Paralysis or weakness on one side of the body, caused by damage or disease affecting the motor nerve tracts in the opposite side of the brain. A common cause is a *stroke*. Others include *head injury*, *brain tumour*, *brain haemorrhage*, *encephalitis* (brain inflammation), *multiple sclerosis*, complications of *meningitis*, or a *conversion disorder* (a type of psychological disorder). Treatment is for the underlying cause, and is carried out in conjunction with *physiotherapy*.

hemivertebra

A *birth defect* in which half of a vertebra (spinal bone) fails to develop fully.

Hemoccult

A brand name for a type of *faecal occult blood test* that uses *guaiac* to screen for gastrointestinal bleeding, a possible sign of colorectal cancer (see *colon*, *cancer of rectum*, *cancer of*).

Henoch–Schönlein purpura

Inflammation of small blood vessels, causing leakage of blood into the skin, joints, kidneys, and intestine. The dis-

ease is most common in young children, and may occur after an infection such as a sore throat. Henoch–Schönlein purpura may also be due to an abnormal allergic reaction.

The main symptom is a raised purplish rash on the buttocks and backs of the limbs. The joints are swollen and often painful, and colicky abdominal pain may occur. In some cases, there is intestinal bleeding, leading to blood in the faeces. The kidneys may become inflamed, resulting in blood and protein in the urine.

The only treatment usually required is bed rest and *analgesic drugs* (painkillers). Complications may arise if kidney inflammation persists. In severe cases, *corticosteroid drugs* may be given.

heparin

An *anticoagulant drug* used to prevent and treat abnormal *blood clotting*. Heparin is given by injection and is used as an immediate treatment for *deep vein thrombosis* or for *pulmonary embolism*; it may also be given as a preventative measure to people immobilized as a result of illness or surgery. Low molecular weight heparins, such as *tinzaparin*, which only need to be injected once a day, are now widely used and can be self-administered at home.

Adverse effects of heparin include rash, aching bones, and abnormal bleeding in different parts of the body. Long-term use may cause *osteoporosis*.

hepatectomy, partial

Surgical removal of part of the *liver*. This procedure may be needed to remove a damaged area of liver following injury, or to treat noncancerous liver tumours and *hydatid disease*. Rarely, *liver cancer* is treated in this way.

hepatectomy, total

Surgical removal of the *liver*. Hepatectomy is the first stage in a *liver transplant* operation.

hepatic

Relating to the *liver*.

hepatic encephalopathy

A brain disorder caused by a build-up of toxins in the body as a result of *liver failure*. (See also *encephalopathy*.)

hepatic failure

This is the medical term for *liver failure*, in which the function of the liver is severely impaired.

hepatitis

Inflammation of the *liver*, with accompanying damage to liver cells. The condition may be acute (see *hepatitis, acute*) or chronic (see *hepatitis, chronic*) and may have various causes. (See also *hepatitis A; hepatitis B; hepatitis C; hepatitis D; hepatitis E; hepatitis, viral.*)

hepatitis A

Also known as epidemic hepatitis, this disorder is caused by the hepatitis A virus, which exists in the urine and faeces of infected people and is transmitted in contaminated food or drink. The incubation period lasts for 15–40 days, after which nausea, fever, and *jaundice* develop. Recovery usually occurs within three weeks. Serious complications are rare. Active *immunization* gives the best protection against hepatitis A, and may be advised for people travelling to Mediterranean or developing countries. An attack of the disease can confer immunity against subsequent infection.

hepatitis, acute

Short-term inflammation of the *liver*. Acute hepatitis usually clears up in one to two months. In some cases, the disorder may progress to chronic hepatitis (see *hepatitis, chronic*), but it rarely leads to acute *liver failure*.

Acute hepatitis is fairly common. The most frequent cause is infection with one of the hepatitis viruses (see *hepatitis, viral*), but it can arise as a result of other infections such as *cytomegalovirus* infection. It may also occur as a result of overdose of *halothane* or *paracetamol*, or because of exposure to toxic chemicals including alcohol (see *liver disease, alcoholic*). Symptoms range from mild to severe. They include tiredness; fever; nausea and vomiting; pain in the upper right side of the abdomen; and *jaundice*.

Blood tests, including *liver function tests*, may be used for diagnosis. In most cases of acute viral hepatitis, natural recovery occurs within a few weeks. If the disorder is caused by exposure to a chemical or drug, detoxification using an *antidote* may be possible. *Intensive care* may be required if the liver is badly damaged. Rarely, a *liver transplant* is the only way of saving life. In all cases, alcohol should be avoided after the illness.

hepatitis B

A disorder caused by the hepatitis B virus. The infection is transmitted in blood, blood products, or other body fluids

(often through contact with used needles and syringes); blood transfusions; or sexual contact. After an incubation period of one to six months, the onset of symptoms, such as headache, fever, and *jaundice*, may be sudden or gradual; sometimes, there are no symptoms. Most affected people recover, but hepatitis B can be fatal. A vaccine is available; it is usually given to people at high risk of coming into contact with the virus, such as health-care workers or people visiting areas where the disease is common.

In a few cases, the virus continues to cause inflammation and can still be detected in the blood for longer than six months after infection. People who suffer from persistent infection are at long-term risk of *liver cancer* and *cirrhosis* and may need to be treated with *interferon*.

hepatitis C

Caused by the hepatitis C virus and formerly known as non-A non-B *hepatitis*, this infection is often transmitted through sharing needles. Blood transfusions no longer pose a significant risk in the UK because all blood used for transfusions is now routinely screened for the virus.

Hepatitis C has an incubation period of six to 12 months. It begins as a mild illness, which may go undetected. In about three in four patients, chronic hepatitis develops (see *hepatitis, chronic*), which can progress to *cirrhosis* of the liver and an increased risk of *hepatoma* (a type of liver cancer).

hepatitis, chronic

Inflammation of the *liver* that persists for a prolonged period. Eventually, chronic hepatitis causes scar tissue to form and may lead to the development of *cirrhosis*.

The disorder may develop following an attack of acute hepatitis (see *hepatitis, acute*) or *hepatitis C*. It may also occur as the result of an *autoimmune disorder*, a viral infection (see *hepatitis, viral*), a reaction to certain types of prescribed drugs or, more rarely, to a *metabolic disorder*, such as *haemochromatosis* or *Wilson's disease*. In some cases, no obvious cause can be found.

Symptoms of chronic hepatitis, such as *jaundice* and slight fatigue, may alternate with periods in which there are no symptoms at all. If left untreated, the condition may progress to *liver failure*.

Chronic hepatitis is diagnosed by *liver biopsy*. Autoimmune hepatitis is treated with *corticosteroid drugs* and *immunosuppressants*. Viral infections often respond

to *interferon*. In the drug-induced type of chronic hepatitis, withdrawal of the medication can lead to recovery. For metabolic disturbances, treatment is for the underlying disorder.

hepatitis D

An infection of the liver caused by the hepatitis D virus, which occurs only in people who already have *hepatitis B* infection. People who develop hepatitis D will usually suffer from severe chronic liver disease. Hepatitis D is also known as delta hepatitis.

hepatitis E

A type of *hepatitis* caused by the hepatitis E virus, which is transmitted in contaminated food or drink. The disease is similar to *hepatitis A*.

hepatitis, serum

The former name for *hepatitis B*.

hepatitis, viral

Any type of *hepatitis* caused by a viral infection. Five viruses that attack the liver as their primary target have been identified. They cause *hepatitis A, hepatitis B, hepatitis C, hepatitis D*, and *hepatitis E*.

hepatocele

The medical term used to describe the protrusion of part of the *liver* through the wall of the abdomen.

hepatocellular carcinoma

The most common type of primary *liver cancer* that arises from within mature liver cells. Hepatocellular carcinoma may develop in people who are suffering from *cirrhosis* of the liver, especially following infection with *hepatitis B* or *hepatitis C*. Incidence of hepatocellular carcinoma is far greater in tropical areas of the world. Symptoms of the condition include hepatomegaly (enlargement of the liver), *jaundice*, and weight loss.

hepatoma

A tumour of the *liver*. A cancerous hepatoma is also known as a *hepatocellular carcinoma*.

hepatomegaly

Enlargement of the *liver*, occurring as a result of any liver disorder (see *liver, disorders of*).

hepatotoxic

A term for substances, such as certain drugs, that cause damage to liver cells.

MAIN TYPES OF VIRAL HEPATITIS		
	Viral hepatitis type A (epidemic hepatitis)	Viral hepatitis types B and C
Transmission of infection	The virus is present in the faeces of infected people and is transmitted by faecal contamination of water and food (such as through poor hygiene in food handling). Faeces are infective from two to three weeks before until about eight days after the onset of jaundice. Local epidemics can occur.	These viruses are present in the blood and other body fluids of infected people, many of whom appear to be in normal health. Infection is spread sexually or by sharing hypodermic needles; in the past it was spread by use of contaminated blood and blood products.
Groups at particular risk	Travellers to areas where hygiene standards are poor and prevalence of the virus is high (such as parts of Asia, Africa, or South America) are most at risk.	Those most at risk are male homosexuals, people with multiple sexual partners, intravenous drug users, healthcare workers, or babies born to mothers with the virus.
Incubation period	This lasts for 15–40 days after the virus has entered the body.	This lasts for 1–6 months (type B) and 6–12 months (type C) after infection.
Symptoms and outlook	In many cases there are no symptoms. There may be nausea, vomiting, malaise, and a mild flulike illness with jaundice, lasting about two to three weeks. The condition never progresses to chronic hepatitis.	Symptoms are similar to those of the type A virus, although they may be more severe. Up to ten per cent of adults with type B and up to 70 per cent with type C develop chronic hepatitis, with continuing illness and eventual cirrhosis of the liver.
Preventive measures	Travellers should take advice about the need for immunization for travel to a given destination. Active immunization involves two doses of the hepatitis A vaccine, given six to 12 months apart; this provides immunity for up to ten years.	Measures include the screening of blood donors, treatment of donated blood, and safe sex. Intravenous drug users should not share needles. Immunization against hepatitis B may be offered to people at high risk of contracting the virus (such as babies of infected mothers, healthcare workers, and drug users). Travellers should take advice about the need for immunization for their destination. The vaccine is given in three doses; the second dose is given one month after the first, and the third six months after the first.

herald patch

A single pink patch with a scaly edge that appears on the skin of the trunk. A herald patch develops about a week before the full rash of the skin disorder *pityriasis rosea* breaks out.

herbal medicine

Systems of medical treatment in which various parts of different plants are used to promote health and to treat symptoms of illness. Herbal medicine is a form of *complementary medicine*. Herbal remedies are also used in treatments such as *homeopathy* and *Chinese medicine*.

Although herbal medicine is thought by some to be harmless because it is natural, some herbal remedies contain significant amounts of pharmalogically

active substances that may interact with other drugs or affect other medical conditions. Herbal remedies should only be used on the advice of an approved practitioner; a patient should always inform his or her doctor of any herbal medicine he or she is using.

herd immunity

Protection of a whole community from an infectious disease as a result of immunity in a majority, but not all, of that community. Such immunity may be naturally acquired or may be induced by *immunization*. For example, vaccination of more than 85 per cent of a population against diphtheria will prevent the spread of the disease, should it occur, due to an insufficient number of

susceptible people who could catch it and pass it on to others. As a result, even those people without immunity receive a degree of protection from being part of an immune population.

hereditary haemorrhagic telangiectasia

An inherited condition in which capillaries (tiny blood vessels) in the skin and in the mucous membranes of areas such as the nose, mouth, and gastrointestinal tract are distended and prone to recurrent bleeding. The condition can result in iron deficiency anaemia (see *anaemia, iron deficiency*). Hereditary haemorrhagic telangiectasia shows an autosomal dominant pattern of inheritance (see *genetic disorders*). (See also *telangiectasia*.)

hereditary spherocytosis

See *spherocytosis, hereditary*.

heredity

The transmission of traits and disorders through genetic mechanisms. Each individual inherits a combination of *genes* via the sperm and egg cells from which he or she is derived. The interaction of the genes determines inherited characteristics, including, in some cases, disorders or susceptibility to disorders. (See also *genetic disorders; inheritance*.)

heritability

A measure of the extent to which a disease or disorder is the result of inherited factors, as opposed to environmental influences such as diet and climate. Certain disorders (such as *haemophilia* or *cystic fibrosis*) are known to be caused entirely by hereditary factors. In contrast, others are caused wholly by environmental factors. However, existing between these extremes are many disorders (such as *schizophrenia*) in which both inheritance and environment probably play a part.

A rough estimate of heritability can be obtained from the known incidence of a disorder in the first-degree relatives (parents or siblings) of affected people compared with the incidence of the disorder in a population exposed to similar environmental influences. Estimates of heritability are useful in *genetic counselling*. (See also *genetic disorders*.)

hermaphroditism

A *congenital* disorder in which *gonads* (testes or ovaries) of both sexes are present within one individual, and in

which the external genitalia are not clearly male or female. True hermaphroditism is extremely rare and its cause is unknown. A more common condition is *pseudohermaphroditism*, in which the gonads of only one sex are present, but the external genitalia are not clearly either male or female, or are those of the opposite sex.

hernia

Protrusion of an organ or tissue through a weak area in the muscle or tissue that normally contains it. The term is usually applied to a protrusion of the intestine

through the abdominal wall. In a *hiatus hernia*, the stomach protrudes through the diaphragm, into the chest.

CAUSES

Abdominal hernias may be caused by a *congenital* weakness in the wall of the abdomen. Hernias may also be the result of damage caused by lifting heavy objects, persistent coughing, or straining to defaecate, or they may develop following an operation.

TYPES

There are several types of abdominal hernia, which are classified according to their location in the body. The most

important are inguinal hernias, which mainly affect men; femoral hernias, which are more common in overweight women; and umbilical hernias, which occur in babies.

SYMPTOMS AND TREATMENT

The first symptom of an abdominal hernia is usually a bulge in the abdominal wall. There may also be some abdominal discomfort.

Sometimes the protruding intestine can be pushed back into place (known as a reducible hernia). In other cases, however, the hernia bulges out and cannot be put back (an irreducible hernia). This condition is painful, and surgery is usually necessary to repair the weakened area (see *hernia repair*).

If the trapped portion of intestine becomes twisted, the blood supply to the area will be impaired. This problem, known as a strangulated hernia, needs urgent treatment, otherwise *gangrene* of the bowel may develop.

Umbilical hernias in babies can usually be left untreated as they tend to disappear naturally by age five.

hernia repair

Surgical correction of a *hernia*. Surgery is usually performed to treat a hernia of the abdominal wall that is painful or cannot be pushed back into place. A strangulated hernia (in which the blood supply to a trapped portion of intestine is cut off) requires an emergency operation.

During surgery, the protruding intestine is pushed back into the abdomen and the weakened muscle wall strengthened. Either open or *minimally invasive surgery*, using an endoscope to repair the hernia from within the abdominal cavity, may be used.

herniated disc

See *disc prolapse*.

herniorrhaphy

See *hernia repair*.

heroin

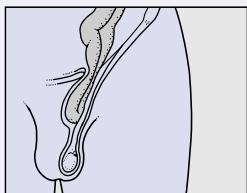

A *narcotic drug* similar to *morphine*. When used for medical purposes, it is generally known as *diamorphine*. Heroin may also be abused for its mood-altering effects (see *heroin abuse*).

heroin abuse

Nonmedical, illicit use of heroin. The heroin taken by drug abusers is a white or brownish powder that can be smoked, sniffed, or dissolved in water and injected.

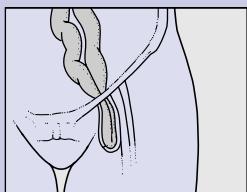

MAIN TYPES OF ABDOMINAL HERNIA

Inguinal hernia

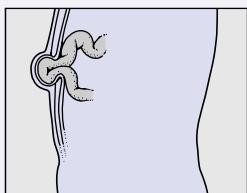

At least 2 per cent of adult males in the UK suffer at some time from this kind of hernia, in which part of the intestine bulges through the inguinal canal (the passage through which the testes descend into the scrotum). The hernia is detected as a bulge in the groin or scrotum; untreated, the hernia may become stuck, so early surgery is generally recommended.

Femoral hernia

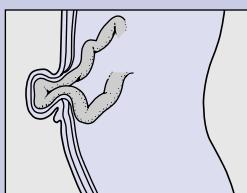

This type of hernia occurs most commonly in obese women; part of the intestine emerges where the femoral vein and artery pass from the abdomen to the thigh. A femoral hernia is noticed as a swelling of the top front of the thigh. Although the hernia itself may be large, its neck is narrow, and the condition can only be corrected by surgery.

Epigastric hernia

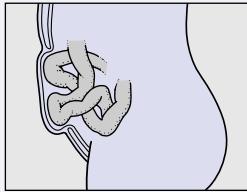

Also called a ventral hernia, an epigastric hernia is caused by a weakness in the muscles of the central upper abdomen; the intestine bulges out at a point between the navel and the breastbone. This form of hernia is three times more common in men than in women and is most likely to occur in people between 20 and 50 years old.

Umbilical hernia

This occurs when part of the intestine protrudes through the abdominal wall at the navel. Babies are the most common sufferers; the hernia can be repaired surgically or it may disappear naturally by about the age of five. A similar problem, a paraumbilical hernia, occurs mostly in obese, middle-aged women who have had several children.

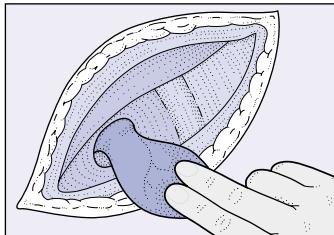

Incisional hernia

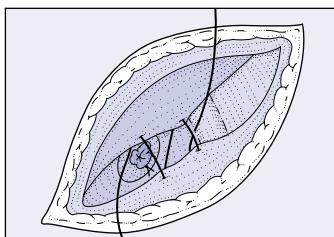

An area of weakness may occasionally develop following a surgical incision in the wall of the abdomen. This area may then develop into an incisional hernia. The defect may become so severe that a large amount of intestine bulges through the abdominal wall; if this happens, a repair using a piece of mesh may be necessary.

HERNIA REPAIR

During surgery the hernia is removed or repositioned and the weakened abdominal wall is reinforced with stitching or mesh.

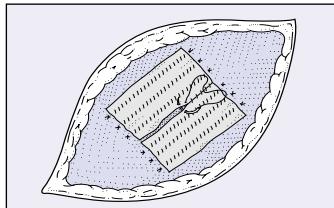

1 The protruding sac of intestine is pushed back into the abdomen or, in some cases (such as strangulation), the sac is removed surgically.

2 The muscular wall of the abdomen may then be repaired by overlapping the edges of the weakened area and securing them with rows of stitching.

LARGE HERNIAS

Alternative method

For repair of some large or recurrent hernias, two mesh leaves are secured by rows of stitching, then joined at the centre.

Heroin has an analgesic effect and produces sensations of warmth, calmness, drowsiness, and a loss of concern for outside events. Long-term drug use causes *tolerance* and psychological and physical dependence (see *drug dependence; heroin abuse*). Sudden withdrawal produces shivering, abdominal cramps, diarrhoea, vomiting, and restlessness.

Heroin addiction has many adverse effects on the user, including injection scars, skin abscesses, weight loss, im-

potence, and the risk of infection with *hepatitis B*, *hepatitis C*, and *HIV* through sharing needles. Death commonly occurs from accidental overdose.

herpangina

A throat infection caused by *coxsackievirus*. Herpangina most commonly affects young children. The virus is usually transmitted via infected droplets coughed or sneezed into the air. Many people harbour the virus but do not have symptoms.

SYMPOTMS

After an incubation period of two to seven days, there is a sudden onset of fever, accompanied by a sore throat and sometimes also headache, abdominal discomfort, and muscular pains. The throat becomes red and a few small blisters appear, which enlarge and burst, forming shallow ulcers. These symptoms usually clear up within a week, without specific treatment.

herpes

Any of a variety of conditions that are characterized by an eruption of small, usually painful, blisters on the skin. The term "herpes" usually refers to an infection with the *herpes simplex* virus. Two forms of this virus, called HSV1 and HSV2, are generally responsible for *cold sores* and genital herpes (see *herpes, genital*), respectively.

A closely related organism, the varicella-zoster virus, is responsible for two other conditions in which skin blisters are a feature: *chickenpox* and *herpes zoster* (shingles).

herpes, genital

A *sexually transmitted infection* caused mainly by HSV2, one form of the *herpes simplex* virus. Rarely, genital infections can be due to HSV1 that has been transmitted by oral contact with the genitals. After an incubation period of about a week, the virus produces soreness, burning, itching, and small blisters in the genital area. The blisters burst to leave small, painful ulcers, which heal in 10 to 21 days. The lymph nodes in the groin may become enlarged and painful, and the person may develop other symptoms such as a headache, fever, and aching muscles.

TREATMENT

Genital herpes cannot be cured, but early treatment can reduce the severity of symptoms. *Antiviral drugs*, such as *aciclovir* make the ulcers less painful and also encourage healing. Other measures

that may be taken include taking *analgesic drugs* and bathing the genital area in a salt solution.

OUTLOOK

Once the virus has entered the body, it stays there for the rest of the person's life. Recurrent attacks may occur, usually during periods when the person is feeling run down, anxious, or depressed, or, in some cases, a few days before menstruation. The virus may be shed continuously and can be transmitted to others through sexual intercourse, even when the infected person has no symptoms. Recurrent attacks tend to become less frequent and less severe over time.

Genital herpes may be passed from a pregnant woman to her baby during delivery. If the genital herpes develop in late pregnancy, delivery by *caesarean section* is usually recommended.

herpes gestationis

A rare skin disorder of pregnant women that produces crops of tense, itchy blisters on the legs and abdomen. Herpes gestationis is an *autoimmune disorder* that is essentially a type of *pemphigoid* triggered by pregnancy.

Severe herpes gestationis is treated with *corticosteroid drugs* in tablet form. An affected woman may need to be monitored closely as there is an increased risk of *fetal prematurity* and low *birthweight*. The disorder may initially worsen after delivery but then clears up. It tends to recur in subsequent pregnancies.

herpes simplex

A common viral infection that is characterized by small, fluid-filled blisters. Herpes simplex infections are *contagious* and are usually spread by direct contact. Most infections are quite mild.

TYPES

There are two forms of the virus: HSV1 (herpes simplex virus, type 1) and HSV2 (herpes simplex virus, type 2). Most people are infected with HSV1 at some time in their lives, usually during childhood. HSV1 is usually associated with infections of the lips, mouth, and face; HSV2 is often associated with infections of the genitals and infections acquired by babies at birth. There is considerable overlap between the two types; sometimes, conditions usually due to HSV1 are caused by HSV2, and vice versa.

Type 1 virus The initial infection may be symptomless; alternatively, it may cause a flu-like illness with mouth ulcers. Thereafter, the virus remains dormant in nerve

cells in the facial area. In many people, the virus is periodically reactivated, causing *cold sores* that invariably erupt in the same site (usually around the lips).

Sometimes the virus can infect a finger after touching a cold sore, causing a painful eruption called a *herpetic whitlow*. HSV1 may also produce eczema herpeticum (an extensive rash of skin blisters) in a person with a pre-existing skin disorder, such as *eczema*. Eczema herpeticum may require hospital admission. If the virus gets into an eye it may cause *conjunctivitis*, which usually lasts only a few days; more seriously, it may cause a *corneal ulcer*.

Rarely, HSV1 spreads to the brain, leading to *encephalitis*. The virus may cause a potentially fatal generalized infection in a person with an *immunodeficiency disorder* or in someone taking *immunosuppressant drugs*.

Type 2 virus HSV2 is the usual cause of sexually transmitted genital herpes (see *herpes, genital*), in which painful blisters erupt in the genital area. In some people, the blisters tend to recur.

TREATMENT

Treatment of herpes simplex depends on its type, site, and severity of symptoms. *Antiviral drugs*, such as *aciclovir*, may be helpful, particularly if used early in an infection.

herpes zoster

An infection of the *nerves* supplying certain skin areas that is characterized by a painful rash of small crusting blisters. Also called shingles, herpes zoster is especially common among older people.

TYPES

Herpes zoster usually affects only one side of the body, and follows the path of a nerve. It commonly develops on a strip of skin over the ribs, although the rash may also appear on the neck, arm, or lower part of the body. Sometimes the infection involves the face and eye; this form of the disorder is called herpes zoster ophthalmicus.

CAUSES

Herpes zoster is caused by the *varicella-zoster virus*, which also causes *chickenpox*. After an attack of chickenpox, some of the viruses survive and lie dormant for many years in the nerve cells near the spinal cord. In some people, a decline in the efficiency of the *immune system* – especially in old age – because of disease or severe stress, allows the viruses to re-emerge and cause herpes zoster. The disorder is also

Example of herpes zoster

An extensive rash of blisters has spread around one side of the body, just under the ribs, and on to the front of the abdomen.

common in people whose immune system is weakened by stress or by certain drugs, such as *corticosteroid drugs* or *anticancer drugs*.

SYMPTOMS

The first indication of herpes zoster is excessive sensitivity in the skin, followed by pain, which is often severe. The infection can be difficult to diagnose at this stage and may be mistaken for a different condition; for example, pain in the chest wall may be mistaken for angina pectoris. After about five days, the rash appears as small, raised, red spots that soon turn into blisters. Within a few days, the blisters dry, flatten, and develop crusts. Over the next two weeks, the crusts drop off, sometimes leaving small pitted scars.

The most serious feature of herpes zoster is pain after the attack, known as postherpetic neuralgia, which affects about a third of all infected people. This pain is caused by nerve damage, and may last for months or years. Herpes zoster ophthalmicus may cause a *corneal ulcer* or *uveitis* (inflammation of the part of the eye known as the uvea).

TREATMENT

If treatment is begun soon after the rash appears, *antiviral drugs*, such as *aciclovir*, will reduce the severity of the symptoms and minimize nerve damage. *Analgesic drugs* (painkillers) may also be helpful in relieving pain. If *postherpetic neuralgia* is a problem, *anticonvulsant drugs*, such as *gabapentin*, may be helpful.

herpetic whitlow

A painful swelling on the finger caused by infection with the *herpes simplex* virus. (See also *whitlow*.)

heterosexuality

Sexual attraction of an individual to members of the opposite sex. (See also *bisexuality*; *homosexuality*.)

heterozygote

A term used to describe a person whose cells contain two different *alleles* (forms of a particular gene) controlling a specified inherited trait. A *homozygote* has identical alleles controlling that trait. (See also *inheritance*; *genetic disorders*.)

hexachlorophene

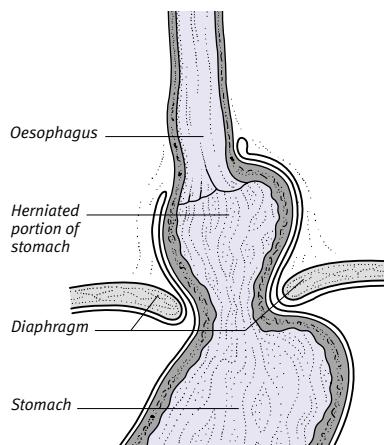

An *antibacterial drug* used in dusting powder form to prevent *staphylococcal infections* in newborns, and to prevent and treat *bedsores*.

hiatus hernia

A condition in which part of the *stomach* protrudes upwards into the chest through an opening in the *diaphragm* called the hiatus, which is normally occupied by the *oesophagus*. The cause is unknown, but hiatus hernia is more common in obese people. In some cases, it is present at birth.

Many people have no symptoms. In some people, however, the hiatus hernia impairs the efficiency of the oesophageal sphincter, the muscle at the junction between the oesophagus and the stomach. Weakness in this muscle allows *acid reflux* as the stomach acid escapes into the oesophagus. This problem may lead to *oesophagitis* (inflammation of the oesophagus) or to *heartburn*, which produces pain or discomfort in the centre of the chest.

Antacid drugs, H₂ receptor antagonists, or proton pump inhibitors (all types of *ulcer-healing drug*) may be given to reduce stomach acidity. In severe cases, surgery may be required to return the stomach to its normal position and to

Common type of hiatus hernia

Part of the stomach slides into the chest through the oesophageal hiatus (opening).

tighten the oesophageal sphincter. This can now be carried out by *minimally invasive surgery* through an endoscope.

Hib vaccine

A vaccine administered routinely at two, three, and four months of age to provide immunity to the bacterium *HAEMOPHILUS INFLUENZAE* type b (Hib). Before the vaccine was generally available, Hib infection was a common cause of bacterial *meningitis* and *epiglottitis* in children.

hiccup

A sudden, involuntary contraction of the *diaphragm* followed by rapid closure of the *vocal cords*. Most attacks of hiccups last only a few minutes, and are not medically significant. Rarely, they may be due to a condition, such as *pneumonia* or *pancreatitis*, that causes irritation of the diaphragm or *phrenic nerves*. *Chlorpromazine*, *haloperidol*, or *diazepam* may be prescribed for frequent, prolonged attacks.

Hickman catheter

A flexible plastic tube, also known as a skin-tunneled catheter, that is passed through the chest and inserted into the subclavian vein, which leads to the heart. It is often used in people who have *leukaemia* or other cancers and need regular *chemotherapy* and blood tests. The catheter allows drugs to be injected directly into the bloodstream and blood samples to be obtained easily. It is inserted under local *anaesthesia*. A Hickman catheter can remain in position for months; the external end is plugged when not in use.

hidradenitis suppurativa

Inflammation of the *sweat glands* in the armpits and groin due to a bacterial infection. Abscesses develop beneath the skin; the affected area becomes reddened and painful and may ooze pus. The condition tends to be recurrent and can eventually cause scarring. *Antibiotic drugs* may help to reduce the severity of an outbreak.

hidrosis

The medical term for *sweating*. (See also *hyperhidrosis*; *hypohidrosis*.)

high density lipoprotein

A type of lipoprotein, made up of protein and *lipid* (fat), that transport lipids in the blood. High levels of high density lipoprotein (HDL) can help to protect against *atherosclerosis* (fatty deposits on artery walls) because it removes chole-

sterol from the circulation and takes it to the liver for processing. (See also *fats and oils*; *low density lipoprotein*.)

high-dependency unit

A level of hospital inpatient care intermediate between that of a general ward and that of an *intensive care* unit. Also known as a "step-down" facility, staff in a high-dependency unit provide monitoring and support for acutely ill patients. It also has facilities for short-term *ventilation* (use of a machine to assist breathing) and emergency resuscitation.

hilum

The term that is used to describe a small indentation on the surface of an internal organ where blood vessels, nerve fibres, or other similar structures enter or leave the organ. For example, the hilum of the lung is its junction with the main bronchus and the major vessels. A commonly used alternative term is "hilus".

hindmilk

The breast milk that is produced at the end of a feed. Hindmilk contains more fat than *foremilk* and therefore provides the baby's main source of energy. (See also *breast-feeding*.)

hindwaters

A term for the *amniotic fluid* that is discharged behind the presenting part of the baby (usually the head) during pregnancy and delivery. In contrast, the forewaters (the "waters") precede the presenting part of the baby and may rupture (or "break") before or after the onset of labour.

hinge joint

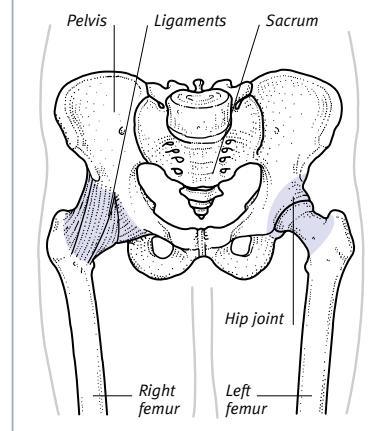

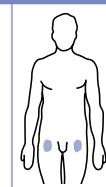

A type of mobile *joint* that allows movement in one plane only (forwards and backwards). Examples of hinge joint are the knee joint and the elbow joint.

hip

The *joint* between the *pelvis* and the upper end of the *femur* (thigh bone). The hip is a ball-and-socket joint; the smooth, rounded head of the femur fits securely into the acetabulum, a cup-like cavity in the pelvis. Tough ligaments attach the femur to the pelvis, further stabilizing the joint and giving it the necessary strength to support the weight of the body and take the strain of leg movements. The structure of the hip allows a considerable range of leg movement.

LOCATION OF HIP

The hip is a ball-and-socket joint comprising the dome at the top of the femur (thigh bone) and the cup-shaped depression in the pelvic bone.

DISORDERS

Injuries to the hip joint, such as dislocation of the joint, are usually caused by extreme force, as in a road traffic accident. Fractures may also occur in the hip joint, due to breaks in the head or neck of the femur (see *femur, fracture of*). This type of injury is more common in elderly people, whose bones are weakened by osteoporosis (loss of bone density).

Osteoarthritis (degeneration of bone ends within a joint) is a common disorder of the hip. It causes symptoms such as pain and stiffness (particularly during activity), swelling, and restricted joint movement.

Certain forms of hip disorder occur in babies and children. *Developmental hip dysplasia* is a condition that is present at birth; in this disorder, the hip socket is malformed and the head of the femur does not fit correctly into it. *Perthes' disease* is a rare condition affecting young children, in which the head of the femur breaks down; it causes limping, pain in the hip, and restricted movement in the joint.

hip, clicking

A fairly common condition in adults in which a characteristic dull clicking can be heard and felt during certain movements of the hip joint. Clicking hip is caused by a tendon slipping over the

bony prominence on the outside of the *femur* (thigh bone), and does not indicate disease.

Clicking of the hip may sometimes be heard during examination of newborn babies; in this instance, it indicates possible dislocation of the hip (see *developmental hip dysplasia*).

hip, congenital dislocation of

See *developmental hip dysplasia*.

hip dysplasia, developmental

See *developmental hip dysplasia*.

H

hippocampus

A structure in the *limbic system* of the brain. The hippocampus, consisting of a band of *grey matter*, is involved with some learning processes and long-term memory storage.

Hippocratic oath

A set of ethical principles that are derived from the writings of the Greek physician Hippocrates that is concerned with a doctor's duty to work for the good of the patient.

hip replacement

A surgical procedure to replace all or part of a diseased *hip* joint with an artificial substitute. The replacement is most often carried out in older people whose joints are stiff and painful as a result of *osteoarthritis*. It may also be needed if *rheumatoid arthritis* has spread to the hip joint or if the top end of the femur (thigh bone) is badly fractured (see *femur, fracture of*).

Hirschsprung's disease

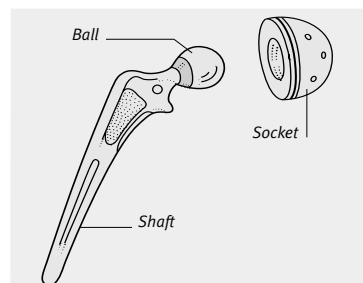

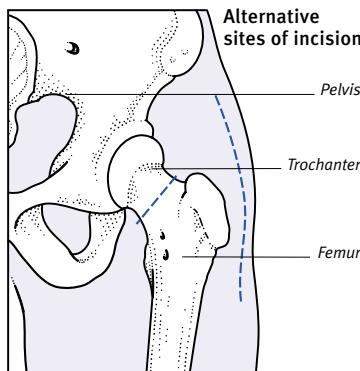

A *congenital* disorder in which the *rectum*, and sometimes the lower part of the *colon*, lack the ganglion cells that control the intestine's rhythmic contractions. The affected part of the colon becomes narrowed and blocks the movement of faecal material.

