HAEMORRHOIDS

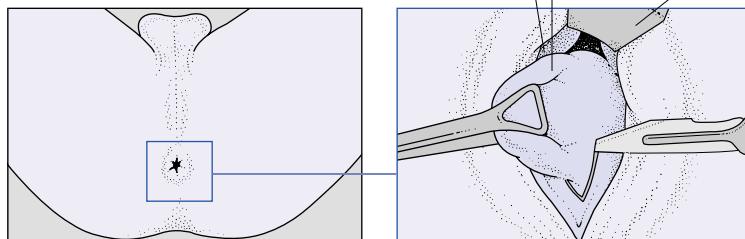

1 This common, simple, and effective procedure is usually painless (causing no more than a mild ache afterwards) and no anaesthesia is required. The patient lies on one side, the proctoscope (instrument for examining the rectum) is positioned, and the haemorrhoid is grasped with forceps.

2 The banding instrument is inserted and pressed into the anal wall. Gentle traction is applied to draw the mass into the drum of the instrument.

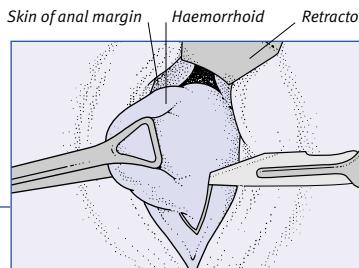

3 The trigger mechanism of the banding instrument is fired and the bands are squeezed on to the neck of the mass. The proctoscope is withdrawn, leaving the haemorrhoid with its base tightly constricted by the bands. The haemorrhoid then withers and drops off painlessly within a few days of the operation.

HAEMORRHOIODECTOMY

Stages of the procedure

Under general or epidural anaesthesia, the patient's rectum is examined with a proctosigmoidoscope to exclude a diagnosis

of tumour. The patient is then placed in the lithotomy position. The haemorrhoid is clamped, placed under traction (as shown above), secured with a suture, and then removed with a knife.

haemosiderosis

A general increase in *iron* stores in the body. Haemosiderosis may occur after repeated blood transfusions or, more rarely, as a result of excessive iron intake.

haemospermia

The medical term for blood in the semen (see *semen, blood in the*).

haemostasis

The arrest of *bleeding*. There are three main natural mechanisms by which bleeding is stopped after injury. First, small blood vessels constrict. Second, small *blood cells* called platelets aggregate

and plug the bleeding points. Third, the blood plasma coagulates, forming filaments of a substance called *fibrin*, which help to seal the damaged blood vessel (see *blood clotting*). Defects in any of these mechanisms can cause a *bleeding disorder*.

haemostatic drugs

A group of drugs to treat bleeding disorders and to control bleeding. Haemostatic preparations that help blood clotting are given to people with clotting factor deficiencies. For example, *factor VIII* is used for *haemophilia*. Drugs that prevent the breakdown of fibrin in clots, such as *tranexamic acid*, can also help stop bleeding.

haemothorax

A collection of blood in the pleural cavity (the space between the chest wall and the lung). Haemothorax is most commonly caused by chest injury, but it may arise spontaneously in people with defects of blood coagulation or as a result of cancer.

Symptoms of haemothorax include pain in the affected side of the chest and upper abdomen, and breathlessness. If extensive, there may be partial lung collapse. Blood in the pleural cavity is withdrawn through a needle.

Hailey–Hailey disease

Also known as benign familial *pemphigus*, a form of pemphigus (a blistering skin disease) that mainly affects the neck, armpits, and groin. Hailey–Hailey disease tends to run in families.

hair

A threadlike structure composed of dead cells containing *keratin*, a fibrous protein.

STRUCTURE AND FUNCTION

The root of each hair is embedded in a tiny pit in the dermis (inner) layer of the skin called a hair *follicle*. Each shaft of hair consists of a spongy semihollow core (the medulla), a surrounding layer of long, thin fibres (the cortex), and, on the outside, several layers of overlapping cells (the cuticle).

While a hair is growing, the root is enclosed by tissue called a bulb, which supplies the hair with keratin. The bulb is the pale swelling that sometimes can be seen when a hair is pulled out. The upgrowth of dead cells and keratin from the root forms the hair. Once the hair has stopped growing, the bulb retracts from the root and the hair eventually falls out.

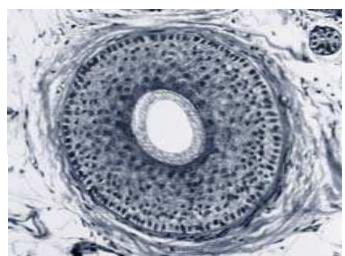

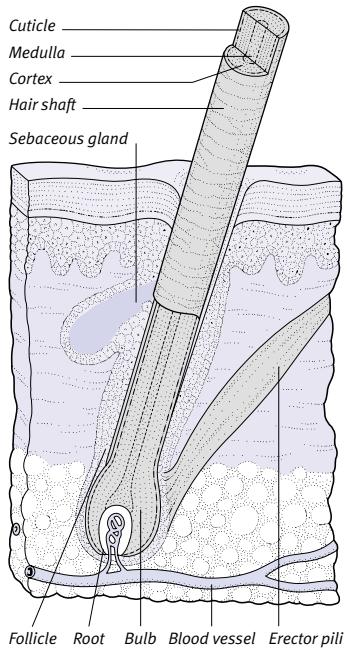

Hair is involved in the regulation of body temperature (known as thermoregulation). If the body is too cold, erector pili muscles in the skin contract, pulling the hairs upright to form goose pimples. Erect hairs trap an insulating layer of air next to the skin.

TYPES

There are three types of human hair. From the fourth month of gestation, the fetus is covered with downy hair called lanugo, which is shed during the ninth month. After birth and until puberty, vellus hair, which is fine, short, and colourless, covers most of the body. The third type, terminal hair, is thicker, longer, and often pigmented; it grows on the scalp, the eyebrows, and the eyelashes. At

THE STRUCTURE OF A HAIR

The hair shaft consists of dead cells and keratin. It has three layers: the medulla (core), the cortex, and the cuticle (covering).

Cross-section through a hair

In this light micrograph, the medulla, the cortex, and the outer cuticle of the hair can all be clearly differentiated.

puberty, terminal hair replaces vellus in the pubic area and the armpits. In most men and some women the process continues on the face, limbs, and trunk.

COLOUR AND TEXTURE

Hair colour is determined by the amount of pigment called melanin that is present in the hair shaft. Melanin is produced by cells called melanocytes at the base of the hair follicle. Red melanin is responsible for red and auburn hair; black melanin for all other colours. If cells receive no pigment, the cortex of each hair becomes transparent and

the hair appears white. The degree of curliness of a hair depends on the cross-section shape of its follicle.

DISORDERS

Brittle hair may be due to excessive styling, *hypothyroidism* (underactivity of the thyroid gland), or severe vitamin or mineral deficiency. Very dry hair can be caused by malnutrition. Ingrown hairs occur when the free-growing end of the hair penetrates the skin near the follicle, which may cause inflammation. (See also *hirsutism*; *hypertrichosis*.)

hairball

A ball of hair in the stomach, found in people who nervously suck or chew their hair (see *bezoar*).

hair cycle

The alternating phases of activity in a hair follicle. There are two main phases: an active phase, when new hair forms in the follicle, and a resting phase, when cell activity slows down and stops. The active phase lasts for several years, until a hair has reached its maximum length. During the resting phase, that hair dies. During the next growth phase, a new hair is formed and pushes the dead one out of the follicle.

The growth cycles of hairs may be disrupted by various factors, including hormonal or immune system disorders; pregnancy; adverse reactions to drugs; and *radiotherapy*.

hairiness, excessive

See *hirsutism*; *hypertrichosis*.

hair removal

Hair is usually removed from the body purely for cosmetic reasons. It may also be shaved from around an incision site before surgery. Temporary methods of hair removal include shaving, waxing, *depilatory* creams, and waxing; *electrolysis*, however, is the only permanent method of removal.

hair transplant

A cosmetic operation in which hairy sections of scalp are removed and transplanted to hairless areas to treat *alopecia* (baldness). There are several different techniques available.

HOW IT IS DONE

In strip grafting, a strip of skin and hair is taken from a donor site, usually at the back of the scalp or behind the ears. The removed hairs and their follicles are then inserted into numerous incisions

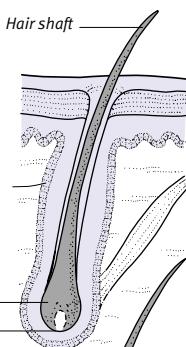

made in a bald area, known as the recipient site. The procedure usually takes 60–90 minutes. The patient is given a mild sedative and the donor and recipient sites are anaesthetized. The donor site heals in about five days. Although transplanted hairs fall out shortly afterwards, new hair growth appears from the follicles between three weeks and three months later.

Other transplant techniques include punch grafting, in which a punch is used to remove small areas of bald scalp, which are replaced with areas of hairy scalp; flap grafting, in which flaps of hairy skin are lifted, rotated, and stitched to replace bald areas; and male pattern baldness reduction, which involves cutting out areas of bald skin and stretching surrounding areas of hair-bearing scalp to replace them.

SCALP HAIR GROWTH

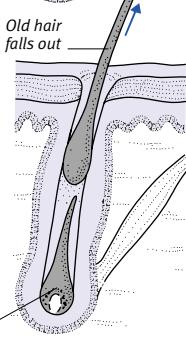

There are about 100,000 hairs on the scalp, though there is considerable individual variation. The exact number depends on the number of hair follicles, which is established before birth. Scalp hair grows about one centimetre per month. Each hair goes through alternating periods of growth and rest. On average, a person sheds about 100 scalp hairs a day.

Growth phase
At the start of a growth phase (which, on the scalp, lasts about three years for each hair), the hair root stimulates the growth of a bulb and then a shaft.

Rest phase
During the rest phase (which lasts about three months on the scalp), the bulb retracts from the root and eventually the hair falls out. A new hair begins to grow in the same follicle.

New hair forms

hairy cell

A large, abnormal white blood cell with numerous hairlike projections. Hairy cells occur with a rare form of *leukaemia*, known as hairy cell leukaemia, when they proliferate in the blood, bone marrow, liver, and spleen.

Haldol

A brand name for the antipsychotic drug *haloperidol*.

half-life

The time taken for the activity of a substance to reduce to half its original level. The term is usually used to refer to the time taken for the level of *radiation* emitted by a radioactive substance to decay to half its original level. The concept is useful in *radiotherapy* for assessing how long material will stay radioactive in the body. Half-life is also used to refer to the length of time taken by the body to eliminate half the quantity of a drug.

halitosis

The medical term for bad breath. Halitosis is usually the result of smoking, drinking alcohol, eating onions or garlic, or poor oral hygiene. Persistent bad breath not caused by any of these may be a symptom of mouth infection, *sinusitis*, or certain lung disorders, such as *bronchiectasis*.

Hallervorden–Spatz syndrome

A very rare disorder thought to be caused by a build-up of iron in certain areas of the brain. The symptoms, which are progressive, usually appear in early childhood and include abnormal muscle rigidity and spasms (see *dystonia*).

Hallgren's syndrome

A *congenital* disorder (present at birth) that is characterized by *deafness*; *congenital cataract* (opacity of the lens of the eye); and *ataxia* (clumsiness and incoordination) due to brain damage.

hallucination

A perception that occurs when there is no external stimulus. Auditory hallucinations (the hearing of voices) are a major symptom of *schizophrenia* but may also be caused by *manic-depressive illness* and certain brain disorders. Visual hallucinations most often occur in states of *delirium* brought on by a physical illness (such as *pneumonia*) or alcohol withdrawal (*delirium tremens*). *Hallucinogenic drugs* are another common cause of

visual hallucinations. Hallucinations of smell are associated with *temporal lobe epilepsy*. Those of touch and taste are rare, however, and occur mainly in people with *schizophrenia*. People subjected to *sensory deprivation* or overwhelming physical stress sometimes suffer from temporary hallucinations.

hallucinogenic drug

A drug that causes *hallucination*. Hallucinogens include certain drugs of abuse, such as *LSD*, *marijuana*, *mescaline*, and *psilocybin*. Some prescription drugs, such as *anticholinergic drugs* and *levodopa*, occasionally cause hallucinations.

hallux

The medical name for the big toe.

hallux rigidus

Loss of movement in the large joint at the base of the big toe as a result of *osteoarthritis*. The joint is usually tender and swollen. Treatment comprises resting the toe and wearing a support insert in the shoe. Surgery may be required.

hallux valgus

A deformity of the big toe in which the joint at the base projects out from the foot, and the top of the toe turns inwards. The condition is more common in women, because it is usually associated with wearing narrow, pointed, high-heeled shoes, but it may be caused by an inherited weakness in the joint. A hallux valgus often leads to formation of a *bunion* or to *osteoarthritis* in the joint, causing pain and limiting foot movement. Severe deformity may be corrected by *osteotomy* (removal of part of a bone) or *arthrodesis* (fusion of bones in a joint).

haloperidol

An *antipsychotic drug* used to treat mental illnesses such as *schizophrenia* and *mania*. Haloperidol is also given to control the symptoms of *Gilles de la Tourette's syndrome* (a rare neurological disorder) and, in small doses, to sedate people who are aggressive due to *dementia*. Side effects include drowsiness, lethargy, weight gain, dizziness, and *parkinsonism* (symptoms such as abnormal movements and stiffness of the face and limbs).

halothane

A colourless liquid inhaled as a vapour to induce and maintain general anaesthesia (see *anaesthesia, general*). Repeated use

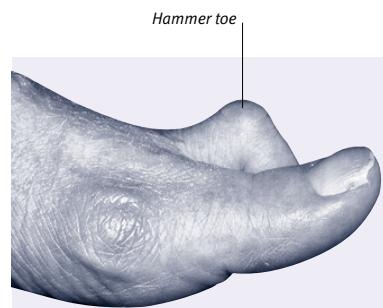

of halothane may result in damage to the *liver* and, for this reason, it is now less widely used.

hamartoma

A noncancerous mass, resembling a tumour, which consists of an overgrowth of tissues that are normally found in the affected part of the body. Hamartomas are common in the skin (the most common is a *haemangioma*), but they also occur in the lungs, heart, or kidneys.

hammer-toe

A deformity of the toe (usually the second toe) in which one of the joints remains in a bent position due to a *tendon* abnormality. A painful *corn* often develops on this joint. A protective pad can ease pressure on the joint and relieve pain, but surgery may be needed if the pain is persistent.

Appearance of hammer-toe

This photograph shows the typical appearance of a hammer-toe, in which one of the joints of the second toe is fixed in a bent position.

hamstring muscles

A group of *muscles* at the back of the thigh. The upper ends of the hamstring muscles are attached by *tendons* to the *pelvis*; the lower ends are attached by tendons called hamstrings to the *tibia* and *fibula*. The hamstring muscles bend the knee and swing the leg backwards from the thigh.

Tearing of the hamstring muscles is common in sports. The injury happens suddenly and is very painful. Bruising over the area develops several days later. Repeated strenuous exercise may sprain the muscles (see *overuse injury*). Both types of injury can often be prevented by warming-up exercises.

Painful spasms of the hamstring muscles can also sometimes occur as a protective response to a knee injury; by restricting movement of the damaged knee joint, the muscle spasms help to limit further injury.

hand

The hand, which is the most versatile part of the body, allows humans (and other primates) to hold and manipulate objects. This ability is primarily due to the fact that the fingers and thumb can move independently and can grip.

STRUCTURE

The hand is made up of the *wrist*, palm, and fingers. Movement of the hand is achieved mainly by *tendons* that attach the muscles of the forearm to the bones of the hand (the carpal, metacarpals, and phalanges). These tendons are surrounded by synovial sheaths containing a lubricating fluid that prevents friction. Other movements are controlled by short muscles in the palm of the hand; some of these muscles make up the prominent areas along the sides of the hand from the bases of the thumb and little fingers to the wrist.

Blood is supplied to the hand by two arteries (the radial on the thumb side of the wrist and the ulnar on the little finger side). Prominent veins on the back of the hand drain blood away. Sensation and movement in the hand are controlled by the radial, ulnar, and median nerves.

DISORDERS

The hands are highly susceptible to injury, including cuts, burns, bites, fractures, and tendon injuries. *Dermatitis* is also common, since the hands are exposed to a considerable variety of irritating substances.

Other hand disorders include *Dupuytren's contracture*, which causes shrinkage of tissues in the palm, and *Volkmann's*

contracture, in which damage to muscles in the forearm causes wrist and finger deformities. Degeneration of a tendon sheath on the upper side of the wrist may cause a harmless swelling called a *ganglion*. *Osteoarthritis* commonly affects the joint at the base of the thumb. *Rheumatoid arthritis* may cause deformity by attacking the joints at the base of the fingers and rupturing tendons.

hand-arm vibration syndrome

Pain and numbness in the *hand* and arm due to prolonged use of vibrating tools. Symptoms often also include blue or white coloration of the fingers and a tingling sensation in affected areas. Hand-arm vibration syndrome tends to develop slowly over years and is the result of repeated damage to blood vessels and nerves. Exposure to cold tends to aggravate the condition.

There is no specific treatment, but avoiding vibrating tools is essential to prevent the disease progressing. In some cases, *calcium channel blockers* may help to relieve some symptoms.

handedness

Preference for using the right or left hand. Some 90 per cent of adults use the right hand for writing; two thirds prefer the right hand for most activities requiring coordination and skill. The others are either left-handed or ambidextrous (able to use both hands equally well).

It is uncertain why all humans are not simply ambidextrous. Up to the age of about 12, it is possible to switch

handedness if, for example, the dominant hemisphere of a person's brain has been damaged.

Handedness is related to the division of the brain into two hemispheres, each of which controls movement and sensation on the opposite side of the body. In most right-handed people the speech centre is in the left brain hemisphere. *Inheritance* is probably the most important factor in determining an individual's handedness.

hand-foot-and-mouth disease

An infectious disease, mainly affecting young children, that is caused by the *coxsackievirus*. Hand-foot-and-mouth disease may occur in small epidemics, usually in the summer.

The illness is usually mild and lasts for only a few days. Symptoms include blistering of the palms, soles of the feet, and inside of the mouth, and a slight fever. There is no treatment other than mild *analgesic drugs*. This infectious disease is not related to foot-and-mouth disease, which occurs in cattle.

handicap

The extent to which a physical or mental *disability* interferes with a person's normal functioning and causes him or her to be disadvantaged.

Hand–Schuller–Christian disease

A form of *histiocytosis X* that affects children. Problems include patchy bone loss, loose teeth, exophthalmos (protruding eyeballs), and swollen *lymph nodes*. Involvement of the pituitary gland can result in *diabetes insipidus* and *growth hormone* deficiencies.

hangnail

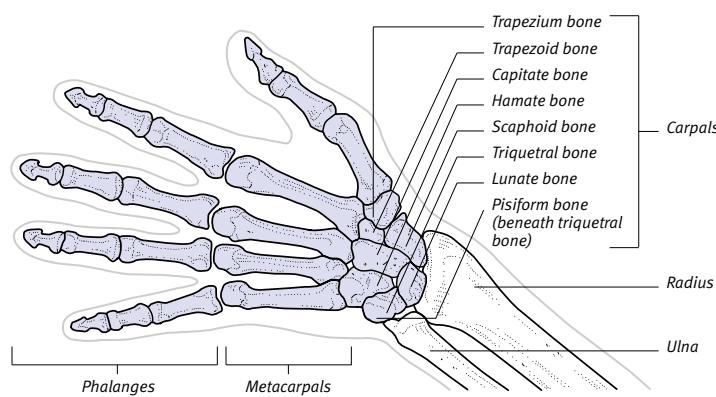

A strip of skin torn away from the side or base of a fingernail, exposing a raw, painful area. Hangnails usually occur when frequent immersion in water has dried the skin on the fingers. Biting the nails is another common cause. Unless trimmed away and covered until it heals, a hangnail may develop into *paronychia* (infection of the skin fold around the nail).

hangover

The unpleasant effects that are commonly experienced after over-indulgence in *alcohol*, characterized by headache, nausea, *vertigo*, and depression. Alcohol increases production of urine, and some

THE SKELETAL STRUCTURE OF THE HAND AND WRIST

Four of the eight wrist bones (carpal) articulate with the radius and ulna. The rest are connected to the five bones of the palm (metacarpals). Each metacarpal, in turn, articulates with a phalanx (a finger bone).

of the symptoms of a hangover are a result of mild dehydration. (See also *alcohol intoxication*.)

Hanhart's syndrome

A *birth defect* in which there are severe physical deformities, including underdevelopment of the lower jaw (see *micrognathia*) and tongue, misshapen and missing teeth, and malformations of the limbs.

Hansen's disease

A chronic bacterial infection, also called leprosy, that damages nerves, mainly in the limbs and facial area, and may cause skin damage.

CAUSE

The disease is caused by a bacterium, *MYCOBACTERIUM LEPRAE*, which is spread in droplets of nasal mucus. Hansen's disease is not highly contagious; a person is infectious only in the early stages. Prolonged close contact puts people at risk. The disease is most prevalent in Asia, Central and South America, and Africa.

SYMPOTMS AND SIGNS

Hansen's disease has a long incubation period – about three to five years. There are two main types: the lepromatous type, in which damage is widespread, progressive, and severe; and the tuberculoid type, which is milder. Damage is initially confined to the skin or to peripheral nerves supplying the skin and muscles. Skin areas supplied by affected nerves become lighter or darker and sensation and sweating are reduced. As the disease progresses, the peripheral nerves swell and become tender. Hands, feet, and facial skin eventually become numb and muscles become paralysed, leading to deformity. Other possible features include blindness, destruction of bone, and sterility.

DIAGNOSIS AND TREATMENT

The presence of the causative bacteria is confirmed by a *skin biopsy*. Drug treatment may be with a combination of *dapsone*, *rifampicin*, and *clofazimine*, which kills most of the bacteria in a few days. Any damage that has occurred before treatment, however, is irreversible. *Plastic surgery* may be necessary to correct deformities; and nerve and tendon transplants may improve the function of damaged limbs.

hantavirus

A viral infection that is transmitted to humans through the urine or faeces of infected rodents, such as rats. Symp-

toms range from a minor flu-like illness with headache and a sore throat to high fever, nausea and vomiting, and abnormal bleeding. Some strains of hantavirus can cause severe infections that may lead to *kidney failure*, serious lung damage, and death.

Harada's syndrome

A combination of certain eye and brain disorders that occurs in the Far East, particularly in Japan. The condition usually affects young adults.

The eye problems, which affect both eyes, include severe inflammation of the *iris*, the *ciliary body*, or the *choroid*; oedema (a build-up of fluid) in the *retina*; and *retinal detachment*. These problems are associated with *meningoencephalitis* (inflammation of the brain tissue and the membranes surrounding it). Other conditions that occur with Harada's syndrome include deafness, alopecia (hair loss), and patchy loss of pigmentation in the skin, eyes, and ends of the hair.

hardening of the arteries

The popular term for *atherosclerosis*.

harelip

A common term for the *birth defect* in which there is a split in the upper lip due to failure of the two sides to fuse during fetal development. A harelip is often associated with a similar failure of the two halves of the palate to join. (See also *cleft lip and palate*.)

Harrison's sulcus

A depression seen at the lower part of the ribcage of a child that is usually caused by exaggerated suction of the *diaphragm muscle* in respiratory conditions such as severe *asthma*. Harrison's sulcus may also be the result of the normal pull of the diaphragm on ribs that have been weakened – for example, in conditions such as *rickets*.

Hartnup disease

A rare disorder, inherited in an autosomal recessive manner (see *genetic disorders*), in which the body does not absorb and process sufficient amounts of certain *amino acids* (chemical compounds that make up proteins), particularly *tryptophan* (see *metabolism, inborn errors of*).