The disease is rare and tends to run in families. It occurs about four times more often in boys. Symptoms, which include constipation and bloating, usually develop in the first few weeks of life. The child usually has a poor appetite and may fail to grow properly.

A *barium X-ray examination* can show the narrowed segment of the intestine. A *biopsy* may also be taken. Treatment of Hirschsprung's disease involves removing the narrowed segment and rejoining the normal part of the intestine to the anus.

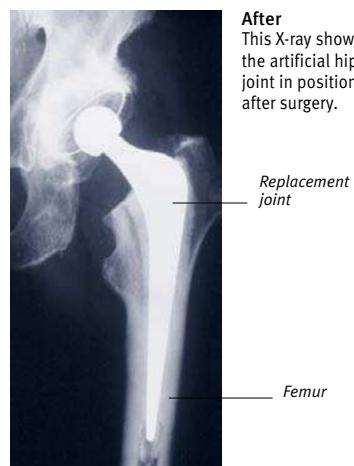

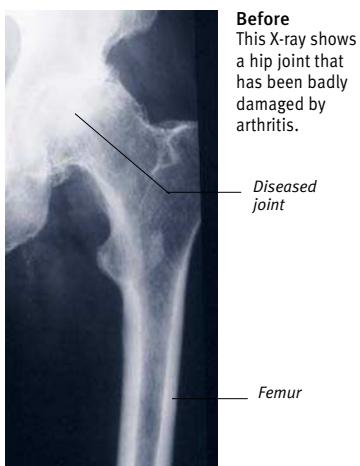

PERFORMING A HIP REPLACEMENT

In this operation, the surgeon pushes aside or cuts through the surrounding muscles to expose the hip joint. The femur (thigh bone) is cut and the pelvis is drilled to make room for the two components of the artificial joint. These parts are secured in place, the femur is repaired, and the muscles and tendons are replaced and repaired.

Components

An artificial hip joint has two parts. The ball and shaft are metal; the socket may be metal or plastic.

hirsutism

Excessive hairiness, which particularly appears in women. The additional hair is coarse in texture and grows in a male pattern on the face, trunk, and limbs. Hirsutism can be a symptom of certain conditions, such as *polycystic ovary syndrome* and congenital *adrenal hyperplasia*, in which the level of naturally occurring male hormones in the blood is abnormally high. Hirsutism can also be a result of taking anabolic steroids (see *steroids, anabolic*). More commonly, however, hirsutism is not a sign of any disorder at all; it occurs mildly in many normal women, especially after the *menopause*, in which hormone balance is upset (See also *hypertrichosis*.)

hirudin

An anticoagulant contained in the saliva of leeches (see *leech*) that prevents blood from clotting.

histamine

A chemical present in cells (mainly *mast cells*) throughout the body that is released during an allergic reaction (see *allergy*). Histamine activates two main types of receptors: H_1 and H_2 . H_1 activation is responsible for the swelling and redness that occur in *inflammation*. It also narrows the airways in the lungs and causes itching. H_2 activation stimulates acid production by the stomach, but in large amounts it can irritate the stomach lining, causing *gastritis* or *peptic ulcers*.

Allergic reactions caused by H₁ can be controlled by *antihistamine drugs*. Over-production of stomach acid due to H₂ can be counteracted by H₂-receptor antagonists (see *ulcer-healing drugs*).

histamine₁-receptor antagonists

See *H₁-receptor antagonists*.

histamine₂-receptor antagonists

See *H₂-receptor antagonists*.

histiocytosis X

A rare childhood disease, now more commonly known as Langerhans cell histiocytosis, in which there is an overgrowth of a type of tissue cell called a histiocyte. The cause is unknown, but the condition probably results from a disturbance of the *immune system*. In the mildest form, rapid cell growth occurs in one bone only, usually the skull, a clavicle, a rib, or a vertebra, causing swelling and pain. In the most severe, and least common, form, there is a rash and enlargement of the liver, spleen, and lymph nodes, as well as lung involvement. In these cases, treatment is with *anticancer drugs*, but the outlook is poor.

histocompatibility antigens

A group of proteins that have a role in the *immune system*. Certain types of histocompatibility antigen are present on every cell in the body; they are essential for the immunological function of *killer T cells*, which help to defend the body against disease. The antigens act as a guide enabling the killer T cells to distinguish between self and nonself and to kill abnormal or foreign cells.

The main group of histocompatibility antigens is the human leukocyte antigen (HLA) system, which consists of several series of antigens. There are six different genes known as HLA-A, HLA-B, HLA-C, HLA-DP, HLA-DQ, and HLA-DR. Each of these has many different forms, or *alleles*; for example, HLA-B has over 40 different numbered alleles. A person's tissue type (the particular set of HLAs in the body tissues) is unique, except in the case of identical twins, who have identical sets of HLAs.

HLA analysis has some useful applications. Comparison of HLA types may show that two people are related, and it has been used in *paternity testing*. The HLA system is also used in *tissue-typing* to help match recipient and donor tissues before *transplant surgery*. Certain

HLA types occur more frequently in people with particular diseases. For example, HLA-B27 is associated with several forms of arthritis, particularly *ankylosing spondylitis*, and HLA-DR2 and an HLA-DQ type with *narcolepsy*. HLA testing can help to confirm the diagnosis in someone who may have one of these conditions.

histology

The study of tissues, including their cellular structure and function. The main application of histology in medicine is in the diagnosis of disease. This process often involves obtaining a sample of tissue (see *biopsy*) and examining it under a microscope to detect any abnormalities, such as cancerous cells or areas of scar tissue. Examination of tissue samples may also be performed to determine the extent of a disease, such as cancer, once it has been detected. If a cancerous tumour is found, for example, it may be removed, together with an area of surrounding tissue; by examining this material, doctors can tell whether the whole of the diseased area has been removed or whether cancerous cells have spread beyond the edges of the tumour.

histopathology

A branch of *histology* concerned with the effects of disease on the microscopic structure of tissues.

histoplasmosis

An infection caused by inhaling spores of the fungus *HISTOPLASMA CAPSULATUM*, which is found in soil contaminated with bird or bat droppings. Histoplasmosis occurs in parts of the Americas, the Far East, and Africa. Treatment is by intravenous infusion of *antifungal drugs*.

history-taking

The process by which a doctor gathers information from patients regarding the symptoms of their illnesses and details of any previous disorders. (See also *diagnosis*.)

histrionic personality disorder

A psychiatric disorder characterized by exaggerated emotional reactions and attention-seeking behaviour. Affected people also constantly demand praise or reassurance, and require immediate satisfaction of their demands. The disorder usually first appears in early adulthood, and is more common in women.

HIV

The abbreviation for human immunodeficiency virus. HIV is a *retrovirus* that infects and gradually destroys cells in the immune system and may eventually lead to *AIDS* (acquired immunodeficiency syndrome). There are two closely related viruses: HIV-1, which is the most common cause of AIDS throughout the world; and HIV-2, which is largely confined to West Africa.

METHODS OF TRANSMISSION

HIV is transmitted in body fluids, such as blood, semen, and vaginal secretions. It most commonly gains access to the body during sexual activity (either vaginal, anal, or oral), particularly when contaminated body fluids come into contact with broken skin. Other sources of infection are nonsterile needles (for example, among people who abuse intravenous drugs and share needles and syringes) and, in some parts of the world, contaminated blood transfusions. In addition, if a pregnant woman is infected, the virus can pass to the fetus via the *placenta*. It is not transmitted by everyday physical contact such as shaking hands or hugging.

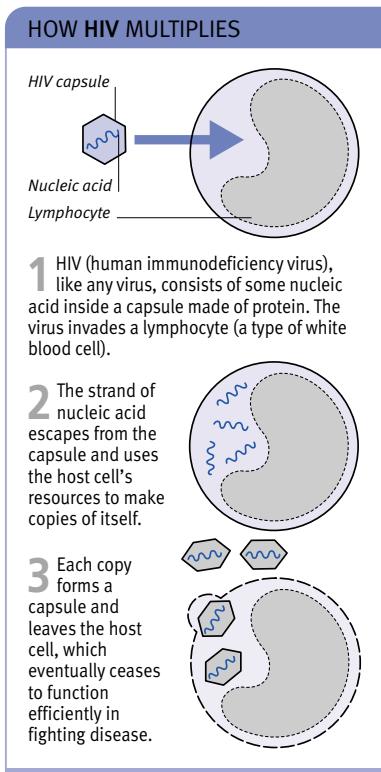

EFFECTS OF THE VIRUS

HIV infects cells that have a special structure, called a CD4 receptor, on their surface. This includes immune system cells called CD4 lymphocytes, which defend the body against cancerous and infected cells, as well as certain cells in other tissues, such as the brain. The virus multiplies within the cells, killing them in the process; the dead cells then release more virus particles into the blood. If the virus is untreated, the number of CD4 lymphocytes falls. This results in a reduced ability to fight off infections and certain types of cancer.

HIV is extremely successful at withstanding any attempt by the body to destroy it. Every time HIV replicates, it changes its *antigen* makeup, thereby ensuring that it is extremely difficult for the body to mount an effective immune response to it.

SYMPOTMS

Initially, some people who are infected with HIV may have no symptoms. However, between six and eight weeks after exposure, some people develop a flulike illness similar to glandular fever (see *mononucleosis, infectious*), with fever, fatigue, sore throat, aching muscles, and swollen lymph nodes. These symptoms usually clear up after a few weeks. Some people may then develop

persistent enlargement of the lymph nodes and sometimes of the spleen, as well as features of *AIDS-related complex*, such as weight loss and fever.

Minor features of infection with HIV include skin disorders such as seborrhoeic *dermatitis*. More severe features include persistent *herpes simplex* infections, oral *candidiasis* (thrush), *herpes zoster* (shingles), *tuberculosis*, and *shigellosis* (bacterial infection of the intestine). HIV may also affect the brain, causing a variety of neurological disorders, including *dementia*.

If HIV infection is untreated, the infected person may eventually develop full-blown AIDS. In this condition, the immune system is severely weakened, resulting in severe infections caused by organisms that are usually harmless as well as in certain types of cancer.

DIAGNOSIS, TREATMENT, AND OUTLOOK

HIV is diagnosed through an *HIV test*, a blood test that detects the presence of *antibodies* (proteins manufactured by the immune system) to HIV in the blood.

People infected with HIV should have regular monitoring in order to determine when specific treatments, such as *antiretroviral drugs*, are necessary. The main types of antiretroviral used are *protease*

inhibitors, such as indinavir and lopinavir, and *reverse transcriptase inhibitors*, such as *zidovudine*. These drugs can slow the course of the disease and may prevent the development of full-blown AIDS.

In wealthier countries, HIV infection is no longer necessarily a fatal disease. It remains life-threatening, however, and the most effective strategy for defeating it is prevention of infection.

PREVENTION

The risk of infection with HIV can most easily be reduced by practising *safer sex*. Intravenous drug users should take care not to share needles. Others who may be at risk, such as healthcare workers who may come into contact with infected body fluids or needles, should observe recommended safety regulations.

hives

An alternative name for *urticaria*.

HIV test

A *blood test* that is used to detect the presence in the blood of *antibodies* to HIV, the virus that can lead to AIDS. Antibodies are proteins manufactured by the *immune system* in response to a foreign protein (antigen) in the body, although they may not develop for three months after initial infection with HIV. A positive result, in which these antibodies are detected, indicates the presence of HIV.

HLA

The abbreviation for *human leukocyte antigen*.

HLA types

See *histocompatibility antigens*.

hoarseness

A rough, husky, or croaking voice. Hoarseness is usually due to irritation of, or strain on, the *larynx* (voicebox).

CAUSES

Short-lived hoarseness is often due to overuse of the voice, which strains the muscles in the larynx. It is also commonly caused by inflammation of the vocal cords in acute *laryngitis*.

Persistent hoarseness may be due to chronic irritation of the larynx, which can be caused by smoking, excessive alcohol consumption, chronic *bronchitis*, or constant dripping of mucus from the nasal passages. *Polyps* (harmless growths) on the vocal cords may also cause hoarseness. In people with *hypothyroidism* (underactivity of the thyroid gland),

hoarseness can result from formation of tissue on the vocal cords. In young children, it may be a symptom of *croup*.

Occasionally, persistent hoarseness in adults has a more serious cause, such as cancer of the larynx (see *larynx*, *cancer of*, *thyroid cancer*, or *lung cancer*).

TREATMENT

In cases where voice strain or laryngitis is the cause, resting the voice often helps recovery. If hoarseness persists for more than two weeks, a doctor should be consulted. A *laryngoscopy* (examination of the larynx with a mirror or with a more specialized viewing instrument) may be performed to exclude any serious underlying causes.

Hodgkin's disease

An uncommon cancerous disorder in which there is a proliferation of cells in lymphoid tissue (which is found mainly in the *lymph nodes* and *spleen*). This is also known as a *lymphoma*. Men are affected more commonly than women. The cause is unknown.

SYMPTOMS AND SIGNS

The most common sign is the painless enlargement of lymph nodes, typically in the neck or armpits. There may be a general feeling of illness, with fever, weight loss, and night sweats. There may also be generalized itching and, rarely, pain in the swollen lymph nodes after drinking alcohol. As the disease progresses, the *immune system* becomes increasingly impaired.

DIAGNOSIS AND TREATMENT

A diagnosis of Hodgkin's disease is usually made by performing a *biopsy* (removal of a small sample of tissue for microscopic analysis) of an enlarged lymph node. The identification of characteristic cells, called Reed–Sternberg cells, in the biopsy confirm the diagnosis. The extent of the disease (its *stage*) can be assessed by *chest X-ray*, *CT scanning*, or *MRI* of the abdomen and a *bone marrow biopsy*. The disease can usually be cured with *radiotherapy*, *chemotherapy*, or a combination of the two treatments. (See also *lymphoma*, *non-Hodgkin's*.)

hole in the heart

The common term for a *septal defect*.

holistic medicine

A form of therapy that treats the whole person rather than the specific disease symptoms. A holistic approach is emphasized by many practitioners of *complementary medicine*.

Holmes–Adie pupil

Also known as Adie's syndrome, a dilated *pupil* (the circular opening in the centre of the iris), usually only in one eye, that may be irregular in shape. The pupil does not respond, or may respond only very slowly, to bright light; in addition, it responds only partially when focusing on different distances. The condition, which is most common in young women, is of unknown cause and has no detrimental effects.

Holmes–Rahe questionnaire

A survey, devised in the 1960s, that is used to determine the comparative stress levels caused by certain common life events, such as the death of a partner, changes in financial or social circumstances, and serious illness.

Each potentially stressful event on the scale is allotted a specific score, with the death of a partner given the maximum (100) and the other stressors ranked in order of their scores. People undergoing the test select all of the stressful events that apply to them from the scale, then add together the scores for these stressors to determine their overall stress level.

Holter monitor

A wearable device used in *ambulatory electrocardiography* (ECG) to record the heart's electrical activity continuously for 24 hours or longer. The monitor records this activity by means of electrodes attached to the chest and allows the detection of intermittent *arrhythmias* (irregularities in the heartbeat). (See also *telecardiography*.)

Holt–Oram syndrome

A *genetic disorder* in which there is an atrial septal defect (a hole in the wall dividing the upper chambers of the heart) together with various malformations of the upper limbs, particularly of the hands and forearms.

homeopathy

A holistic system of *complementary medicine* that aims to treat the whole person rather than only the symptoms of a condition. Homeopathy works on the principle that the mind and body are so closely linked that physical conditions cannot be successfully treated without an understanding of a person's constitution and character. The particular remedy chosen to give to a patient with a condition may depend on a variety of factors, such as the patient's temperament, state of mind, and lifestyle.

Homeopathy is based on a principle defined as "like cures like". According to this theory, the substances that provoke a particular symptom in a healthy person can also cure sicknesses that produce that symptom. Homeopathy involves administering minute doses of these substances as medicines; it is believed that the medicinal substances become more potent the more they are diluted.

homeostasis

The automatic processes by which the body maintains a constant internal environment despite changes within or outside it. Homeostasis is vital for the body, because tissues and organs can only function efficiently within a narrow range of physical conditions. The body regulates conditions such as temperature and acidity by means of negative *feedback*; for example, when the body overheats, *sweating* is stimulated until the temperature returns to normal. Homeostasis also involves the regulation of *blood pressure* and the levels of natural chemicals such as *glucose*.

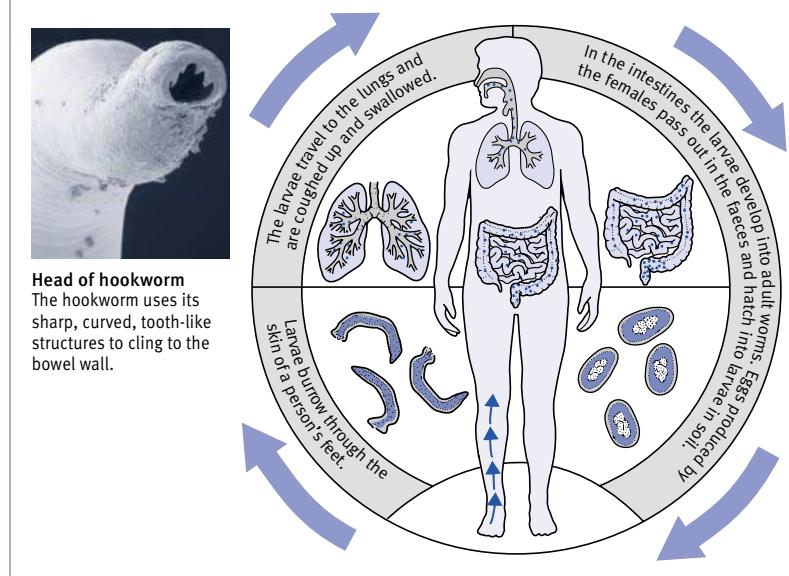

Homeostatic mechanisms sometimes malfunction. In *diabetes mellitus*, for example, blood glucose levels can no longer be regulated properly because of a malfunction in insulin production.

HOOKWORM LIFE-CYCLE

Infestation begins with larvae that penetrate the skin or are ingested and enter the bloodstream. They migrate throughout the body, particularly to the small intestine. Adult worms develop and lay eggs, which leave the body in faeces and eventually hatch into larvae.

Head of hookworm
The hookworm uses its sharp, curved, tooth-like structures to cling to the bowel wall.

homocystinuria

A rare, inherited condition caused by an *enzyme* deficiency. Homocystinuria is a type of inborn error of metabolism (see *metabolism, inborn errors of*) in which there is an abnormal presence of homocystine (an *amino acid*) in the blood and urine. Affected people may be very tall, with long limbs and fingers. Some have skeletal deformities and abnormalities of the eye *lens*. The condition is incurable, but it may be improved by a special diet.

homosexuality

Sexual attraction to people of the same sex. (See also *bisexuality; heterosexuality*.)

homozygote

A term used to describe a person whose cells contain two identical *alleles* (forms of a gene) controlling a specified inherited trait. The cells of a *heterozygote* contain two different alleles controlling that trait. (See also *inheritance; genetic disorders*.)

hookworm infestation

An infestation of the small intestine by small, round, bloodsucking worms of the *NECATOR AMERICANUS* or *ANCYLOSTOMA DUODENALE* species. Infestation with

hookworm occurs mainly in the tropics, particularly in areas where sanitation is poor or where human faeces is used as fertilizer for agriculture.

The larvae enter the body by penetrating the skin of the feet or by ingestion. They migrate throughout the body and grow to maturity in the small intestine. Adult worms are about 12 mm long and have mouths with hooked teeth; they feed by attaching themselves to the intestinal wall and sucking blood. The female worms lay eggs, which then pass out in the faeces.

When larvae penetrate the skin, a red, itchy rash may develop on the feet. In light infestations, there may be no further symptoms. However, in heavier infestations, migration of the larvae through the lungs may produce coughing and, in some cases, *pneumonia*; adult worms in the intestines may cause abdominal discomfort. The most important problem is iron-deficiency *anaemia* due to loss of blood.

Diagnosis is made by microscopic examination of the faeces for worm eggs. *Anthelmintic drugs* kill the worms. (See also *larva migrans*.)

hordeolum

The medical name for a *sty*.

hormonal contraception

See *contraception, hormonal methods of*.

hormonal disorders

Conditions caused by malfunction of an *endocrine gland*.

hormone

A hormone is a chemical messenger that is released into the bloodstream by a gland or tissue in order to have a specific effect on tissues elsewhere in the body, altering their activity. Hormones control a wide variety of body functions, including *metabolism* of cells, growth, sexual development, and the body's response to stress or illness.

Many hormones are produced by *endocrine glands*. The primary function of the major endocrine glands (the pituitary, thyroid, parathyroid, and adrenal glands and the pancreas, ovaries and testes) is the production of various hormones. Hormones are also secreted by other organs (see *Sources and effects of particular hormones* table, opposite), including the brain, kidneys, intestines, and, in pregnant women, the *placenta*.

hormone antagonist

A drug that is used to block the action of a *hormone*.

hormone replacement therapy (HRT)

COMMON DRUGS

OESTROGEN DRUGS • Conjugated oestrogens

- Estradiol • Estriol • Estrone • Estropipate

PROGESTOGEN DRUGS • Dydrogesterone

- Levonorgestrel • Medroxyprogesterone

OTHERS • Tibolone

The use of a synthetic or natural *hormone* to treat a hormone deficiency. Most commonly, the term HRT refers to the use of female hormones to replace those lost after the *menopause*. This loss may occur naturally or as a result of treatment such as *radiotherapy* or the removal of the ovaries.

BENEFITS AND RISKS

The benefits of HRT have to be weighed against the risks. In the short term, HRT relieves symptoms of oestrogen withdrawal, particularly night sweats, *hot flushes*, and vaginal dryness. The minimum effective dose should be used for the shortest duration, however.

In the long term, HRT may give protection against *osteoporosis* (the loss of bone density that can lead to fractures). However, HRT is now only used for this purpose in women who are unable to take other treatments, such as *bisphosphonate drugs*; when other treatments have been unsuccessful; or in women who have gone through a premature menopause (before the age of 40).

Minor adverse effects of HRT include nausea, breast tenderness, fluid retention, and leg cramps. HRT may increase the risk of abnormal blood clotting, the likelihood of deep vein thrombosis (see *thrombosis, deep vein*) and *pulmonary embolism* developing may also increase. Women taking HRT have an increased risk of developing *breast cancer* compared to women who are not taking it, and the risk increases the longer it is continued.

Whether or not HRT is appropriate depends on the individual woman concerned. Women who are considering HRT should consult their doctor, who will discuss their specific circumstances. Once it has been started, the therapy should be reviewed regularly by a doctor.

TYPES OF HRT

In women with a uterus, HRT involves taking a continuous dose of an *oestrogen drug*, which is combined with an

additional *progestogen drug* for ten to 13 days of the 28-day cycle. The progestogen drug provokes bleeding which is similar to that of menstruation. This is necessary to prevent excessive thickening of the lining of the uterus and the risk of it becoming cancerous.

Alternatively, in cases in which more than one year has passed since the woman's last menstrual period, continuous bleed-free HRT, or a single drug with both oestrogenic and progestogenic effects (such as *tibolone*), can be used. Women who have had a *hysterectomy* need only take oestrogen drugs.

Oestrogen drugs can be given in the form of tablets, skin patches, gels, or implants; progestogen drugs are given as tablets, skin patches, or vaginal gel.

horn, cutaneous

A hard, noncancerous protrusion occasionally found on the skin of the elderly. Caused by overgrowth of *keratin*, they vary in colour from yellow to brown or black. They may develop where there was previously a wart and may grow slowly. Left untreated, they can grow considerably; surgical removal may be advised.

Appearance of cutaneous horn

The horny protuberance that has developed on this woman's face results from an overgrowth of keratin (a skin protein).

Horner's syndrome

A group of physical signs (such as narrowing of the eye pupil, drooping of the eyelid, and absence of sweating) affecting one side of the face that indicates damage to part of the sympathetic nervous system (see *autonomic nervous system*).

horseshoe kidney

A *congenital* abnormality in which the two kidneys are fused at the base, forming a so-called horseshoe shape. The joined kidneys usually function normally, but this condition may be associated with other kidney problems, such as urinary tract infection.

SOURCES AND EFFECTS OF PARTICULAR HORMONES

The various glands of the hormonal system constitute a control and communications network that is complementary to the nervous system. However, instead of using nerve impulses, the glands secrete chemical messages (in the form of hormones) to affect other glands and tissues in various

parts of the body. Hormones are carried in the bloodstream to their targets, where they exert their specific effects. The table below lists the hormones that are secreted by different parts of the body and gives a description of their wide-ranging actions.

Gland or hormone-secreting tissue	Hormone secreted	Effects
Hypothalamus	Releasing or inhibiting hormones	Stimulate or suppress hormone secretion by pituitary gland
Pituitary gland	Growth hormone	Stimulates growth and metabolism
	Prolactin	Stimulates milk production after childbirth
	ACTH (adrenocorticotrophic hormone)	Stimulates hormone production by adrenal glands
	TSH (thyroid-stimulating hormone)	Stimulates hormone production by thyroid gland
	FSH (follicle-stimulating hormone); LH (luteinizing hormone)	Stimulate gonads (ovaries or testes)
	ADH (antidiuretic hormone)	Acts on kidneys to conserve water
	Oxytocin	Stimulates contractions of uterus during labour and milk let-down reflex in breast-feeding
	MSH (melanocyte-stimulating hormone)	Acts on skin to promote production of skin pigment (melanin)
Brain	Endorphins; enkephalins	Alleviate pain; boost mood
Thyroid gland	Thyroid hormones	Increase metabolic rate; affect growth
	Calcitonin	Lowers level of calcium in blood
Parathyroid glands	Parathyroid hormone	Increases level of calcium in blood
Thymus	Thymic hormone	Stimulates lymphocyte development
Heart	Atrial natriuretic factor	Lowers blood pressure
Adrenal glands	Adrenaline (epinephrine); noradrenaline (norepinephrine)	Prepare body for physical and mental stress
	Hydrocortisone	Affects metabolism
	Aldosterone	Regulates sodium and potassium excretion by kidneys
	Androgens	Affect growth and sex drive (in both males and females)
Kidneys	Renin	Regulates blood pressure
	Erythropoietin	Stimulates production of red blood cells
Pancreas	Insulin	Lowers blood sugar level
	Glucagon	Raises blood sugar level
Placenta	Chorionic gonadotrophin (HCG); oestrogens; progesterone	Maintain pregnancy
Gastrointestinal tract	Gastrin; secretin; cholecystokinin	Regulate secretion of some digestive enzymes
Testes	Testosterone	Affects development of male secondary sexual characteristics and genital organs
Ovaries	Oestrogens; progesterone	Affect development of female secondary sexual characteristics and genital organs; control menstrual cycle; maintain pregnancy

hospice

A hospital or part of a hospital devoted to the care of patients who are terminally ill (see *dying, care of the*).

hospitals, types of

Most of the hospitals in the UK are part of the National Health Service. Each NHS district has a general hospital providing services that include medicine, surgery, *gynaecology*, *obstetrics*, and *pae-diatrics*. Some more specialist services are concentrated in fewer centres. Many of the UK's private hospitals cater for nonemergency surgery, obstetric care, or inpatient care for the mentally ill.

H**host**

In medical terminology, an organism, either animal (including human) or plant, in which a parasite lives for part or all of its *life cycle*.

hot abscess

An *abscess* (a collection of pus) that is of relatively brief duration, but which causes severe, painful inflammation that is red, swollen, and hot to the touch. (See also *cold abscess*.)

hot flushes

Temporary reddening of the face, neck, and upper trunk that is accompanied by a sensation of heat and is often followed by *sweating*. Hot flushes are usually the result of decreased *oestrogen* production during or following the *menopause*, and they sometimes occur following the removal of the ovaries (see *oophorectomy*). If they are severe, hot flushes can often be alleviated by *hormone replacement therapy* (*HRT*), but this is not advised in the long term. Alternatively, they can be treated with *clonidine*, an antihypertensive drug.

hot spot

An area of increased radionuclide uptake as seen on a *radionuclide scan*. A hot spot usually indicates an abnormal area in which there is increased activity in the tissue. The term may be used in relation to any radionuclide scan, but it is commonly applied to a bone scan in which the hot spot may indicate an abnormality such as an infection or a tumour.

house dust mite

A microscopic organism commonly found in homes that may cause a variety of allergic reactions. Inhalation of dust containing the faeces of the house-dust mite is a common cause of *asthma*,

eczema, and allergic rhinitis (see *rhinitis, allergic*) in susceptible people.

The mites are most abundant in warm, humid conditions. Effective control of mites involves lowering air humidity; increasing ventilation; and limiting the habitats of mite colonies by frequent and thorough cleaning of critical areas, including carpets, mattresses, and bed frames. Placing soft toys and furnishings in the freezer or tumble drier is another effective method of destroying the mites. (See also *mites and disease*.)

household poisons

Toxins that are commonly found and used in the home. Accidental *poisoning* with such chemicals accounts for about one in 50 of all serious domestic injuries. The most frequent victims are young children.

Swallowed household poisons commonly include cleaning products such as detergents, bleach, and stain removers; prescription and over-the-counter medicines (see *drug poisoning*); cosmetics, including nail varnish, perfumes, and skin lotions; paints, paint strippers, and varnishes; and rodent bait and insecticides. Powerful domestic chemicals, such as oven cleaner, can cause poisoning when absorbed through the skin.

Vapour from aerosol sprays and fumes from many cleaning and DIY products can be poisonous if they are inhaled, especially if they are concentrated within a confined space. Improperly maintained fuel-burning appliances, such as hot-water heaters, can produce *carbon monoxide*, a poisonous gas that is potentially fatal if inhaled.

All drugs, cleaning materials, and other household chemicals should be kept well out of the reach of children. Chimneys and flues, as well as heating systems and gas appliances, should be checked annually for carbon monoxide buildups. For extra protection, carbon monoxide alarms can also be fitted.

In the event of ingestion of a household poison, an ambulance should be called, the victim's breathing and pulse monitored continuously, and emergency first aid given if necessary (see *rescue breathing*; *cardiopulmonary resuscitation*). Even if there are no symptoms, a doctor should always be consulted and provided with as much information as possible about the ingested substance. The victim should be given nothing to drink, and vomiting should not be induced unless trained medical personnel instruct otherwise.

housemaid's knee

Also known as prepatellar *bursitis*, inflammation of the fluid-filled sac that acts as a cushion over the kneecap.

HPV

The abbreviation for *human papil-lomavirus*.

HRT

See *hormone replacement therapy*.

5HT₁ agonists

Another name for *serotonin agonists*.

5HT₃ antagonists

Another name for *serotonin antagonists*.

HTLV

The abbreviation for *human T-lym-photropic virus*.

Hughes' syndrome

A potentially serious condition, also called antiphospholipid syndrome, that is characterized by an increased tendency for the blood to clot inside the blood vessels (see *thrombosis*). The syndrome is sometimes referred to as "sticky blood".

CAUSE

Hughes' syndrome is thought to be an *autoimmune disorder*, in which the immune system attacks fatty molecules called phospholipids, which are found throughout the body (particularly in cell membranes). The condition may occur alone or with another autoimmune disease, such as *systemic lupus erythematosus*. It is most common in women.

SYMPTOMS AND COMPLICATIONS

Thrombi (clots) may form in both arteries and veins anywhere in the body. The legs are most commonly affected (see *deep vein thrombosis*). In the brain, a clot can cause areas of tissue to be starved of blood, leading to headaches, migraines, and memory loss. In the lungs, they can cause shortness of breath, chest pain, or coughing up blood. Other possible symptoms include dizziness or disturbances in balance; visual disturbances; and "pins and needles". The blood vessels under the skin may also be affected, particularly on the wrists and knees, causing a red, lacy rash called *livedo reticularis*.

Clotting within an artery may lead to life-threatening complications such as *myocardial infarction* (heart attack), *pul-monary embolism*, *transient ischaemic attack*, or *stroke*. These disorders may occur at an unusually young age (under age 45). In pregnant women, clots may

develop in the placenta, disrupting the blood supply to the fetus and causing *miscarriage*; affected women may have several consecutive miscarriages.

TREATMENT AND OUTLOOK

Hughes' syndrome is treated with drugs that reduce the tendency of the blood to clot: aspirin, heparin, or warfarin. Treatment is long-term or even lifelong, but greatly improves the outlook. It enables people to lead a completely normal life and, in women of childbearing age, drastically reduces the risk of miscarriage.

human chorionic gonadotrophin

See *gonadotrophin, human chorionic*.

human gamma-globulin

See *gamma-globulin*.

human genome

See *genome, human*.

human leukocyte antigen (HLA)

A protein that belongs to the group of proteins called *histocompatibility antigens*, which play a role in the *immune system*.

human papillomavirus

A type of *virus* that is responsible for *warts* and *genital warts*. There are over 70 subtypes of human papillomavirus. At least two of these subtypes are thought to be a causative factor in *cervical cancer* and anal cancer.

human T-cell lymphotropic virus

A type of retrovirus, also called human T-cell leukaemia virus or HTLV. There are several types of HTLV, the most common of which is HTLV-1, which is endemic in tropical regions, including southern Japan, the Caribbean, South America, and West Africa. The virus can be transmitted by sexual contact, breastfeeding, a transfusion of contaminated blood, or by intravenous drug users who share contaminated needles.

SYMPTOMS AND TREATMENT

Most people who become infected with HTLV-1 have no symptoms, but a small percentage (less than one in 20) may develop serious disorders. One such disorder is the cancerous condition adult T-cell leukaemia, which may appear up to 20 years after infection. In this disease, there is a rapid and abnormal turnover of white blood cells in the bone marrow and of cells in lymphoid tissue. Typically, *lymph nodes*, the *liver*, and the *spleen* are enlarged. *Anticancer drugs* may halt the condition temporari-

ly, by killing abnormal cells, but people tend to survive for only a few months to a few years.

Another condition associated with HTLV-1 is *myelopathy* (spinal cord disease). This condition causes pain in the lower back and legs, together with progressively worsening weakness of the legs and difficulty in walking.

humerus

The bone of the upper arm. The dome-shaped head of the bone lies at an angle to the shaft and fits into a socket in the *scapula* (shoulderblade) to form the *shoulder joint*. Below its head, the bone narrows to form a cylindrical shaft, which has a spiral groove housing the *radial nerve* (one of the main nerves in the arm, running from the shoulder to the hand). It flattens and widens at its lower end, forming a prominence on each side called an *epicondyle*. At its base, it articulates with the *ulna* and the *radius* (the bones of the forearm) to form the *elbow*.

humerus, fracture of

The *humerus* (upper arm bone) is most commonly fractured at its neck (the upper end of the shaft, below the head), particularly in elderly people. Fractures of the shaft occur in adults of all ages. Fractures at the lower end of the humerus occur most commonly in children.

COMPLICATIONS

Certain complications may arise if the broken bone ends are displaced and damage surrounding tissues. A fracture in the shaft of the humerus can result in damage to the radial nerve; in severe cases, this damage may lead to wrist-drop. Fractures may also be associated with damage to the brachial artery, which runs down the inner side of the upper arm. If such damage goes undetected, the blood circulation to the forearm and hand may be impaired, resulting in a deformity called Volkmann's contracture.