A deficiency in tryptophan may result in episodes of various symptoms, in particular *cerebellar ataxia* (a poorly coordinated, unsteady gait); symptoms

similar to those of *pellagra*: a red, scaly rash on skin exposed to the sun; depression; and thought disorders. There may also be headaches and diarrhoea. Symptoms can be triggered by infections, stress, or exposure to sunlight and last for up to four weeks. Flare-ups are often followed by long periods of remission.

The diagnosis can be confirmed by testing the urine for abnormally high levels of amino acids. Treatment with *nicotinic acid* and a high-protein diet often offers a good prognosis. The frequency of attacks usually decreases with increasing age.

Hashimoto's thyroiditis

An *autoimmune disorder* in which the body's immune system develops *antibodies* against its own thyroid gland cells. As a result, the thyroid gland cannot produce enough *thyroid hormones*, a condition known as *hypothyroidism*. Hashimoto's thyroiditis is eight times more common in women than men. The principal symptoms of Hashimoto's thyroiditis are tiredness, muscle weakness, and weight gain, and the thyroid gland becomes enlarged (see *goitre*).

A positive diagnosis is confirmed by *blood tests* indicating the presence of antithyroid antibodies and low levels of thyroid hormones. Treatment is by lifelong thyroid hormone replacement therapy. In some cases, other autoimmune disorders may also develop.

hashish

Sometimes shortened to "hash", this is another name for *marijuana*.

Haverhill fever

A form of rat-bite fever (see *rats, diseases from*) caused by infection with the bacterium *STREPTOBACILLUS MONILIFORMIS*. Unlike other forms of the disease, Haverhill fever can not only be transmitted through the bite of a rodent but can also be passed on indirectly, in contaminated water or milk products.

Havrix

The brand name for one form of a *vaccine* given to provide protection against *hepatitis A*.

hay fever

The popular name for the seasonal form of allergic rhinitis (see *rhinitis, allergic*) that is often combined with another condition, allergic *conjunctivitis*.

Hb

The abbreviation for *haemoglobin*, an oxygen-carrying component of red blood cells.

HCG

The abbreviation for the hormone human chorionic gonadotrophin (see *gonadotrophin, human chorionic*).

HDL

The abbreviation for the lipoprotein known as *high density lipoprotein*.

head

The part of the body that contains the *skull*, the *brain*, and the organs of sight, hearing, smell, and taste. The term head is also used to refer to the uppermost part of any structure and to the rounded portion of a *bone* that slots into an area of another bone to form a *joint*.

headache

One of the most common types of pain. A headache is only rarely a symptom of a serious underlying disorder. The pain arises from tension in the *meninges* (the membranes around the brain), and in the blood vessels and muscles of the scalp.

Headache may be felt all over the head or may occur on only one side, or in the forehead or the back of the neck. Sometimes the pain shifts from one area to another. The pain of headache may be superficial, throbbing, or sharp and may be accompanied by nausea, vomiting, and visual or other sensory disturbances.

TYPES

Many headaches are simply a response to some adverse stimulus, such as hunger. Headaches such as these usually clear up quickly. Tension headaches, due to tightening in the face, neck, and scalp muscles as a result of stress or poor posture, are also common, and may last for days or weeks. *Migraine* can be a severe, incapacitating headache that is preceded or accompanied by visual and/or stomach disturbances. *Cluster headaches* cause intense pain behind one eye.

CAUSES

Common causes of headache include *hangover* and noisy or stuffy environments. Some headaches are caused by the overuse of painkillers (see *analgesic drugs*). Other possible causes include *sinusitis*, *toothache*, *cervical osteoarthritis*, and *head injury*. *Food additives* may also be a cause. Among the rare causes of headache are a *brain tumour*, *hypertension*

(high blood pressure), *temporal arteritis* (inflammation of arteries in the face, neck, and scalp), an *aneurysm* (ballooning of a blood vessel), and increased pressure within the skull.

TREATMENT

Most headaches can be relieved by painkillers and rest. If a neurological cause is suspected, *CT scanning* or *MRI* (magnetic resonance imaging) may be performed.

head-banging

The persistent, rhythmic banging of the head against a wall or hard object. Head-banging is seen in some people with severe *learning difficulties*, particularly those who lack stimulation. It also occurs in some normal toddlers, often when they are frustrated or angry; most children grow out of the behaviour.

head injury

Injury to the head may occur as a result of traffic accidents, sports injuries, falls, assault, accidents at work and at home, or bullet wounds. Most people suffer a minor head injury at least once in their lives, but very few of the injuries are severe enough to require treatment.

A head injury can damage the scalp, skull, or brain. Minor injuries usually cause no damage to the underlying brain. Even when there is a *skull fracture*, or the scalp is split, the brain may not be damaged. However, a blow to the head may severely shake the brain, and this can sometimes cause *brain damage* even when there are no external signs of injury.

A blow often bruises the brain tissue, causing death of some of the brain cells in the injured area. When an object actually penetrates the skull, foreign material and dirt may be implanted into the brain and lead to infection. A blow or a penetrating injury may also tear blood vessels causing *brain haemorrhage* (bleeding in or around the brain). Head injury may cause swelling of the brain; this is particularly evident after bullet wounds because their high velocity causes extensive damage. If the skull is fractured, bone may be driven into the underlying brain.

SYMPTOMS AND SIGNS

If the head injury is mild, there may be no symptoms other than a slight headache. In some cases there is *concussion*, which may cause confusion, dizziness, and blurred vision (sometimes persisting for several days). More severe head injuries, particularly blows to the head, may result in unconsciousness that lasts

longer than a few minutes, or *coma* (a state of unconsciousness and unresponsiveness to stimuli), which may be fatal.

Post-concussive *amnesia* (loss of memory of events that occurred after an accident) may occur, especially if the skull has been fractured. This amnesia usually lasts more than an hour after consciousness is regained. There may also be pretraumatic amnesia (loss of memory of events that occurred before the accident). The more serious the injury to the brain, the longer unconsciousness and amnesia are likely to last.

After a severe brain injury, a person may suffer some muscular weakness or paralysis and loss of sensation.

Symptoms such as persistent vomiting, pupils of unequal size, double vision, or a deteriorating level of consciousness suggest progressive brain damage.

TREATMENT

Investigations may include *skull X-rays* and *MRI* or *CT scanning* (techniques that produce cross-sectional or three-dimensional images of body structures). A blood clot inside the skull may be life-threatening and requires surgical removal. Severe skull fractures may also require surgery.

OUTLOOK

Recovery from concussion may take several days. There may be permanent physical or mental disability if the brain has been damaged. Recovery from a major head injury can be a very slow process and there may be signs of progressive improvement for several years after the injury.

head lag

The backward flopping of the head that occurs when an infant is placed in a sitting position. Head lag is obvious in a newborn because the neck muscles are still weak, but by four months the baby can hold his or her head upright (see *child development*).

head lice

Tiny, wingless insects (*PEDICULUS HUMANUS CAPITIS*) that live on the human scalp and feed by sucking blood. Infestation with head lice is extremely common, especially among young school children, and is not caused by low standards of hygiene. An affected child may often pass head lice on to other family members.

The insects do not fly or jump but are spread through head-to-head-contact or shared combs, hairbrushes, and hats. Female lice stick their eggs (which are

known as nits) to hair shafts, close to the scalp. The nits may be seen as small, white specks; often, however, the first sign of infestation is intense itching due to an *allergy* to lice bites.

TREATMENT

Infestations can be treated with medicated lotions containing insecticides, which kill the lice. Because head lice can develop resistance to particular chemicals, a pharmacist should be consulted about local patterns of resistance. For children under two years of age or those with eczema or asthma, treatment should be discussed with a doctor or pharmacist. It is important to treat all family members at the same time.

Some people are reluctant to use insecticides repeatedly. An alternative method of ridding the scalp of head lice is to apply liberal amounts of hair conditioner and comb through the hair carefully with a fine tooth comb to remove the insects and nits. This procedure needs to be repeated every few days in order to be effective and to prevent recurrences. Whichever method is used, frequent inspection of a child's head is the key to controlling head lice.

Heaf test

A type of *tuberculin test*.

healing

The process by which the body repairs bone, tissue, or organ damage caused by injury, infection, or disease.

The initial stages of healing are the same in all parts of the body. After injury, *blood clots* form in damaged tissues. White *blood cells*, *enzymes*, *histamine*, other chemicals, and *proteins* from which new cells can be made accumulate at the site of damage. Fibrous tissue is laid down within the blood clot to form a supportive structure, and any dead cells are broken down and absorbed by the white blood cells. Some tissues, such as bone and skin, are then able to regenerate by the proliferation of new cells around the damaged area. In skin injuries, the fibrous tissue shrinks as new skin forms underneath. The tissue hardens to form a scab, which falls off when new skin growth is complete. A scar may remain.

An inadequate blood supply or persistent infection prevents regeneration, and some tissues, such as nerve tissue, may be unable to regenerate. In these cases, the fibrous tissue may develop into tough scar tissue, which keeps the tissue structure intact but may impair its function.

health

At its simplest, a term that is used to describe the absence of physical and mental disease. A wider concept promoted by the World Health Organization is that all people should have the opportunity to fulfil their genetic potential. This includes their ability to develop without the impediments of poor nutrition, environmental contamination, or infectious diseases. (See *diet and disease*; *health hazards*.)

health centre

Premises in which healthcare professionals, such as health visitors, district nurses, and general practitioners, work together.

health food

A term applied to any food products thought to promote health.

health hazards

Environmental factors that are known to cause, or are suspected of causing, disease. The major types of health hazard are the numerous infectious diseases that are transmitted by contact or by insects or other animals (see *bacteria*; *fungal infections*; *insects and disease*; *viruses*; *zoonosis*); an insufficient supply, or the contamination, of food and water (see *food additives*; *food-borne infection*; *food poisoning*); work-related hazards (see *occupational disease and injury*); hazards associated with domestic and social life; *smoking* and *alcohol* consumption; and global environmental hazards (see *pollution*; *radiation hazards*; *sunlight, adverse effects of*).

health promotion

The work of healthcare professionals in encouraging people to adopt a healthier lifestyle and so reduce their risk of developing various diseases. The print and broadcast media, as well as patient self-help or campaigning groups, also have a role to play in health promotion at a national or community level.

Health promotion involves the recommendation of specific tests as appropriate. Examples include encouraging women to undergo regular *cervical smear tests* and mammograms (see *mammography*) to detect early signs of cervical or breast cancer, and advising people at increased risk of coronary heart disease to have their blood *cholesterol* levels checked.

In addition, health promotion may involve a formal individual consultation to review a person's health and make

appropriate recommendations for him or her, for example regarding diet and exercise. Healthy living advice may also be given opportunistically; for example, individuals may be advised to give up smoking when they see their doctor for blood pressure checks.

hearing

The sense that enables sound to be perceived. The *ear* transforms the sound waves it receives into nerve impulses that pass to the *brain*.

Each ear has three distinct regions: the outer, middle, and inner ear. Sound waves are channelled through the ear canal to the middle ear, from where a complex system of membranes and tiny bones conveys the vibrations to the inner ear. The vibrations are converted into nerve impulses in the *cochlea*. These impulses travel along the auditory nerve to the medulla of the brain. From there, they pass via the *thalamus* to the superior temporal gyrus, part of the cerebral cortex involved in perceiving sound. For further details, see *Hearing box*, overleaf. (See also *deafness*.)

hearing aids

Electronic devices that improve hearing in people with certain types of *deafness*. A hearing aid consists of a tiny microphone (to pick up sounds), an amplifier (to increase their volume), and a speaker (to transmit sounds). Newer devices are now small enough to be hidden completely within the ear canal. The particular device required depends on the type and cause of the hearing loss. (See also *cochlear implant*.)

hearing loss

A deterioration in the ability to perceive sound. (See also *deafness*.)

hearing tests

Tests carried out to assess *hearing*. In newborns and young babies, *otoacoustic emission* tests can be used to check for a normal response of the inner ear to sound. Hearing tests are also performed as part of a routine assessment of *child development* and whenever hearing impairment is suspected. They are sometimes included in a general medical examination. The tests may also be used in people with *tinnitus* or dizziness.

An audiometer (an electrical instrument) is used to test the ability of an individual to hear sounds at different frequencies and volumes. The lowest

HEARING

The ears are the organs of hearing. Each ear has three regions: the outer ear, middle ear, and inner ear. The outer ear channels sound vibrations through the eardrum to the middle ear. The eardrum has to have equal air pressure on each side so that it can vibrate freely; the pressure is equalized via the eustachian tube, which runs from the back

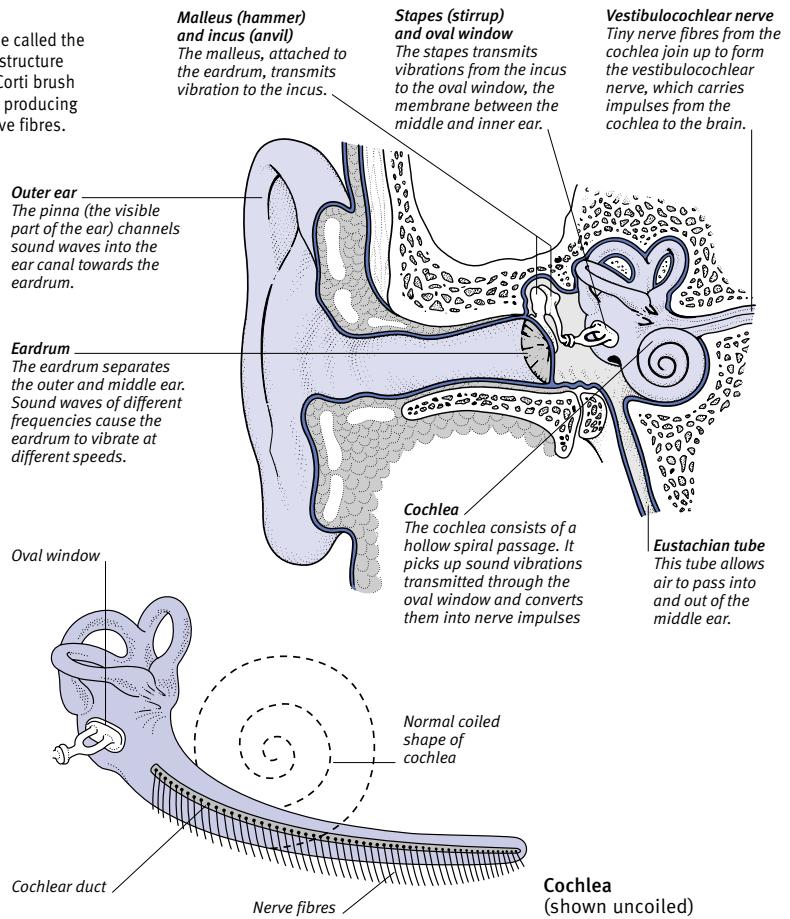

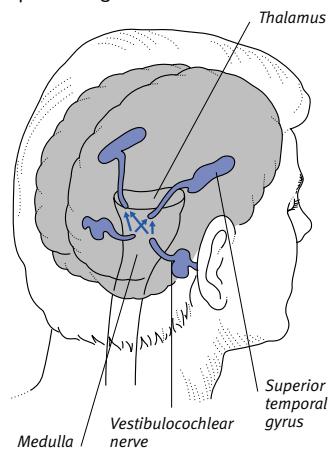

of the throat to the middle ear. Inside the middle ear, a complex system of membranes and tiny bones conveys the vibrations to the inner ear via a membrane called the oval window. In the inner ear, the vibrations are converted to nerve impulses and sent to the brain via the vestibulocochlear nerve.

Structure and function of cochlea

Running the length of the cochlea is a fluid-filled tube called the cochlear duct. It contains several membranes and a structure called the organ of Corti. Tiny hairs on the organ of Corti brush against a membrane called the tectorial membrane, producing electrical signals. These signals are detected by nerve fibres.

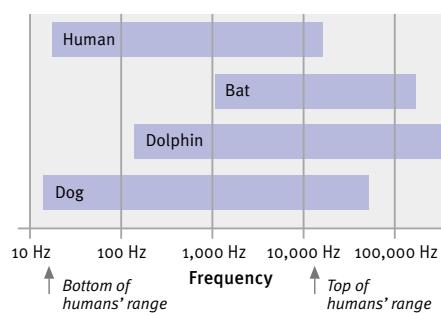

ROUTE TO THE BRAIN

Electrical signals are picked up by nerve fibres in the cochlea and pass along the vestibulocochlear nerve to the medulla. From there, they pass via the thalamus to the superior temporal gyrus – the part of the cerebral cortex (see brain) involved in receiving and perceiving sound.

COMPARISON OF FREQUENCY RANGES

The frequency of a sound (how high or low it is) is measured in Hertz (Hz). Different animals can hear different ranges of sound frequencies. The diagram shows the normal ranges that can be heard by a human, a bat, a dolphin, and a dog. Humans can hear a range between about 20 and 20,000 Hz.

Electron micrograph of inner ear
This image shows four rows of hair cells (centre) in the organ of Corti. On their surfaces are sensory hairs (top right), which convert sound waves into electrical impulses; these are picked up by the vestibulocochlear nerve (bottom right).

level at which a person can hear and repeat words (the speech reception threshold) is tested in each ear, as is the ability to hear words clearly (speech discrimination). Tuning fork tests (see *Rinne's test*) can be used to determine whether hearing loss is conductive or sensorineural (see *deafness*).

heart

The muscular pump in the centre of the chest that beats continuously and rhythmically to send *blood* to the lungs and the rest of the body. During an average lifetime, the heart contracts more than 2,500 million times.

STRUCTURE

Much of the heart consists of myocardium, a type of muscle, which, when given oxygen and nutrients, contracts rhythmically and automatically without any other stimulus. The internal surface of the heart is lined with a smooth membrane called endocardium, and the entire heart is enclosed in a tough, membranous bag, the *pericardium*.

Inside the heart there are four chambers. A thick central muscular wall, the septum, divides the heart cavity into right and left halves. Each half consists of an upper chamber, called an *atrium* (plural: *atria*), and a larger lower chamber, called a *ventricle*. (See *Structure of the heart* box, overleaf.)

The body's principal blood vessels emerge from the top and sides of the heart. The superior and inferior venae cavae (see *vena cava*), the largest veins, deliver deoxygenated blood from the body to the heart. The *aorta*, which is the main artery, carries oxygen-rich blood to be circulated around the body. The pulmonary vessels carry blood to and from the lungs, where the blood absorbs oxygen and releases the waste product carbon dioxide.

FUNCTION

The two sides of the heart have distinct, though interdependent, functions. The right atrium receives deoxygenated blood from the entire body via the two venae cavae. This blood is transferred to the right ventricle, then pumped to the lungs via the pulmonary artery to be oxygenated and lose carbon dioxide. The left atrium of the heart receives oxygenated blood from the lungs (via the pulmonary veins); this is transferred to the left ventricle and pumped to all body tissues. One-way valves at the chamber exits ensure that blood flows in one direction (see *heart valves*).

HEARING TESTS

Tests	Function
Tuning fork tests	These basic tests are used to determine whether hearing loss is conductive or sensorineural. In <i>Rinne's test</i> , the patient is asked whether the sound is louder with the vibrating tines held near the opening of the ear canal (air conduction) or with the base of the fork held against the mastoid bone (bone conduction). In a normal ear or one with sensorineural loss, air conduction is greater than bone conduction. In conductive hearing loss, bone conduction is greater than or equal to air conduction. <i>Weber's test</i> , in which the base of the fork is placed on the forehead, is useful for diagnosing unilateral hearing loss. If the hearing loss is conductive, the patient hears the tuning fork better in the ear with the poorer hearing.
Pure-tone audiometry	This is a test in which an audiometer is used to generate sounds of different frequencies and intensities and a person's ability to hear these sounds is measured. Hearing is first assessed by transmitting the sounds through one earphone while the other ear is prevented from hearing them. The sound frequencies range from 250 to 8,000 Hertz; for each frequency, the sound is increased in intensity until it can be heard. The patient gives a signal at the moment when he or she detects each sound and the results are recorded on a graph called an audiogram. Bone conduction is then assessed in the same way but the signal is transmitted through a rubber pad held against the bone behind the ear.
Auditory evoked response	This test may be used to evaluate the presence of hearing in someone who cannot cooperate with other tests (such as a very young baby). The brain's response to sound stimulation produced by an audiometer is analysed by means of electrodes placed on the scalp. Auditory evoked response can also help to rule out acoustic neuroma (a benign tumour affecting the auditory nerve, part of the vestibulocochlear nerve).
Impedance audiometry	Also known as tympanometry, this test is used to assess middle-ear damage occurring in cases of conductive deafness or to detect the effects of fluid within the middle ear. A probe is fitted tightly into the entrance of the ear canal, thereby sealing off the outside air pressure and sound. The probe emits a continuous sound. Air is pumped through the probe at varying pressures and, at the same time, a microphone in the probe registers the differing reflections of sounds from the eardrum as pressure changes in the ear canal. The reflections are recorded on a graph known as a tympanogram. The pattern of differing reflections relates to the type of disease that is causing the deafness.

THE CARDIAC CYCLE

The pumping action of the heart consists of three phases, which together make up a cycle corresponding to one heartbeat (see *Heart cycle* box, overleaf). These phases are called diastole, atrial systole, and ventricular systole. In diastole, the heart muscle relaxes and the heart fills with blood. In atrial systole, the atria contract, sending blood into the ventricles. In ventricular systole, the ventricles contract, pumping blood into the blood vessels.

For the heart to function efficiently, the muscular contractions must occur in a precise sequence. This sequence is regulated by electrical impulses that emanate from the *sinoatrial node* (an area of specialized muscle at the top of the right atrium), the heart's natural pacemaker. The electrical impulses are

carried to the atria and ventricles partly by the heart muscle itself and partly by nerve fibres.

In order to prevent bottlenecks from developing in the blood circulation, the volume that is pumped at each beat by the two sides of the heart must be balanced exactly. Resistance to blood flow through the general circulation is much greater than resistance through the lungs. Therefore, the left side of the heart must contract more forcibly than the right; for this reason, the left side has greater muscular bulk.

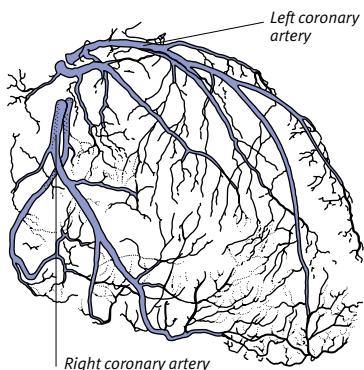

heart, artificial

An implantable mechanical device that takes over the action of the *heart*. However, the term is also used to describe devices that assist the heart in maintaining the circulation.

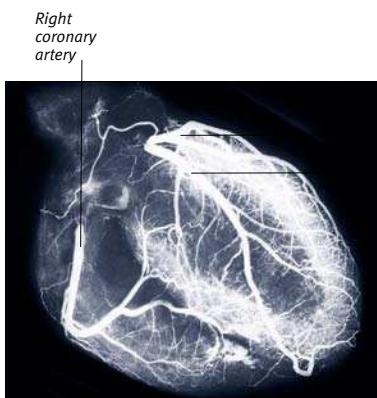

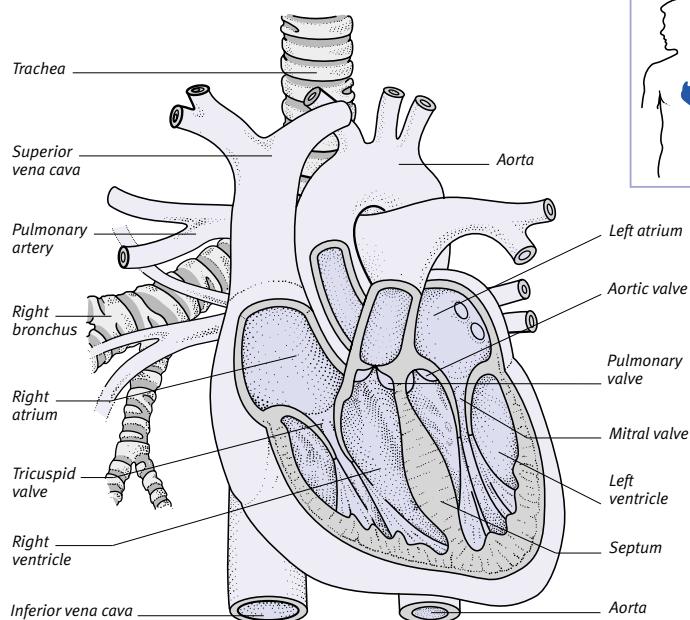

STRUCTURE OF THE HEART

The heart is positioned centrally in the chest, with its right margin directly underneath the right side of the sternum (breastbone). The rest of the heart points to the left, with its lowest point (the apex) located underneath the left nipple.