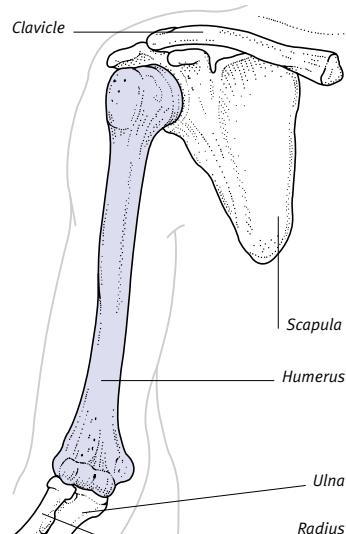

Some supracondylar fractures (breaks just above the elbow) fail to heal properly despite treatment. As a result, the elbow may be deformed and there is an increased risk that *osteoarthritis* may subsequently develop in the joint.

DIAGNOSIS AND TREATMENT

An *X-ray* can show a fracture of the humerus. A fracture at the neck of the bone usually requires only a *sling* to immobilize the bone; a fracture of the shaft or lower bone normally needs a plaster *cast*. Most fractures of the humerus heal in six to eight weeks.

LOCATION OF HUMERUS

The humerus is the bone of the upper arm, located between the shoulder and elbow joints.

humoral immunity

A state of protection against disease that is brought about by the production of antibodies by the immune system to combat infection. In contrast, cellular immunity is the direct response of lymphocytes (a type of white blood cell) to infection and abnormal cells in the body.

humours

A term that describes any liquid or jelly-like substance in the body. Humours usually refers to the *aqueous humour* and *vitreous humour* that occur in the *eye*.

hunchback

See *kyphosis*.

hunger

A disagreeable feeling caused by the need for food; it is different from *appetite*, which is a pleasurable sensation caused by the presence of food. Hunger occurs when the stomach is empty and the blood *glucose* level is low, which may occur several hours after the last meal or following strenuous exercise. In response to these stimuli, messages from the *hypothalamus* in the brain cause the muscular stomach wall to contract rhythmically; these contractions, if they are pronounced enough, can produce hunger pains.

Hunger can also occur in *thyrotoxicosis* (a disorder of the thyroid gland), and in *diabetes mellitus* when there is an incorrect balance between insulin and carbohydrate intake that causes abnormally low blood glucose levels (see *hypoglycaemia*).

Huntington's disease

An uncommon disease that causes degeneration of the *basal ganglia* (paired nerve cell clusters in the brain). The disease is due to a defective *gene* and is inherited in an autosomal dominant manner (see *genetic disorders*).

Symptoms of Huntington's disease do not usually appear until age 35 to 50, although they can develop in childhood. The main symptoms are *chorea* (rapid, jerky, involuntary movements) and *dementia* (progressive mental impairment). The chorea usually affects the face, arms, and trunk, resulting in random grimaces and twitches, and clumsiness. Dementia takes the form of irritability, personality and behavioural changes (including outbursts of aggressive, antisocial behaviour), memory loss (especially short-term memory), and apathy. The disease progresses slowly; affected people live for about ten to 20 years after the onset of symptoms.

At present, there is no cure for Huntington's disease. Treatment is aimed at reducing symptoms with drugs; for example, *antipsychotic drugs* may help to control the abnormal muscle movements. Speech therapy and occupational therapy may also be of benefit. Genetic testing is available for people with family members affected by the condition. However, because there is no effective treatment for Huntington's disease, this may raise difficult ethical questions.

Hurler's syndrome

A rare, inherited condition caused by an *enzyme* defect. The syndrome is a type of inborn error of metabolism (see *metabolism, inborn errors of*) in which there is an abnormal accumulation of substances called mucopolysaccharides in the body tissues (see *mucopolysaccharidosis*).

Affected children may appear normal at birth; however, at six to 12 months of age, they develop cardiac abnormalities, umbilical *hernia*, skeletal deformities, and enlargement of the tongue, *liver*, and *spleen*. Growth is limited and mental development slows. If the condition is diagnosed in early infancy, a *bone marrow transplant* may be curative.

H

hyaline cartilage

The most common type of *cartilage*. Hyaline cartilage is also known as intra-articular cartilage. This type of cartilage is a smooth, tough, connective tissue that covers and protects the bone surfaces that are in contact with each other within a *joint*.

hyaline casts

Cylinders of semi-transparent matter that may be seen in urine viewed under a microscope. Hyaline casts are moulded in the same shape as the kidney tubules and are composed of protein derived from the breakdown of cells. Although they may be present in people with *kidney disease*, hyaline casts may also be a normal finding, particularly if an individual has exercised prior to giving the urine sample.

hyaline membrane disease

A lung condition affecting premature babies that is more commonly known as *respiratory distress syndrome*.

hyaluronic acid

A component of connective tissue and the fluid surrounding most joints (see *synovium*). Synthetic hyaluronic acid can be injected into joints affected by *osteoarthritis* and may help to relieve pain for up to six months.

hyaluronidase

A type of *enzyme* (a protein that regulates a chemical reaction in the body) that occurs naturally in the *testes*, the *spleen*, and certain other body tissues. Hyaluronidase increases tissue permeability and is used in pharmaceutical preparations to enhance the body's absorption of injected fluids.

HyCoSy

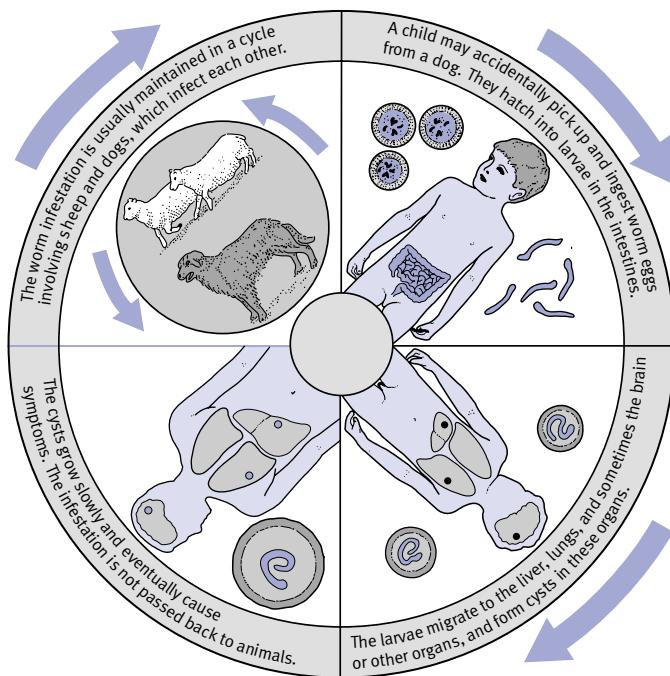

See *hysterocontrast sonography*.

hydatid disease

A rare infestation that is caused by the larval stage of the small tapeworm *ECHINOCOCCUS GRANULOSUS* (see *tapeworm infestation*). Larvae usually settle in the

ORIGINS OF HYDATID DISEASE

The infestation is generally confined to dogs and sheep, but occasionally a child swallows eggs from dog faeces. The worm eggs hatch into larvae, which migrate through the body, especially to the liver or lungs, to form slow-growing cysts. Symptoms may not appear until years later.

liver, lungs, or muscle, causing the development of cysts. In rare cases, the brain is affected.

The infestation is generally confined to dogs and sheep, but may be passed on to humans through accidental ingestion of worm eggs from materials contaminated with dog faeces.

SYMPOTMS, DIAGNOSIS, AND TREATMENT

The cysts grow slowly, and symptoms may not appear for some years. In many cases, there are no symptoms.

Cysts in the liver may cause a tender lump or lead to *bile duct obstruction* and *jaundice*. Cysts in the lungs may press on an airway and cause inflammation; rupture of a lung cyst may cause chest pain, the coughing up of blood, and wheezing. Cysts in the brain may cause *seizures*. Ruptured cysts may, rarely, cause *anaphylactic shock*, a severe allergic reaction that can be fatal.

Diagnosis of hydatid disease is by *CT scanning* or *MRI* (magnetic resonance imaging). The cysts are usually drained or removed surgically.

hydatidiform mole

An uncommon noncancerous tumour that develops from placental tissue early in a pregnancy in which the *embryo* has failed to develop normally. A hydatidiform mole is thought to be the result of a chromosomal abnormality that occurs at conception. A pregnancy in which a hydatidiform mole occurs is known as a *molar pregnancy*.

The mole, which resembles a bunch of grapes within the uterus, is caused by degeneration of the *chorionic villi* – minute, finger-like projections in the *placenta*. The cause of the degeneration is unknown. In a small number of affected pregnancies, the mole develops into a *choriocarcinoma*, a cancerous tumour that can invade the walls of the uterus if left untreated.

SYMPOTMS, DIAGNOSIS, AND TREATMENT
Vaginal bleeding and severe morning sickness generally occur in early pregnancy and the uterus may be larger than expected for the duration of the pregnancy. There is no viable fetus.

Diagnosis of a hydatidiform mole is by *ultrasound scanning*, which will reveal the tumour, and urine and by blood tests to detect excessive amounts of human chorionic gonadotrophin, or HCG (see *gonadotrophin*, *human chorionic*), a hormone that is produced by the tumour. The mole is removed by emptying the uterus using suction. This

procedure is carried out under general anaesthetic (see *anaesthesia, general*).

There is a small risk that the condition may occur in a subsequent pregnancy. Women who have had a hydatidiform mole should have their levels of HCG monitored for at least two years, and should not conceive again until their HCG levels have been normal for at least one year.

hydralazine

An *antihypertensive drug* that is used principally as an emergency treatment for *hypertension* (high blood pressure). Hydralazine may cause nausea, headache, dizziness, irregular heartbeat, loss of appetite, rash, and joint pain. Taken for the long term and in high doses, it may cause the connective tissue disorder *lupus erythematosus*.

hydramnios

See *polyhydramnios*.

hydration

In medical terms, either the ingestion of water or the amount of water present in an individual or a tissue. (See also *dehydration*; *rehydration therapy*.)

hydrocele

A soft, painless swelling in the *scrotum* caused by the space around a *testis* filling with fluid. A hydrocele may be caused by inflammation, infection, or injury to the testis; occasionally, the cause is a tumour. More often, there is no apparent cause. Hydroceles commonly occur in middle-aged men, and treatment is rarely necessary. If the swelling is uncomfortable or painful, however, the fluid may be withdrawn through a needle. Recurrent swelling may be treated by surgery.

hydrocephalus

An excessive build-up of *cerebrospinal fluid* within the skull. The condition occurs either because too much cerebrospinal fluid is produced or because the fluid does not drain away normally. The excess fluid causes an increase in pressure within the skull, which may lead to brain damage.

Hydrocephalus may be *congenital* (present at birth), when it is often associated with other abnormalities, such as *spina bifida*. Or it may be a result of major *head injury*, *brain haemorrhage*, infection (such as *meningitis*), or tumour.

With congenital hydrocephalus, the main feature is an enlarged head that

Baby with hydrocephalus

The skull enlargement is due to pressure from excess fluid within the cavities of the brain. To prevent brain damage, the fluid must be drained by means of a tube inserted into the skull.

continues to grow rapidly. Other features include rigidity of the legs, vomiting, *epilepsy*, irritability, lethargy, and the absence of normal reflex actions. If it is not treated, hydrocephalus progresses to severe brain damage, which may result in death within weeks.

If hydrocephalus occurs later in life, when the skull bones have fused, the skull is unable to expand to accommodate the extra fluid. In this situation, the raised pressure within the skull causes symptoms including headache, vomiting, loss of coordination, and the deterioration of mental function.

In most cases, treatment of hydrocephalus involves a surgical procedure in which a tube called a shunt is inserted into the skull. This tube enables the fluid from the brain to drain into another part of the body, for example, the abdominal cavity, where it can be absorbed. In older children and adults, treatment is given for any underlying cause of the condition, such as a brain tumour.

hydrochloric acid

A strong acid released by the stomach lining. This acid forms part of the stomach juices and helps in the digestion of proteins. Excessive production of hydrochloric acid, which may be triggered by smoking or stress, can lead to irritation of the stomach lining, and is an important factor in the development of *peptic ulcers*. If the acid escapes from the stomach into the oesophagus (see *acid reflux*), it can irritate the tissues, causing *oesophagitis* and *heartburn*.

hydrochlorothiazide

A *thiazide diuretic drug* that is used to reduce *oedema* (fluid retention) in people with *heart failure*, *nephrotic syndrome*

(a kidney disorder), and *cirrhosis*. It is also given for *hypertension* (high blood pressure). Adverse effects include leg cramps, dizziness, rash, and impotence. The drug may, rarely, cause *gout* and may aggravate *diabetes mellitus*.

hydrocortisone

Also called cortisol, a *hormone* produced naturally by the *adrenal glands*. Synthetic hydrocortisone is used as a *corticosteroid drug* to treat severe allergic conditions; for example, it is given by injection to treat *anaphylactic shock*. It is also used as a replacement treatment when the adrenal glands fail to function (see *Addison's disease*). Hydrocortisone is widely given in the form of a cream or ointment, to treat inflammatory skin conditions, such as heat rash, and is effective at reducing itching; however, used to excess, hydrocortisone creams may cause thinning of the skin, wrinkles or loss pigmentation.

hydrogen peroxide

A substance used as mild *antiseptic* solution or cream to treat infections of the skin or mouth, or used to bleach hair. Hydrogen peroxide combines with catalase, an enzyme present in the skin and mouth, to release oxygen. This reaction kills bacteria. Solutions used to treat the skin and mouth usually contain three per cent hydrogen peroxide; those used for bleaching hair are stronger. Occasionally, solutions containing hydrogen peroxide may irritate the skin.

hydronephrosis

A condition in which a *kidney* becomes swollen with urine due to an obstruction in the *urinary tract*. The excess urine causes pressure to build up inside the kidney and prevents it from functioning normally. Hydronephrosis may affect one or both kidneys.

In some cases, hydronephrosis may be due to a *congenital* narrowing of the *ureter*. In other cases, the obstruction of a ureter may be caused by a stone (see *calculus, urinary tract*), a *kidney tumour*, or a blood clot. Occasionally, hydronephrosis is caused by obstruction to the outflow of urine from the bladder by an enlarged prostate gland (see *prostate, enlarged*) in men, or by enlargement of the uterus in pregnant women. In such cases, both kidneys are affected.

Acute hydronephrosis, in which there is a sudden blockage of the ureter, causes severe pain in the abdomen and the small of the back. Chronic hydronephro-

sis, in which the obstruction develops slowly, may cause no symptoms until total blockage results in *kidney failure*. Hydronephrosis also increases the risk of kidney infection because bacteria can multiply more easily in stagnant urine.

Hydronephrosis can be diagnosed using X-rays (see *intravenous urography*), *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures). Following diagnosis, it is usually possible to relieve pressure by draining urine through a tube either directly onto the surface of the skin or by bypassing the blockage. Further treatment will then be needed to treat the cause of the blockage.

If the blockage can be removed surgically, the kidney is likely to function normally again. Occasionally, however, a kidney is so badly damaged that it requires removal (see *nephrectomy*).

hydrophobia

A popular term, now almost obsolete, for *rabies*.

hydrops

An abnormal accumulation of fluid in a body tissue (see *oedema*), cavity, or sac (a baglike body structure).

hydrops fetalis

Serious *oedema* (swelling of the body tissues) that occurs in a *fetus* before birth. Hydrops fetalis is often the result of Rhesus incompatibility (see *haemolytic disease of the newborn*). In pregnant women who are affected by Rhesus incompatibility, additional *ultrasound scanning* may be carried out to detect any swelling and help doctors to determine whether any treatment will be necessary for the fetus.

hydrotherapy

A form of *physiotherapy* in which exercises are performed in water to aid recovery from injury or to improve mobility. Hydrotherapy includes the use of exercise pools, whirlpool baths, and showers.

People who cannot bear their full body weight on a limb (such as people with arthritis or those who have fractured a limb) may undergo exercises in a hydrotherapy pool. The buoyancy of the water supports the person's body; in addition, the water provides gentle resistance that helps to improve muscle strength. Warm whirlpool baths can also provide a gentle massage to stimulate areas of the body and relieve stiffness.

hydrous ointment

An oil-and-water based greasy skin preparation that is used to treat dry or scaling skin conditions such as *eczema* and *psoriasis*. Such ointment hydrates the affected area and can provide relief from itching.

hydroxocobalamin

A long-acting synthetic preparation of *vitamin B₁₂*. Hydroxocobalamin is given by injection to treat disorders involving vitamin B₁₂ deficiency, particularly pernicious anaemia (see *anaemia, megaloblastic*), in which vitamin B₁₂ cannot be absorbed from the intestines.

hydroxyapatite

A complex crystalline form of calcium phosphate that occurs naturally in the body as a major component of bones and teeth. A synthetic form of hydroxyapatite is used as a *calcium* supplement to reduce bone loss when the intake of dietary calcium is inadequate.

5-hydroxytryptamine

Another name for *serotonin*.

hydroxyzine

A sedating *antihistamine drug* used to relieve itching and, occasionally, in the treatment of *anxiety*.

hygiene

The science and practice of preserving health. The word "hygiene" is commonly used of personal cleanliness. It can also refer to *public health* – the scientific study of various environmental influences on health, such as safe sanitation and good housing. The terms "industrial hygiene" and "occupational hygiene" refer to the scientific discipline of assessing and regulating the work environment in order to prevent *occupational disease and injury*.

hygiene, oral

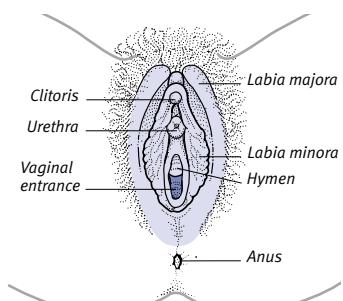

See *oral hygiene*.

hygroma, cystic

A *lymphangioma* (a type of noncancerous tumour) that occurs around the head and neck, the armpits, or the groin and contains clear fluid. Cystic hygromas are usually present from birth, reach their maximum size by the time the child is about two years old, then gradually disappear. The tumour may be surgically removed if it is obstructing the airway, but the final appearance is usually better if surgery can be avoided.

LOCATION OF HYMEN

The membrane that forms the hymen surrounds the opening to the vagina, inside a woman's labia minora.

**hymen**

The thin membrane around the vaginal opening. The hymen has a central perforation which is usually stretched or torn by the use of tampons or during first sexual intercourse.

Imperforate hymen is a rare condition in which the hymen has no perforation; as a result, at the onset of menstruation, menstrual blood collects in the *vagina*, causing lower abdominal pain. The condition is easily corrected by a minor operation.

hyoid

A small, U-shaped bone that is situated centrally in the upper part of the neck. The hyoid bone is not joined to any other bone but is suspended by ligaments from the base of the skull. It provides an anchor point for the muscles of the tongue and for the muscles of the upper front part of the neck. The hyoid bone may be fractured as a result of deliberate *strangulation*.

hyoscine

An *anticholinergic drug* prescribed in two distinct forms: hyoscine butylbromide which is used to relieve the symptoms of *irritable bowel syndrome*, and hyoscine hydrobromide, which is used to control *motion sickness*. Hyoscine hydrobromide eye-drops may be given to dilate the pupil before an eye examination or surgery. An injection of hyoscine hydrobromide may be given as part of a *premedication* because it dries secretions in the mouth and lungs.

Possible adverse effects of both forms of the drug include a dry mouth, blurred vision, drowsiness, and constipation.

hyper-

A prefix that is placed before a word to mean "above", "excessive", or "greater than normal".

hyperacidity

A condition in which excess acid is produced by the *stomach*. Hyperacidity is often confused with *acid reflux* or *waterbrash*. It occurs in people who have a duodenal ulcer (see *peptic ulcer*) or *Zollinger-Ellison syndrome*.

hyperactivity

A behaviour pattern in which children are overactive and have difficulty in concentrating. The occasional occurrence of such behaviour in small children is considered to be normal. If a child exhibits persistent hyperactivity, however, and other possible causes (such as a stressful home environment or physical illness) have been eliminated, he or she may have a condition known as *attention deficit hyperactivity disorder (ADHD)*. Assessment by a paediatrician is needed before a decision on treatment is made.

hyperacusis

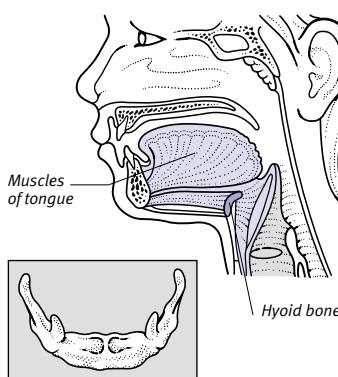

An excessively sensitive sense of hearing. In people who have hyperacusis, exposure to loud noises may cause pain or discomfort in the ears.

hyperaemia

Excess blood in part of the body. Hyperaemia can occur if the outflow of blood from an area is blocked. The condition more commonly arises due to an

LOCATION OF HYOID BONE

The U-shaped hyoid bone provides an anchor for the muscles at the back of the tongue.

inflammatory reaction in which the flow of blood to a particular area increases; for example, around a wound or an insect bite. The skin over the affected area may be warm and red.

hyperaesthesia

The medical term for an extreme sensitivity of the skin to normal stimuli, such as touch.

hyperaldosteronism

An alternative term for *aldosteronism*, a metabolic disorder caused by overproduction of the hormone *aldosterone* by the *adrenal glands*.

hyperalimentation

Administration of increased amounts of *nutrients*. Hyperalimentation is usually given intravenously or through a stomach tube (see *feeding, artificial*).

hyperbaric oxygen treatment

A procedure designed to increase the amount of *oxygen* in the tissues. This increase is achieved by placing a person in a special chamber and exposing him or her to oxygen at a much higher atmospheric pressure than normal.

Hyperbaric oxygen treatment is used to treat any condition in which the body tissues are deprived of oxygen. For example, it is used to treat *carbon monoxide* poisoning; in this condition, carbon monoxide attaches to *haemoglobin* (the oxygen-carrying pigment in red blood cells), preventing the blood from carrying sufficient oxygen to the tissues. The treatment is also used for people with *decompression sickness* due to activities such as diving. In addition, the treatment may be used for people who have suffered severe soft tissue injuries, such as deep *burns* and *crush injury*, in which *oedema* (a buildup of fluid in the tissues) hinders the passage of oxygen from the blood to the tissues.

Another use for hyperbaric oxygen treatment is to treat *gas gangrene*. This condition is caused by bacteria that thrive in an oxygen-free environment; the bacteria cannot survive once oxygen is supplied to the affected tissues. The use of hyperbaric oxygen in the treatment of *multiple sclerosis* has not been shown to be effective.

hyperbilirubinaemia

A raised level of *bilirubin* (a breakdown product of red blood cells) in the blood. Mild hyperbilirubinaemia may

be undetectable except by a blood test, but if the blood bilirubin rises to twice the normal level, *jaundice* develops.

hypercalcaemia

An abnormally high level of *calcium* in the blood. Hypercalcaemia may be a result of *hyperparathyroidism* (overproduction of parathyroid hormone, a substance that normally helps to control the level of calcium in the blood). Cancer may also cause hypercalcaemia, either by spreading to the bones or by producing abnormal hormones that cause the bones to release calcium. Less commonly, the condition occurs as a result of intaking excessive amounts of *vitamin D* or of certain inflammatory disorders, such as *sarcoidosis*.

SYMPOTMS

Hypercalcaemia causes nausea, vomiting, lethargy, depression, thirst, and excessive urination. Higher blood levels of calcium produce confusion, extreme fatigue, and muscle weakness. If the disorder is left untreated and the calcium levels continue to rise, hypercalcaemia can be extremely serious, causing cardiac *arrhythmias* (irregularities of the heartbeat), *kidney failure*, *coma*, and may even lead to death.

Long-standing hypercalcaemia may cause *nephrocalcinosis* (calcification of the kidney) or kidney stones (see *calculus, urinary tract*).

DIAGNOSIS, AND TREATMENT

Diagnosis is by *blood tests* to measure the blood level of calcium and further tests to help reveal the cause. Treatment involves rehydration and, if necessary, reduction of dangerously high calcium levels with drugs such as *bisphosphonate drugs* or *corticosteroid drugs*. At the same time, the underlying cause is treated if possible.

hypcapnia

An excess of carbon dioxide in the blood. The condition is caused by failure of internal mechanisms, such as *breathing rate*, that normally control blood carbon dioxide levels. Hypcapnia leads to respiratory *acidosis*.

hypercholesterolaemia

A condition in which there is an increased concentration of *cholesterol* in the blood. Hypercholesterolaemia is thought to be associated with high levels of *low density lipoprotein* (LDL) in the blood; the condition may be caused by a genetic defect in which there is a lack

of LDL receptors, which remove cholesterol from the bloodstream. (See also *hyperlipidaemias*.)

hyperemesis

The medical term for excessive *vomiting*. Hyperemesis may cause dehydration and weight loss.

The condition may occur during pregnancy, when it is known as *hyperemesis gravidarum*. Unlike morning sickness, the vomiting is so severe that the affected woman cannot keep down any food or fluid. The cause is not known, but a contributing factor is thought to be an excess of the hormone *human chorionic gonadotrophin* (HCG), which is due to the existence of more than one fetus or to a *hydatidiform mole*. Psychological stress may aggravate the symptoms. If left untreated, hyperemesis gravidarum may be life-threatening for the mother and fetus. (See also *vomiting in pregnancy*.)

hyperglycaemia

An abnormally high level of *glucose* in the blood that occurs in people with untreated or inadequately controlled *diabetes mellitus*. Hyperglycaemia may also occur in people with diabetes as a result of an infection, stress, or surgery.

Features of hyperglycaemia include the passing of large amounts of urine, thirst, *glycosuria* (glucose in the urine), and *ketosis* (accumulation in the body of organic substances called ketones). If it is severe, hyperglycaemia can lead to confusion and *coma*, which requires emergency treatment with *insulin* and *intravenous infusion* of fluids.

hypergonadism

Overactivity of the gonads (*testes* or *ovaries*) that results in overproduction of *androgen hormones* or *oestrogen hormones*. Hypergonadism may be caused by disorders of the gonads or a disorder of the *pituitary gland* that results in overproduction of *gonadotrophin hormones*. If hypergonadism develops during childhood, it results in premature sexual development (see *precocious puberty*) and excessive growth.

hyperhidrosis

A term used to describe excessive *sweating*. Hyperhidrosis may be localized (affecting only the armpits, feet, palms, or face), or it may affect all body areas supplied by *sweat glands*. The condition may be caused by hot weather, exercise,

or anxiety. In some cases it is due to an infection, *thyrotoxicosis*, *hypoglycaemia*, or a nervous system disorder. Usually, however, it has no known cause and begins at puberty, disappearing by the person's mid-20s or early 30s.

If hyperhidrosis in a particular area, such as the armpits, is persistent and cannot be controlled by *antiperspirants*, surgery may be considered to destroy the nerve centres that control sweating in that area (see *sympathectomy*).

hyperkalaemia

Abnormally high blood levels of *potassium*, often due to failure of the kidneys to excrete it. Hyperkalaemia can lead to a fatal heart irregularity if severe.

hyperkeratosis

Thickening of the skin's outer layer due to an increased amount of *keratin*, a tough protein that is the major component of the outer skin layer. The most common forms of hyperkeratosis affect small, localized areas of skin and include *corns*, *calluses*, and *warts*. A rare, inherited form affects the whole of the soles and palms. The term "hyperkeratosis" may also be used to describe thickening of the nails.

hyperlipidaemias

A group of *metabolic disorders* that are characterized by high levels of *lipids* (fats) in the blood.

CAUSES

Some hyperlipidaemias are inherited, resulting from inheritance of an abnormal *gene* (unit of hereditary material). Hyperlipidaemias may also be associated with another disorder, such as *hypothyroidism* (underactivity of the thyroid gland), *diabetes mellitus*, *kidney failure*, or *Cushing's syndrome* (high levels of corticosteroid hormones in the blood). Sometimes they may result from the use of *corticosteroid drugs*.

Hyperlipidaemias are classified according to which forms of lipids have elevated levels in the blood. Lipids are carried in the blood in several forms, principally *cholesterol* and *triglycerides* in the form of lipoproteins (lipid molecules linked to protein molecules). Lipoproteins are classified according to their density, which depends on their relative proportions of cholesterol and protein: the higher the proportion of cholesterol, the lower the density of the lipoprotein. Elevated levels of *low density lipoproteins* (LDLs) and *very low density*

lipoproteins (VLDLs) contribute to hyperlipidaemias. *High density lipoproteins* (HDLs) are not involved.

RISKS AND SYMPTOMS

Hyperlipidaemias are associated with an increased risk of *atherosclerosis* (narrowing of the arteries as a result of fatty deposits) and *coronary artery disease*.

The symptoms depend on the particular type of hyperlipidaemia; they may include fatty yellow nodules in the skin on the back of the hands, on the tendons around the ankles and on the wrist joints; a white line around the rim of the *cornea*; and abdominal pain.

DIAGNOSIS AND TREATMENT

A diagnosis is made using *blood tests*. Treatment is designed to reduce blood lipid levels, usually by means of weight loss, a low-fat diet, and *lipid-lowering drugs*. Early treatment can reduce the risk of a heart attack. There is no known cure for inherited hyperlipidaemias. (See also *hypercholesterolaemia*.)

hypermagnesaemia

An abnormally high level of *magnesium* in the blood. The most common cause of hypermagnesaemia is *kidney failure*, although the condition may also be caused by excessive magnesium intake; *hypothyroidism* (underactivity of the thyroid gland); *Addison's disease*; and it may be associated with *hypercalcaemia*. Hypermagnesaemia may lead to lethargy, weakness, and irregularities with the electrical activity of the heart. As levels of magnesium increase, the condition may result in *coma*. Treatment of hypermagnesaemia is of the underlying cause.

hypermetropia

Commonly known as longsightedness, hypermetropia is an error of *refraction* (the focusing of light rays within the eye) that initially causes difficulty in seeing near objects and goes on to affect distance vision. The condition tends to run in families.

Hypermetropia is caused by the eye being too short from front to back, which results in images not being clearly focused on the *retina*. The error is present from birth, but symptoms do not generally appear until later life because the focusing power of *accommodation*, which compensates for hypermetropia, declines with age.

Glasses or *contact lenses* with convex lenses reinforce focusing power.

hypernephroma

A type of *kidney cancer*, also known as renal cell carcinoma.

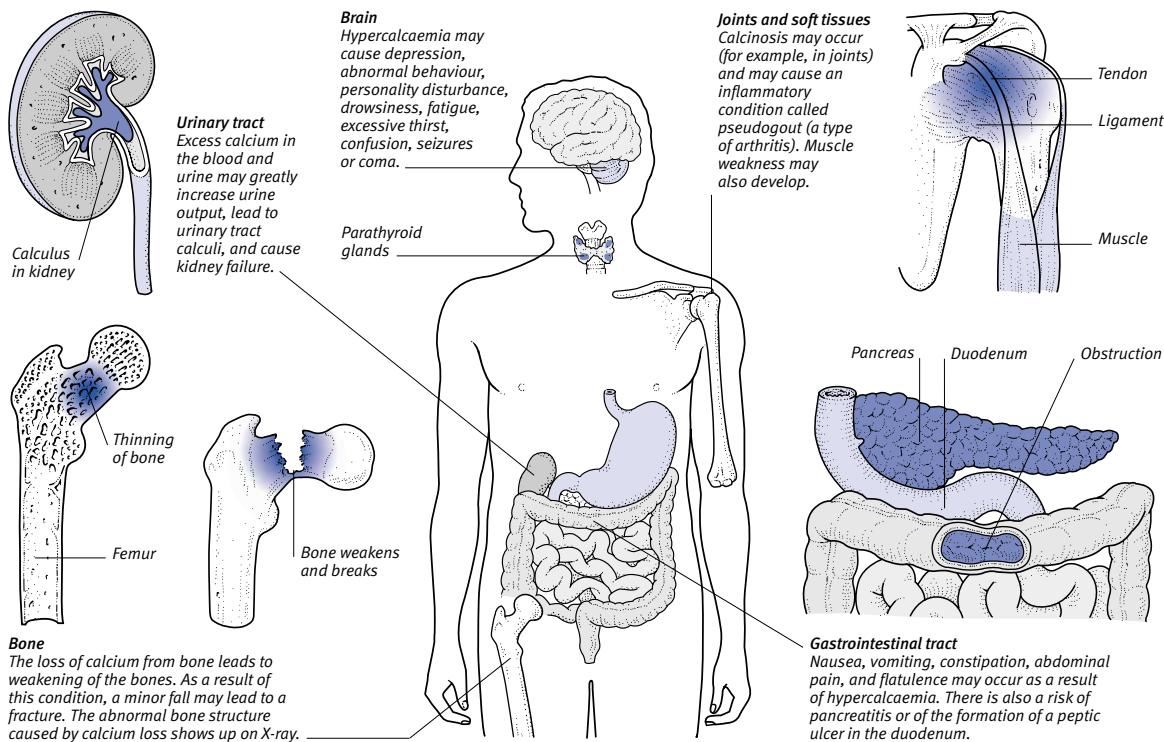

hyperparathyroidism

Overproduction of parathyroid hormone (PTH) by the *parathyroid glands*. Normally, PTH, together with *vitamin D* and another hormone called *calcitonin*, controls the level of *calcium* in the body. An excess of PTH raises the level of calcium in the blood (see *hypercalcaemia*).

HYPERPARATHYROIDISM

In this disorder, the parathyroid glands produce too much parathyroid hormone. Symptoms, signs, and complications of the disorder occur as a result of an increased calcium level in the blood and urine, the loss of calcium from bones,

and calcinosis (the formation of calcium deposits in different tissues). Surgical removal of abnormal parathyroid tissue is carried out to prevent complications.

by removing calcium from bones. This activity can lead to bone disorders, such as *osteoporosis*. In an attempt to bring the high calcium level back to normal, the kidneys excrete large amounts of calcium in the urine, which can lead to the formation of kidney stones (see *calculus, urinary tract*).

CAUSES

Hyperparathyroidism is most often caused by a small noncancerous tumour of one or more of the parathyroid glands, in which case is known as primary hyperparathyroidism. This usually develops after the age of 40 and is twice as common in women as in men. Hyperparathyroidism may also occur when all the glands become enlarged for no known reason. It may also develop in response to a condition that causes abnormally low levels of calcium, such as chronic *kidney failure*, in which case it is known as secondary hyperparathyroidism.

SYMPOTMS

Hyperparathyroidism may cause muscular aches and pains, depression, and abdominal pain. Often however, the only symptoms are those that are caused by kidney stones. If hypercalcaemia is severe, there may be nausea, tiredness, excessive urination, confusion, and muscle weakness.

DIAGNOSIS AND TREATMENT

The condition is diagnosed by *X-rays* of the hands and skull and by *blood tests* to measure levels of calcium and PTH.

If the hyperparathyroidism is only mild, no treatment may be needed; instead, the affected person's blood calcium levels and kidney function will be monitored annually. More serious cases may need treatment with drugs to lower the blood calcium levels. If a parathyroid tumour is found, the affected gland will be surgically removed; this usually cures the condition. If the remaining tissue is unable to produce enough PTH, treatment for *hypoparathyroidism* (underactivity of the parathyroid glands) is required.

hyperphosphataemia

An abnormally high level of *phosphates* in the blood. Hyperphosphataemia is usually caused by decreased phosphate excretion as a result of impaired kidney function or *kidney failure*. It may also be associated with *hypoparathyroidism* (underactivity of the parathyroid gland) or *hypocalcaemia* (low blood calcium levels). A side effect of hyperphosphat-

aemia is the formation of calcium phosphate crystals in the blood and soft tissue. This can cause *arteriosclerosis*, which may lead to *myocardial infarction* (heart attack) or *stroke*. Treatment is of the underlying cause.

hyperpigmentation

Abnormally dark coloration of the skin. Hyperpigmentation is usually seen in scar tissue and damaged areas of skin, such as in areas affected by *acne*. The condition results in permanent changes in skin colour and is more obvious in darker skin. Hyperpigmentation is also a feature of *Addison's disease*.

hyperplasia

Enlargement of an organ or tissue due to an increase in the number of its cells. However, unlike the cells of a tumour, the new cells are normal. Hyperplasia is usually the result of hormonal stimulation. It may occur normally (such as in the enlargement of breast tissue in pregnancy) or it may indicate a disorder. (See also *hypertrophy*.)

hyperplasia, gingival

Abnormal enlargement of the gums. Causes include *gingivitis* (inflammation of the gums), ill-fitting dentures, persistent breathing through the mouth, and taking the anticonvulsant drug *phenytoin*. Surgical treatment may be needed.

hyperpyrexia

A term used to refer to extremely high body temperature (see *hyperthermia*).

hypersensitivity

Overreaction of the *immune system* (defence against infection) to an *antigen* (a protein that is recognized as foreign). Hypersensitivity reactions occur only on second or subsequent exposures to particular antigens, after the first exposure has sensitized the immune system. Such reactions have the same mechanisms as those of protective *immunity*; however, while the latter may protect against disease, hypersensitivity reactions lead to tissue damage and disease.

There are four main types of hypersensitivity reaction.

TYPE I

Type I is associated with *allergy*. After first exposure to an antigen (which may be a harmless substance such as grass pollen), *antibodies* (substances that can recognize and bind to the antigen) are formed. These antibodies coat mast cells

in various tissues. On second exposure, the antigen and antibodies combine, causing the mast cells to disintegrate and release chemicals that cause the symptoms of *asthma*, *allergic rhinitis* (hay fever), *urticaria* (nettle rash), *anaphylactic shock* (a severe allergic reaction), or other allergic illnesses.

TYPE II

In type II reactions, antibodies bind to antigens on the surfaces of cells in particular tissues, leading to possible destruction of those cells. Type II reactions may lead to certain *autoimmune disorders* (in which antibodies attack the body's own tissues). They may also be responsible for some cases of *haemolysis* (destruction of red blood cells) triggered by certain drugs.

TYPE III

In type III reactions, antibodies combine with antigens to form particles known as immune complexes. These particles lodge in various tissues and activate further responses from the immune system, leading to tissue damage. This type of reaction is responsible for *serum sickness*, *allergic alveolitis* (a lung disease caused by exposure to the spores of certain fungi), and the large swellings that sometimes form after a person has a booster vaccination.

TYPE IV

In type IV reactions, sensitized *T-lymphocytes* (a class of white *blood cell*) bind to antigens and release chemicals known as lymphokines, which promote an inflammatory reaction. Type IV reactions are responsible for *contact dermatitis* and the rash that occurs in *measles*; they may also play a part in some "allergic" reactions to drugs.

TREATMENT

Treatment of hypersensitivity depends on the type, cause, and severity. When possible, exposure to the offending antigen should be avoided.

hypersplenism

Overactivity of the *spleen* that results in, and which is associated with, blood disease. One of the functions of the spleen is to break down *blood cells* as they age and wear out. An overactive spleen may begin to destroy cells regardless of their age and condition, causing a deficiency of any of the types of blood cell. In most cases, the spleen will also be enlarged.

If the condition occurs for no reason it is called primary hypersplenism. More commonly, however, it is secondary to

another disorder, such as *Hodgkin's disease* or *malaria*, in which the spleen has become enlarged.

Signs of hypersplenism include *anaemia* and *thrombocytopenia* (deficiency of platelets). There may also be decreased resistance to infection. Primary hypersplenism is treated with *splenectomy* (removal of the spleen). Treatment of secondary hypersplenism is aimed at control of the cause.

hypertension

Persistently raised *blood pressure* (the pressure of blood in the main arteries). Blood pressure goes up temporarily as a normal response to stress and physical activity, and it rises naturally with increasing age and weight. A person with hypertension, however, has persistently high blood pressure even when at rest. Because the condition itself causes no symptoms, a large number of people have hypertension without realizing it; however, because hypertension causes the risk of developing serious cardiovascular disorders to increase, regular medical checks are advised in order to detect the condition at an early stage. Hypertension is very common, particularly in men, and its incidence is highest in the middle-aged and elderly.

Blood pressure is measured as two values, each expressed as millimetres (mm) of mercury (chemical symbol Hg) or mmHg. The systolic value (the higher value) is the pressure when blood surges into the aorta from the heart; the diastolic value is the pressure when the ventricles (lower chambers of the heart) relax between beats. A blood pressure consistently exceeding about 140 mmHg (systolic) and 90 mmHg (diastolic) at rest is defined as hypertension.

SYMPTOMS AND COMPLICATIONS

Hypertension is usually symptomless, and generally goes undiscovered until detected during a routine physical examination. However, if it is severe or accelerated (see *malignant hypertension*) it may cause headaches, breathlessness, and visual disturbances. The condition puts considerable strain on the heart and blood vessels, increasing the risk of *stroke*, *coronary artery disease*, and *heart failure*. Hypertension may eventually lead to kidney damage and *retinopathy* (damage to the retina at the back of the eye).

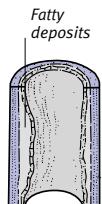

CAUSES

In many cases, there is no obvious cause, in which case the condition is

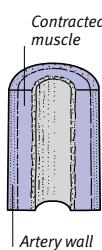

HYPERTENSION

Hypertension (high blood pressure) affects ten to 20 per cent of adults in the UK. It is diagnosed if a person's resting *blood pressure* is persistently raised. Blood pressure is expressed by two values – the systolic and diastolic pressures – and measured in millimetres of mercury.

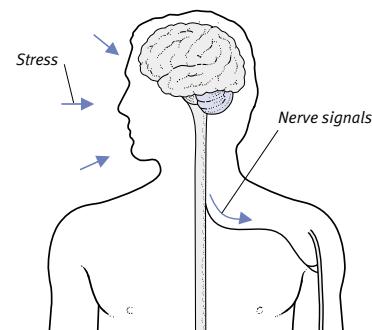

Although hypertension rarely causes symptoms, it is a serious condition. It may cause excessive strain on the arteries. Left untreated, it increases the risk of stroke and other disorders. In many cases there is no obvious cause for hypertension, but in some people there is a specific cause, such as a kidney disorder, pregnancy, or the use of oral contraceptives. Hypertension is linked to obesity and, in some people, to a high salt intake. Smoking compounds the risks of the condition.

Atheroma
Hypertension and atherosclerosis, in which arteries are narrowed by fatty deposits called atheroma (left), are closely linked both to each other and to obesity.

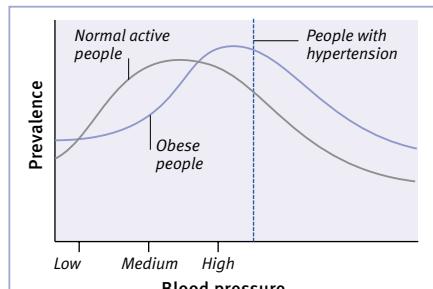

Constriction
Factors such as nicotine in tobacco cause constricted arteries (left) and a short-term rise in blood pressure that may worsen hypertension.

Stress and hypertension

Acute stress or pain act on the nervous system, causing blood vessels to constrict and the heart to work harder. Both lead to a brief rise in blood pressure. Hence, pressure should be measured when a person is relaxed. It is possible (but unproven) that frequent stress may eventually cause hypertension.

Variation in blood pressure

In any population, blood pressure varies over a wide range in the same way as height. Many people are considered to be hypertensive because they are at the top end of this range (see above). In obese people, the range is similarly wide but shifted towards the top end: hence, more obese people are hypertensive.

COMMON FACTORS AND PREVENTIVE MEASURES

Factors associated with essential hypertension	<ul style="list-style-type: none"> ● Age (incidence higher in the elderly) ● Family history of the condition ● Gender (incidence higher in men than in women)
Factors that may aggravate hypertension	<ul style="list-style-type: none"> ● Smoking ● Obesity ● Excess alcohol intake ● Diabetes mellitus ● High salt intake
Self-help and treatment	<ul style="list-style-type: none"> ● Regular screening of blood pressure is important for early diagnosis and can help to prevent complications. ● Sufferers from essential hypertension should: Reduce weight; Not smoke; Reduce or stop alcohol intake Reduce salt intake; Take regular exercise; Learn relaxation. ● Antihypertensive drugs, prescribed by a doctor, can usually keep high blood pressure under control.

called essential hypertension. Genetic factors are important, although hypertension is not attributed to a specific gene. Other factors that are associated with hypertension include high alcohol intake, a high-salt diet, obesity, *diabetes mellitus*, a sedentary lifestyle, and smoking. There is also evidence that low birth weight increases the risk of developing hypertension in later life.

If hypertension results from a specific disorder, the condition is known as secondary hypertension. Causes include various *kidney* disorders; certain disorders of the *adrenal glands*; *pre-eclampsia* (a complication of pregnancy); *coarctation of the aorta* (a congenital heart defect); and the use of certain drugs. Taking the combined contraceptive pill (see *oral contraceptives*) can lead to hypertension in susceptible women.

DIAGNOSIS

The patient's blood pressure is measured at rest on several occasions in order to make a diagnosis. If there is any doubt, an ambulatory blood pressure device is fitted to monitor blood pressure over a 24 hour period. This may detect a condition known as white coat hypertension, in which blood pressure is raised during a test by a doctor, but it is otherwise normal and does not require treatment. The eyes may also be examined for evidence of longstanding hypertension. If secondary hypertension is suspected, *blood tests*, *X-rays*, and other appropriate tests are carried out to exclude any potential causes.

TREATMENT

With mild to moderate hypertension, if no underlying cause is found, lifestyle changes are recommended as the first line of treatment. For example, smokers should give up their habit and drinkers should reduce their consumption of alcohol. Any overweight person with hypertension should try to lose weight by modifying the diet and introducing gradually increasing amounts of exercise into the daily routine. *Biofeedback training* and relaxation techniques can also help to reduce blood pressure.

If self-help measures have no effect, or if hypertension is severe, *antihypertensive drugs* may be given. There is a large range of drug treatments available and the treatment chosen depends on the presence of other disorders, such as *diabetes mellitus*. The response of the condition to treatment, as well as any side effects it has provoked, may prompt a change of treatment. Usually,

the patient is monitored by having regular blood pressure checks, so that adjustments to drug type or dosage can be made if necessary. It may be possible for the patient to monitor his or her own blood pressure at home, but the individual's machine should be checked regularly and calibrated against the doctor's machine.

In many cases, drug treatment must continue for life, but this may help to extend life expectancy significantly. (See also *intracranial hypertension, benign; portal hypertension; pulmonary hypertension*.)

hypertension, malignant

See *Malignant hypertension*.

hypertensive arteriosclerosis

Thickening and loss of flexibility in the walls of arteries (see *arteriosclerosis*) as a result of persistent *hypertension* (high blood pressure).

hypertensive encephalopathy

A variety of symptoms, including headache, *seizures*, and loss of consciousness, caused by malignant, or accelerated, *hypertension* (high blood pressure). (See also *encephalopathy*.)

hypertensive retinopathy

Damage to the *retina* (the light-sensitive layer at the back of the eye) caused by persistent *hypertension* (high blood pressure) affecting the blood vessels in the eyes. Any changes visible in the retina reflect those occurring in small blood vessels throughout the body. Examination of the retina is therefore important in the assessment of hypertension. (See also *retinopathy*.)

hyperthermia

A medical term for very high body temperature.

hyperthermia, malignant

Also known as malignant hyperpyrexia, a sudden rise in body temperature to a dangerously high level, which is brought on by general anaesthesia (see *anaesthesia, general*). The condition is caused by exposure to inhaled anaesthetics such as *halothane* and *enflurane*, or to the *muscle-relaxant drug succinylcholine*. In most cases, susceptibility to malignant hyperthermia is inherited, with an autosomal dominant pattern of inheritance (see *genetic disorders*). People with certain muscle disorders may also be at risk. The condition is rare.

The patient's body temperature rises soon after the anaesthetic is given, sometimes as high as 42°C (107.6°F). At the same time, large amounts of *lactic acid* pass from the muscles into the blood, causing *acidosis* and possibly leading to kidney damage. There are signs of greatly increased *metabolism*, such as an increase in heart rate and breathing rate. The muscles stiffen and the patient turns blue (see *cyanosis*). Without emergency treatment, *seizures* and death may follow rapidly.

Malignant hyperthermia may be suspected if a patient does not relax normally in the early stages of anaesthesia. If it occurs, the anaesthetic is stopped immediately and the patient's body is cooled with ice packs. Oxygen and repeated intravenous injections of dantrolene sodium are given until the body temperature returns to normal. The patient will also receive care in an intensive care unit.

If a person is known to be susceptible to malignant hyperthermia, or has a family history of the condition, the anaesthetist must be informed before any surgical procedure, even if the patient has previously undergone general anaesthesia with no problems. The patient may be given dantrolene sodium before surgery to prevent hyperthermia.

hyperthyroidism

Production of excess *thyroid hormones* by an overactive *thyroid gland* (speeding up body functions). The most common form of hyperthyroidism is *Graves' disease*, which is an *autoimmune disorder* (in which the immune system attacks the thyroid tissue). Less commonly, the condition is associated with enlarged nodules in the thyroid gland.

SYMPTOMS AND SIGNS

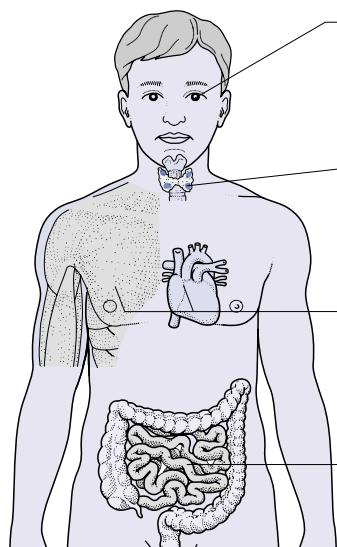

The characteristic signs of hyperthyroidism include increased appetite, weight loss, increased sweating, heat intolerance, rapid heart rate, and protruding eyes (in people with Graves' disease). In severe cases, the thyroid gland often becomes enlarged (see *goitre*) and there is physical and mental hyperactivity and muscle wasting (see *Symptoms and signs of hyperthyroidism* box, overleaf).

DIAGNOSIS, TREATMENT, AND OUTLOOK

The diagnosis of hyperthyroidism is confirmed by measuring the level of thyroid hormones present in the blood. The condition can be treated with drugs that inhibit the production of thyroid hormones (see *antithyroid drugs*) or by

SYMPOMS AND SIGNS OF HYPERTHYROIDISM

Hyperthyroidism (oversecretion of thyroid hormones) produces a range of symptoms associated with overactivity of the body's metabolism. Early signs of the condition include weight loss, increased appetite, intolerance to heat, and increased sweating; there may also be tremors and a rapid heart rate.

One form of the condition, called Graves' disease, may cause bulging eyes. In severe cases of hyperthyroidism, the thyroid gland is often enlarged, causing a visible swelling (goitre) in the neck, and there tends to be physical and mental hyperactivity and muscle wasting.

Protruding eyes
This symptom (known as exophthalmos) affects 30–50 per cent of people with Graves' disease.

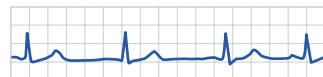

Thyroid gland enlargement
This symptom (known as goitre) may be due to hyperthyroidism; however, it may also be associated with hypothyroidism (underactivity of the thyroid gland).

Muscle wasting
Severe hyperthyroidism may cause wasting of both skeletal and heart muscle.

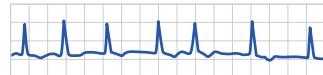

Increased appetite
This symptom is a result of metabolic overactivity, causing increased energy use. Despite increased appetite, the affected person may lose weight.

HYPERTHYROID HEART RATE

Excessively high levels of thyroid hormones may speed up the heart rate and may also cause an irregular heart rhythm.

Healthy heartbeat
This diagram of an ECG trace shows a normal heart rate and rhythm.

Hyperthyroid heartbeat
This trace shows the fast, irregular rate and rhythm seen in hyperthyroidism.

Appearance of exophthalmos
In people with Graves' disease, overactivity of the thyroid may cause swelling of the tissues around one or both eyes, resulting in a staring appearance.

the removal of part of the thyroid gland. People suffering from hyperthyroidism may be given radioactive iodine to destroy part of the thyroid tissue.

Many people recover fully after treatment, but their hormone levels need to be monitored regularly so that any further abnormal changes can easily be detected and treated. Treatment with radioactive iodine may result in development of *hypothyroidism* (underactivity of the thyroid gland).

hypertonia

Increased rigidity in a muscle. Hypertonia may be caused by damage to the nerves supplying the muscle or by changes within the muscle itself. The condition causes episodes of continuous muscle spasm. Persistent hypertonia in limb muscles following a *stroke* or *head injury* leads to *spasticity*.

hypertonic solution

A fluid that is more concentrated than blood plasma or the fluid within cells. If a hypertonic solution is introduced into the body, water will pass from the cells

into the solution (see *osmosis*). If the solution is too concentrated, the body's cells may lose too much water. Fluids used for intravenous infusion are usually *isotonic* (having the same concentration as the fluids in cells); if they are being used to treat dehydration, infused fluids are mildly *hypotonic*.

hypertrichosis

Growth of excessive hair, all over the body, even in places that are not normally hairy. Hypertrichosis often occurs as a result of taking certain drugs (including *ciclosporin* and *minoxidil*). It may also be associated with *anorexia nervosa*. In addition, the term "hypertrichosis" is used to describe hair growth in a mole (see *naevus*).

Hypertrichosis is not the same as *hirsutism*, which is excessive hair growth (particularly in women) due to abnormal levels of male hormones.

hypertrophic cardiomyopathy

A disease of the heart muscle (see *cardiomyopathy*) in which the walls of the left *ventricle* (the heart's lower chamber)

become abnormally thickened, preventing the heart from pumping efficiently. This may lead to breathlessness, chest pain, and *palpitations*.

Hypertrophic cardiomyopathy is most commonly inherited, and it shows an autosomal dominant pattern of inheritance (see *genetic disorders*). Family members can be screened (see *familial screening*) by means of *echocardiography*, although the condition may not become apparent until after puberty. Hypertrophic cardiomyopathy is sometimes a cause of sudden death (see *death, sudden*) in young people.

Treatment is with *antiarrhythmic drugs* and, in some cases, an implantable defibrillator (see *defibrillation*).

hypertrophic pulmonary osteoarthropathy

A condition in which severe pain and swelling of the wrists and ankles is associated with *clubbing* of the ends of the fingers and toes. The most common cause of the condition is *lung cancer*. X-rays of the affected bones show new bone formation in the long bones near

the painful joints. Hypertrophic pulmonary osteoarthropathy may sometimes improve with treatment of the underlying lung cancer.

hypertrophy

Enlargement of an organ or tissue due to an increase in the size, rather than number, of its constituent cells. For example, skeletal muscles enlarge in response to increased physical demands. (See also *hyperplasia*.)

hyperuricaemia

An abnormally high level of *uric acid* in the blood. Hyperuricaemia may lead to *gout* due to the deposition of uric acid crystals in the joints; it may also cause kidney stones (see *calculus*, *urinary tract*) and collections of crystals in other body tissues (see *tophus*).

CAUSES

Hyperuricaemia may be caused by an inborn error of metabolism (see *metabolism*, *inborn errors of*), by the rapid destruction of cells in a disease such as *leukaemia*, or by any medication that reduces the excretion of uric acid by the kidneys, such as *diuretic drugs*. Large amounts of *purine* (a nitrogen-containing substance) in the diet may also cause hyperuricaemia.

TREATMENT

Drugs such as *allopurinol* or *sulfinpyrazone* may be prescribed for the duration of the patient's life. Purine-rich foods, such as liver, poultry, and dried pulses, should be avoided.

hyperventilation

The term used to describe abnormally deep or rapid breathing. Hyperventilation is usually caused by *anxiety*. It may also develop as a result of uncontrolled *diabetes mellitus* or *kidney failure*; oxygen deficiency; some lung disorders; or abuse of *stimulant drugs*.

Hyperventilation causes an abnormal loss of carbon dioxide from the blood, which can lead to an increase in blood alkalinity (see *alkalosis*). Symptoms of hyperventilation include numbness of the extremities, faintness, *tetany* (painful muscle cramps and twitches, especially in the hands and feet), and a sensation of not being able to take a full breath.

If the hyperventilation is due to anxiety, the affected person may find it helpful to breathe in and out of a paper bag. This action reduces the loss of carbon dioxide and may help to relieve the symptoms of alkalosis.

Controlled hyperventilation of patients, using mechanical *ventilators*, is often part of the treatment for *cerebral oedema* (swelling of the brain) after injury or surgery to the brain.

hypervigilance

A feature of *post-traumatic stress disorder* involving a continuously heightened state of arousal and an exaggerated startle reaction.

hypervitaminosis

Any condition caused by an excess intake of one or more *vitamins* (usually from unnecessary use of vitamin supplements). Hypervitaminosis is most likely to arise with *vitamin A* and *vitamin D* because excess amounts of these vitamins are stored in the body rather than excreted.

hyphaema

Blood in the front chamber of the *eye*, usually caused by an injury that ruptures a small blood vessel in the *iris* or *ciliary body*. Initially, there may be blurred vision, but the blood usually disappears completely within a few days and vision is restored.

Appearance of hyphaema

Blood that has collected in the front chamber of the eye is clearly visible in front of the iris. This case, like most instances, was caused by injury.

hypnagogic

A term that refers to the state of transition between wakefulness and sleep. Hypnagogic images are vivid mental pictures that occur just before sleep. Distressing hypnagogic hallucinations may feature in *narcolepsy* (a sleep disorder).

hypnosis

A trance-like state of altered awareness characterized by extreme suggestibility. Some psychoanalysts induce a hypnotic state as a means of helping patients remember and come to terms with disturbing events. More often, hypnosis is used to help patients to relax. It may be useful in people suffering from *anxiety*, *panic attacks*, or *phobias*, or in those wishing to correct addictive habits.

hypnotherapy

The use of *hypnosis* as part of a psychological therapy.

hypnotic drugs

Drugs that induce sleep (see *sleeping drugs*).

hypo-

A prefix meaning "under", "below", or "less than normal".

hypoaldosteronism

A rare condition that is characterized by a deficiency of the hormone *aldosterone*, which is produced by the *adrenal glands*. The condition may be caused by damage or disease affecting the adrenal glands. It may occur in *Addison's disease*, in which the adrenal glands are damaged, often as a result of an autoimmune process. Hypoaldosteronism may produce muscle weakness. It is treated by the drug *fludrocortisone*.

hypocalcaemia

An abnormally low level of *calcium* in the blood. The most common cause is *vitamin D* deficiency. More unusual causes include chronic *kidney failure* and *hypoparathyroidism* (underactivity of the parathyroid glands).

In mild cases, hypocalcaemia is symptomless; in severe cases, it leads to *tetany* (painful muscle spasms and twitches, especially in the hands and feet). It may also result in bone softening, causing *rickets* in children and *osteomalacia* in adults.

hypocapnia

Abnormally low *carbon dioxide* levels in the blood. Hypocapnia may be caused by *hyperventilation* (abnormally deep or rapid breathing); it can result in a pins-and-needles sensation and painful muscle cramps and spasms.

hypochondriasis

A disorder that is characterized by a person's unrealistic belief that he or she is suffering from a serious illness, despite medical reassurance to the contrary. In its mildest form, hypochondriasis causes people to worry constantly about their health and interpret any symptom, however trivial, as evidence of disease. In its most severe form, hypochondriasis may dominate the person's life; he or she may constantly seek medical advice and may undergo numerous tests and treatments for disease.

The likelihood of hypochondriasis occurring is increased in people who have had past experience of a serious disorder (particularly during childhood) or have seen such disorders in relatives. Other predisposing factors include social stresses and personality type. The condition may also be a complication of other psychological disorders such as *phobia*, *obsessive-compulsive disorder*, *generalized anxiety disorder*, and brain diseases such as *dementia*.

Where possible, treatment is designed to relieve the underlying mental disorder. Hypochondriasis without an underlying cause is difficult to treat.

hypochondrium

The area on each side of the upper abdomen, below the lower ribs.

hypodermic

A term that means "under the skin". The word is usually used to describe injections that are delivered into the layer of fat beneath the skin, as well as for the needles and syringes used to administer these injections.

hypogammaglobulinaemia

An abnormally low blood level of *immunoglobulins* (proteins produced by immune system cells to fight infection; also called antibodies) that belong to a group called *gamma-globulins*. Hypogammaglobulinaemia is associated with an increased susceptibility to infections. The condition may be either inherited or acquired.

Inherited hypogammaglobulinaemia is an X-linked disorder (see *genetic disorders*) that results in susceptibility to infections from approximately three to six months of age. This condition requires repeated treatment with intravenous immunoglobulin.

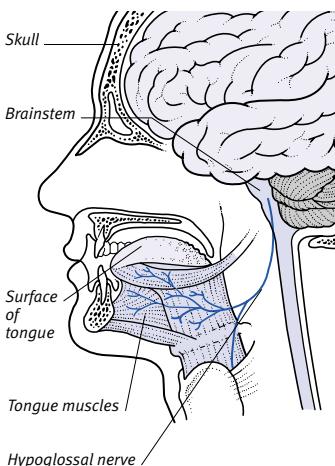

There are several types of acquired hypogammaglobulinaemia. Common variable hypogammaglobulinaemia may appear during childhood or may occur later in adult life and requires regular replacement of immunoglobulin. Immunoglobulin A (IgA) deficiency is a very common form of hypogammaglobulinaemia that may have no symptoms and may carry no heightened risk of infection. Secondary hypogammaglobulinaemia occurs in connection with a number of other diseases, including *multiple myeloma* and chronic lymphocytic leukaemia (see *leukaemia, chronic lymphocytic*).

hypoglossal nerve

The 12th *cranial nerve*, which controls movement of the tongue.

LOCATION OF HYPOGLOSSAL NERVE

The hypoglossal nerve arises in the medulla oblongata (part of the brainstem), passes through the base of the skull, and runs around the throat to the tongue.

hypoglycaemia

An abnormally low level of *glucose* in the blood. Almost all cases of hypoglycaemia occur in people with Type 1 *diabetes mellitus*, in whom the *pancreas* fails to produce enough *insulin*, resulting in an abnormally high glucose level. To lower the level, insulin is given. Too high a dose of insulin can reduce the blood glucose to an excessively low level. Hypoglycaemia can also occur if a diabetic person misses a meal or takes strenuous exercise.

Less commonly, the condition may occur in people with Type 2 diabetes mellitus (in which body cells are resistant to the effects of insulin). Rarely, the condition can result from drinking too much alcohol or from an insulin-producing pancreatic tumour.

Symptoms include *sweating*, hunger, dizziness, trembling, headache, *palpitations*, confusion, and sometimes double vision. The person's behaviour is often irrational and aggressive. *Coma* may occur in severe cases. Hypoglycaemia may also be the cause of seizures and jittery behaviour in newborn babies (see *neonatal hypoglycaemia*).

At the first sign of a hypoglycaemic attack, an affected person should consume a sugary food or drink. If the person has lost consciousness, emergency medical help is required; the patient must receive an injection of glucose solution or the hormone glucagon. (See also *reactive hypoglycaemia*.)

hypoglycaemics, oral

COMMON DRUGS

SULPHONYLUREA DRUGS

- Glibenclamide • Gliclazide • Glimepiride
- Glipizide • Gliquidone • Tolbutamide

OTHERS

- Acarbose • Glucagon
- Insulin • Insulin lispro • Metformin
- Pioglitazone • Repaglinide • Rosiglitazone

A group of *antidiabetic drugs* that are used to reduce the blood glucose levels of people with type 2 *diabetes mellitus*.

Oral hypoglycaemics have many different modes of action. Sulphonylurea drugs act by increasing the body's *insulin* production. *Metformin* increases the uptake of glucose into body tissues and increases its use by the body, thereby helping to reduce blood glucose levels. Other oral hypoglycaemics work in a variety of ways. For example, *acarbose* and *guar gum* reduce or slow absorption of carbohydrate from the intestines after meals; *repaglinide* stimulates the release of insulin from the pancreas; and *rosiglitazone* and *pioglitazone* reduce resistance to the effects of insulin in the tissues.

Too high a dose of hypoglycaemic drugs may provoke the onset of *hypoglycaemia* (abnormally low blood sugar levels), causing symptoms such as dizziness, nausea, and sweating. The use of metformin, acarbose, or guar gum does not usually result in this condition.

hypogonadism

Underactivity of the gonads (*testes* or *ovaries*). Hypogonadism may be caused by disorders of the gonads or a disorder of the *pituitary gland* that causes deficient production of *gonadotrophin hormones*. In men, hypogonadism causes the symptoms and signs of *androgen hormone* deficiency; in women, it causes those of *oestrogen* deficiency.

hypohidrosis

Reduced activity of the *sweat glands*. Hypohidrosis is a feature of hypohidrotic ectodermal dysplasia, a rare, inherited, incurable condition that is characterized by reduced sweating and is accompanied

by dry, wrinkled skin, sparse hair, small, brittle nails, and conical teeth. Other causes of hypohidrosis include *exfoliative dermatitis* and some *anticholinergic drugs*.

hypokalaemia

A deficiency of *potassium* in the blood. Hypokalaemia is usually caused by excess fluid loss due, for example, to severe diarrhoea, but may be the result of treatment with *diuretic drugs*.

hypomagnesaemia

An abnormally low level of *magnesium* in the blood. Hypomagnesaemia may result from malabsorption, malnutrition, alcohol abuse (see *alcohol-related disorders*), severe diarrhoea, or some *kidney diseases*. Magnesium deficiency causes impaired nerve and muscle function and may lead to *seizures*. Treatment of hypomagnesaemia is by injection of magnesium salts.

hypomania

A mild degree of *mania*.

hypoparathyroidism

Insufficient production of *parathyroid hormone* by the *parathyroid glands*. A deficiency of this hormone results in low levels of *calcium* in the blood (see *hypocalcaemia*).

The most common cause of hypoparathyroidism is damage to the parathyroid glands during surgery. Occasionally, the glands are absent from birth or may cease to function for no apparent reason.

A low level of calcium in the blood may lead to *tetany* (increased excitability of the nerves, causing uncontrollable, painful, cramplike spasms, especially in the hands and feet). Occasionally, *seizures* similar to those of an epileptic attack may occur.

The condition is diagnosed by *blood tests*. To relieve an attack of tetany, calcium may be injected slowly into a vein. To maintain the blood calcium at a normal level, a lifelong course of calcium and *vitamin D* tablets is necessary.

hypophosphataemia

An abnormally low level of *phosphates* in the blood. Hypophosphataemia may be associated with *hyperparathyroidism*, *osteomalacia*, *rickets*, and certain kidney abnormalities, such as *Fanconi's syndrome*. It may cause symptoms such as fatigue, muscle weakness, *haemolysis* (premature breakdown of red blood cells), confusion, and *seizures*. Treat-

ment of hypophosphataemia involves replacement of phosphates and, if possible, treatment of the underlying cause.

hypophysectomy

The surgical removal or destruction (by radiotherapy) of the *pituitary gland*. Hypophysectomy may be performed to treat a *pituitary tumour*. Life-long hormone treatment is necessary following hypophysectomy because *hypopituitarism* is an inevitable result.

hypopigmentation

A lack or absence of normal colour in the skin. The condition is due to under-production of *melanin*, the brown pigment in skin, hair, and eyes. It may be the result of inflammation, scarring, or the skin condition *vitiligo*.

hypopituitarism

Underactivity of the *pituitary gland*, resulting in inadequate production of one or more pituitary *hormones*. The effects depend on which hormones are affected. Possible causes are a *pituitary tumour*, an abnormality affecting the *hypothalamus* (part of the brain), or injury to the pituitary gland. Hypopituitarism may also follow surgery or radiotherapy of the pituitary gland (see *hypophysectomy*). Treatment involves replacing the deficient hormones.

hypoplasia

The failure of an organ or a body tissue to develop fully and to reach its normal adult size.

hypoplasia, enamel

A defect in tooth enamel (see *enamel*, *dental*), sometimes due to *amelogenesis imperfecta*. It may also be caused by vitamin deficiency, injury, or infection of a primary tooth that interferes with enamel maturation.

hypoplastic left-heart syndrome

A very serious form of congenital heart disease (see *heart disease, congenital*), in which a baby is born with a poorly formed left *ventricle* (pumping chamber), often associated with other heart defects. The *aorta* is malformed and blood can reach it only via a duct (the *ductus arteriosus*) that links the aorta to the pulmonary artery.

At birth, the baby may seem healthy. However, within a day or two the *ductus arteriosus* naturally closes off and the baby collapses, becoming pale and

breathless. Hypoplastic left-heart syndrome can be treated surgically, sometimes by heart transplant.

hyposensitization

A preventive treatment of *allergy* to specific substances, such as grass pollens and insect venom. Hyposensitization involves giving gradually increasing doses of the allergen (substance to which the person is allergic) so that the *immune system* becomes less sensitive to that substance. The treatment, which may need to be repeated annually for a number of years, carries the risk of *anaphylactic shock*.

hypospadias

A *congenital* defect of the *penis*, in which the opening of the *urethra* is on the underside of the *glans* (head of the penis) or shaft. In some cases, the penis curves downwards, a condition that is known as *chordee*. Hypospadias can usually be corrected by surgery.

hyposplenism

A condition characterized by diminished functioning of the *spleen*. If the spleen suffers a loss of function, there is a resultant reduction in production of the *antibodies*, *lymphocytes*, and *phagocytes* that act to destroy invading microorganisms. Hyposplenism therefore results in increased susceptibility to certain severe infections. Those people whose spleen has been removed (see *splenectomy*) or is failing to function normally are advised to have pneumococcal immunization and long-term *antibiotic drugs*.

hypostasis

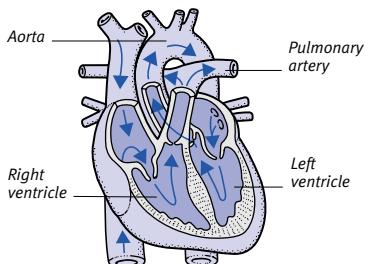

The pooling of blood in the lowest areas of limbs or organs, due to gravity. Hypostasis usually occurs as a result of poor circulation. The condition also occurs after death, when blood settles in the parts of the body that were lowest at the time of death.

hypotension

The medical term for low *blood pressure*. In its most common form, known as postural hypotension, symptoms occur when a person abruptly stands or sits up. Normally, blood pressure is maintained with changes in posture; in people with postural hypotension, it falls. Postural hypotension may be a side effect of *antidepressant drugs* or *antihypertensive drugs*. It may also occur in people with *diabetes*.