The heart acts as a dual pump. Deoxygenated blood from the body arrives, via the two *venae cavae*, in the right atrium (upper heart chamber), is transferred to the right ventricle (lower chamber), and is then pumped via the pulmonary artery to the lungs. There it is reoxygenated and returns, via the pulmonary veins, to the left side of the heart. It enters the left atrium, is transferred to the left ventricle, and is then pumped, via a large vessel (the aorta), to all parts of the body.

**Blood supply**

Although the heart muscle is continually pumping blood, it cannot obtain much oxygen from this flow, so it needs its own blood supply. This is provided by the two coronary arteries, which arise from the aorta. These arteries, with their branches, supply the entire heart muscle. A network of veins, called coronary veins (not shown), drains blood back into the right atrium.

**Angiogram of coronary arteries**

This image (left) gives a view of the heart from the rear and clearly shows the coronary arteries. The image was achieved by angiography: an X-ray of the heart was taken after the coronary arteries had been injected with a contrast medium (a fluid that shows up on X-rays).

An intra-aortic balloon pump, comprising a balloon in the *aorta* that inflates with each *heartbeat*, increases the volume of blood entering the circulation. This is a commonly used means of mechanical circulatory support and may be used for the first few days after a *myocardial infarction* (heart attack) until the heart is able to maintain blood pressure unassisted. A left ventricular assist device takes blood from the left *ventricle* and pumps it electrically into the abdominal aorta. True artificial hearts are mechanical hearts, which are powered from outside the body by battery packs.

Problems with artificial hearts include the formation of blood clots within the device and infection. They are therefore used as a temporary measure until a *heart transplant* can be performed.

heart attack

See *myocardial infarction*.

heartbeat

A contraction of the *heart* that pumps blood to the lungs and the rest of the body. The different parts of the heart contract in a precise sequence that is regulated by electrical impulses emanating from the *sinoatrial node*, at the top

of the right *atrium*. Each heartbeat consists of three phases, which occur in a cycle: the diastole (resting phase), the atrial systole (contraction of the heart's upper chambers), and the ventricular systole (contraction of the lower chambers). The rate at which contractions occur is called the *heart rate*.

The term *pulse* refers to the character and rate of the heartbeat when felt at a point on the body, such as the wrist.

heart block

A common disorder of the *heartbeat* that is caused by an interruption to the passage of electrical impulses through

the heart's conducting system. Heart block may be congenital or may be due to heart disease, such as *coronary artery disease*. Other causes include overdose of a *digitalis drug* (used in the treatment of heart disease) and *rheumatic fever*.

TYPES

There are two main types of heart block: *atrioventricular block*, a blockage in the heart's conducting system between an *atrium* (upper chamber of the heart) and a *ventricle* (lower chamber of the heart); and *bundle branch block*, in which the block is confined to conduction within the ventricles.

Atrioventricular block There are three degrees of atrioventricular heart block. In first degree block, there is an increased delay between contraction of the atria and that of the ventricles. In second degree heart block, some atrial beats fail to reach the ventricles. In complete heart block, there is a total blockage in the heart's conducting system that prevents atrial beats from being conducted to the ventricles. The two chambers therefore beat at their own intrinsic rate, with the ventricles beating very slowly and completely independently of the atria.

Bundle branch block Each ventricle has its own conduction system, known as the right and left bundle branches. These work together. Blockage in one or other of the bundle branches (or, less commonly, both) leads to an abnormal pattern of conduction through the ventricles.

Right bundle branch block can sometimes be seen in a healthy heart. It may also be due to certain conditions, such as congenital heart disease (see *heart disease, congenital*). Left bundle branch block is more serious and is always a sign of an underlying cardiac disorder. It is usually caused by *coronary artery disease* but may also occur as a result of *hypertension* (high blood pressure) or *aortic stenosis*.

SYMPTOMS

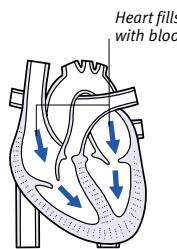

First degree heart block and left or right bundle branch block alone usually cause no symptoms. However, in more severe atrioventricular heart block, the rate of ventricular contraction does not increase in response to exercise. This may cause breathlessness as a result of *heart failure* (reduced pumping efficiency) or chest pains due to *angina pectoris* (caused by reduced blood supply to the heart muscle). If the ventricular beat becomes very slow, or if it stops altogether for a few seconds, episodes of loss of consciousness may occur.

HEART CYCLE

There are three main phases in each heartbeat. The beat is generated by electrical waves that emanate from the heart's own pacemaker, the sinoatrial node. The images in this box show blood flow, an electrocardiogram tracing, and the direction of electrical impulses at each stage of the cycle.

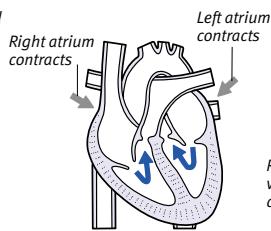

Diastole

In this resting phase, the heart fills with blood. Deoxygenated blood flows into the right side of the heart; at the same time, oxygenated blood flows into the left side.

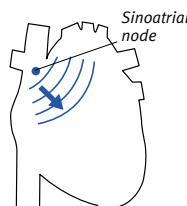

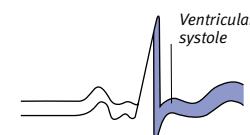

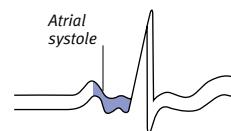

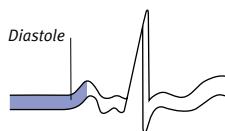

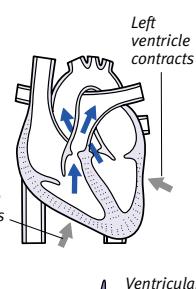

Atrial systole

In this second phase, the two atria (upper chambers of the heart) contract, squeezing more blood into the ventricles (lower chambers) and filling them completely.

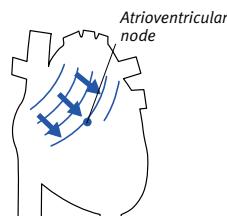

Ventricular systole

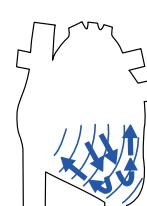

The two ventricles contract to pump deoxygenated blood into the pulmonary artery and oxygenated blood into the aorta. Once the heart is empty, diastole begins again.

In diastole, the heart muscle is at rest. Towards the end of this phase, the sinoatrial node emits an electrical impulse, which starts to spread through the heart muscle.

As the electrical impulse spreads through the two atria, it causes them to contract. By the end of atrial systole, the impulse reaches another node, the atrioventricular node.

After a momentary pause, waves of electrical activity from the atrioventricular node pass along special fibres to all parts of the ventricles, producing ventricular systole.

DIAGNOSIS AND TREATMENT

Both types are usually diagnosed on an *ECG* (electrocardiogram) trace. Heart block with no symptoms may not require any treatment. Heart block causing symptoms is usually treated by fitting a permanent artificial *pacemaker*. Drugs to increase the heart rate and the strength of the heart's contractions may be given temporarily. Any underlying heart disease is treated as necessary.

heartburn

A burning pain in the centre of the chest, which may travel from the tip of the breastbone to the throat. Heartburn

is often brought on by lying down or bending forwards. It may be caused by eating rich or spicy food, or by drinking alcohol. Recurrent heartburn is a symptom of *oesophagitis* (inflammation of the oesophagus), which is usually caused by *acid reflux*.

heart disease, congenital

A term that is used to describe any abnormality of the heart that is present from birth. Congenital defects (see *Types of congenital heart disease* box, overleaf) may affect different parts, including the chambers, valves, or main blood vessels of the heart.

Developmental errors leading to defects arise early in the life of the *embryo*. *Rubella* (German measles) in the mother is the most common known cause, but in most cases the reasons for the defects are not known.

Hereditary factors do not seem to be significant. If a couple have an affected child, there is little increased risk of a second child being affected. People born with heart defects have little increased risk of having an affected child.

SYMPOTMS AND COMPLICATIONS

Symptoms of congenital heart disease arise from either insufficient or excessive circulation of blood to the lungs or the body. Defects in heart anatomy can also cause some deoxygenated blood to be pumped to the body instead of the lungs or some oxygenated blood to the lungs instead of the body. Some heart anomalies cause *cyanosis* (blueness of the skin) and breathlessness, but others may go undetected.

Possible complications resulting from an untreated heart defect include underdevelopment of the limbs and muscles, and *pneumonia* after even mild respiratory infections. With prolonged cyanosis, *clubbing* (thickening and broadening) of the ends of fingers and toes may develop. If there is insufficient capacity in the heart to increase blood flow on effort, the child may rapidly tire during physical exercise. In some untreated cases, a serious complication called *Eisenmenger complex* (increased resistance of the lungs to blood flow) develops.

DIAGNOSIS AND TREATMENT

Antenatal diagnosis, using specialized *ultrasound scanning*, is possible for most defects. After birth, any suspected defect is investigated using *chest X-rays*, *ECG*, or *echocardiography*.

Oxygen and various drug treatments may improve the symptoms. Some conditions, such as small septal defects or patent ductus arteriosus, may become

smaller or may disappear of their own accord. Other defects will require surgical correction. Narrowed heart valves can often be treated by balloon *valvoplasty*. In other cases, *open heart surgery* or a *heart transplant* may be required.

OUTLOOK

Following successful surgery, the child's health often improves dramatically, with resumed growth, increased activity, and a near-normal life expectancy.

Children with heart defects (corrected or uncorrected) are at an increased risk of bacterial *endocarditis*, a potentially dangerous infection of the heart lining and heart valves. To prevent this, such children are given *antibiotic drugs* before all surgical procedures, including dental treatments.

heart disease, ischaemic

The most common form of heart disease. In ischaemic heart disease, there is narrowing or obstruction of the coro-

DISORDERS OF THE HEART

Heart disorders are by far the most common cause of death in developed countries. They also affect the quality of life of millions of people. A wide range of conditions can affect the heart's structure and/or disrupt its action.

Congenital defects

Structural abnormalities in the heart are among the most common birth defects. They result from errors of development in the fetus and include *septal defects* ("holes in the heart") and some types of *heart valve* abnormalities (see *heart disease, congenital*).

Genetic disorders

Genetic factors do not usually play a large part in causing heart disorders. They do, however, contribute to *hyperlipidaemias*, which predispose affected people to *atherosclerosis* and *coronary artery disease*.

Infection

Infection of the lining of the heart and of the heart valves (see *endocarditis*) can result in malfunction of the heart valves. Viral infections can lead to some types of *cardiomyopathy* (malfunctioning of the heart muscle) or *myocarditis* (inflammation of the heart muscle).

Tumours

Tumours arising in the heart tissues are rare. The main types are noncancerous *myxomas*, which develop inside the heart chambers, and cancerous *sarcomas*.

Secondary tumours, spreading from elsewhere in the body, are more common than primary tumours.