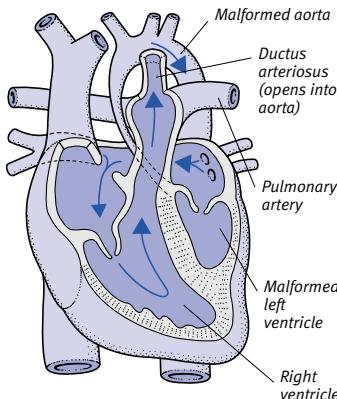

HYPOPLASTIC LEFT-HEART SYNDROME

The heart defects associated with this syndrome are shown on the right and compared with those of the normal heart, on the left. Neither the left ventricle (pumping chamber) nor the aorta is properly formed.

Defect of the heart

In a normal heart, blood is pumped by the left ventricle to the body via the aorta. If the left ventricle is poorly formed, blood can reach the body only via the ductus arteriosus, which closes soon after birth.

mellitus. Acute hypotension is a feature of shock, and may be caused by serious injury or a disease such as *myocardial infarction* (heart attack) or *adrenal failure*.

Treatment depends on the cause. In the absence of serious disease, low blood pressure is associated with a decreased risk from *cardiovascular disorders* and *stroke*. Symptomless hypotension does not require treatment.

hypothalamus

A region of the *brain*, roughly the size of a cherry, situated behind the eyes and under another area of the brain called the thalamus. The hypothalamus has nerve connections to most other regions of the nervous system.

FUNCTION

The hypothalamus controls the sympathetic nervous system (part of the *autonomic nervous system*). In response to sudden alarm or excitement, signals are sent from higher regions of the brain to the hypothalamus, initiating sympathetic nervous system activity. This causes a faster *heartbeat*, widening of the pupils, an increase in breathing rate and blood flow to muscles (together called the “fight or flight” response).

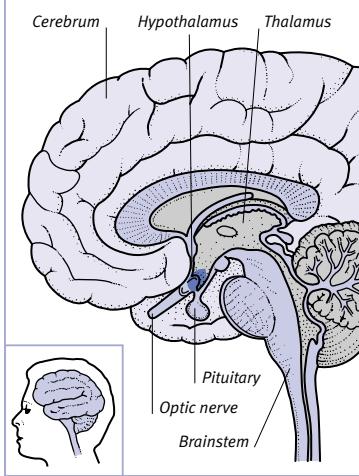

Other groups of nerve cells in the hypothalamus are concerned with the control of body temperature. When blood flowing to the brain is hotter or cooler than normal, the hypothalamus switches on mechanisms that regulate body temperature (including sweating and shivering). It receives information

from internal sense organs regarding the body's water content and the level of glucose in the blood; if these are too low the hypothalamus stimulates thirst and appetite for food. (See *feedback mechanism*.) The hypothalamus is also involved in regulating sleep, motivating sexual behaviour, and determining mood and emotions.

A further role of the hypothalamus is to coordinate the functions of the nervous and endocrine (hormonal) systems.

LOCATION OF THE HYPOTHALAMUS

This small area of the forebrain, shown in blue, lies under the thalamus and above the pituitary gland.

The area connects with the *pituitary gland* through a short stalk of nerve fibres and controls hormonal secretions from this gland. One form of control is through direct nerve connections. The other is through specialized nerve cells, which secrete hormones called releasing factors; these factors enter specialized blood vessels and pass to the pituitary gland. In this way, the hypothalamus converts nerve signals into hormonal signals; therefore, it indirectly controls many *endocrine glands*, including the *thyroid gland*; the cortex of the *adrenal glands*; and the *ovaries* or *testes*.

DISORDERS

Disorders of the hypothalamus are usually due to an *intracerebral haemorrhage* or a *hypothalamic* or *pituitary tumour*. They have diverse effects, ranging from hormonal disorders to disturbances in temperature regulation, and increased or decreased need for food and sleep.

hypothermia

A fall in body temperature to below 35°C. Hypothermia most often occurs in sick, elderly people who are exposed to low temperatures. The body loses its sensitivity to cold as it ages, becoming less able to reverse a fall in temperature. Hypothyroidism (underactivity of the thyroid gland) also predisposes an individual to hypothermia. Babies may also have an increased risk of hypothermia because they lose heat rapidly and cannot easily reverse a fall in temperature. The condition is also common in climbers and walkers who are inadequately dressed for cold weather.

SYMPTOMS AND SIGNS

A person suffering from hypothermia is usually pale and listless. The *heart rate* is slow, the body is cold, and the victim is often drowsy and confused. In severe hypothermia, breathing becomes slow and shallow, the muscles are stiff, the victim may become unconscious, and may actually appear dead. Eventually, the heart may stop beating.

TREATMENT

Hypothermia is a medical emergency. Treatment varies according to the age of the victim. A baby or child can be warmed by direct skin-to-skin contact; for example, by being held inside an adult's clothing. A young person may be placed in a warm bath. An elderly victim is usually warmed gradually by being covered with layers of heat-reflecting material in a room temperature of 25°C. If the person is fully conscious,

they may be given a warm non-alcoholic drink. Alcohol should not be given as it can exacerbate the condition. In cases where hypothermia is life-threatening, victims may be admitted to an intensive care unit for controlled warming in which warmed fluids are administered intravenously.

Most people suffering from hypothermia make a full recovery – the outlook is best in the case of young, otherwise healthy individuals.

hypothermia, surgical

The deliberate reduction of body temperature to prolong the period for which the vital organs can safely be deprived of their normal blood supply during *open heart surgery*. Cold reduces the rate of metabolism in tissues and thus increases their tolerance to lack of oxygen. Cooling may be achieved by continuously instilling cold saline at about 4°C into the open chest cavity.

hypothyroidism

The underproduction of *thyroid hormones* by an underactive *thyroid gland*. These hormones are important in *metabolism* and a deficiency therefore causes many of the body's functions to slow down. Most cases are caused by an *autoimmune disorder* such as *Hashimoto's thyroiditis*. More rarely, however, hypothyroidism results from the removal of part of the thyroid gland to treat *hyperthyroidism* (overactivity of the thyroid).

SYMPOMTS AND SIGNS

Symptoms of hypothyroidism include tiredness, lethargy, and cold intolerance. There may also be muscle weakness, cramps, a slow heart rate, dry skin, hair loss, constipation, a husky voice, and weight gain. Women may experience heavy menstrual periods. A syndrome called *myxoedema*, in which the skin and other tissues thicken, may develop. Enlargement of the thyroid gland may also occur (see *goitre*). If the condition occurs in childhood, it may retard growth and normal development.

DIAGNOSIS AND TREATMENT

The disorder is diagnosed by measuring the level of thyroid hormones in the blood. Treatment consists of replacement therapy with the thyroid hormone *thyroxine*, usually for life. In adults, the symptoms usually improve about three weeks after the start of treatment. Hormone treatment is monitored regularly so that the correct dosage is maintained.

hypotonia

Abnormal *muscle* slackness. Normally, a muscle that is not being used has a certain inbuilt tension, but in a number of disorders affecting the nervous system this natural tension is reduced.

hypotonia in infants

Also known as floppy infant syndrome, excessive limpness in infants. Hypotonic babies cannot hold their limbs up against gravity and tend, therefore, to lie flat with their arms and legs splayed.

Hypotonia may be caused by *Down's syndrome* or *hypothyroidism* (underproduction of thyroid hormones) and may be an early feature of *cerebral palsy*. It occurs in disorders of the spinal cord, such as *Werdnig-Hoffman disease*, and in some children with *muscular dystrophy*.

hypotonic solution

A fluid that is less concentrated than blood plasma or the fluid within cells. If a hypotonic solution is introduced into the body, the water in the fluid will pass through cell walls and into the cells (see *osmosis*). If the solution is too weak (for example, if it is pure water), the body's cells will become over-filled and will rupture. Fluids used for intravenous infusion are *isotonic* (having the same concentration as the fluids in cells), except when they are being used to treat dehydration, in which case they are mildly hypotonic.

hypoventilation

A condition in which too little air enters the alveoli (tiny air sacs) in the lungs. Hypoventilation is due to breathing that is too shallow or slow, or to a reduction in lung function (for example, from a disorder such as *emphysema*). The inadequate air supply leads to insufficient oxygen passing from the alveoli into the bloodstream (see *respiration*), and as a result too little oxygen reaches the body tissues (see *hypoxia*) and carbon dioxide builds up.

hypovitaminosis

Any condition that results from the deficiency of one or more *vitamins*. Hypovitaminosis may be due to an inadequate dietary intake or a digestive disorder that causes *malabsorption*.

hypovolaemia

An abnormally low volume of blood in the circulation, usually following blood loss due to injury, internal bleeding, or

surgery. Hypovolaemia may also be due to loss of fluid from *diarrhoea* and *vomiting*. Untreated, it can lead to *shock*.

hypoxaemia

An abnormally low level of oxygen in the arterial blood (the blood that carries oxygen to the body tissues). This condition may lead to *hypoxia*.

hypoxia

An inadequate supply of *oxygen* to the tissues. Temporary hypoxia may result from strenuous exercise. More serious causes include impaired breathing (see *respiratory failure*), *ischaemia* (reduced blood flow to part of the body), and severe *anaemia*. A rare cause is *carbon monoxide* poisoning. Severe, prolonged hypoxia may lead to tissue death.

Hypoxia in muscles forces the muscle cells to produce energy by *anaerobic* processes, which can lead to cramps. In heart muscle, it may cause *angina pectoris*. In the brain, it causes confusion, dizziness, and loss of coordination; and may lead to unconsciousness and death if it is persistent.

Hypoxia can be assessed by using an *oximeter* to measure the oxygen concentration of blood in the tissues. Severe hypoxia may require *oxygen therapy* or artificial *ventilation*.

hypromellose

A substance that is included in artificial tears (see *tears, artificial*). Hypromellose is applied as eye-drops.

hysterectomy

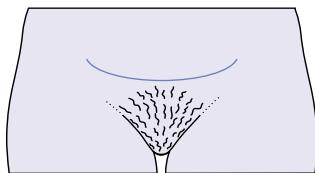

Surgical removal of the *uterus*. Hysterectomy may be performed to treat *fibroids* (noncancerous tumours of the uterus), and cancer of the uterus (see *uterus, cancer of*) or cervix (see *cervix, cancer of*). It may also be performed to treat *endometriosis* (displaced fragments of the uterine lining) and to remove a prolapsed uterus (see *uterus, prolapse of*). Hysterectomy used to be performed frequently to relieve heavy menstrual bleeding, but alternative treatments, such as *endometrial ablation* or insertion of a progestogen *IUD*, are now increasingly used in these instances.

TYPES

The most common type of hysterectomy is a total hysterectomy, in which both the uterus and the cervix are removed. Occasionally, the fallopian tubes and ovaries are removed as well. For the treatment of cervical cancer, a rad-

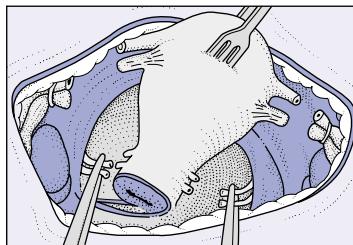

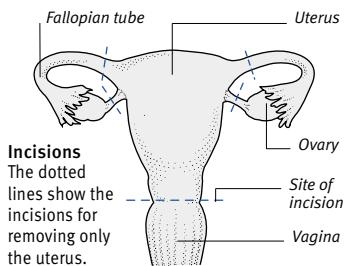

PERFORMING A HYSTERECTOMY

Hysterectomy may be performed through the abdomen or the vagina. For an abdominal hysterectomy, the incision is made in the lower abdomen (see below). In vaginal hysterectomy, the uterus is removed through an incision at the top of the vagina.

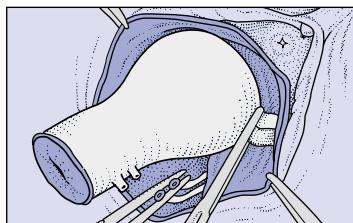

Site of incision for abdominal hysterectomy

The incision is made in the lower abdomen (in this case horizontally) level with the top of the pubic hair.

Abdominal hysterectomy

The uterine vessels are clamped. Traction is placed on the top of the uterus and the vessels are tied and then divided. In some cases, the fallopian tubes are cut and the tubes and ovaries left in place.

Vaginal hysterectomy

After a vaginal incision is made, the uterus and cervix are removed. (The ovaries cannot be removed in a vaginal hysterectomy.) The upper end of the vagina is repaired by stitching.

ical hysterectomy (in which the uterus, cervix, and pelvic lymph nodes are removed) is performed.

Hysterectomy may be performed through the vagina or through an incision in the abdomen. A procedure known as laparoscopically assisted vaginal hysterectomy is carried out partly through the vagina and partly using *minimally invasive surgery*. Vaginal hysterectomy has the advantage of needing no external incision, and, as a result, the patient usually recovers more rapidly. However, a vaginal hysterectomy cannot be performed if the uterus is significantly enlarged or if the hysterectomy is a treatment for cancer.

RECOVERY AND OUTLOOK

After the operation, a drainage tube may be inserted at the site of the incision to aid healing. For a few days there may be some vaginal bleeding and discharge, as well as tenderness and pain. A vaginal hysterectomy requires a short hospital stay; any further stay depends on the age and health of the woman and whether there are any postoperative problems. Full recovery usually takes between three

and six weeks; sexual intercourse can be resumed about a month after surgery. The recovery period after an abdominal hysterectomy may be longer and may also require a longer stay in hospital.

Following a hysterectomy, a woman is unable to bear children; she does not have menstrual periods and does not need to use contraception. If a woman's ovaries have also been removed before or around the woman's menopause, *hormone replacement therapy (HRT)* may be given. It is not uncommon for a woman to suffer from depression after a hysterectomy if she has not been adequately counselled beforehand.

hysteria

An old-fashioned term encompassing a wide range of physical or mental symptoms that are attributed to mental stress. Symptoms formerly grouped under this term are now included in the more specific diagnostic categories of *conversion disorder*; *somatization disorder*; *dissociative disorders*; and *factitious disorders*. The term is still used loosely to describe irrational behaviour.

hysterocontrast sonography (HyCoSy)

Ultrasound examination of the uterine cavity and the fallopian tubes. A *contrast medium* visible on ultrasound is introduced into the uterine cavity through the vagina and the cervix. Hysterocontrast sonography is a technique that is used to investigate *infertility*; the advantage that this method has over *hysterosalpingography* is that it does not involve *X-rays*.

hysterosalpingography

An *X-ray* procedure in which a dye (*radiopaque contrast medium*) is introduced into the cavity of the *uterus* through the *cervix* to make the uterus and *fallopian tubes* visible on *X-rays*. Hysterosalpingography is used to investigate *infertility*.

Hysterosalpingography

This image shows the uterus (centre) and fallopian tubes. The right tube (left on image) is blocked near the uterus, allowing no contrast medium into it; the other is obstructed further down and has dilated.

hysteroscopy

A technique that uses a hysteroscope (a type of *endoscope*) to view the inside of the *uterus* and *fallopian tubes* for the purposes of diagnosing disorders. Hysteroscopy can be performed under local *anaesthesia*. Minor surgery, such as the removal of *fibroids* (noncancerous tumours of the uterus), may also be performed using a hysteroscope.

iatrogenic

A term meaning “physician-produced”. It may be applied to any medical condition, disease, or adverse event resulting from medical treatment.

IBS

See *irritable bowel syndrome*.

Ibugel

A brand name for a topical gel containing *ibuprofen* that is used for relieving muscle pain.

Ibuleve

A brand name for a topical gel containing *ibuprofen* that is used to relieve muscle pain.

ibuprofen

A *nonsteroidal anti-inflammatory drug* (NSAID) used as a painkiller to treat conditions such as headache, menstrual pain, and injury to soft tissues. The drug's anti-inflammatory effect also helps to reduce the joint pain and stiffness that occurs in types of *arthritis*.

Side effects may include abdominal pain due to inflammation of the stomach lining; nausea; heartburn; and diarrhoea.

ICD

The commonly used abbreviation for International Classification of Diseases, a list of all known diseases that is published by the *World Health Organization*. An updated version is produced approximately every ten years. ICD enables countries and organizations to gather statistical information on the frequency of a disease and causes of death.

Icelandic disease

A previously used term for *chronic fatigue syndrome*.

ice-packs

A means of applying ice (wrapped in a towel or other material) to the skin in order to reduce inflammation or swelling, relieve pain, or stem bleeding.

The low temperature causes the blood vessels to constrict (narrow), thus reducing the blood flow.

Ice-packs are used to relieve pain in a variety of disorders, including severe *headache*. They are used on sports injuries to minimize swelling and bruising, and they can also be used to help stop bleeding from small vessels, as in a nosebleed.

ichthammol

A drug used in skin preparations for the treatment of *eczema*, to reduce itching.

Ichthopaste

A brand name for a medicated bandage that is impregnated with the drug *ichthammol* and *zinc* paste. Ichthopaste is used in the treatment of chronic *eczema*, to reduce itching.

ichthyosis

A rare, inherited condition in which the skin is dry, thickened, scaly, and darker than normal due to abnormal production of *keratin*. Ichthyosis usually appears at, or shortly after, birth and usually improves during childhood. Commonly affected areas are the thighs, arms, and backs of the hands.

There is no particular treatment, but lubricants and emulsifying ointments may be applied to help relieve the dryness, and bath oils may also be used to moisten the skin.

ICP

The abbreviation for *intracranial pressure*.

ICSI

See *intracytoplasmic sperm injection*.

icterus

A term for *jaundice*.

ICU

The abbreviation for *intensive care unit*.

id

One of the three constituents of the personality (together with the *ego* and *superego*) described by Sigmund Freud. The id is defined as the primitive, unconscious energy store from which come the instincts for food, love, sex, and other basic needs. It thus guides behaviour and also fuels the turmoil leading to the conflict and guilt of neurosis. The id seeks simply to gain pleasure and avoid pain. (See also *psychoanalytic theory*.)

IDDM

The abbreviation for insulin-dependent *diabetes mellitus* (type 1 diabetes).

ideas of reference

An individual affected by ideas of reference finds personal significance in casual remarks made or action taken by other people. The individual may feel that people in public places are talking about, or laughing at, him or her. The condition falls short of a *delusion* because affected individuals are aware that they are not actually noticed more than others; however, they may be unable to discuss these feelings.

identical twins

Two offspring, also known as *monozygotic twins*, who develop from a single fertilized *ovum* (egg) and share identical genes. (See also *twins*.)

identification

A term used in *psychology* to refer to the process of unconsciously taking on another person's traits or behaviour. In children, identification with an older person, usually a parent, is considered a normal part of development.

identity crisis

A colloquial term used to describe feelings of uncertainty about one's own personality and characteristics. Experiencing an “identity crisis” is common in periods of emotional turmoil, such as *adolescence*.

idiopathic

A term that is used to refer to a medical condition that has no known cause. As science advances, causes may be found for conditions previously considered to be idiopathic.

idiopathic epilepsy

A term used to describe *epilepsy* that has no known physical cause (such as brain injury, for example).

idiopathic hypertension

See *essential hypertension*.

idiopathic thrombocytopenic purpura (ITP)

An *autoimmune disorder* in which *platelets* are destroyed, leading to bleeding beneath the skin (see *purpura*).

ITP may be acute or chronic. Acute ITP mainly affects children, is usually mild, and disappears without treatment.

Chronic ITP generally affects adults and is much more serious. Initial treatment is with *corticosteroid drugs*; if this fails, a *splenectomy* (surgical removal of the spleen) is required. *Immunosuppressant drugs* may be given if all other treatment fails.

idoxuridine

An *antiviral drug* used in skin preparations to treat the blistering rashes caused by *herpes simplex* and *herpes zoster* (shingles) infections. Recently developed antiviral drugs, such as *aciclovir*, are more effective and idoxuridine is now used less often.

Ig

The abbreviation for *immunoglobulin*.

IgA nephropathy

A kidney disease that causes *haematuria* (passage of blood in the urine) and in which deposits of IgA *immunoglobulins* (certain proteins produced by the *immune system* to combat infection) are found within the kidneys. Excessive amounts of IgA are sometimes produced in response to a throat infection. In such cases, IgA complex collects in the filtering units of the kidneys. IgA nephropathy is the most common form of *glomerulonephritis*.

The condition mainly affects children and young men. It may cause either microscopic haematuria (in which blood is passed in the urine but cannot be seen by the naked eye) or episodes of macroscopic haematuria (in which blood can be seen in the urine). In some cases, *nephrotic syndrome* develops; in this condition, large amounts of protein are passed in the urine, leading to raised blood pressure and *oedema* (swelling of the tissues).

Treatment of IgA nephropathy may involve *corticosteroid drugs* and *immunosuppressant drugs*, in addition to treatment to relieve any symptoms. Overall, the prognosis for IgA nephropathy is good. In some cases, however, kidney function deteriorates and, in up to one in five people, *kidney failure* develops after many years.

ileal conduit

A section of the *ileum* (the final part of the small intestine) used by a surgeon to provide a substitute channel for urine outflow when the bladder has been removed. (See *urinary diversion*; see also *cystectomy*.)

ileal pouch

A reservoir constructed from loops of the *ileum* (lower part of the small intestine) to replace a rectum that has been surgically removed. If an ileal pouch cannot be created, a permanent *ileostomy* will be required.

ileitis, regional

An outdated name for *Crohn's disease*.

ileostomy

An operation in which the *ileum* (lower part of the small intestine) is cut and the end brought through the abdominal

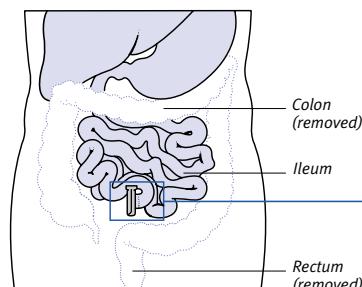

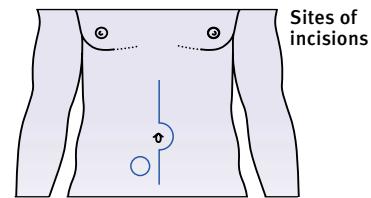

wall and formed into an artificial opening called a *stoma*. Waste is discharged from the remaining ileum into a disposable bag (stoma bag) or drained into a pouch made from the end of the ileum and situated beneath the skin (a procedure called a *continent ileostomy*). In the latter situation, faeces draining into the pouch are emptied regularly through a soft catheter. An ileostomy may be either permanent or temporary.

WHY IT IS DONE

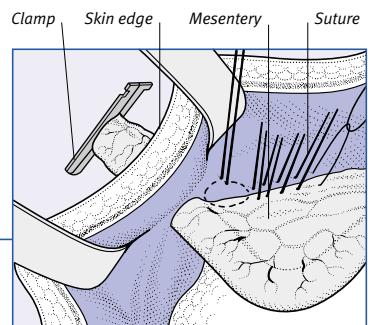

Permanent ileostomy is usually performed on people who have severe,

PROCEDURE FOR ILEOSTOMY

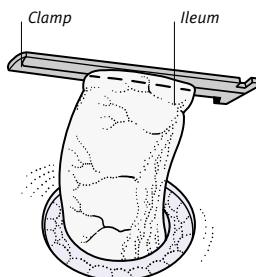

Two incisions are made in the abdominal wall (usually on the right side): a small circular cut for the stoma (usually sited about 5 cm below the waist and away from the hip bone and groin crease) and a vertical cut to give access to the intestine and the *mesentery*. The site of the stoma is discussed with the patient prior to surgery.

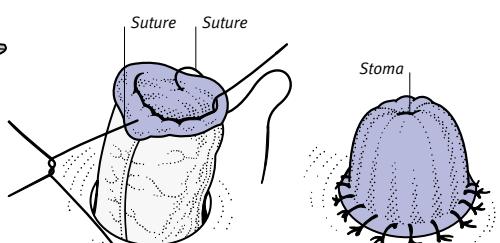

1 After removal of the colon, the cut end of the ileum is clamped and part of the mesentery is cut to free a short length of ileum for the stoma.

2 The free end of the ileum is pushed out through the circular incision in the abdomen; the mesentery is then stitched to the inner abdominal wall.

3 The main vertical incision is closed, and the clamp is removed from the protruding end of the ileum (left). This end is then turned back and attached to the abdominal surface with sutures (middle). When completed, it

forms a protruding spout of ileum (right). After the intestine begins to function normally, an ileostomy bag is fitted around the stoma. The bag is attached to the skin by adhesive seals.

uncontrolled *ulcerative colitis*. The operation is done after a total *colectomy* (removal of the colon and rectum).

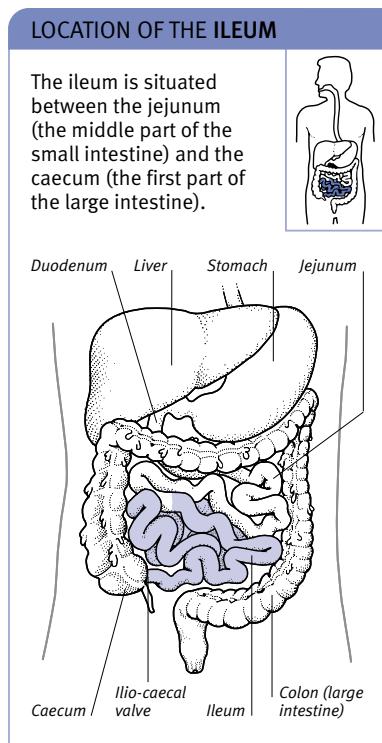

Temporary ileostomy is sometimes performed at the same time as partial *colectomy* (removal of part of the colon) to allow the colon to heal before waste material passes through it. It may also be done as an emergency treatment for an obstruction in the intestine. The stoma is created from a loop of the intestine that is brought to the skin surface. Once the intestine has healed, a second operation is carried out to close the temporary ileostomy.

RECOVERY PERIOD

During convalescence, patients are given counselling and are taught the practical aspects of stoma care or drainage of continent ileostomies. Full recovery from the operation takes about six weeks.

ileum

The final, longest, and narrowest section of the small intestine. It is joined at its upper end to the *jejunum* and at its lower end to the large intestine (caecum, colon, and rectum). The ileum's function is to absorb nutrients from food that has been digested in the stomach and the first two sections of small intestine (the *duodenum* and *jejunum*).

DISORDERS

Occasionally, the ileum becomes obstructed – for example, by pushing through a weakness in the abdominal wall (see *hernia*) or by becoming caught up with scar tissue following abdominal surgery (see *adhesion*). Other disorders of the ileum include *Meckel's diverticulum* (a pouch in the ileum wall that may become ulcerated) and diseases in which the absorption of nutrients is impaired, such as *Crohn's disease*, *coeliac disease*, *tropical sprue*, and *lymphoma*.

ileus, gallstone

The blockage of the small intestine by a *gallstone* that has travelled from the biliary tract. Gallstone ileus is sometimes a complication of *cholecystitis* (inflammation of the gallbladder). Symptoms may include severe abdominal pain and bloating, vomiting, and lack of bowel movements. Surgery is usually needed to remove the stone. The gallbladder is generally removed at the same time.

ileus, paralytic

A disorder in which the muscles of the intestines are unable to contract normally, and as a result the intestinal contents cannot pass out of the body. Paralytic ileus is usually a temporary condition. It commonly follows abdominal surgery and may also be induced by severe abdominal injury, *peritonitis* (inflammation of the membrane lining the abdomen), acute *pancreatitis* (inflammation of the pancreas), major disturbances in blood chemistry (such as *diabetic ketoacidosis*), or interference with the blood or nerve supply to the intestine. Symptoms include a swollen abdomen, vomiting, and failure to pass faeces.

The condition is treated by resting the intestine. A tube passed through the nose or mouth into the stomach or intestine removes accumulated fluids and keeps the stomach empty. Body fluid levels are maintained by *intravenous infusion* (drip).

ilium

The largest of the hip bones that form part of the *pelvis*.

illness

Perception by a person that he or she is not well. Illness is a subjective sensation; it may have both physical and psychological causes. The term "illness" is also used to mean disease or disorder.

illusion

A distorted sensation that is based on the misinterpretation of a real stimulus (for example, a pen is seen as a dagger). Illusion differs from a *hallucination*, in which a perception occurs without any stimulus. Usually, illusions are brief and can be understood when they are explained. They may be caused by tiredness or anxiety, to drugs, or to forms of brain damage. *Delirium tremens* (a condition usually arising from alcohol withdrawal in alcoholics) often brings on illusions.

image, body

See *body image*.

imaging techniques

Techniques that produce images of structures within the body (see *Imaging the body* box).

X-RAY TECHNIQUES

The most commonly used and simplest techniques are the *X-rays* (sometimes called plain X-rays) used to view dense structures such as bone. Simple X-ray examinations include those of the chest, skull, and limbs following injury.

Contrast X-rays involve the introduction into the body of a medium that is opaque to X-rays. The techniques include *barium X-ray examinations* (used to examine the oesophagus, the stomach and the intestine); *cholecystography* (used to visualize the gallbladder and common bile duct); *bronchography* (to view the airways connecting the windpipe to the lungs); *angiography* and *venography* (to provide images of the blood vessels); *intravenous urography* (to visualize the kidneys and urinary tract); and *ERCP* (in which the pancreatic duct and biliary system are examined after introducing a contrast medium through an *endoscope*).

Many X-ray techniques have now been superseded by newer procedures that are simpler to perform and safer and more comfortable for the patient.

ULTRASOUND TECHNIQUES

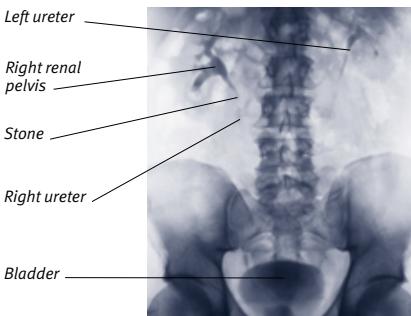

Ultrasound scanning involves the passing of high-frequency sound waves through the body using a transducer placed against the skin. The waves are reflected to varying degrees by structures of different density; the pattern of echoes is recorded electronically on a screen. Ultrasound scanning can now be used to produce three-dimensional images as well as moving images to show, for example, the opening and closing of a valve or blood flow within a vessel.

IMAGING THE BODY

Over the past two decades many methods of imaging the body have been developed and are now widely used. These techniques have made it possible to visualize internal structures in a variety of ways. Today, in addition to conventional X-rays (which primarily show bones), techniques such as CT scanning, radionuclide scanning, ultrasound scanning, MRI, and PET scanning are used to provide detailed diagnostic pictures of soft tissues and organs. The examples given here show some of the different ways in which the kidneys can be imaged.

X-RAYS

Radiopaque contrast media may be utilized to give distinct X-ray images of soft tissues, as in intravenous urography, which is used to give clear images of the kidneys and urinary tract.

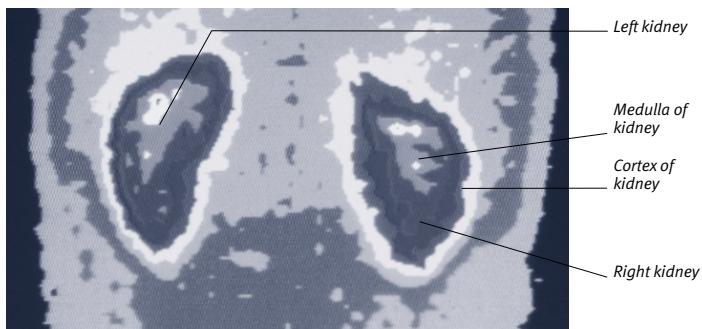

Intravenous urogram
This intravenous urogram shows the renal pelvises (urine-collecting areas of the kidneys) and the ureters, which have been filled with contrast medium. In the right-hand renal pelvis and ureter (on the left of the urogram), the medium has been retained due to a kidney stone blocking the ureter; the stone appears as a small gap in the ureter.

SCANNING TECHNIQUES

The body, particularly the soft tissues, can be imaged using a variety of modern techniques. Some of these techniques, such as CT scanning and MRI, rely on computers to process the raw imaging data and produce the actual image.

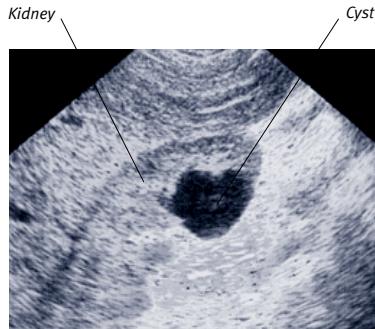

Others, such as ultrasound scanning and radionuclide scanning, can produce images without the need of a computer for image processing, although one may be used for image enhancement.

Radionuclide scanning

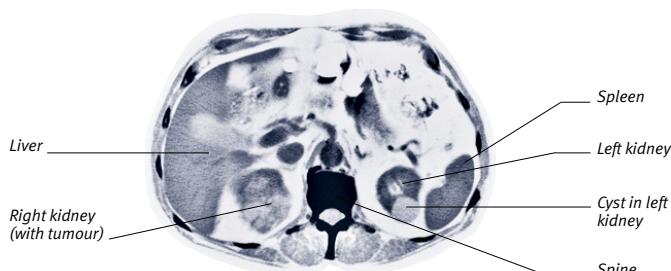

A radioactive substance is introduced into the body, and the radiation emitted is detected by a gamma camera, which then converts it into an image. Active or overactive cells will take up more of the substance, and

will appear brighter, than underactive cells. This scan (taken from the back) shows healthy kidneys. In each kidney, the medulla (central part) has absorbed more of the radioactive substance than the cortex (outer part).

Ultrasound scanning

Ultra-high-frequency sound waves reflected from tissues in the body are converted into an image by special electronic equipment. This scan shows a fluid-filled cyst inside a kidney; the cyst appears as a dark area on the image.

CT scanning and MRI

These techniques produce cross-sectional images (slices) or three-dimensional images of body structures. This CT scan shows a cross-section through the body, as seen from below; the front of the body is at the top of the image. The right kidney (shown on the left of the image) is enlarged and distorted by a tumour. The left kidney has a cyst.

COMPUTER-ASSISTED SCANNING

Many scanning techniques use computers to process the raw imaging data and produce the actual image. In *CT scanning* (computed tomography scanning), X-rays are passed through the body at different angles. The computer analyses the data to produce cross-sectional images ("slices") of the tissues that are being examined. Newer CT scanners can use a spiral technique to produce three-dimensional images of structures.

In *MRI* (magnetic resonance imaging), the patient is placed in a strong magnetic field within the scanner and radiofrequency waves are passed through the body. A computer analyses changes in the magnetic alignment of the nuclei in the hydrogen cells to give either a cross-sectional or a three-dimensional image of the tissues. This technique provides greater contrast between normal and abnormal tissues than that given by CT scanning.

PET scanning (positron emission tomography scanning) involves the introduction of very short-lived radioisotopes into the tissues of the brain. A computer analyses the paths of the gamma rays emitted by these radioisotopes, thereby providing information about both the structure and function of the brain.

In *radionuclide scanning*, a gamma camera records radiation emitted from tissues into which a radioactive substance has been introduced. A computer transforms the recordings into images and may be used to obtain more information from the results. Certain radioactive substances are taken up, to varying degrees, by different tissues, allowing specific organs to be studied in isolation.

Imdur

A brand name for a slow-release preparation of *isosorbide mononitrate*, a drug used in the treatment of *angina pectoris* (chest pain caused by an inadequate blood supply to the heart).

imidazole drugs

A specific group of *antifungal drugs* used for the treatment of fungal infections such as *candidiasis* (vaginal thrush) and *tinea* (ringworm).

Imigran

A brand name for *sumatriptan*, a *serotonin agonist* drug that is used to treat *migraine* or cluster headaches. Imigran is available in different forms, including tablets, injection, and nasal spray.

imipramine

A tricyclic *antidepressant drug* that is most commonly used in the long-term treatment of *depression*. Possible adverse effects of imipramine include excessive sweating, blurred vision, dizziness, dry mouth, constipation, nausea, and, in older men, difficulty passing urine.

immersion foot

A type of *cold injury*, also called trench foot, occurring when the feet are wet and cold for a long time. Initially, the feet turn pale and have no detectable pulse; later, they become red, swollen, and painful. If the condition is ignored, muscle weakness, skin ulcers, or *gangrene* may develop.

immobility

Reduced physical activity, for example through disease, injury, or following major surgery. Immobility is particularly harmful in elderly people because it causes muscle wasting and progressive loss of function.

COMPLICATIONS

Total immobility can produce various complications including *bedsores*, *pneumonia*, or *contractures* (deformity caused by the shrinkage of tissue). A common complication that occurs with partial immobility is *oedema* (fluid retention), which causes swelling of the legs. Rarely, sluggish blood flow encourages formation of a *thrombus* (abnormal blood clot) in a leg vein.

TREATMENT

Regular *physiotherapy* and adequate nursing care are important for any person who is totally immobile.

immobilization

An orthopaedic term that describes techniques that are used to prevent movement of joints or displacement of fractured bones. Immobilization is performed so that fractured bones can reunite properly (see *fracture*).

immune complex

A combination of an *antigen* (any substance that the body identifies as foreign and that provokes an immune response) and an *antibody* (a protein produced by the immune system for the purpose of attacking foreign substances). Immune complexes are normally removed from the circulation by the liver and spleen. However, they may sometimes continue to circulate and eventually become trapped in organs or other tissues, caus-

ing inflammation, tissue damage, and specific immune complex diseases (which are also known as type III *hypersensitivity* reactions).

One example of an immune complex disease is extrinsic allergic *alveolitis – farmer's lung*, for example. In this disorder, immune complexes form after exposure to allergens such as fungal spores; they then collect in the lungs, causing inflammation of the *alveoli* (tiny air sacs). Other conditions caused by immune complexes include some forms of *glomerulonephritis* (inflammation of the tiny structures in the kidneys that help to filter blood); certain connective tissue diseases, including systemic *lupus erythematosus* and *rheumatoid arthritis*; and adverse reactions to *streptokinase*, a thrombolytic drug used in the treatment of myocardial infarction (heart attack).

immune response

The body's defensive reaction to micro-organisms, cancer cells, transplanted tissue, and other substances or materials that are recognized as antigenic or "foreign". The immune response consists of the production of cells called *lymphocytes*; substances called *antibodies* or *immunoglobulins*; and other substances and cells that act to destroy the anti-genic material. (See also *immune system*).

immune system

A collection of cells and proteins that works to protect the body from harmful microorganisms, such as *bacteria*, *viruses*, and *fungi*. The immune system also plays a role in the control of *cancer* and is responsible for the phenomena of *allergy*, *hypersensitivity*, and rejection after *transplant surgery*.

NATURAL IMMUNITY

The term "natural (or innate) immunity" is given to the protection every individual is born with, such as the skin and mucous membranes that line the mouth, nose, throat, intestines, and vagina. Natural immunity also includes *antibodies*, or *immunoglobulins* (protective proteins), that are passed to the child from the mother via the placenta. If microorganisms penetrate these defences, they encounter "cell-devouring" white blood cells called *phagocytes*, and other types of white cells, such as cell-killing (cytotoxic) cells.

Microorganisms may also encounter substances that are naturally produced within the body (such as *interferon*) or

THE INNATE IMMUNE SYSTEM

Each of us has many inborn defences against infection. These defences include external barriers such as the skin and eye surfaces (below), the inflammatory response (right), and the action of white blood cells called phagocytes (below right). Others include a substance called complement (which is activated by and attacks bacteria) and another called *interferon* (which has antiviral effects).

All of these defences are nonspecific and quick-acting. By contrast, the adaptive immune system (see overleaf) mounts specific attacks against particular microbes. These cells are most effective on second exposure to the organisms.

The two parts of the immune system work together; antibodies produced by the adaptive immune system assist phagocyte action.

Physical and chemical barriers

These barriers, briefly described below, provide the first line of defence against harmful microbes (bacteria, viruses, and fungi).

Eyes

Tears produced by the lacrimal apparatus help to wash away microorganisms; tears contain an enzyme called lysozyme, which can destroy bacteria.

Mouth

Lysosome present in saliva destroys bacteria.

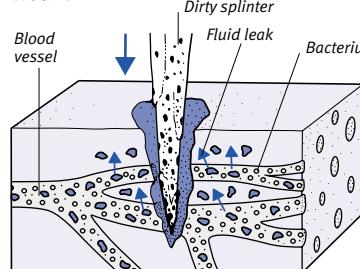

Breast-feeding

Antibodies (proteins with a protective role) formed by the mother against particular microbes are transferred to the baby in breast milk. Breast-feeding provides some extra immunity until the baby can form his or her own specific antibodies.

THE INFLAMMATORY RESPONSE

If microbes break through the body's outermost barriers, inflammation is the second line of defence. Chemicals such as histamine are released, prompting the effects shown below, including the attraction of phagocytes to the microorganisms and the release of substances such as complement. The symptoms of inflammation are redness, pain, swelling, and heat.

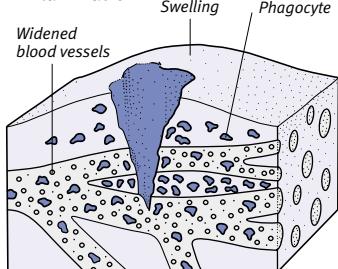

Wound

Inflammatory process

Following tissue injury (here due to a splinter in the skin) and the entry of bacteria or other microbes, blood vessels in the area widen and there is an increased leakage of fluid from the

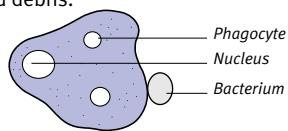

Inflammation

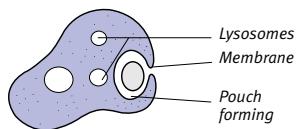

blood into the tissues. These reactions allow easier access for immune system components that will fight the invaders, including phagocytes and soluble factors (such as the group of substances known as complement).

ACTION OF PHAGOCYTES

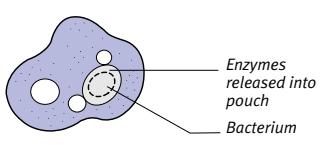

These white blood cells are attracted to sites of infection, where they adhere to, engulf, and digest microorganisms and debris.

1 Adherence The phagocyte comes into contact with a microbe and recognizes it as foreign. This process is assisted by chemicals released during inflammation.

2 Ingestion The phagocyte engulfs the microbe in a pouch formed in its membrane. Fluid-filled particles, lysosomes, move towards the microbe.

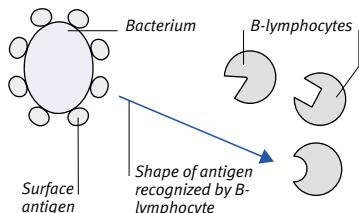

3 Digestion Enzymes within the lysosomes are released into the pouch to help digest the microbe. Debris from this process is later ejected.

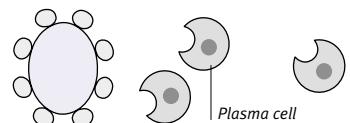

THE ADAPTIVE IMMUNE SYSTEM

This system is based on white blood cells called lymphocytes. It has two parts. Humoral immunity relies on the action of B-lymphocytes; these cells produce antibodies, which circulate and attack specific microbes. In cellular immunity, cells called T-lymphocytes are activated and attack specific microbes or abnormal cells (such as virally infected cells or tumour cells).

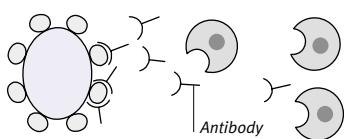

HUMORAL IMMUNITY

1 A humoral response is started when an antigen (foreign protein), here on the surface of a bacterium, is recognized by one type of B-lymphocyte and activates it.

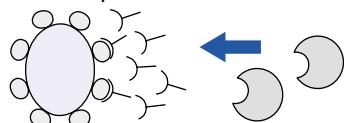

2 This particular type of B-lymphocyte multiplies, forming cells called plasma cells, which make antibodies designed specifically to attack the bacterium.

3 After a few days, the antibodies are released. They attach themselves to the antigen. This triggers more reactions, which ultimately destroy the bacterium.

Second exposure

4 Some B-lymphocytes remain in the body as memory cells; if the bacterium enters the body again, they rapidly produce large amounts of antibodies to halt the infection.

EXAMPLES OF INFECTIOUS ORGANISMS COMBATED

Humoral immunity particularly important against:

- Some viruses (e.g. hepatitis)
- Many bacteria (e.g. cholera)
- Some parasites (e.g. malaria)

Cellular immunity particularly important against:

- Many viruses (e.g. herpes simplex)
- Some bacteria (e.g. tuberculosis)
- Some fungi (e.g. candidiasis)

a group of blood proteins called the complement system, which act to destroy the invading organisms.

ACQUIRED IMMUNITY

The second part of the immune system, which is known as "acquired (or "adaptive") immunity", comes into play when the body encounters certain organisms that overcome the innate defences. The acquired, or adaptive, immune system responds specifically to each type of invading organism, and retains a memory of the invader so that defences can be rallied instantly in any future invasion.

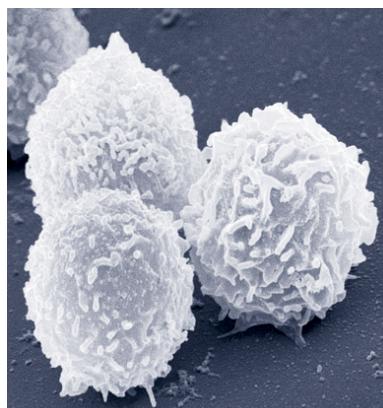

The acquired immune system first must recognize part of an invading organism or tumour cell as an antigen (a protein that is foreign to the body). One of two types of response (humoral or cellular) is then mounted against the invading antigen.

HUMORAL IMMUNITY

Humoral immunity is important in the defence against bacteria. Following a complex recognition process, certain B-lymphocytes multiply and produce vast numbers of antibodies that bind to the antigens on the invading organism; the bacterium is then engulfed by phagocytes and destroyed. The binding of antibody and antigen may activate the complement system, which increases the efficiency of the phagocytes.

CELLULAR IMMUNITY

Cellular immunity is particularly important in the defence against viruses, some types of parasites that hide within cells, and, possibly, against cancer cells. Cellular immunity involves two

Lymphocytes

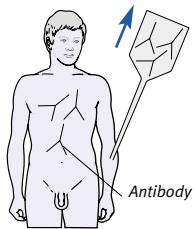

These types of white blood cells are found in the blood and the lymphoid organs (the lymph nodes, spleen, and thymus). The two main types (B- and T-lymphocytes) have different functions but look similar under the microscope.

TYPES OF IMMUNIZATION

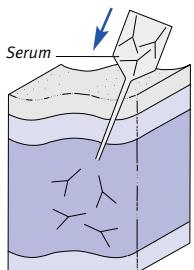

Two main types of immunization exist. In passive immunization, antibodies (protective proteins) are injected into the body and provide immediate, but short-lived, protection against specific disease-causing bacteria, viruses, or toxins. Active immunization primes the body to make its own antibodies against such microorganisms and confers longer-lasting immunity.

PASSIVE IMMUNIZATION

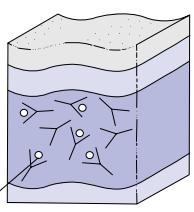

- 1 Blood is taken from a person or, rarely, an animal previously exposed to a particular microorganism. The blood will contain antibodies against that microorganism.

- 2 An extract from the blood containing the antibodies (known as immune serum or antiserum) is injected into the person to be protected.

- 3 The antibodies help to destroy the microorganism if it is present in the blood or enters it over the following few weeks.

types of T-lymphocyte: helper cells, which play a role in the recognition of antigens, and killer cells (the second type of T-lymphocyte), which are activated by helper cells and destroy cells that have been invaded.

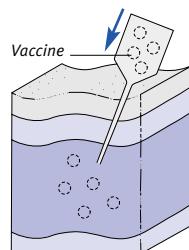

immune system disorders

Disorders of the immune system include immunodeficiency disorders and *allergy*, in which the immune system has an inappropriate response to usually innocuous antigens such as pollen.

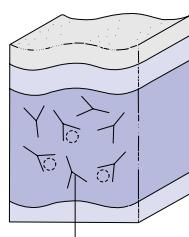

In certain circumstances, such as following tissue transplants, *immunosuppressant drugs* are used to suppress the immune system and thus prevent the body rejecting the donor tissue as a foreign organism.

ACTIVE IMMUNIZATION

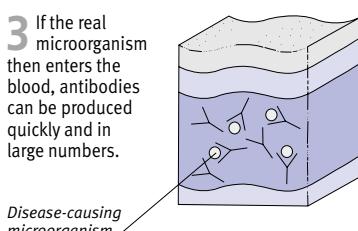

- 1 The person to be protected is inoculated with a killed or modified microorganism (vaccine) that does not cause disease.

- 2 The immune system is provoked to make antibodies against the modified microorganism; it also retains a "memory" of the organism.

- 3 If the real microorganism then enters the blood, antibodies can be produced quickly and in large numbers.

immunization

The process of artificially inducing *immunity* as a preventive measure against *infectious diseases*.

TYPES AND BENEFITS

Immunization may be active or passive. In the passive form, *antibodies* are injected into the blood to provide immediate but short-lived protection against specific *bacteria*, *viruses*, or *toxins*. Active immunization, also called vaccination, primes the body to make its own antibodies and confers longer-lasting immunity. It also protects the more vulnerable members of a community, such as the very old or the very young (see *herd immunity*).

WHO SHOULD BE IMMUNIZED

Routine childhood immunization programmes exist for diseases such as *diphtheria*, *tetanus*, *pertussis*, *poliomyelitis*, and *haemophilus influenzae* (Hib) (see *DTaP/IPV/Hib*); measles, mumps, and rubella (see *MMR vaccination*); meningitis C; and tuberculosis (see *BCG vaccination*). For injections and timings, see *Typical childhood immunization schedule*, overleaf.

Additional immunizations may also be necessary before foreign travel (see *travel immunization*).

POSSIBLE RISKS

Immunizations are usually given by injection, and most of them have no after-effects. Some vaccines, however, cause pain and swelling at the site of injection and may produce a slight fever or flulike symptoms. Others may produce a mild form of the disease. Very rarely, severe reactions occur as a result of, for example, an allergy to one of the vaccine's components. Not all immunization provides complete protection against disease; *typhoid fever* vaccinations, in particular, give only partial protection.

People with *immunodeficiency disorders* or who have widespread *cancer*, or those taking oral *corticosteroid drugs* should not receive vaccines containing live organisms. Those who have previously had a severe reaction to a vaccine should not be immunized. Some vaccines should not be given to young children, during pregnancy, or to HIV positive individuals.

immunoassay

A group of laboratory techniques, which include *radioimmunoassay* and *ELISA* (enzyme-linked immunosorbent assay), that are used in the diagnosis of infectious diseases, to confirm *immunity*, and also to investigate *allergies*. The

TYPICAL CHILDHOOD IMMUNIZATION SCHEDULE	
Age	Disease
2 months	Diphtheria/tetanus/pertussis/poliomyelitis/haemophilus influenzae b (Hib)*; meningococcus c
3 months	Diphtheria/tetanus/pertussis/poliomyelitis/haemophilus influenzae b (Hib)*; meningococcus c
4 months	Diphtheria/tetanus/pertussis/poliomyelitis/haemophilus influenzae b (Hib)*; meningococcus c
12–15 months	Measles/mumps/rubella (MMR)*
3–5 years	Diphtheria/tetanus/pertussis/poliomyelitis*†; measles/mumps/rubella*†
10–14 years (tuberculin-negative children)	Bacillus Calmette Guerin (BCG) against tuberculosis
13–18 years	Diphtheria/tetanus/poliomyelitis*†; in addition, meningococcus c can be given up to age 24 if not had already

*Combined injection †Booster

tests are performed to determine the presence or absence of particular *antigens* (proteins that are present on the surface of microorganisms or allergens) or *antibodies* (proteins that are formed by the immune system to combat a particular microorganism or allergen). Immunoassay procedures may also be used to measure blood levels of *hormones* (which are also proteins).

immunocompromised

A term used to describe a person whose immune system activity has been reduced by disease (such as *AIDS* or *cancer*) or by certain medical treatments (such as treatment with *immunosuppressant drugs*). An immunocompromised person is at a greater than normal risk of contracting infections, particularly so-called *opportunistic infections* (diseases caused by organisms that rarely pose a threat to healthy people).

immunodeficiency disorders

Disorders in which the defences of the *immune system* fail to fight infection and tumours. Immunodeficiency disorders may be due to an inherited or a *congenital* defect or may be the result of acquired disease. The result is persistent or recurrent infection, including infections with organisms that would not ordinarily cause disease (see *oppor-*

tunistic infections), and an undue susceptibility to certain forms of *cancer*. Opportunistic infections include *pneumocystic pneumonia*, *fungal infections*, and widespread *herpes simplex* infections.

INHERITED IMMUNODEFICIENCY

Congenital or inherited deficiencies can occur in either of the two prongs of the adaptive immune system – humoral or cellular immunity – or in both.

Deficiencies of the humoral system include hypogammaglobulinaemia and agammaglobulinaemia. The former may cause few or no symptoms, depending on the severity of the deficiency, but agammaglobulinaemia can be fatal if not treated with *immunoglobulin*.

Congenital deficiencies of *T-lymphocytes* may lead to problems such as persistent and widespread *candidiasis* (thrush). A combined deficiency of both humoral and cellular components of the immune system, called severe combined immunodeficiency (SCID), is usually fatal in the first year of life unless treatment can be given by *bone marrow transplant*.

ACQUIRED IMMUNODEFICIENCY

Acquired immunodeficiency may be due to disease processes (such as infection with *HIV*, which leads to *AIDS*). It may also be caused by damage to the immune system as a result of its suppression by drugs, either intentionally

due to autoimmune diseases or after organ transplantation, or as a side effect of treatment for another condition. Severe malnutrition and many cancers can also cause immunodeficiency. Mild immunodeficiency arises through a natural decline in immune defences with age.

immunoglobulin

Also known as an *antibody*, a type of protein found in blood and tissue fluids. Such proteins are produced by *B-lymphocytes* (a type of white blood cell). Their function is to bind to substances in the body that are recognized as foreign *antigens*, such as proteins on the surfaces of bacteria and viruses. This binding is crucial for the destruction of antigen-bearing microorganisms. Immunoglobulins also play a key role in *allergies* and *hypersensitivity* reactions.

There are five main classes of immunoglobulin in the blood (IgA, IgD, IgE, IgG, and IgM). IgA is mainly found in secretions of the respiratory tract, intestine, and urinary tract. Only low levels of IgD are present in the body and its function is not known. IgE is involved in the immune response to worm infestations; high levels are also produced to fight atopic (allergic) conditions. IgG is the major class of immunoglobulin, with four subclasses; its molecule consists of two parts, one of which binds to an antigen and the other to other cells of the immune system, which then engulf the microorganisms bearing the antigen. The most important function of IgG is to mount a response to bacterial infections. IgM is produced promptly in response to infection and then levels fall; IgM present in an infant at birth is an indicator of intrauterine infection.

Immunoglobulins can be extracted from the blood of people who have recovered from certain infectious diseases and used for passive *immunization*.

immunoglobulin injection

The administration of *immunoglobulin* preparations (antibodies) to prevent or treat infectious diseases. Such preparations, also known as *immune globulin* or *gamma-globulin* injections, work by passing on antibodies obtained from the blood of people who have previously been exposed to these diseases.

The main use of these injections is to prevent infectious diseases, such as chickenpox, in those people exposed to infection who are not already immune, or in those who are at special

risk (during cancer treatment, for example). They are also given intravenously on a regular basis for *immuno-deficiency disorders*. Side effects of such injections include rash and fever, and pain and tenderness at the injection site if injected into a muscle.

immunology

The discipline that is concerned with the *immune system*. Immunologists study the immune system's functioning and investigate and treat immune system disorders, including *autoimmune disorders*, *allergies*, and *immunodeficiency disorders* such as *AIDS*.

Immunologists are also concerned with finding ways in which the immune system can be stimulated to provide immunity. In addition, they play a role in *transplant surgery*. Before operations, they look for a good match between recipient and donor organ; after transplantation they use drugs to suppress the recipient's immune system, in order to minimize the chances of organ rejection.

immunostimulant drugs

COMMON DRUGS

- Aldesleukin • BCG • Interferon alfa
- Interferon beta • Peginterferon alfa

A group of drugs that increase the efficiency of the body's *immune system*. Immunostimulant drugs include *vaccines*, *interferon*, and aldesleukin (interleukin-2). Interferon alfa is used to treat persistent viral infections, such as hepatitis C. Interferon beta is used to treat some types of *multiple sclerosis*. Aldesleukin is used in the treatment of *kidney cancer*.

immunosuppressant drugs

COMMON DRUGS

ANTICANCER DRUGS • Azathioprine

- Chlorambucil • Cyclophosphamide
- Methotrexate • Mycophenolate mofetil

CORTICOSTEROID DRUGS • Prednisolone

ANTIBODIES • Anti-lymphocyte globulin

- Basiliximab • Daclizumab

OTHER DRUGS • Ciclosporin • Tacrolimus

A group of drugs that are used to reduce the activity of the *immune system*. Immunosuppressants are given to prevent rejection of donor tissue after *transplant surgery*. They are also given to slow the progress of *autoimmune disorders* such as *rheumatoid arthritis* and *systemic lupus erythematosus*.

The drugs work by suppressing the production and activity of white blood cells called *lymphocytes*. Side effects vary, but all of these drugs increase the risk of infection and of the development of certain *cancers*.

immunotherapy

Stimulation of the *immune system* as a treatment for *cancer*. The term is also used to describe *hyposensitization* treatment for *allergy*.

One type of immunotherapy that is employed in the treatment of cancer uses *immunostimulant drugs*. For example, treatment of bladder cancer may involve the introduction of *BCG* into the bladder. More recently, *genetic engineering* has been used to manufacture monoclonal antibodies (see *antibody*, *monoclonal*) to be directed against tumours. *Interferon* or chemical poisons can be linked to these antibodies in order to increase their ability to destroy tumour cells without damaging normal cells.

Imodium

A brand name for *loperamide*, an *antidiarrhoeal drug*.

impaction, dental

Failure of a tooth to emerge completely from the gum. It may occur because of *overcrowding* or when a tooth grows in the wrong direction.

Impacted wisdom teeth are common when the teeth come through in early adulthood. If they cause no symptoms, they do not need to be removed. In some cases, however, impacted wisdom teeth partially penetrate the gum, leaving a flap of tissue over most of the crown. *Plaque*, bacteria, and food debris may then collect between the

Impacted wisdom teeth

This X-ray shows impacted upper and lower wisdom teeth. The teeth are wedged against an adjacent molar and are unable to erupt normally; the tooth in the lower jaw is lying horizontally.

tooth and the gum, causing pain and inflammation in the gum tissues (see *gingivitis*). If the problem persists, the affected teeth need to be removed.

impaction, faecal

See *faecal impaction*.

impedance audiometry

A *hearing test* used to investigate the performance of the middle ear in cases of conductive *deafness*.

imperforate

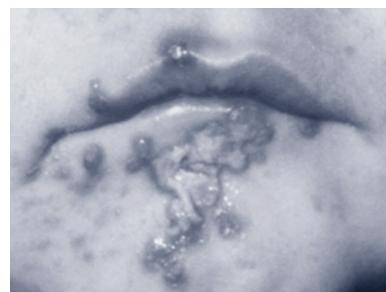

A term meaning "without an opening". The term is used to describe a body structure, such as the *hymen* or the *anus* (see *anus*, *imperforate*), which should have an opening but does not.

impetigo

A highly contagious skin infection, common in children, that most commonly occurs around the nose and mouth, but can affect the skin anywhere on the body.

CAUSE AND SYMPTOMS

Impetigo is caused by bacteria (usually *staphylococci*) entering areas of broken skin. The skin reddens and small, fluid-filled blisters appear. The blisters tend to burst, leaving moist, weeping

The appearance of impetigo

Fluid-filled blisters appear on the skin (in this case, on a young child's mouth and chin). The blisters often burst, releasing fluid that dries to leave pale brown crusts on the skin.

areas that dry to leave honey-coloured or golden crusts. In severe cases, there may be swelling of the *lymph nodes* in the face or neck and fever.

TREATMENT AND PREVENTION

Treatment is with topical (locally administered) *antibiotic drugs* unless the condition is widespread, in which case oral antibiotics are usually given.

As the condition is highly contagious, to prevent the spread of the infection, towels, flannels, and pillowcases should

not be shared. Children should not go to school or mix with others until they have been treated and the condition has cleared up.

implant

Any material, either natural or artificial, that is inserted into the body for medical or cosmetic purposes.

implantation, egg

Attachment of a fertilized *ovum* (egg) to the wall of the *uterus*. Implantation occurs about six days after *fertilization*, when the blastocyst (early embryo) comes into contact with the uterus wall.

As the cells of the developing *embryo* continue to divide, the outer cell layer penetrates the lining of the uterus to obtain oxygen and nutrients from the mother's blood; later, this layer develops into the *placenta*. The embryo usually implants in the upper part of the uterus; if it implants low down near the cervix, *placenta praevia* may develop. Rarely, implantation occurs outside the uterus, possibly in a fallopian tube, resulting in an *ectopic pregnancy*.

implant, dental

A post that is surgically embedded in the jaw for the attachment of a dental prosthesis (an artificial tooth). Titanium or synthetic materials may be used. A dental implant is fitted under either a local or general anaesthetic (see *anaesthesia, dental*). A hole is drilled in the jaw and the post inserted. Several months later, an attachment that protrudes from the gum is screwed into the post; a few weeks after that, the prosthesis is fitted.

implosive therapy

A form of *behaviour therapy*, also known as *flooding*, used for desensitizing a person to the cause of a *phobia*.

impotence

The inability to achieve or maintain an *erection*. Impotence, known medically as erectile dysfunction, is the most common male sexual disorder, affecting most men at some time in their lives.

CAUSES

Impotence is usually caused by psychological factors, be they temporary (for example, due to stress) or longstanding (such as due to anxiety and guilt originating in childhood). Impotence may be a symptom of *depression*.

Some cases of impotence are caused by a physical disorder, such as *diabetes*

mellitus, damage to the *spinal cord*, or an *alcohol-related disorder*. Impotence may be caused by taking various drugs, such as *antidepressant drugs* and *antihypertensive drugs*. Impotence is found to be more common in older men, which is possibly due to altered circulation or reduced levels of the male sex hormone *testosterone*.

TREATMENT

Tests may be performed to eliminate the possibility of a physical disorder. A change in current medication may also be advised to see if the condition of impotence is affected.

If the cause of impotence is psychological, *counselling* or *sex therapy* may be recommended and is often found to be a successful treatment.

Treatment of a physical cause may be possible, for example, with the drug *sildenafil* (Viagra). However, due to the drug's effects on the vascular system, it should be used with caution in men with certain disorders, such as *angina pectoris*; it should not be used after a recent *stroke* or *myocardial infarction* (heart attack). Sildenafil should never be taken without medical advice. Other treatments include self-administered injections into the penis and a surgical implant, which can produce a sustained erection.

impression, dental

A mould taken of the *teeth*, *gums*, and *palate*. A quick-setting material, such as alginate, is placed in a mould over the teeth. The mould is then removed, and plaster of Paris poured into it to obtain a model of the area. This model is then used as a base on which to build a *denture, bridge*, or dental *inlay*.

Dental impressions are also used in *orthodontics* to study the position of the teeth, and to make *orthodontic appliances* to correct irregularities.

impulse

A sudden, spontaneous force or action. In biology and medicine, the term "impulse" is usually used to refer to the electrical activity that travels along a *nerve* which may result, for example, in a muscle contraction.

inattention, sensory

In *neurology* (the study of diseases of the nervous system), a term meaning the inability to recognize a tactile stimulus (such as a pinprick) on one side of the body, while reacting normally to

a simultaneous stimulus on the other side. Visual inattention (failure to respond to local visual stimuli) may also be present. The condition is most commonly the result of a *stroke*.

inborn errors of metabolism

See *metabolism, inborn errors of*.

incest

Sexual intercourse between close relatives, such as with a parent, a son or daughter, a brother or sister, an uncle or aunt, a nephew or niece, or a grandparent or grandchild. Incest is illegal or taboo in most societies and is against the teaching of many religions.

incidence

One of the two principal measures (the other is *prevalence*) of how common a disease is in a defined population. The incidence of a disease is the number of new cases that occur during a given period (for example, 17 new cases per 100,000 people per year).

incision

A cut made into the tissues of the body by a scalpel (surgical knife). Most incisions are made to gain access to tissue inside the body, usually to repair or remove a diseased organ. An incision may also be made to allow pus to drain from an *abscess* or boil.

incisional hernia

A type of *hernia* in which the intestine bulges through a scarred area of the abdominal wall because the surrounding muscle has been weakened by a previous surgical *incision*.

incisor

One of the eight front teeth (four in the upper jaw and four in the lower) used for cutting through solid food (see *teeth*).

incompatible blood transfusion

A blood transfusion in which the patient's immune system reacts against the donor blood as a foreign invader (see *blood transfusion, incompatible*).

incompetence

A medical term applied to a structure that should close tightly but does not. For example, valve incompetence (see *aortic incompetence*; *mitral incompetence*) causes leakage of blood; *cervical incompetence* may result in a miscarriage.

incomplete abortion

The retention in the uterus of placental or fetal tissue after a *miscarriage* or a medical abortion (see *abortion, induced*). If this tissue is not promptly removed, it may become infected, resulting in a dangerous condition called *septic abortion* and haemorrhage (bleeding).

incontinence, faecal

Inability to retain *faeces* in the *rectum*, leading to involuntary defaecation.

CAUSES

A common cause of faecal incontinence is *faecal impaction*, which often results from long-standing *constipation*. In this condition the rectum becomes overfull, causing faecal fluid and small pieces of faeces to be passed involuntarily around the impacted mass of faeces. Temporary loss of continence may also occur in severe *diarrhoea*. Other causes include injury to the anal muscles (as may occur during childbirth), *paraplegia* (damage to the nerves in the lower trunk, including those supplying the intestines), and *dementia* (loss of normal brain functions, such as control of the bowels).

TREATMENT

Faecal incontinence can usually be successfully treated. If the underlying cause of faecal impaction is constipation, recurrence may be prevented by eating a high-fibre diet. Suppositories containing *glycerol* or *laxative drugs* may be recommended. Pelvic floor and anal sphincter damage can often be surgically repaired. Faecal incontinence in people with dementia or a nerve disorder may be avoided by regular use of *enemas* or *suppositories* to empty the rectum.

incontinence, urinary

Involuntary passing of *urine*, often due to injury or disease of the *urinary tract*. There are several types.

TYPES AND SYMPTOMS

Stress incontinence refers to the involuntary escape of urine when a person coughs, laughs, picks up a heavy object, runs, or jumps. It develops when the urethral sphincter muscles (which normally keep the bladder outlet closed) have been stretched and weakened. Stress incontinence is common in women, particularly after childbirth or in patients with prolapse of the uterus or vagina. This condition results in the loss of small amounts of urine.

In urge incontinence, also known as irritable bladder, an urgent desire to pass urine (even though the bladder is

not full) is accompanied by inability to control the bladder as it contracts. Once urination starts, it cannot be stopped, leading to the loss of large volumes of urine. Urge incontinence is often caused by irritability of the bladder lining. The problem may be caused by infection or inflammation (see *cystitis*). It may also result from the presence of stones (see *calculus, urinary tract*) or bladder tumours; disorders affecting the nerves that supply the bladder (such as *stroke* or *multiple sclerosis*); or *anxiety*. In some cases the bladder muscles are too sensitive to increasing pressure within the bladder, inappropriately triggering emptying.

Total incontinence is a complete lack of bladder control due to loss of function in the urethral sphincter. It may be associated with spinal cord damage, due to disease or injury, that affects the nerves supplying the bladder.

Overflow incontinence occurs in long-term *urinary retention*, often because of an obstruction such as an enlarged *prostate gland*. The bladder is always full, leading to constant dribbling of urine.

Incontinence due to lack of control by the brain commonly occurs in young children (see *enuresis*) or elderly people, and in those with *learning difficulties*.

TREATMENT

A wide range of treatments for urinary incontinence are available, and most affected people achieve significant improvement. If weak pelvic muscles are causing stress incontinence, *pelvic floor exercises* may be helpful. Sometimes, surgery may be needed to tighten the pelvic muscles or correct a prolapse. *Anticholinergic drugs* may be used to relax the bladder muscle if irritable bladder is the cause. *Collagen* injections into the urethral wall, performed under anaesthetic, may also be effective.

If normal bladder function cannot be restored, incontinence pants can be worn; men, alternatively, can wear a penile sheath leading into a tube connected to a urine bag. Some people can avoid incontinence by means of self-catheterization (see *catheterization, urinary*). Permanent catheterization is necessary in some cases.

incoordination

Loss of the ability to produce smooth, muscular movements, leading to clumsiness and unsteady balance. The term "incoordination" can also mean the failure of a group of organs to work together successfully. (See also *ataxia*.)

incubation period

The time during which an *infectious disease* develops, from the point when the infectious organism enters the body until symptoms appear. Different infections have characteristic incubation periods; for example, 14–21 days for chickenpox and 7–14 days for measles. The incubation period for cholera may be as short as several hours.

incubator

A transparent plastic cot that provides premature or sick infants with ideal conditions for survival. In an incubator, oxygen, temperature, and humidity levels are controlled. Incubators have portholes to allow handling of the baby, and smaller ones through which monitoring cables and intravenous and respiratory tubing can pass.

Premature infant in an incubator
Portholes make it possible for medical staff or parents to handle the infant without disturbing the special conditions in the incubator.

incus

One of the three tiny, linked bones (*ossicles*) in the middle *ear* that convey sound vibrations. The incus (the Latin name for an anvil) is so called because it is said to resemble an anvil.

indapamide

A diuretic drug used in the treatment of *hypertension* (high blood pressure). Possible side effects include headaches, fatigue, and muscle cramps. Less common adverse effects include dizziness, fainting, "pins and needles", sore throat, rash, and *jaundice*; these problems need prompt medical attention.

Inderal

A brand name for *propranolol*, a *beta-blocker drug* used to treat heart and circulatory disorders as well as some mental problems.