Arterial disorders

The coronary arteries (supplying blood to the heart) may become narrowed due to atherosclerosis. Areas of heart muscle may be starved of oxygen, and *angina pectoris* or, eventually, *myocardial infarction* may result.

Nutritional disorders

Obesity is an important factor in heart disease, probably through its effect on other risk factors, such as *hypertension*, *diabetes mellitus*, and *cholesterol*.

Malnutrition may cause the heart muscle to become thin and flabby from lack of protein and calories. *Thiamine* (vitamin B₁) deficiency, common in alcoholics, causes *beriberi* with congestive *heart failure*.

Poisoning

The most common toxin affecting the heart is alcohol. Excessive drinking over many years may cause a type of *cardiomyopathy*. Another common source of toxins is smoking; nicotine and carbon

monoxide in tobacco smoke are thought to encourage the development of atherosclerosis, which can lead to coronary artery disease.

Drugs

Certain medications, such as the anticancer drug *doxorubicin*, *tricyclic antidepressants*, and even drugs used to treat heart disease, may disturb the heartbeat or damage the heart muscle.

Other heart disorders

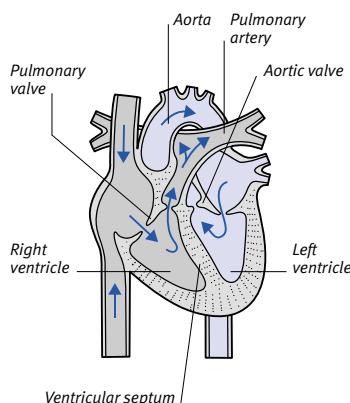

Many disorders may be complications of an underlying condition, such as *cardiomyopathy* or a congenital defect. They include cardiac *arrhythmia*; some cases of *heart block*; heart failure; and *cor pulmonale*, which is a failure of the right side of the heart due to lung disease.

INVESTIGATION

Techniques used for investigating heart disorders include auscultation (listening to the heart); *ECG* (electrocardiography); *imaging techniques* such as *chest X-ray*, *echocardiography*, *coronary angiography*, *CT scanning*, and *MRI*; *cardiac catheterization* (see *catheterization, cardiac*); *blood tests*; and, rarely, by a *biopsy* of the heart muscle.

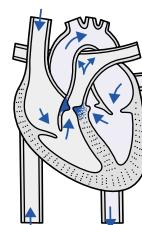

TYPES OF CONGENITAL HEART DISEASE

The major malformations are atrial and ventricular septal defects; coarctation of the aorta; transposition of the great vessels; patent ductus arteriosus; tetralogy of Fallot; hypoplastic left heart syndrome; pulmonary stenosis; and aortic stenosis (not shown). Affected areas are shown in dark blue.

How blood circulates

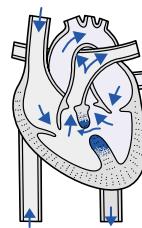

Deoxygenated blood (grey) is pumped from the right ventricle through the pulmonary arteries into the lungs, where it exchanges carbon dioxide for oxygen. Oxygenated blood (blue) enters the left side of the heart; it is pumped from the left ventricle through the aorta to the body tissues.

5%

Pulmonary stenosis

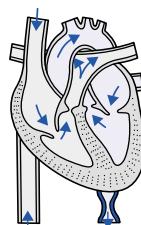

This is a narrowing of the pulmonary valve, or (rarely) of the upper right ventricle, and reduces the blood flow to the lungs.

25%

Ventricular septal defect

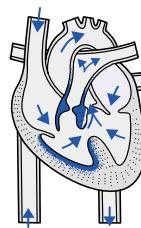

This is a hole in the wall (septum) between the ventricles, causing blood to flow from the left ventricle to the right and into the lungs.

10%

Coarctation of the aorta

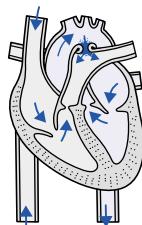

In this disorder, localized narrowing of the aorta reduces the supply of blood to the lower part of the body.

7%

Patent ductus arteriosus

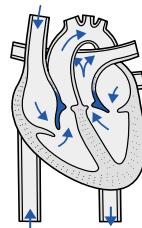

The ductus arteriosus fails to close after birth and blood from the aorta continues to flow through it into the pulmonary artery.

8%

Tetralogy of Fallot

This defect includes a hole in the ventricular septum, pulmonary stenosis, a displaced aorta, and a thickened right ventricle.

14%

Transposition of the great vessels

Oxygenated blood passes back to the lungs, instead of through the aorta to the body tissues.

nary arteries, usually due to *atherosclerosis*, that results in a reduced blood supply (see *coronary artery disease*).

heart failure

Inability of the *heart* to cope with its workload of pumping blood to the lungs and to the rest of the body. Heart failure can primarily affect either the right or the left side of the heart; however, it most commonly affects both sides. Heart failure can be acute or chronic (congestive).

TYPES AND CAUSES

Left-sided heart failure Left-sided failure may be due to *hypertension* (high blood pressure), *anaemia*, *hyperthyroidism* (overactivity of the thyroid gland), a *heart valve defect* (such as *aortic stenosis*, *aortic incompetence*, or *mitral incompetence*), or a congenital heart defect (see *heart disease, congenital*). In all of these conditions, the left side of the heart must work harder than normal to pump the same amount of blood. Sometimes, the heart can compensate for the extra workload

by an increase in the size of the left side and in the thickness of its muscular walls, or by an increase in the *heart rate*. This compensation is only temporary, however, and heart failure eventually follows.

Other causes of left-sided heart failure include *coronary artery disease*, *myocardial infarction* (heart attack), *cardiac arrhythmias* (irregularities of heart rhythm), and *cardiomyopathy* (disease of the heart muscle). In cardiomyopathy, the pumping power of the heart is reduced to a point where it can no longer deal with its normal workload.

Whatever the underlying cause, in left-sided heart failure the left side of the heart fails to empty completely with each contraction, or has difficulty in accepting blood that has been returned from the lungs. The retained blood creates a "back pressure" that causes the lungs to become congested with blood. This condition leads to *pulmonary oedema* (excess fluid in the lungs), of which the main symptom is shortness of breath, eventually even when at rest. The patient

may awaken at night with attacks of breathlessness, wheezing, and sweating.

Right-sided heart failure Right-sided failure is most often caused by *pulmonary hypertension* (raised blood pressure in the arteries supplying the lungs). This is itself caused by left-sided heart failure, or a lung disease such as *chronic obstructive pulmonary disease* (see *pulmonary disease, chronic obstructive*). Right-sided failure can also be due to a heart valve defect, such as *tricuspid incompetence*, or to a congenital heart defect.

In all types of right-sided heart failure, there is back pressure in the circulation from the heart into the venous system, causing swollen neck veins, enlargement of the liver, and *oedema* (excess fluid in body tissues), especially swelling of the legs and ankles. In addition, the intestines may become congested, causing discomfort and indigestion.

INVESTIGATION AND TREATMENT

Investigation of suspected heart failure may involve a physical examination, *X-ray*, *ECG*, and *echocardiography*.

Attacks of acute heart failure may subside of their own accord or may require urgent, life-saving treatment. Immediate treatment of heart failure consists of bed rest, with the patient sitting up. *Diuretic drugs* are given to increase the output of urine from the kidneys, thereby ridding the body of excess fluid and reducing blood volume. *Morphine* and *oxygen* may be given as emergency treatment in acute left-sided heart failure. Long-term drug treatment usually involves the use of *ACE inhibitor drugs* and diuretics. *Angiotensin-II antagonists*, other *vasodilator drugs*, and *beta blocker drugs* may also be required. If heart failure is associated with *atrial fibrillation*, *digoxin* will most likely be prescribed to control the heart rate.

Other possible treatments of heart failure include fitting a *pacemaker*, *coronary artery bypass*, and *heart transplant*.

heart imaging

Any technique that provides images of heart structure. Imaging is used to detect disease or abnormalities.

TYPES

A *chest X-ray*, the simplest and most widely used method of heart imaging, shows heart size and shape, and the presence of abnormal *calcification*. *Pulmonary oedema* (excess fluid in the lungs) and engorgement of the vessels connecting the heart and lungs are also usually detectable with X-rays.

Echocardiography is useful for investigating congenital heart defects and abnormalities of the valves or heart wall. An ultrasound technique that uses the *Doppler effect*, known as Doppler echocardiography, allows measurement of blood flow through valves. *Angiography* may be used to assess the condition of the coronary arteries and valves.

Radionuclide scanning can be used to detect *myocardial infarction* (heart attack), to measure myocardial function and its blood supply, or to determine the viability of the heart muscle following disruption to the blood supply. The information that is obtained depends upon the radioisotope used; for example, thallium-201 may be used to investigate if heart muscle is still viable. Radionuclide scans can also be used to produce images of ventricular function. For example, a *MUGA scan* is used to determine how much blood the heart can pump with each beat and whether different parts of the heart wall are contracting properly.

High-speed *CT scanning* and *MRI* can both be used to produce detailed cross-sectional or three-dimensional images of cardiac structure.

heart-lung machine

A machine that temporarily takes over the function of the *heart* and *lungs* in order to facilitate operations such as *open heart surgery*, *heart transplant*, and *heart-lung transplant*.

A heart-lung machine consists of a pump (to replace the heart's function) and an oxygenator (to replace the lungs' function). It bypasses the heart and lungs. Once the machine is in operation, the patient's heart can be stopped while surgery is carried out.

The use of a heart-lung machine tends to damage red blood cells and to cause blood clotting. These problems can be minimized, however, by the administration of *heparin*, which is an anticoagulant drug.

heart-lung transplant

A procedure in which the *heart* and *lungs* of a patient are removed, to be replaced by donor organs. This surgery is used to treat diseases in which lung damage has affected the heart, or vice versa. Such diseases include *cystic fibrosis*, *fibrosing alveolitis*, and some severe congenital heart defects (see *heart disease, congenital*). A *heart-lung machine* is used to take over the function of the patient's heart and lungs during the operation. A heart-lung transplant is no more dangerous than a *heart transplant* and is technically more straightforward because blood vessels to the lungs need not be disturbed.

heart rate

The rate at which the *heart* contracts to pump blood around the body. In most people, heart rate is between 60 and 100 beats per minute at rest. It tends to be faster in childhood and to slow slightly with age. Very fit people may have a rate below 60 beats per minute.

CHANGES IN HEART RATE AND OUTPUT

The rate at which the heart beats, and the amount of blood pumped out with each contraction, can vary considerably according to the body's demands for oxygenated blood. At rest, the heart contracts at 60 to 80 beats per minute and each ventricle puts out about 80 ml of blood at each beat (about six litres per minute). During vigorous exercise, the heart rate may increase to 200 contrac-

tions per minute; the output may increase to almost 250 ml per beat, producing a total output of 50 litres per minute. Such changes in heart rate and output are brought about by the action of heart muscle and by the involvement of the *autonomic nervous system* (the part of the nervous system concerned with automatic control of body functions).

First, the heart muscle responds automatically to any increase in activity by increasing its output. This increase occurs because active muscles squeeze the veins that pass through them, pushing the blood back towards the heart. The more the ventricles are filled with blood during diastole (the filling phase of the heart's cycle), the more forcibly they contract during ventricular systole to expel the blood.

Second, the heart rate is under the control of the autonomic nervous system. The parts of the system concerned with heart action are a nucleus of nerve cells called the cardiac centre, in the *brainstem*, and two sets of nerves called parasympathetic and sympathetic nerves, whose activities, controlled by the cardiac centre, exert opposing effects on the heart.

When a person is at rest, the parasympathetic nerves (particularly the *vagus nerve*) are active. Signals carried along the vagus nerve act on the sinoatrial node to slow the heart rate from its inherent rate of about 140 impulses per minute to around 70 impulses per minute (a process called *vagal inhibition*). During or in anticipation of muscular activity, vagal inhibition lessens and the heart rate speeds up. The speed may increase even more when the sympathetic nerves come into action. These nerves release the hormone *noradrenaline*, which increases heart rate and the force of contractions. The release of *adrenaline* and noradrenaline by the adrenal glands also acts to increase the heart rate.