Indian medicine

A system of medicine originally based largely on herbal treatment, although simple surgical techniques were also used. Indian medicine, also known as ayurvedism, later developed into a scientifically based system with a wide range of surgical techniques (such as operations for cataracts and kidney stones) alongside emphasis on purifying techniques, diet, yoga, breathing exercises, and the herbal tradition. Indian medicine has been used effectively to treat a variety of conditions, including digestive problems, *rheumatoid arthritis*, allergies, viral infections, and anxiety-related disorders such as insomnia.

indigenous

Native to a particular place or country. In medicine, this concept is important when investigating the effect of environmental factors on disease patterns.

indigestion

A common term (known medically as *dyspepsia*) covering a variety of symptoms brought on by eating, including *heartburn*, *abdominal pain*, *nausea*, and *flatulence* (excessive wind in the stomach or intestine, that causes belching and discomfort).

Discomfort in the upper abdomen is often caused by eating too much, too quickly, or by eating very rich, spicy, or fatty foods. Persistent or recurrent indigestion may be due to a *peptic ulcer*, *gallstones*, *oesophagitis* (inflammation of the oesophagus), or, rarely, *stomach cancer*.

Antacid drugs help to relieve the symptoms, but they may mask an underlying cause that needs medical attention. They should not be taken for longer than two weeks without medical advice.

indole

A substance produced by the breakdown of the *amino acid* tryptophan in the intestine. Indole is excreted in urine. An indole compound (5-hydroxy-indole acetic acid) is measured in the urine in the investigation of possible *carcinoid tumours*.

indolent ulcer

A term describing an *ulcer* that is slow to heal but usually causes little pain.

indometacin

A *nonsteroidal anti-inflammatory drug* (NSAID) used to relieve pain, stiffness, and inflammation caused by disorders

such as *rheumatoid arthritis*, *osteoarthritis*, and *tendinitis*. It is also prescribed to relieve the pain that is caused by injury to soft tissues, such as muscles and ligaments. Side effects of indometacin include abdominal pain, nausea, heartburn, headache, dizziness, and an increased risk of *peptic ulcer*.

indoramin

An *alpha-blocker drug* used to treat *hypertension* (high blood pressure). It acts by relaxing the muscles in the blood vessel walls, thus allowing the vessels to widen and easing the flow of blood. In lower doses, indoramin is also prescribed to relieve the symptoms of an enlarged prostate gland (see *prostate, enlarged*); it relaxes the muscle of the prostate and thereby enables urine to be passed more easily.

When first taken, indoramin can cause a rapid fall in blood pressure. For this reason, the first dose is usually small and is taken lying down. Indoramin may also cause drowsiness at the start of treatment and whenever the dosage is increased.

induction of labour

Use of artificial means to begin *labour* if the health of the mother or baby would be at risk if the pregnancy was allowed to continue for longer.

WHY IT IS DONE

The most common reason for inducing labour is that the pregnancy has continued past the estimated delivery date, which increases the chance of complications during childbirth. Other reasons for induction are *pre-eclampsia* (a serious condition involving high blood pressure and fluid accumulation), *Rhesus incompatibility* (a difference between the blood groups of mother and fetus), or *intrauterine growth retardation* (poor growth of the developing fetus).

HOW IT IS DONE

Different methods of induction are used, depending on the stage of labour and cervical condition. A *prostaglandin* pessary may be inserted high into the vagina to encourage the cervix to soften and open. The hormone *oxytocin* may also be given as a continuous intravenous infusion in order to stimulate uterine contractions.

induration

A specific medical term meaning the hardening or thickening of areas of soft tissue (for example, the skin or

blood vessel walls) or an organ (such as the lung or liver) due to inflammation or disease. (See also *sclerosis*.)

industrial diseases

See *occupational disease and injury*.

industrial psychology

A field of *psychology* in which human behaviour is studied in relation to the effects and influences of the workplace. The principles of industrial psychology are applied to such issues as leadership, communications, motivation, job analysis, and selection of employees.

indwelling catheter

A *catheter* (flexible tube) that remains in place for a prolonged period. The term usually refers to a urinary catheter that is used to drain the contents of the bladder via the *urethra*; it is held in place with a balloon (see *balloon catheter*).

in extremis

The Latin term for "at the point of death".

Infacol

A brand name for *dimecitone* (an anti-foaming agent used to relieve *colic*).

infant

A term usually applied to a baby up to the age of 12 months.

infantile autism

An alternative term for *autism*, a disorder that usually develops in early childhood and causes severe impairment of language and communication skills.

infantile cataract

A *congenital* disorder (one present from birth) in which a baby's sight is seriously impaired by opacity of the lens of the eye (see *cataract*). Causes include infections, such as *rubella* (German measles) and *toxoplasmosis*, passed from mother to baby before birth. Surgical removal of the cataract may be beneficial.

infantile colic

See *colic, infantile*.

infantile eczema

An alternative term for *atopic eczema* that first develops in early childhood.

infantile spasms

A rare type of recurrent seizure, also called progressive myoclonic encephalopathy or salaam attacks, that affects

babies. The condition is a form of *epilepsy* and first occurs around four to nine months of age.

Spasms may occur hundreds of times a day, each lasting a few seconds. During a seizure, the baby's head suddenly falls forwards, the body stiffens, and the limbs bend, then the arms and hands extend and move outwards. These seizures are usually a sign of brain damage; affected babies usually have severe *developmental delay*.

infant mortality

The number of infants who die during the first year of life per 1,000 live births (usually expressed as per year). The majority of infant deaths occur during the neonatal period (the first month of life). Most of those who die are very premature and of low birth weight, or have severe congenital abnormalities.

infarction

Death of an area of tissue due to ischaemia (lack of blood supply). One common example is *myocardial infarction*, commonly called a heart attack. Another is pulmonary infarction, which is lung damage caused by a pulmonary embolism – a blood clot that has moved into a vessel in the lung and is obstructing the flow of blood. (See also *necrosis*).

infection

The establishment in the body of disease-causing microorganisms (such as *bacteria*, *viruses*, or *fungi*). The organisms reproduce and cause disease by direct damage to cells or by releasing toxins. This activity normally provokes the *immune system* into responding, which accounts for many common symptoms.

Infection can be localized within a particular area or tissue, as in a boil, or be systemic (spread throughout the body), as in *influenza*. Localized infection may result from the spread of organisms through wounds, or during surgery. This form of infection is generally associated with pain, redness, swelling, and formation of a pus-filled abscess at the site of infection, and a rise in temperature. Weakness, aching joints, and fever are expressions of systemic infectious disease.

Many minor infections are dealt with by the immune system and need no specific treatment. A localized infection that has produced pus may be drained surgically. Severe systemic infections may need treatment with drugs such as

antibacterials or *antivirals*. For further information about different infectious diseases, see the accompanying tables.

infection, congenital

Infection that is acquired by a baby in the uterus or during birth.

INFECTIONS ACQUIRED IN THE UTERUS

Many microorganisms can pass from the mother, by way of the placenta, into the circulation of the growing fetus. Particularly serious infections that may be acquired in the uterus are *rubella*, *syphilis*, *toxoplasmosis*, and *cytomegalovirus*. All these infections may cause *intrauterine growth retardation*. Rubella that occurs in early pregnancy may cause *deafness*, *congenital heart disease*, and eye disorders.

Some diseases in later pregnancy may also damage the fetus severely. One such condition is infection with a *herpes* virus. A woman infected with *HIV* risks passing it on to her baby during pregnancy, but the risk can be reduced by use of *antiretroviral drugs* during the pregnancy.

INFECTIONS ACQUIRED DURING BIRTH

Infections acquired during birth are almost always the result of microorganisms in the mother's vaginal secretions or uterine fluid. Premature rupture of the membranes is associated with increased risk of disease, particularly *streptococcal*

infections. Conditions that may be acquired during delivery include *herpes*, *chlamydial infections*, and *gonorrhoea*.

TREATMENT

Treatment of the baby depends on the type of infection. Some birth defects caused by infection (such as certain types of heart defect) can be treated; others (such as congenital deafness) are usually not treatable.

infectious disease

Any illness that is caused by a specific microorganism. The most important disease-causing organisms are *viruses*, *bacteria*, including rickettsiae, chlamydiae, mycoplasmas, and *fungi*. Others are *protozoa* and *worms*.

INCIDENCE

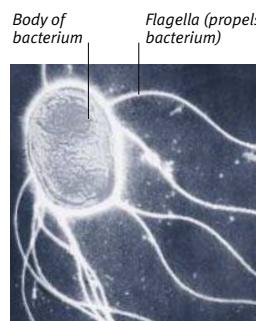

In affluent countries, infectious diseases are generally less of a threat than in the past because of better methods to control the spread of disease organisms (such as improved sanitation and water purification); effective drugs; *immunization*; and better general health and nutrition. In poorer countries, such diseases still pose a threat, both to people who live in these countries and to travellers who visit them.

INCUBATION PERIOD

For most infectious diseases, there is a time gap between the entry of the microorganisms into the body and the first

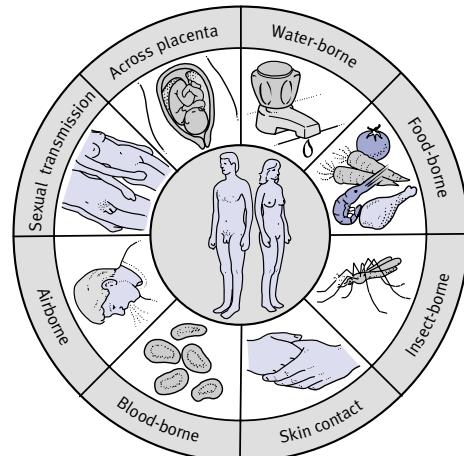

HOW INFECTIOUS DISEASES ARE TRANSMITTED

In affluent countries, infections are usually spread by sexual transmission, airborne transmission, blood-borne transmission, or direct skin contact. In poorer countries, insects, food, and water are other important mechanisms of transmission. Certain infectious diseases can also pass from a pregnant woman's blood across the placenta into the blood of the fetus.

Salmonella bacterium

This image shows the bacterium *Salmonella enteritidis*, which can cause food poisoning. These bacteria may be found in meat, eggs, and milk.

appearance of symptoms. This incubation period, during which an infected person is likely to pass the microorganism to others, may vary from a few hours or days to, in some cases, several months.

TREATMENT

Antibiotic drugs and other antimicrobial drugs are the mainstay of treatment for

bacterial infection. For viral infection, however, drug treatment is restricted to severe infections and often relies on supportive measures alone.

OUTLOOK

Progress has been made in the fight against infectious diseases, but many problems remain. The spread of diseases

such as *sexually transmitted infections* is difficult to control and, for many infections, no effective *vaccine* exists.

Some bacteria have developed *resistance* to the drugs available; this could lead to a rise in potentially fatal bacterial infections similar to those common before the development of

INFECTIOUS DISEASES: VIRAL INFECTIONS

Disease	Infective agent	Transmission	Incubation period	Symptoms	Treatment
AIDS/HIV infection	Human immunodeficiency virus (HIV)	Sexual contact; sharing hypodermic needles; mother to fetus or to breast-fed baby; unscreened blood transfusions	6–8 weeks	Flulike illness; fever; fatigue; sore throat; muscle aches; swollen lymph nodes; skin disorders; fungal, viral, or bacterial infections	Treatment given for complicating infections; antiviral drugs can prolong life expectancy
Chickenpox	Varicella-zoster virus (herpes zoster virus)	Airborne droplets; direct contact	7–21 days	Slight fever; malaise; crops of itchy blisters	Relief of symptoms; aciclovir beneficial in adults
Common cold	Numerous rhino- and adenoviruses; coronaviruses	Airborne droplets; hand-to-hand contact	1–3 days	Sneezing; chills; muscle aches; runny nose; cough	Relief of symptoms
Hepatitis, viral	Hepatitis virus types A, B, C, D, or E	A, E: infected food or water B, C, D: sexual contact; infected blood; sharing needles	A, E: 3–6 weeks B, C, D: a few weeks to several months	Flulike illness; jaundice; many people are asymptomatic	Relief of symptoms; interferon may be beneficial in some cases
Influenza	Influenza virus types A, B, or C	Airborne droplets	1–3 days	Fever; chills; aches; headache; sore throat; cough; runny nose	Relief of symptoms; fluids
Measles	Measles virus (a paramyxovirus)	Airborne droplets	7–14 days	Fever; coldlike symptoms; mottled red rash that fades to leave staining; conjunctivitis	Relief of symptoms
Meningitis, viral	Various viruses	Various methods, including via rodents	Variable	Fever; headache; drowsiness; confusion	Relief of symptoms
Mononucleosis, infectious (glandular fever)	Epstein–Barr virus	Possibly via saliva	1–6 weeks	Swollen glands; fever; sore throat; headache; malaise; lethargy	Relief of symptoms; rest; fluids
Poliomyelitis	3 polioviruses	From faeces to mouth via hands; airborne droplets	3–21 days	Minor illness: headache; sore throat; vomiting Major illness: fever; stiff neck and back; muscle aches; paralysis	Relief of symptoms
Rabies	Rabies virus (a rhabdovirus)	Bite, or lick on broken skin, from infected animal	Usually 2–8 weeks, but may be over 1 year	Fever; malaise; irrationality; throat spasms; hydrophobia	No effective treatment
Rubella	Rubella virus	Airborne droplets; mother to fetus	14–21 days	Low fever; characteristic rash; congenital abnormalities in fetus, including ear, eye, and heart defects	Relief of symptoms

INFECTIOUS DISEASES: BACTERIAL INFECTIONS

Disease	Infective agent	Transmission	Incubation period	Symptoms	Treatment
Gonorrhoea	NEISSERIA GONORRHOEAE	Sexual contact; mother to baby at delivery	2–6 days	Pain on passing urine; discharge; pain in abdomen	Penicillin; ampicillin; other antibiotics for resistant forms
Meningitis, bacterial	NEISSERIA MENINGITIDIS (meningococcus); STREPTOCOCCUS PNEUMONIAE; others	Airborne droplets	Less than 3 weeks; may be less than 48 hours	High fever; stiff neck; nausea; confusion; purple rash that does not fade (in meningococcus)	Immediate treatment with antibiotics
Pertussis (whooping cough)	BORDETELLA PERTUSSIS	Airborne droplets	1–2 weeks	Runny nose and moderate fever; slight cough leading to characteristic cough spasms and vomiting	Erythromycin to prevent spread of infection; small children may require hospital admission
Pneumonia	STREPTOCOCCUS PNEUMONIAE; MYCOPLASMA PNEUMONIAE; others	Airborne droplets	1–3 weeks	Cough; fever; chest pain; shortness of breath	Antibiotics
Tuberculosis	MYCOBACTERIUM TUBERCULOSIS	Airborne transmission; unpasteurized cows' milk	4–12 weeks for primary infection; disease may be reactivated later in life	Fever; malaise; weight loss; cough; shortness of breath; chest pain	Multiple antituberculous drugs for several months
Typhoid fever	SALMONELLA TYPHI	Food or water contaminated with infected faeces	1–2 weeks, sometimes longer	Headache; lethargy; constipation; very high, prolonged fever; dry cough	Antibiotics

INFECTIOUS DISEASES: CHLAMYDIAL INFECTIONS

Disease	Infective agent	Transmission	Incubation period	Symptoms	Treatment
Nongonococcal urethritis (in men) / Chlamydia (in women)	CHLAMYDIA TRACHOMATIS	Sexual contact	1–4 weeks	Nongonococcal urethritis: pain on passing urine; watery mucous discharge Nonspecific genital infection: often no symptoms	Antibiotics
Psittacosis	CHLAMYDIA PSITTACI	Inhalation of dust containing faeces from infected birds	1–3 weeks	Flulike and feverish symptoms; shortness of breath	Antibiotics

INFECTIOUS DISEASES: RICKETTSIAL INFECTIONS

Disease	Infective agent	Transmission	Incubation period	Symptoms	Treatment
Q fever	COXIELLA BURNETTI	Inhalation of infected dust	2–4 weeks	Sudden onset of fever and sweating; cough; chest pains; headache	Antibiotics
Epidemic typhus	RICKETTSIA PROWAZEKII	Bite from infected body louse	About 7 days	Severe headache; high fever; muscle aches; weakness; rash	Antibiotics

INFECTIOUS DISEASES: FUNGAL INFECTIONS					
Disease	Infective agent	Transmission	Incubation period	Symptoms	Treatment
Tinea (ringworm)	TRICHOPHYTON RUBRUM; MICROSPORUM CANIS; others	Direct contact with infected humans or animals	Variable	Itchy skin patches; patchy hair loss; cracking skin between toes	Topical or systemic antifungal drugs
Meningitis, fungal	CRYPTOCOCCUS NEOFORMANS	Inhalation of fungus from pigeon droppings	Unknown	Headache; stiff neck; photophobia	Antifungal drugs

INFECTIOUS DISEASES: PROTOZOAL INFECTIONS					
Disease	Infective agent	Transmission	Incubation period	Symptoms	Treatment
Amoebiasis	ENTAMOEBA HISTOLYTICA	Food or water contaminated by faeces	A few weeks to many years	Severe, sometimes bloody diarrhoea	Antiprotozoal drugs (such as metronidazole)
Giardiasis	GIARDIA LAMBLIA	Food or water contaminated by faeces; sexual contact	7–40 days	Diarrhoea; abdominal discomfort; bloating	Antiprotozoal drugs (such as metronidazole)
Malaria	PLASMODIUM FALCIPARUM; PLASMODIUM VIVAX; others	Bite from infected mosquito	10–40 days	Chills; high fever; sweating; headache; fatigue	Various drugs (such as chloroquine)

antibiotics. The majority of viral infections cannot be combated with drugs.

The widespread incidence of HIV, particularly in developing countries, poses a great threat to world health; HIV infection also increases the risk of a surge in less common infections in those people whose immune systems are compromised.

infectious mononucleosis

See *mononucleosis, infectious*.

infective arthritis

An alternative term for septic *arthritis*.

infective endocarditis

See *endocarditis*.

inferior

An anatomical term that is used to describe the lower of two body structures, surfaces, or organs.

inferiority complex

A neurotic state of mind that develops because of repeated hurts or failures in the past. Inferiority complex arises

from a conflict between the positive wish to be recognized as someone worthwhile and the haunting fear of frustration and failure.

Attempts to compensate for the sense of worthlessness may take the form of aggression and violence, or an overzealous involvement in activities. (See also *superiority complex*.)

infertility

The inability to produce offspring, which may result from a problem in either the male or the female reproductive system, or, in many cases, from a combination of problems in both.

MALE INFERTILITY

The main cause of male infertility is a lack of healthy sperm. In *azoospermia*, no sperm are produced; in *oligospermia* only a few sperm are produced. In some cases, sperm are produced but are malformed or short-lived.

The underlying cause of these problems may be blockage of the spermatic tubes or damage to the spermatic ducts, usually due to a *sexually transmitted infection*. Abnormal development of the testes

due to an endocrine disorder (see *hypogonadism*) or damage to the testes by *orchitis* may also cause defective sperm. Smoking, toxins, or various drugs can lower the sperm count (the number of sperm cells in a sample of semen). Other causes are disorders affecting ejaculation (see *ejaculation, disorders of*). Rarely, male infertility is due to a chromosomal abnormality, such as *Klinefelter's syndrome*, or a genetic disease, such as *cystic fibrosis*.

FEMALE INFERTILITY

The most common cause of female infertility is failure to ovulate. Other causes are blocked, damaged or absent *fallopian tubes*; disorders of the uterus, such as *fibroids* and *endometriosis*; problems with *fertilization*; or difficulties with implantation in the uterus (see *implantation, egg*). Infertility also occurs if the woman's cervical mucus contains antibodies that kill or immobilize her partner's sperm. Rarely, a chromosomal abnormality, such as *Turner's syndrome*, is the cause of a woman's infertility.

INVESTIGATION

The initial investigation performed for male infertility is *semen analysis*, which

INVESTIGATING INFERTILITY

First, a general check-up and/or a personal interview regarding sexual behaviour are carried out. If no cause for infertility is found at this stage, more specialized tests may be performed.

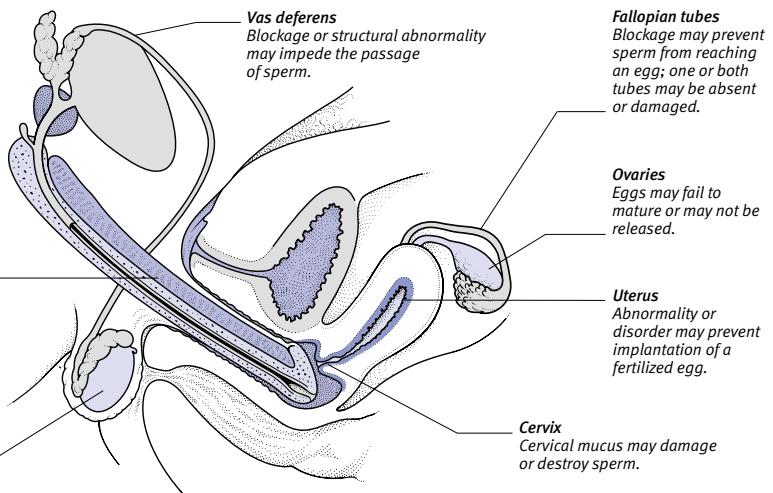

It is important that both partners are tested for infertility, because infertility can be attributed to one person, to both people, or to mutual incompatibility.

CAUSES OF INFERTILITY

Conception is a complicated process; the reproductive organs can be affected in numerous ways, resulting in infertility. Some of the principal underlying causes of infertility in men and in women are illustrated on the right.

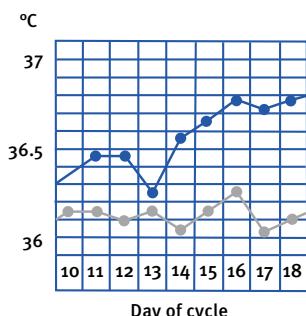

Penis
There may be failure to achieve or maintain an erection, or abnormality of ejaculation.

Testes
Too few sperm may be produced; sperm could be abnormally shaped, too short-lived, or have impaired motility.

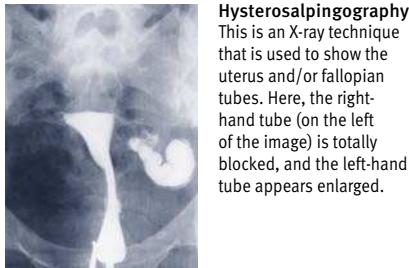

FEMALE INFERTILITY

Investigations to discover the cause of a woman's infertility may include taking a menstrual history and a study of the woman's body temperature during her menstrual cycle (below). There may also be blood and urine tests to discover whether ovulation is normal, hysterosalpingography (right), and/or laparoscopy (below right).

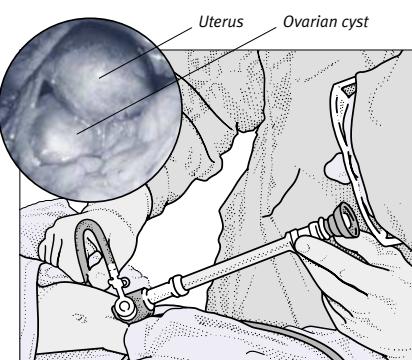

Body temperature and ovulation

Charting the changes in a woman's body temperature during her menstrual cycle can reveal abnormalities of ovulation. The chart above shows typical daily temperature fluctuations during a normal menstrual cycle (blue line) and temperature changes associated with failure to ovulate (grey line).

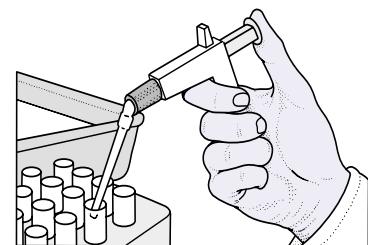

Hysterosalpingography
This is an X-ray technique that is used to show the uterus and/or fallopian tubes. Here, the right-hand tube (on the left of the image) is totally blocked, and the left-hand tube appears enlarged.

Laparoscopy
In this technique, a laparoscope (a type of viewing tube) is inserted through the abdominal wall to examine the woman's reproductive organs and determine whether an abnormality or disorder, such as blocked fallopian tubes or endometriosis, is present. The laparoscopic view above shows an ovarian cyst.

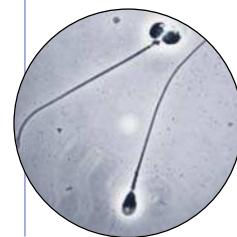

MALE INFERTILITY

The first test for investigating male infertility is semen analysis (below). If it reveals a low sperm count, more tests may be needed to investigate the underlying cause.

Semen analysis

Semen produced by masturbation is examined as soon as possible, and the number, shape, and degree of motility (movement) of the sperm are determined. A postcoital semen test may also be performed.

Abnormal sperm
If a man's semen contains large numbers of abnormally shaped sperm, such as the two-headed one at the top of this image, his fertility may be reduced.

includes a sperm count. Investigations to discover the cause of a woman's infertility may include blood and urine tests to check that ovulation is occurring, ultrasound scanning or X-ray examinations to assess whether the fallopian tubes are blocked, and *laparoscopy* to determine if a condition, such as *endometriosis*, is present.

TREATMENT

Treatment of male infertility is limited. The only option for men with azoospermia is adoption of children or *artificial insemination* by a donor. If the sperm count is low, artificial insemination by the male partner or, alternatively, *in vitro fertilization* (IVF) with *intracytoplasmic sperm injection* may be tried. In some cases of male infertility, *gonadotrophin hormone* therapy may prove useful.

Failure of the woman to ovulate requires ovarian stimulation with a drug such as clomifene, given either with or without a gonadotrophin hormone. *Microsurgery* can sometimes repair damage to the fallopian tubes. If surgery is unsuccessful, IVF is an option. Uterine abnormalities or disorders, such as fibroids, may require treatment. In some cases, provided the woman has normal fallopian tubes, either *gamete intra-fallopian transfer* (GIFT) or *zygote intrafallopian transfer* (ZIFT) may be carried out.

infestation

The presence of animal parasites (such as mites, ticks, or lice) in the skin or hair, or of worms (such as tapeworms) inside the body.

infibulation

A form of female circumcision in which the labia majora (the outer lips surrounding the vagina) are removed and the entrance to the vagina narrowed (see *circumcision, female*).

infiltrate

The term used for a build-up of substances or cells within a tissue that are either not normally found in it or are usually present only in smaller amounts.

The word "infiltrate" may also refer to a drug (such as a local anaesthetic) that has been injected into a tissue, or to the build-up of a substance within an organ (for example, fat in the liver caused by excessive alcohol consumption). In addition, radiologists use the term to refer to the presence of abnormalities, most commonly on a *chest X-ray*, due to conditions such as infection.

infirmity

A term meaning frailty, weakness or lack of strength. It is most commonly used in relation to illness or old age.

inflammation

Redness, swelling, heat, and pain in a tissue due to injury or infection. When body tissues are damaged, *mast cells* release the chemical *histamine* and other substances. Histamine increases the flow of blood to the damaged tissue and also makes the blood capillaries more leaky; fluid then oozes out and into the tissues, causing localized swelling. The inflammatory chemicals stimulate the nerve endings, causing pain. Inflammation is usually accompanied by a local increase in the number of white blood cells. These cells help to destroy invading microorganisms and are involved in repairing the damaged tissue.

Inflammation may be suppressed by *corticosteroid drugs* or by *nonsteroidal anti-inflammatory drugs*.

inflammatory bowel disease

A collective term for chronic disorders that affect the small and/or the large intestine and cause abdominal pain, bleeding, and diarrhoea. *Crohn's disease* and *ulcerative colitis* are the most common types of inflammatory bowel disease.

inflammatory oedema

A term sometimes used to describe the swelling associated with *inflammation*, such as the swelling that develops around a cut as it heals.

infliximab

A drug that inhibits the activity of tumour necrosis factor (TNF), a chemical released by *lymphocytes* causing tissue damage and pain. Such drugs are known as TNF blockers or anti-TNF drugs. Infliximab is used to treat severe *rheumatoid arthritis* and *Crohn's disease* that have not responded to other drug treatment.

influenza

Popularly known as "flu", a viral infection of the respiratory tract (air passages). Influenza is spread by infected droplets from coughs or sneezes. It usually occurs in small outbreaks or every few years in epidemics.

CAUSES

There are three main types of influenza virus: A, B, and C. A person who has had an attack caused by the type C virus acquires *antibodies* that provide immu-

nity against type C for life. Infection with a strain of type A or B virus produces immunity only to that particular strain. Type A and B viruses, however, are capable of altering to produce new strains; type A has been the cause of *pandemics* (disease outbreaks affecting millions of people) in the last century.

SYMPTOMS AND COMPLICATIONS

Types A and B produce classic flu symptoms: fever, headache, muscle aches, and weakness. Type C causes a mild illness indistinguishable from a common cold.

Flu usually clears up completely within 7–10 days. Rarely, however, it takes a severe form, causing acute *pneumonia* that may be fatal within a day or two, even in healthy young adults.

Type B infections in children sometimes mimic *appendicitis*, and they have been implicated in *Reye's syndrome*. In elderly people and those with lung or heart disease, influenza may be followed by a bacterial infection such as *bronchitis* or *pneumonia*.

TREATMENT

Analgesics (painkillers) help to relieve aches and pains and reduce fever. Anti-viral drugs such as zanamivir may be used to treat at-risk people who develop flu; to be effective, treatment must be started within 48 hours of symptoms appearing. *Amantadine* may be used in specific cases for prevention during an outbreak of flu. *Antibiotics* may be used to combat secondary bacterial infection.

PREVENTION

Flu vaccines, containing killed strains of the types A and B virus in circulation, are available, but have only a 60–70 per cent success rate. The immunity that they provide is only short-lived and vaccination (recommended for older people, anyone suffering from respiratory or circulatory problems, chronic renal failure or diabetes mellitus as well as key health workers) must be repeated annually.

informed consent

See *consent*.

infra-

A prefix meaning "below", commonly used in medical terminology.

infrapatellar bursitis

Inflammation of the *bursa* (fluid-filled sac) that lies below the *patella* (kneecap) and over the top of the *tibia* (shinbone) acting as a cushion against friction. The condition is usually the result of prolonged kneeling in an upright position

(which it is why it is sometimes called “clergyman’s knee”). Infrapatellar bursitis is similar to prepatellar bursitis, or *housemaid’s knee*; however, this second condition often results from prolonged kneeling while leaning forwards, which puts excessive pressure on the bursa that lies in front of the kneecap.

Infrapatellar bursitis causes swelling and pain. Knee movement may also be restricted. The swelling usually reduces with rest; *nonsteroidal anti-inflammatory drugs* may help to relieve the discomfort. For persistent symptoms, a doctor may drain the fluid from the bursa and inject a *corticosteroid drug* into the sac. Frequent changes in position and use of foam padding is recommended.

infra-red

A term denoting the part of the electromagnetic spectrum that is immediately beyond the red end of the visible light spectrum (see *colour vision*).

Infra-red radiation is directed on to the skin and heats the skin and the tissues immediately below it. An infra-red lamp is one means of giving *heat treatment* to promote healing from injuries and inflammatory conditions.

infundibulum

The medical term for a funnel-shaped passage or structure. Specifically, infundibulum refers to the short stalk carrying nerve fibres connecting the *hypothalamus* in the brain to the *pituitary gland*.

infusion, intravenous

See *intravenous infusion*.

ingestion

The act of taking any substance (for example, food, drink, or medications) into the body through the mouth. The term “ingestion” also refers to the process by which certain cells (for example, some white blood cells) surround and then engulf small particles.

ingrowing toenail

See *toenail, ingrowing*.

inguinal

A word relating to the groin (the area between the abdomen and thigh), as in *inguinal hernia*.

inguinal hernia

A type of *hernia* in which part of the intestine protrudes through the abdominal wall in the groin. It can be either

direct or indirect. In a direct inguinal hernia, there is a localized weakness in the abdominal wall through which the intestine pushes. In an indirect inguinal hernia the intestine protrudes through the inguinal canal (in males the passage through which the testes descend into the scrotum). An indirect inguinal hernia may also occur in females.

inhalation

The act of taking in breath (see *breathing*). An inhalation is also a medication designed to be breathed in and prepared in the form of a gas, vapour, powder, or aerosol.

inhaler

A device used for administering a drug in powder or vapour form. Inhalers are used mainly in the treatment of various respiratory disorders, including *asthma* and *chronic bronchitis*. Metered-dose inhalers deliver a precise dose when the inhaler is pressed. Drugs taken by inhalation include *bronchodilators* and *corticosteroids*. See the illustrated box for information on using an inhaler.

inheritance

The transmission of characteristics and disorders from parents to their children through the influence of *genes*. Genes

are the units of *DNA* (deoxyribonucleic acid) that are contained in a person’s cells; DNA controls all aspects of the body’s growth and functioning. Half of a person’s genes come from the mother and half from the father.

GENES AND CHROMOSOMES

Genes are organized into *chromosomes* (long, thread-like structures) in the cell nucleus. Genes controlling most characteristics come in pairs, one from each parent. Every individual has 22 pairs of chromosomes (called *autosomes*), with each chromosome in a pair bearing one of the paired genes. In addition, there are two sex chromosomes: females have two X chromosomes, and males have an X and a Y chromosome.

MECHANISMS OF INHERITANCE

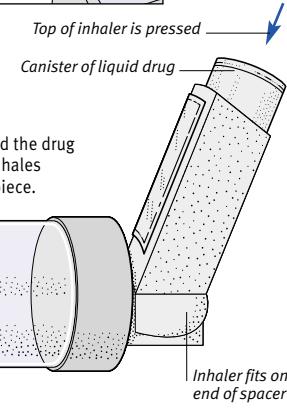

Most physical characteristics, many disorders, and some mental abilities and aspects of personality are inherited. The inheritance of normal traits and disorders can be divided into three groups: those that are controlled by a single pair of genes on the autosomal chromosomes (unifactorial inheritance); those that are controlled by genes on the sex chromosomes (sex-linked inheritance, such as haemophilia); and those that are controlled by the combination of many genes (multifactorial inheritance, such as height).

HOW TO USE A METERED-DOSE INHALER

The user puts the mouthpiece of the inhaler in the mouth, presses the end, and simultaneously breathes in through the mouth. If the device is used correctly, the drug is dispersed to the bronchi. Young children, or people who find it difficult to use an inhaler, can use a spacer. A *nebulizer* is a device that delivers the drug directly as a fine mist, through a face-mask or mouthpiece, over several minutes.

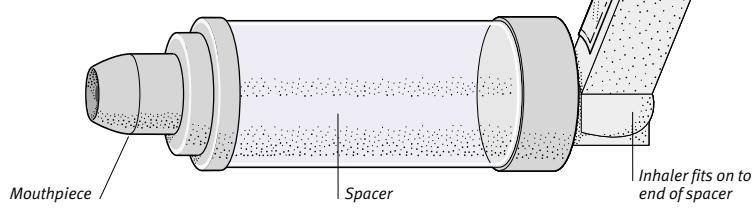

Aerosol inhaler
This type of inhaler delivers a dose of the drug as an aerosol spray when the user presses the top of the inhaler.

Spacer

The inhaler fits on to the spacer and the drug dose is released into it. The user inhales normally from the spacer’s mouthpiece.

UNIFACTORIAL INHERITANCE

Either of the pair of genes controlling a trait may take any of several forms, known as *alleles*.