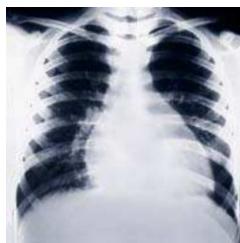

The switch from parasympathetic to sympathetic activity is triggered by any influence on the cardiac centre that signals a need for increased blood output from the heart. Such influences may include fear or anger, low *blood pressure*, or a reduction of oxygen in the blood.

MEASURING HEART RATE

Doctors can measure the rate and rhythm of the heart by feeling the *pulse* or by listening to the heart with a *stethoscope*. A more accurate record can be obtained by *ECG* (a test in which the electrical activity of the heart is measured). A resting heart rate above

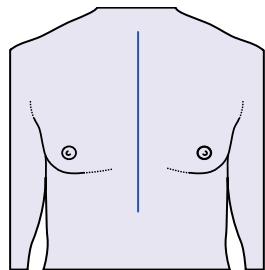

HEART-LUNG TRANSPLANT

In this procedure, both the heart and the lungs of a patient have to be removed and are replaced with organs taken from a brain-dead donor. The donor organs are then inserted into the patient. The removed heart can sometimes be given to another patient. A heart-lung transplant is more straightforward than a *heart transplant* because blood vessels to the lungs need not be disturbed.

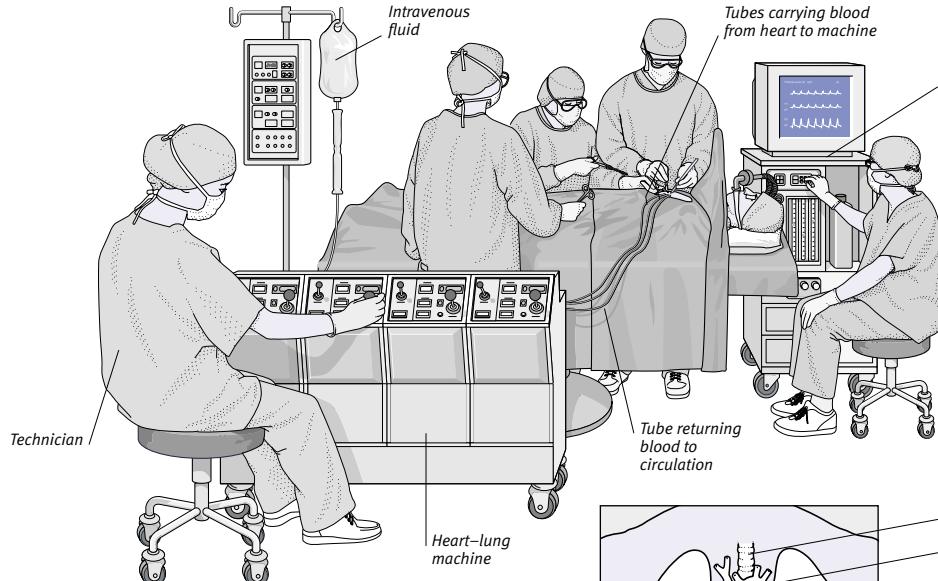

Chest X-ray

1 The donor heart and lungs must be healthy. The lungs must also match the size of the patient's chest, as measured by means of chest X-rays.

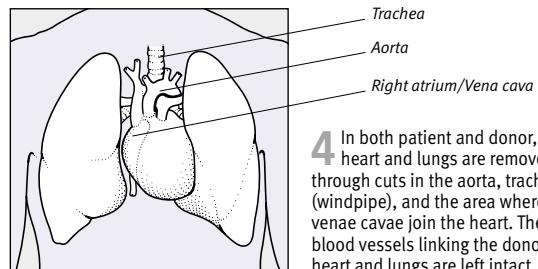

Site of incision

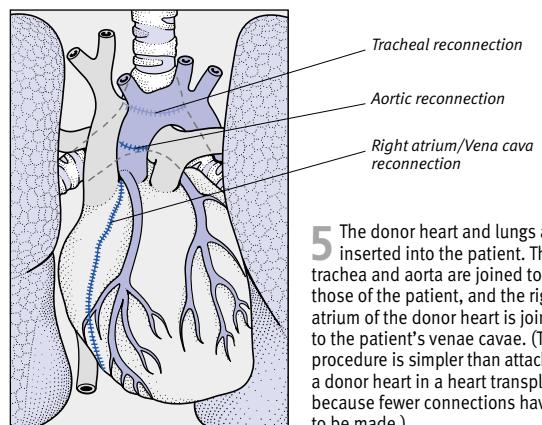

2 In both donor and patient, the heart and lungs are reached via an incision in the sternum (breastbone), and the chest is opened up.

3 The patient is connected to a heart-lung machine. During the operation, this machine takes over the function of heart and lungs, oxygenating blood taken from the venae cavae and pumping it back to the body via the aorta.

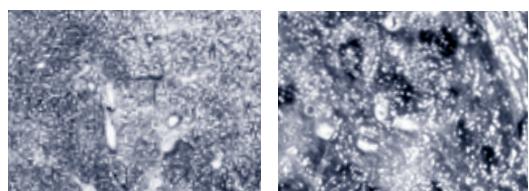

4 In both patient and donor, the heart and lungs are removed through cuts in the aorta, trachea (windpipe), and the area where the venae cavae join the heart. The blood vessels linking the donor heart and lungs are left intact.

5 The donor heart and lungs are inserted into the patient. The trachea and aorta are joined to those of the patient, and the right atrium of the donor heart is joined to the patient's venae cavae. (This procedure is simpler than attaching a donor heart in a heart transplant, because fewer connections have to be made.)

WHY IT IS DONE

Subject to the availability of a donor, a heart-lung transplant can offer hope to someone who is dying of a terminally chronic lung disease, whether or not he or she is also suffering from heart disease. The range of diseases that can be treated with this operation include *emphysema*, *cystic fibrosis*, *sarcoidosis*, and *interstitial pulmonary fibrosis*. The record of success for the heart-lung transplant operation is better than that for lung transplant alone.

Healthy and diseased lung

These images are of a healthy lung (left) and a lung damaged by emphysema (right), in which the alveoli (tiny air sacs) have become greatly enlarged and the walls surrounding them are damaged.

100 beats per minute is termed a *tachycardia*, and a rate below 60 beats per minute is known as a *bradycardia*. (See also *arrhythmia, cardiac*.)

heart sounds

The sounds made by the *heart* during each *heartbeat*. In each heart cycle, there are two main heart sounds that can clearly be heard through a *stethoscope*. The first is like a “lubb”. It results from closure of the *tricuspid* and *mitral valves* at the exits of the atria (upper heart chambers), which occurs when the ventricles (lower heart chambers) begin contracting to pump blood out of the heart. The second sound is a higher-pitched “dupp” caused by closure of the pulmonary and aortic valves at the exits of the ventricles when the ventricles finish contracting.

Abnormal heart sounds may be a sign of various disorders. For example, high-pitched sounds or “clicks” are due to the abrupt halting of valve opening, which can occur in people with certain *heart valve* defects. Heart *murmurs* are abnormal sounds caused by turbulent blood flow. Murmurs may be due to heart valve defects or to congenital heart disease.

heart surgery

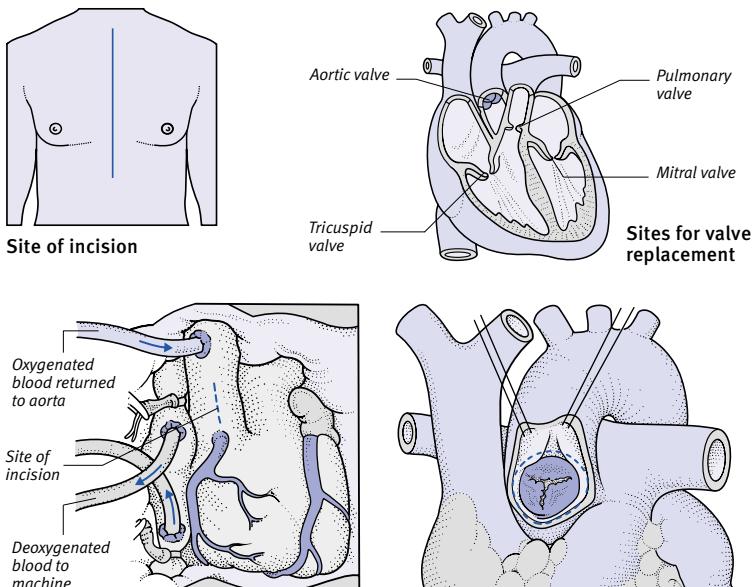

Any operation that is performed on the *heart*. *Open heart surgery* allows the treatment of most types of heart defect that are present at birth (see *heart disease, congenital*) as well as various disorders of the *heart valves*. *Coronary artery bypass* is performed to redirect blood away from a blocked coronary artery. Angioplasty balloons (see *angioplasty, balloon*) can be used to open up narrowed heart valves in cases where the patient is unsuitable for open heart surgery (see *valvuloplasty*). *Heart transplant* surgery can offer hope to people with progressive, incurable heart disease.

heart transplant

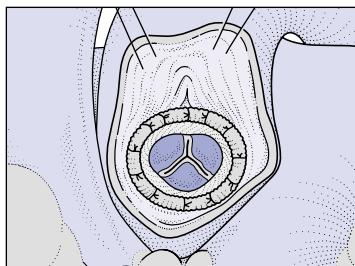

Replacement of a patient’s damaged or diseased *heart* with a healthy heart taken from a donor who has just died. Typically, a transplant patient has advanced *coronary artery disease* or *cardiomyopathy* (disease of heart muscle). During the operation, the function of the heart is taken over by a *heart-lung machine*. Most of the diseased heart is removed, but the back walls of the atria (upper chambers) are left in place. The ventricles (lower chambers) are then attached to the remaining areas of the recipient’s heart. Because the transplant-

HEART-VALVE REPLACEMENT

Any one of the four heart valves (aortic, pulmonary, mitral, or tricuspid) may be replaced by a natural or an artificial valve. The procedure shown in the steps below is for replacement of the aortic heart valve.

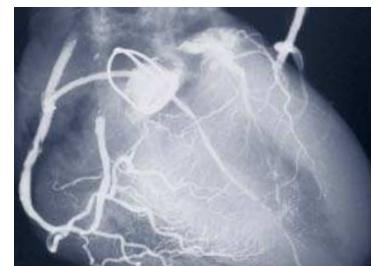

1 In nearly all heart-valve surgery, an incision is made through the breastbone (sternum) into the chest cavity. The patient is put on a *heart-lung machine*, the beating of the heart is stopped, and the heart is opened.

3 The replacement valve is sutured into position and the aorta is closed. The patient is disconnected from the heart-lung machine and the chest wall is sewn up. The operation takes between two and four hours.

2 The valve is first examined to determine whether it can be repaired or whether it must be replaced. If the latter is necessary (as here), the valve is excised. (The dotted line in this picture shows where the incision is made.)

Artificial heart valve in place
This chest X-ray shows the metal components of an artificial heart valve. A ball-and-cage valve has been used to replace the patient’s diseased valve.

ed heart has no nerve supply, patients tend to have a high resting heart rate and no variation in blood pressure from day to night.

After the immediate post-operative period, the outlook is good. Patients do, however, face the long-term problems associated with other forms of *transplant surgery*, including *rejection* and infection. (See *heart-lung transplant*).

heart valve

A structure at the exit of a *heart chamber*, consisting of two or three cup-shaped flaps, that allows blood to flow out of the chamber but prevents it from washing back. There are four heart valves: aortic, pulmonary, mitral, and tricuspid. The opening and closing of the heart valves during each heart cycle produces *heart sounds*.

DISORDERS

Heart valves may be affected by *stenosis* (narrowing), in which the heart must work harder to force blood through, or by incompetence or insufficiency (leakiness), which makes the valve unable to prevent *regurgitation* (backwash) of blood. These defects cause heart *murmurs*.

Defects of the heart valves may be present from birth (see *heart disease, congenital*) or acquired later in life. The most common congenital valve defects are *aortic stenosis* and *pulmonary stenosis*. Acquired heart-valve disease is usually the result of degenerative changes or *ischaemia* (reduced blood supply) affecting part of the heart and leading to aortic stenosis or *mitral incompetence*. *Rheumatic fever* can cause *mitral stenosis*, mitral incompetence, defects of the aortic valve, *tricuspid stenosis*, and *tricuspid incompetence*. Heart valves may also be damaged by bacterial *endocarditis*.

Heart-valve disorders commonly lead to *heart failure*, *arrhythmias*, or symptoms that arise from reduced blood supply to the tissues.

Heart-valve defects may be diagnosed by *auscultation*, *chest X-ray*, *ECG*, or *echocardiography* and may be corrected by *heart-valve surgery*.

heart-valve surgery

An operation to correct a *heart valve* defect or to remove a diseased or damaged valve. A heart valve may have to be repaired, widened, or replaced because it is either incompetent (leaky), stenotic (narrowed), or both. Widening of a valve may involve *valvotomy* or *valvuloplasty*. A damaged valve can be replaced by a mechanical one (fashioned from metal and plastic), a valve constructed from human tissue, a pig valve, or a valve taken from a human donor after death. A *heart-lung machine* is used during valve replacement.

After heart-valve surgery, there may be symptoms of breathlessness for several weeks that require continued medication. Some people require long-term treatment with *anticoagulant drugs* to prevent the formation of blood clots around the new valve. Certain types of

replacement valve, such as mechanical valves, are more likely to cause clots than other types.

heat cramps

Painful muscle contractions caused by salt loss through profuse *sweating*. Heat cramps are usually brought on by strenuous activity in extreme heat. They may develop independently or may occur as a symptom of *heat exhaustion* or *heat stroke*. Prevention and treatment consist of drinking plenty of fluids, although heat cramps often resolve themselves.

heat disorders

The body functions most efficiently at a temperature of about 37°C, and any major deviation from this temperature disrupts body processes. The body has special mechanisms for keeping its internal temperature constant; any malfunctioning or overloading of these mechanisms may cause a heat disorder.

The mechanisms by which the body loses excess heat are controlled by the part of the brain known as the *hypothalamus*.

HEART-VALVE REPLACEMENT TYPES

There are three main types of replacement heart valve: bioprostheses (such as the Carpenter–Edwards valve, right), mechanical valves (such as the tilting-disc valve, centre right), and homografts (valves taken from a human donor, far right). A valve is only replaced if it cannot be repaired. Heart-valve replacement (see previous page) is carried out by open surgery, which requires a *cardiopulmonary bypass*. The most frequently replaced valves are the aortic and mitral valves.

Bioprostheses

These are taken from pigs (as above) or can be made from porcine or bovine tissue and used with or without a stent (a tube to help the valve to hold its shape).

Mechanical valves

There are two main types: those with one (as above) or more tilting-discs, and ball-and-cage. Mechanical valves are made from carbon fibre, metal, and plastic.

Homografts

These are healthy valves taken from a person who has died of a disease that does not affect the heart. Homografts are a type of bioprosthetic.

Examples	Bioprosthetic (xenograft)	Mechanical	Homograft
Made from	Bovine or porcine tissue with or without a stent (rigid tube)	Metal and plastic	Human valve
Availability	Readily available	Readily available	Limited availability
Suitable age group	Over 60	All ages	All ages
Duration	Up to 15 years	Lifetime	15 to 20 years
Post-operative drug therapy	Three months' treatment with anticoagulant drugs	Lifelong treatment with anticoagulant drugs	Three months' treatment with anticoagulant drugs
Possible complications	Infection; stroke; tendency to become calcified	Infection; stroke; calcification; leakage around base of valve	Less prone to infection

When blood temperature rises, the hypothalamus sends out nerve impulses to stimulate the *sweat glands* and dilate blood vessels in the skin. These changes in the skin cool the body down, but excessive sweating may result in an imbalance of salts and fluids in the body, leading to *heat cramps* or *heat exhaustion*. When the hypothalamus is disrupted (for example, by *fever*), the body may overheat, leading to *heatstroke*. Excessive external heat may cause *prickly heat*.

Most heat disorders can be prevented by gradual acclimatization to hot conditions and taking salt tablets or solution. A light diet and frequent cool baths or showers may also help. Alcohol and strenuous exercise should be avoided.

H**heat exhaustion**

Fatigue, leading to collapse, that is caused by overexposure to heat. The principal causes of heat exhaustion are insufficient water intake, insufficient salt intake, and a deficiency in *sweat* production. In addition to fatigue, symptoms may include faintness, dizziness, nausea and vomiting, headache, and, when salt loss is heavy, *heat cramps*. The skin is usually pale and clammy, breathing is fast and shallow, and the pulse is rapid and weak. Unless it is treated, heat exhaustion may develop into *heatstroke*.

Treatment of heat exhaustion involves rest and replenishing lost water and salt. Prevention is usually by gradual acclimatization to hot conditions.

heat, prickly

See *prickly heat*.

heatstroke

A life-threatening condition in which overexposure to heat, coupled with a breakdown of the body's mechanisms for regulating temperature, cause the body to become overheated. A common cause is prolonged, unaccustomed exposure to the sun in a hot climate. Unsuitable clothing, strenuous activity, overeating, and overconsumption of alcohol can also be contributory factors.

Heatstroke is often preceded by *heat exhaustion*, which consists of fatigue and profuse *sweating*. With the onset of heatstroke, the sweating diminishes and may stop entirely. The skin becomes hot and dry, breathing is shallow, and the pulse is rapid and weak. Body temperature rises dramatically and, without treatment, the victim may lose consciousness and even die.

Heatstroke can be prevented by gradual acclimatization to hot conditions (see *heat disorders*). If it does develop, emergency treatment is needed. This consists of cooling the victim by wrapping him or her in a cold, wet sheet, fanning the body, sponging with water, and giving the person a salt solution to drink.

heat treatment

The use of heat to treat disease, aid recovery from injury, or to relieve pain. Heat treatment is useful for certain conditions, such as ligament *sprains*, because it stimulates blood flow and promotes healing of tissues.

Moist heat may be administered by soaking the affected area in a warm bath, or by applying a hot *compress* or *poultice*. Dry heat may be administered by a heating pad, a hot-water bottle, or a heat lamp that produces *infra-red* rays. More precise methods of administering heat to tissues deeper in the body include *ultrasound treatment* and *short-wave diathermy*.

hebephrenia

A form of *schizophrenia* that usually becomes evident in adolescence. It is characterized by inappropriate and disorganized behaviour, withdrawal from social contact, and changes in mood.

Heberden's node

A bony enlargement affecting the joint at the end of the finger, adjacent to the nail. The tendency to develop such nodes is a feature of *osteoarthritis* and is usually inherited.

heel

The part of the *foot* that is situated below the *ankle* and behind the arch. The heel consists of the *calcaneus* (heel bone), an underlying pad of fat that acts as a cushion, and a layer of skin, which is usually thickened and hardened due to pressure from walking.

heel, cracked

Painful cracks that develop in the thickened skin over the heels. Regular removal of any hard skin using a file or pumice stone, combined with the use of moisturizing cream, can reduce the frequency of such cracks and the severity of the pain. Cracked heels may also be caused by a bacterial infection of the skin on the soles of the feet, also known as pitted keratolysis. The disorder causes small, round pits to develop in the skin; these pits eventually join together to form cracks.

heel, painful

Discomfort resulting from disorders of the *calcaneus* (heel bone) or the soft tissues around it. Pain in the heel may result from a fracture of the calcaneus; a spur (a bony growth on the calcaneus); inflammation of the fluid-filled pad cushioning the back of the heel (see *calcaneal bursitis*); or inflammation of the tissues at the bottom of the heel (called *plantar fasciitis*), which, in some cases, is a feature of *ankylosing spondylitis*. In addition, the skin overlying the heel may become blistered and painful as a result of walking long distances and/or wearing ill-fitting shoes.

heel prick blood test

See *Guthrie test*.

height chart

A chart used by a doctor or health visitor to record a child's growth and to compare his or her height with the typical range in a particular age group. (See also *growth, childhood*.)

height velocity

The rate of children's increase in height at a particular age. The measurement is given in centimetres per year.

Heimlich manoeuvre

A first-aid treatment for *choking*. The aim of the Heimlich manoeuvre is to dislodge the material that is causing the blockage.

The first aider stands behind the victim and places one fist, covered by the other, centrally just below the victim's rib cage and pulls sharply inwards and upwards to give an abdominal thrust. This action, like *coughing*, forces air out of the airways and should help to dislodge any blockage.

Helicobacter pylori

A bacterium (see *bacteria*) now known to be the cause of most *peptic ulcers* as well as a factor in *stomach cancer*. The infection is probably acquired during childhood through person-to-person spread. There is an extremely high worldwide incidence of *HELICOBACTER PYLORI* infection, with higher rates in developing countries. Of those infected, only about 15 per cent develop peptic ulcer disease, although 95 per cent of people with duodenal ulcers are found to be infected with *HELICOBACTER PYLORI*. The bacterium is thought to damage the mucus-producing layer of the *stomach* and *duodenum*, bringing gastric acid into contact with the linings of these structures and cause ulceration.

INVESTIGATION AND TREATMENT

There are several different ways of diagnosing *HELICOBACTER PYLORI* infection. A *breath test* relies on the ability of the bacterium to split molecules of radio-tagged *urea*, releasing labelled carbon dioxide, which can then be detected in the breath. Tests to check for the presence of *antibodies* (proteins produced by the immune system) to the bacterium may be useful, but they cannot confirm that infection has been eradicated. A *biopsy* sample taken from the stomach or duodenal lining can be used to conduct chemical tests, for microscopic analysis, or *cultured* for the organism.

Treatment to eradicate the infection with a combined course of acid-suppressing *ulcer-healing drugs* and *antibiotic drugs* has proved successful in achieving long-term recovery from peptic ulcers. Reinfestation is rare. (See also *gastritis*.)

heliotherapy

A form of *phototherapy* involving exposure to sunlight.

helminth infestation

Infection by any parasitic worm. (See *worm infestation*.)

helper T-cell

A type of white blood cell, also known as a helper T-lymphocyte (see *lymphocyte*), that has an important role in the *immune system*. Helper T-cells assist in the destruction of abnormal cells (such as cancer cells) in the body by recognizing foreign *antigens* on the surface of the abnormal cells and subsequently stimulating the production of *killer T-cells*.

Helweg–Larsen's syndrome

An autosomal dominant *genetic disorder*, affecting both sexes, that is chiefly characterized by a reduced ability to lose body heat through sweating. Affected individuals have anhidrosis (inability to sweat) from birth; they have a very small number of sweat glands, and those that do exist are abnormally enlarged. This defect leads to disturbances in body temperature. There are also malformations in the skin and nail tissues. In addition, affected people develop *deafness* due to inner ear problems in their 30s or 40s.

hemianopia

Loss of half of the *visual field* in each eye. Hemianopia may be "homonymous" (in which the same side of both eyes is affected) or "heteronymous" (in which the loss

occurs in opposite sides of the eyes). The visual loss can be either temporary or permanent.

Hemianopia results from damage to the *optic nerves* or the brain. Transient homonymous hemianopia in young people is usually caused by *migraine*. In older people, it occurs in *transient ischaemic attacks* (brief interruptions of blood supply to the brain). Permanent homonymous hemianopia is usually caused by a *stroke*, but it may result from brain damage by a tumour, injury, or infection. Hemianopia may also be caused by pressure on the optic nerve from a *pituitary tumour*.

hemiballismus

Irregular and uncontrollable flinging movements of the arm and leg on one side of the body, caused by disease of the *basal ganglia* (nerve cell clusters in the brain concerned with muscular coordination). (See also *athetosis*; *chorea*.)

hemicolecotomy

The surgical removal of half, or a major portion, of the *colon*. (See also *colectomy*.)

hemiparesis

Muscular weakness or partial *paralysis* in one side of the body (see *hemiplegia*).

hemiplegia