For example, the genes controlling eye colour exist as two main alleles, coding for blue and brown eye colour. The brown allele is dominant over blue in that it "masks" the blue allele, which is described as "recessive" to the brown allele. Only one of the pair of genes controlling a trait is passed to a child from each parent. For example, someone with the brown/blue combination for eye colour has a 50 per cent chance of passing on the blue gene, and a 50 per cent chance of passing on the brown gene, to any child. This factor is combined with the gene coming from the other parent, according to dominant or recessive relationships, to determine the child's eye colour. Certain genetic disorders are also inherited in a unifactorial manner (for example, *cystic fibrosis* and *achondroplasia*).

SEX-LINKED INHERITANCE

Sex-linked inheritance depends on the two sex chromosomes, X and Y. The most obvious example of this type of inheritance is gender of an individual. Male gender is determined by genes on the Y chromosome, which is present only in males.

Any faults in a male's genes on the X chromosome tend to be evident because there is no second, normal X chromosome that would mask the faults (as there is in females). Faults in the genes of the X chromosome include those responsible for colour vision deficiency, haemophilia, and other sex-linked inherited disorders, which almost exclusively affect males.

MULTIFACTORIAL INHERITANCE

Multifactorial inheritance, along with the effects of environment (such as diet and exposure to diseases or toxins), may play a part in causing certain disorders, such as *diabetes mellitus* and *neural tube defects*.

inhibition

The process of preventing any mental or physical activity. Inhibition in the brain and spinal cord is carried out by certain *neurons* (nerve cells), which damp down the action of other nerve cells in order to keep the brain's activity in balance.

In *psychoanalysis*, the term "inhibition" refers to the unconscious restraint of instinctual impulses.

injection

Introduction of a substance into the body from a syringe via a needle. Injections may be intravenous (where

they are given into a vein); intramuscular (into a muscle); intradermal (into the skin); subcutaneous (into the tissue layer under the skin); or intra-articular (into a joint).

injury

Physical harm to any part of the body. Injury may have many possible causes, including environmental influences (for example, force, heat, cold, electricity, vibration, and radiation), chemical causes (such as poisons), bites, or oxygen deprivation.

ink-blot test

An outdated psychological test in which the subject was asked to interpret the appearance of a number of ink blots; the person's responses were thought to reveal aspects of mental function such as emotions and psychological conflicts. The most widely used example was the *Rorschach test*.

inlay, dental

A filling of porcelain or gold used to restore a badly decayed tooth where the cavity is too big to receive amalgam. An inlay may be needed for the back teeth or to protect a weakened tooth.

innate

A term to describe a condition or trait that is present from birth (see *congenital*).

inner ear

The deepest part of the *ear*, lying closest to the brain, that contains the organs of hearing and balance. The inner ear registers air vibrations and other sensory stimuli, such as head movement; cells convert the information into electrical impulses, which pass along nerves to the brain. The other parts of the ear are the outer and middle ear.

innervation

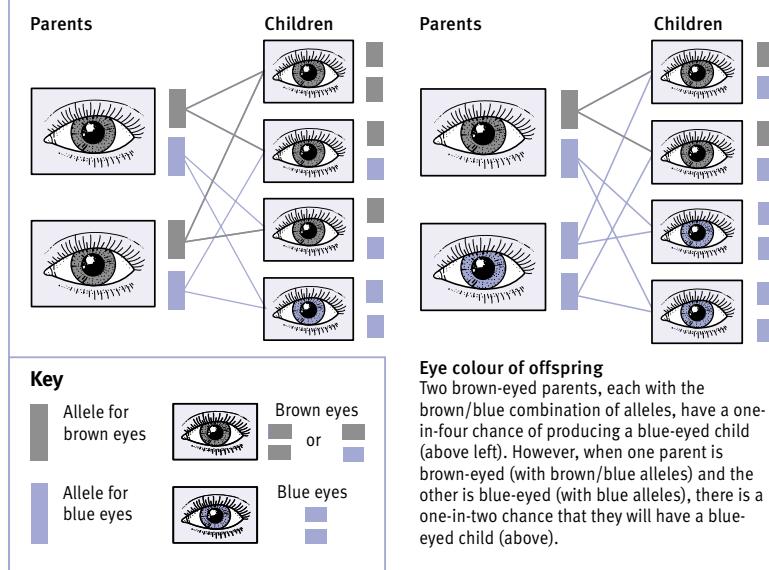

A term meaning the supply of nerves to an organ or other part of the body.

innocent murmur

A *murmur* (a sound made by blood flow through the heart, as heard through a stethoscope) that is not due to any disease of the heart or its valves. Innocent heart murmurs are commonly found in children and may be more noticeable after exercise or during a fever. If there is any doubt about the significance of a murmur, tests such as *echocardiography* or *ECG* may be requested.

INHERITANCE OF EYE COLOUR

Eye colour is determined by two main alleles (forms of a gene), one coding for brown eyes and the other for blue eyes. The brown allele is dominant to the blue one (which is therefore recessive).

inoculation

The act of introducing a small quantity of a foreign substance into the body, usually by injection, for the purpose of stimulating the *immune system* to produce *antibodies* (protective proteins) against the substance, a process known as active *immunity*. Inoculation is usually done to protect individuals against future infection by particular bacteria or viruses (see *immunization*).

inoperable

A term applied to any condition that cannot be alleviated or cured by surgery, particularly cancers.

inorganic

A term used to refer to any of the large group of substances that do not contain carbon. Some examples of inorganic substances include table salt (sodium chloride) and bicarbonate of soda (sodium bicarbonate). The term “inorganic” is also applied to a few of the most simple carbon compounds, such as *carbon dioxide* and *carbon monoxide*.

inotropic

A term used to refer to anything that affects the force or energy of muscular contractions, either positively (strengthening the contractions) or negatively (weakening the contractions).

Inotropic drugs are drugs that stimulate, and increase the force of, heart muscle contractions. Inotropic drugs are sometimes needed immediately after a *myocardial infarction* (heart attack) to maintain blood pressure and tissue circulation. In such cases, drugs such as *dopamine* and *dobutamine* are given by intravenous infusion. In cases of *chronic heart failure*, *digitalis drugs*, and especially *digoxin*, may be used for the same purpose.

inpatient treatment

Care or therapy in hospital following patient admission.

inquest

An official inquiry by a *coroner* into a death that is of unknown cause or is suspected of being unnatural.

INR

The abbreviation for *International Normalized Ratio*, a measure used in the management of *anticoagulant drugs*. It allows for uniform measurement of the anticoagulation status of patients.

insanity

A term commonly used for serious mental disorder. Although used legally, the term has no real technical meaning.

insect bites

Puncture wounds inflicted by bloodsucking insects such as gnats, mosquitoes, fleas, and lice. Most bites cause only temporary pain or itching, but some people have severe skin reactions. In the tropics and subtropics, insect bites are potentially more serious because certain biting species are capable of transmitting disease (see *insects and disease*).

All insect bites provoke a skin reaction to substances in the insect's saliva or faeces, which may be deposited at or near the site of the bite. Reactions vary from red pimples to painful swellings or an intensely itching rash. Some insects, such as bees and wasps, have stings (see *insect stings*) that can produce fatal allergic reactions. (See also *lice; spider bites; mites and disease; ticks and disease*.)

insecticides

See *pesticides*.

insects and disease

Relatively few insect species cause disease directly in humans. Some parasitize humans, living under the skin or on the body surface (see *lice; chigoe; myiasis*). The most troublesome insects are flies and biting insects. Flies can carry infectious microorganisms from human or animal excrement via their feet or legs and contaminate food or wounds.

A number of serious diseases are spread by biting insects. These disorders include *malaria* and *filariasis* (transmitted by mosquitoes), *sleeping sickness* (from tsetse flies), *leishmaniasis* (sandflies), epidemic *typhus* (lice), and *plague* (rat fleas). Mosquitoes, sandflies, and ticks can also spread illnesses such as *yellow fever*, *dengue*, *Lyme disease*, and some types of viral *encephalitis*. Organisms picked up when an insect ingests blood from an infected animal or person are able to survive or multiply in the insect. Later, the organisms are either injected into a new human host via the insect's saliva or deposited in the faeces at or near the site of the bite.

Most insect-borne diseases are confined to the tropics and subtropics, although tick-borne Lyme disease occurs in some parts of the UK.

PREVENTION

The avoidance of insect-borne disease is largely a matter of keeping flies off food, discouraging insect bites by the use of suitable clothing and insect repellents, and, in parts of the world where malaria is present, the use of mosquito nets and screens, *pesticides*, and antimalarial tablets.

insect stings

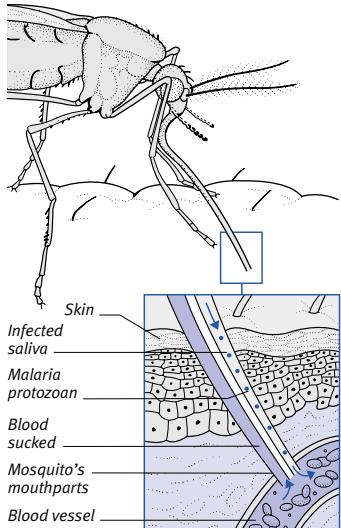

Reactions that are produced by the *stings* of insects such as bees and wasps. Venom injected by the insect contains inflammatory substances that cause local pain, redness, and swelling for about 48 hours.

A sting in the mouth or throat is dangerous because the swelling may obstruct breathing. A severe allergic reaction can occur in response to insect venom, leading to *anaphylactic shock*. A procedure known as *hyposensitization* is sometimes recommended for such individuals.

If the symptoms of anaphylactic shock develop, it is essential to seek emergency medical treatment. Anyone

INSECT-BORNE DISEASES

Malaria is by far the most prevalent of the insect-borne diseases, causing about 300 million acute illnesses and 1 million deaths each year.

Transmission of malaria

When an infected *Anopheles* mosquito feeds on a person's blood, it injects saliva through its mouthparts to stop the blood from clotting; the protozoa that cause malaria enter the blood via the insect's saliva.

who is known to be hypersensitive to bee or wasp venom should obtain and carry an emergency kit for the self-injection of *adrenaline* (epinephrine).

insecurity

Lack of self-confidence and uncertainty about one's abilities, aims, and relationships with others. A feeling of insecurity may be a feature of *anxiety* and other neurotic mental disorders.

insemination

The term used for the introduction of a man's *semen* into a woman's *uterus*. Insemination may occur through *sexual intercourse* or by the use of instruments as part of *infertility* treatment (see *artificial insemination*).

insight

Being aware of one's own mental state. In a general sense, "insight" means knowing one's own strengths, weaknesses, and abilities.

The term also has the specific psychiatric meaning of knowing that one's symptoms are an illness. Loss of insight may be a feature of psychotic disorders (see *psychosis*).

in situ

A Latin term meaning "in place". The phrase "carcinoma *in situ*" is used to describe tissue (particularly of the skin or cervix) that is cancerous only in its surface cells.

insomnia

A regular inability to fall asleep or stay asleep, leading to excessive tiredness.

CAUSES

The most common cause of insomnia is stress, but other causes include physical symptoms such as a cough, itching, or conditions such as *restless legs*. Environmental and lifestyle factors or misuse of *sleeping drugs* are also common causes. Insomnia can be a symptom of a psychiatric illness, such as *anxiety* and/or *depression*. Withdrawal symptoms from *antidepressants*, *antianxiety drugs*, sleeping drugs, and some illicit drugs (see *drug abuse*) may also cause insomnia.

PREVENTION AND TREATMENT

People with insomnia should ensure that they get sufficient exercise during the day and moderate their alcohol and caffeine intake. They should also avoid eating late at night and should establish regular routines and times for going to bed and waking.

Sleeping drugs should be used only on medical advice. Possible complementary therapies for insomnia include *acupuncture* and *aromatherapy* using lavender oil. (See also *nightmares*; *night terrors*; *sleepwalking*.)

inspiratory capacity

The volume of air that can be drawn into the lungs in a maximum inhalation following a normal expiration.

inspiratory reserve volume

The volume of air that can be drawn into the lungs beyond the end of a normal inhalation.

inspiratory stridor

A harsh, high-pitched sound heard on inhaling. Inspiratory stridor is associated with damage to or a disorder of the respiratory tract, particularly in the area of the *larynx* (voice-box). (See also *expiratory stridor*; *stridor*.)

inspissation

Thickening or drying up of secretions as a result of dehydration or evaporation. Inspissated secretions in the airways, for example, can lead to blockage and collapse of areas of lung tissue.

instep

The arched area of the *foot* between the heel and ball of the foot.

instinct

An innate primitive urge. The need for warmth, food, love, and sex are all forms of instinct, but the instinct for survival is probably the most powerful. An instinct is different from a *reflex*, which is an involuntary response to a stimulus (such as withdrawing quickly from a source of pain).

institutionalization

Loss of personal independence that stems from living for long periods under a rigid regime, such as in a prison or other large institution. Apathy, obeying orders unquestioningly, accepting a standard routine, and loss of interests are the main features.

insufficiency

The inability of an organ or body part to perform its intended function. In hepatic insufficiency, for example, the liver cannot carry out its normal work (see *liver failure*). In another example, venous insufficiency, which usually

affects the legs, the blood does not drain adequately through the veins; this condition can sometimes lead to swelling and leg *ulcers*.

insufflation

A technique in which air, another type of gas, or powder is blown into a body cavity. Insufflation may be used during medical investigations in order to make the viewing of organs easier or to identify blockages. In *laparoscopy*, for example, the abdomen is insufflated using carbon dioxide.

insulin

A hormone produced by clusters of cells in the *pancreas*, known as the *Islets of Langerhans*, that regulates the level of *glucose* in the blood. It is produced continuously, but the amount increases in response to a raised glucose level after a meal. Insulin is essential if glucose is to be absorbed into cells where it is converted into energy. Insulin thus prevents a buildup of glucose in the blood and ensures that tissues have sufficient amounts of glucose.

Failure of insulin production results in *diabetes mellitus*. An *insulinoma* is a rare tumour that causes excessive production of insulin and consequent attacks of *hypoglycaemia* (an abnormally low blood glucose level).

INSULIN THERAPY

Insulin replacement, self-administered by injection or through an infusion pump (see *pump, insulin*), is used in the treatment of *diabetes mellitus*. Insulin cannot be taken orally because it is destroyed by stomach acid. This treatment prevents *hyperglycaemia* (high blood glucose) and *ketosis* (a buildup of acids in the blood), which, in severe cases, may cause coma. Human insulin preparations are produced by *genetic engineering*, although older beef or pork insulins are still available.

To high a dose of insulin will cause *hypoglycaemia*, which can be reversed by consuming food or a sugary drink. Severe hypoglycaemia may cause coma, for which emergency treatment with an intravenous injection of glucose, or *glucagon* (a hormone that opposes the effects of insulin) given into a muscle, vein, or subcutaneously is necessary.

insulinoma

A rare noncancerous tumour of the insulin-producing cells of the *pancreas*. The tumour causes abnormal quantities

of insulin to be produced, with the result that the amount of glucose in the blood can fall to dangerously low levels (*hypoglycaemia*). Unless sugar is given immediately, this situation can cause *coma* and death. Once the condition has been diagnosed, a drug (diazoxide) is given to prevent hypoglycaemia from occurring until the tumour is removed.

insulin resistance

An impaired response of body cells to the effects of *insulin*, a hormone produced by the *pancreas* to regulate blood sugar levels. The most common cause of mild insulin resistance is obesity; and sensitivity is regained with weight loss. In type 2 *diabetes mellitus*, raised blood glucose levels are partly due to insulin resistance, but also to a reduced capacity to produce insulin.

Insulin resistance is also a feature of other conditions, such as *polycystic ovary syndrome* and *acanthosis nigricans*. People with unstable diabetes occasionally require massive doses of insulin to achieve a reduction in blood sugar. In such cases, the cause of the insulin resistance is often not known.

insulin shock

An uncommon term for *hypoglycaemia* (abnormally low blood glucose levels).

Intal

A brand name for inhaled *sodium cromoglicate*, an *antiallergy drug* commonly used to prevent *asthma*.

intelligence

The ability to understand concepts and to reason them out. Intelligence can also be considered as having three separate forms: abstract (understanding ideas and symbols); practical (aptitude in dealing with practical problems such as repairing machinery); and social (coping reasonably and wisely with human relationships).

Intelligence has been shown to be partly inherited, although the environment (including early nutrition) also plays a major part, as does physical health and personality. Intelligence increases up to the age of about six years and then stabilizes. Intelligence quotient (IQ), as measured by *intelligence tests*, continues to increase to about the age of 26, stays the same until about the age of 40, and then gradually declines.

Examples of extremes of intelligence occur in people with *learning difficulties* (as defined by a low IQ) and gifted people (as defined by IQ scores over 130).

intelligence quotient (IQ)

See *intelligence tests; IQ*.

intelligence tests

Tests designed to provide an estimate of a person's mental abilities. The most widely used are Wechsler tests. There are two basic types: the Wechsler Adult Intelligence Scale (WAIS) and the Wechsler Intelligence Scale for Children (WISC). Each is divided into verbal (language skills) and performance sections including measures of visual-spatial and perceptual ability (interpretation of shapes) and constructional ability. Other tests include the Stanford-Binet test, used mainly as a measure of scholastic ability.

In most intelligence tests, scoring is based on mental age (MA) in relation to chronological age (CA). The intelligence quotient (IQ) is MA divided by CA, multiplied by 100. The tests are devised to ensure that 3 in 4 people have an IQ between 80 and 120. They are standardized so that the score indicates the same relative ability at different age levels.

Intelligence tests may be used to assess school or job aptitude. They have, however, been criticized for their alleged bias regarding gender and race.

intensive care unit

A medical facility in which critically ill patients are given intensive care (constant close monitoring and treatment).

Intensive care units (ICUs), sometimes called intensive treatment/therapy units (ITUs), contain electronic equipment to monitor vital functions such as blood pressure and heart rate. Blood pressure is monitored by an automatic sphygmomanometer, and heart rate and rhythm by an ECG machine. Frequently, patients in ICUs require mechanical *ventilation*, in which a machine takes over or assists with breathing. Urine is collected via a catheter. Urine output, fluid balance, and blood chemistry are recorded regularly and fluids are given intravenously. If nutrients are needed, they are supplied directly to the stomach through a tube or are administered intravenously. Body fluids and blood sugar levels are maintained by intravenous infusion of salts and glucose. Monitors are fitted with alarms to alert the staff to any dangerous fluctuations.

Intensive care unit

An intensive care unit has sophisticated equipment for constant monitoring of a seriously ill patient. He or she is usually sedated and connected to a ventilator to maintain breathing.

An ICU contains a high ratio of specially trained nursing and medical staff to patients, enabling treatment to be tailored to a patient's condition as it changes. (See also *coronary care unit*.)

intention tremor

A form of *tremor* (involuntary, rhythmic shaking of the muscles) occurring only when a person tries to carry out a conscious movement, such as touching or picking up an object. The tremor worsens as the object is approached. The condition is usually due to disease or damage affecting the *cerebellum* (the area at the back of the brain responsible for coordinating movement).

inter-

A prefix that means between, as in *intercostal* (between the ribs). (See also *intra-*.)

intercostal

A term meaning "between the ribs", as in the intercostal muscles, thin sheets of muscle between each rib.

intercourse, painful

Pain during *sexual intercourse*, known medically as *dyspareunia*, which can affect both men and women. Pain may be superficial (around the external genitals) or deep (within the pelvis).

CAUSES

In men, superficial pain may be due to anatomical abnormalities such as *chordee* (bowed erection) or *phimosis* (tight

foreskin). *Prostatitis* (inflammation of the prostate gland) may cause a widespread pelvic ache, a burning sensation in the penis, or pain on ejaculation.

In women, one possible cause of pain is scarring (after childbirth, for example) and lack of vaginal lubrication, especially after the *menopause*. *Psychosocial dysfunction* may also cause pain during intercourse. *Vaginismus*, a condition in which the muscles of the vagina go into spasm, is usually psychological in origin. Deep pain is frequently caused by pelvic disorders (such as *fibroids*, *endometriosis*, *ectopic pregnancy*, or *pelvic inflammatory disease* due to sexually transmitted infections), disorders of the ovary (such as *ovarian cysts*), and disorders of the *cervix*. Other causes of deep and superficial dyspareunia are *cystitis* and *urinary tract infections*.

TREATMENT

Treatment of painful intercourse is directed at the underlying cause of the pain. If the discomfort is psychological in origin, special counselling may be needed (see *sex therapy*).

intercurrent

A term used to describe a condition, usually an infection, that develops in a person who is already suffering from another disorder.

interdigital

A term meaning between two fingers or toes. Interdigital is used to refer to the skin in such an area.

interferon

One of a group of proteins produced naturally by body cells in response to viral infections and other stimuli. Interferon inhibits viral multiplication and increases the activity of *natural killer cells* (a type of lymphocyte that is part of the *immune system*). The substance may also be produced artificially for use as a drug in the treatment of various disorders. Interferon has to be given by injection.

There are three main types: interferon alfa, beta, and gamma. Interferon alfa is used in the treatment of certain *lymphomas*, a type of *leukaemia*, and chronic *hepatitis B* and *C*. Peginterferon, a modified form of interferon alfa, remains in the circulation longer and is used particularly in the treatment of hepatitis C. Interferon beta is used to treat some patients with relapsing *multiple sclerosis*. Interferon gamma is used

in the treatment of a rare condition called chronic granulomatous disease.

Adverse reactions to interferons are common including fever, headaches, lethargy, depression, and dizziness.

interleukin

One of a group of proteins that occur naturally in the body. Interleukins are involved in the production of different types of *blood cells* and also help to regulate the *immune system*. At least 18 different interleukins have been identified. One form of interleukin, known as interleukin-2 or aldesleukin, is believed to slow the progress of *kidney cancer*. However, it often has very severe side effects, including damage to the brain and bone marrow and leakage of fluid into the lungs.

intermenstrual bleeding

Bleeding from the vagina between menstrual periods (see *menstrual cycle*). The condition may be due to a disorder of the uterus, but is also a common side effect of oral contraception (see *breakthrough bleeding*).

intermenstrual pain

Pelvic pain occurring between menstrual periods, which may be due to a variety of causes. In one type, pain occurs in the middle of the *menstrual cycle*, around the time of ovulation (see *mittelschmerz*).

intermittent claudication

Cramping pain in the legs due to inadequate blood supply (see *claudication*).

intermittent positive pressure ventilation (IPPV)

A form of mechanical *ventilation* in which air is delivered into a person's lungs under pressure and in short bursts, to simulate intakes of breath. IPPV can be administered through a tube into a lung, which may be carried out in an *intensive care unit*. A similar procedure of continuous positive airway pressure (CPAP) can be delivered by mask to treat *sleep apnoea*.

internal cardiac massage

A procedure carried out during surgery on the chest to maintain circulation if the heart has stopped beating (see *cardiac massage*). In internal cardiac massage, the surgeon reaches into the open rib cage and squeezes the heart directly with his or her hands.

internal fixation

A procedure for treating fractured bones (see *fracture*) by surgically inserting metal plates, pins, rods, or wires to hold the broken bone ends together. The procedure is used to treat severe fractures that cannot be stabilized by other means. Once the bone has healed, the devices used for internal fixation are often left in place if they are not causing any problems. In some cases, however, it is necessary to remove them in another operation.

internal haemorrhoids

Swollen veins that develop within the rectum (see *haemorrhoids*).

International Normalized Ratio (INR)

A measure introduced by the World Health Organization to standardize the control of *anticoagulant drug* therapy internationally. The ratio is based on comparing the prothrombin time (see *blood-clotting tests*) of a patient's blood with a control time.

intersex

A group of abnormalities in which the affected person has ambiguous genitalia (abnormal external sex organs) or external genitalia that have the opposite appearance to the chromosomal sex of the individual (see *sex determination*).

interstitial

A word used medically to refer to gaps (interstices) between cells, tissues, or other body structures. For example, *tissue fluid* between the body cells is called interstitial fluid. (See also *interstitial radiotherapy*.)

interstitial cystitis

A chronic inflammation of the bladder lining that causes pain and a frequent urge to pass urine. An *ulcer* usually develops in the bladder wall and, eventually, the bladder muscles thicken and contract (shorten).

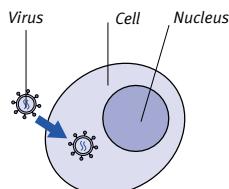

Interstitial cystitis is most likely to occur in women. Unlike most other bladder inflammation (see *cystitis*) the disorder is not due to bacterial infection and the cause is unknown.

The disorder is difficult to treat. In a procedure carried out under general anaesthesia, the bladder may be stretched by being filled with water or other liquids. *Anti-inflammatory drugs* may also be given as a treatment.

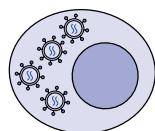

HOW INTERFERON FIGHTS VIRAL INFECTIONS

Interferon is part of the body's immune system, providing a defence against many different types of virally infected cells or tumour cells. It is produced naturally in the body during viral infections, but can also be administered as a drug to enhance its natural actions.

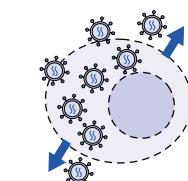

VIRAL MULTIPLICATION

1 A virus can multiply only by first invading one of its host's cells.

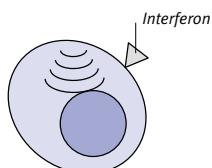

2 The genetic material of the virus takes over the cell's chemical machinery to make copies of the virus.

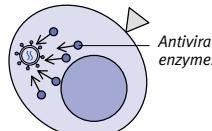

3 The copies of the virus escape, killing the host cell, and invade more cells.

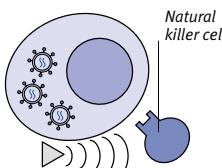

HOW INTERFERON WORKS

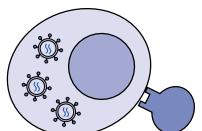

1 Interferon attaches to the membrane of host cells and primes them against viral attack.

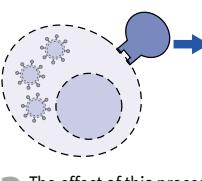

2 If a virus invades a cell primed by interferon, enzymes are produced that impair viral copying.

1 Interferon also causes natural killer cells to attack virally infected cells or tumour cells.

2 A natural killer cell attaches to the abnormal host cell and makes the cell disintegrate.

3 Being unable to copy itself, the virus is nullified, and the infection is either stopped altogether or shortened.

Transplantation of a single lung (see *transplant surgery*) may be considered. The outlook of occupational dust disease depends on the type of dust involved and the level of exposure. If IPF is due to an allergy, however, the condition can more easily be treated and the outlook is better.

INTERSTITIAL RADIOTHERAPY

Treatment of a cancerous tumour by inserting radioactive material into the cancerous growth or into neighbouring tissue. Using this method, which is a type of brachytherapy, radiation can be targeted at the diseased area.

Radioactive material (usually artificial radioisotopes) contained in wires, small tubes, or seeds is implanted into or near to the diseased tissue under general anaesthesia (see *anaesthesia, general*). The material is left in place for variable amounts of time depending on the radioactive substance and the tumour that is being treated. In some cases, such as in prostate cancer, the material is left in place permanently as the radiation decays after a relatively short period of time. (See also *radiotherapy*.)

INTERTRIGO

Inflammation of the skin due to two surfaces rubbing together. Intertrigo is most common in obese people. The affected skin is red and moist and may have an unpleasant odour, and is often accompanied by a fungal infection such as *candidiasis*; there may also be scales or blisters. The condition worsens with sweating.

Treatment consists of weight reduction and keeping the affected areas clean and dry. A cream containing *antifungal drugs*, with or without a *corticosteroid*, is used if candidiasis is found to be present.

INTERVERTEBRAL CARTILAGE

The strong tissue, also called fibrocartilage, that makes up the platelike, shock-absorbing discs between the bones of the spine (see *cartilage; disc, intervertebral*).

INTERVERTEBRAL DISC

See *disc, intervertebral*.

INTERVERTEBRAL FORAMEN

A natural opening between adjacent *vertebrae* (the spinal bones) in the spine formed by the space between

INTERSTITIAL PULMONARY FIBROSIS

Scarring of lung tissue mainly affecting the alveoli (the tiny air sacs in the lungs; see *alveolus, pulmonary*). Interstitial pulmonary fibrosis (IPF) may have various causes, including occupational exposure to mineral dusts; *fibrosing alveolitis* (an *autoimmune disorder* in which the immune system attacks the lung tissue); and an allergic reaction (see *allergy*) that causes inflammation of the alveoli.

SYMPTOMS AND DIAGNOSIS

Symptoms of interstitial pulmonary fibrosis include progressive shortness of breath, coughing, chest pain, and *clubbing* (abnormal thickening and broadening) of the fingertips. There may also be additional symptoms caused by any underlying disease.

The diagnosis of IPF is based on the symptoms and a physical examination; it is confirmed by *chest X-ray* and a *biopsy* (removal of a sample of lung tissue for microscopic examination).

TREATMENT AND OUTLOOK

Treatment for interstitial pulmonary fibrosis depends on the cause. Treatment for fibrosing alveolitis often includes use of immunosuppressant drugs and *corticosteroid drugs*, which suppress the activity of the immune system. However, there is no known treatment for localized fibrosis due to radiotherapy. In other cases, treatment is directed at the underlying cause.

For people with fibrosing alveolitis, the outlook is poor: the lungs become progressively stiffer and *heart failure* and *bronchopneumonia* may develop.

small notches in each side of the *vertebrae*. Such gaps are the exit points for the peripheral nerves branching from the *spinal cord*.

intestinal imaging

See *barium X-ray examinations*.

intestinal lipodystrophy

See *Whipple's disease*.

intestine

The major part of the digestive tract (see *digestive system*), extending from the exit of the stomach to the anus. It forms a long tube divided into two main sections: the small and large intestines.

SMALL INTESTINE

The small intestine is about 6.5 m in length and has three sections: the *duodenum*, the *jejunum* and the *ileum*. Partially digested food from the stomach is forced along the intestine by *peristalsis*.

The small intestine is concerned with the digestion and absorption of food. Digestive enzymes and *bile*, which break down food to release nutrients, are added to the partly digested food in the duodenum via the bile and pancreatic ducts (see *biliary system*). Glands within the walls of each section of the small intestine produce mucus and other enzymes, which also help to break down the food. Blood vessels in the intestinal walls absorb nutrients and carry them to the *liver* for distribution to the rest of the body.

LARGE INTESTINE

The large intestine is approximately 1.5 m long. The main section, the *colon*, is divided into an ascending, a transverse, a descending, and a pelvic portion (the sigmoid colon). The *appendix* hangs from a pouch (the *caecum*) between the small intestine and the colon. The final section before the *anus* is the *rectum*.

Unabsorbed material leaves the small intestine as liquid and fibre. As this material passes through the large intestine, water and mineral salts are absorbed into the bloodstream, leaving faeces that are made up of undigested food residue, fat, various secretions, and bacteria. The faeces are compressed and pass into the rectum for evacuation.

intestine, cancer of

A malignant tumour occurring in the small or the large intestine. Cancer of the small intestine is rare; cancer of the large intestine is one of the most common cancers (see *colon, cancer of*,

rectum, cancer of). Both the small and large intestine may develop carcinoid tumours (causing *carcinoid syndrome*) and *lymphomas*.

intestine, obstruction of

A partial or complete blockage of the small or large intestine.

CAUSES

Possible causes include a strangulated *hernia* (protrusion of the intestines through the abdominal wall); stenosis (narrowing) of the intestine, often due to cancer in the intestine; intestinal *atresia* (congenital closure); *adhesions* (scar tissue); *volvulus* (twisting of loops of bowel); and *intussusception* (in which the intestine telescopes inside itself). Intestinal obstruction can also occur in diseases that affect the intestinal wall, such as *Crohn's disease* or paralysis of the muscles in the intestinal wall (see *ileus, paralytic*).

Less commonly, an internal blockage of the intestine is caused by impacted food, *faecal impaction*, *gallstones*, or by an object of some kind that has been accidentally swallowed.

SYMPTOMS

A blockage in the small intestine usually causes intermittent cramplike pain in the centre of the abdomen with increasingly frequent bouts of vomiting and failure to pass wind or faeces. An obstruction in the large intestine causes pain, distension of the abdomen, and failure to pass wind or faeces.

TREATMENT

Treatments involve emptying the stomach via a *nasogastric tube* and replacing lost fluids through an intravenous drip in some instances, this measure will be sufficient to correct the problem. In many cases, however, surgery to deal with the cause of the blockage is necessary.

intestine, tumours of

Cancerous or noncancerous growths in the intestine. Cancerous tumours commonly affect the large intestine (see *colon, cancer of; rectum, cancer of*); the small intestine is only rarely affected. *Lymphomas* and carcinoid tumours (leading to *carcinoid syndrome*) may sometimes develop in the intestine. Noncancerous tumours include *polyps* in the colon,

DISORDERS OF THE INTESTINE

The intestine is subject to the effects of many infective organisms and parasites. It may also be affected by tumours, structural defects, and other disorders.

Infection and inflammation

Generalized inflammation of the intestine may be caused by viral or bacterial infections such as *food poisoning*, *traveller's diarrhoea*, *cholera*, *typhoid fever*, *amoebiasis*, or *giardiasis*, or to infestation with *roundworms* or *tapeworms*. It may also have noninfectious causes, as in *ulcerative colitis* and *Crohn's disease*. *Gastroenteritis* is the term commonly applied to inflammation of the stomach and intestines. Sometimes, inflammation is localized, as in *appendicitis* and *diverticular disease*.

Tumours

Tumours of the small intestine are rare, but noncancerous growths, *lymphomas*, and carcinoid tumours (causing *carcinoid syndrome*) may occur. Tumours of the large intestine are common (see *colon, cancer of; rectum, cancer of*). Some forms of familial *polyposis*, a condition causing the development of noncancerous growths, may progress to cancer.

Structural abnormalities

Structural defects may be congenital (present from birth) or may develop later. They include *atresia* (congenital closure), *stenosis* (narrowing), and *volvulus* (twisting of loops of bowel). These abnormalities can cause blockage of the intestine (see *intestine, blockage of*). In newborn babies with cystic fibrosis, meconium (fetal intestinal contents) is much thicker than normal and may block the intestine.

Obstruction

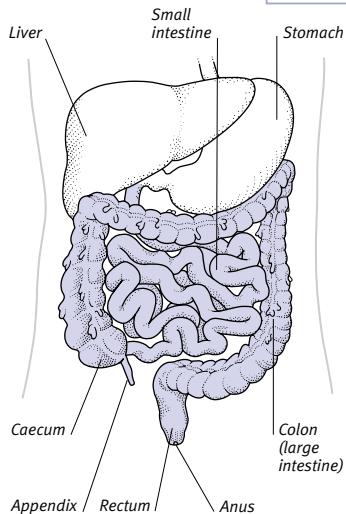

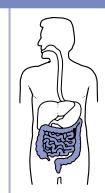

Impaired blood supply (*ischaemia*) to the intestine may result from partial or complete obstruction of the arteries in the abdominal wall (from diseases such as *atherosclerosis*) or from the blood vessels being compressed or trapped, as in *intussusception* or *hernias*. Loss of blood supply may cause *gangrene*.

Other disorders

Other disorders that affect the intestine include *peptic ulcers*, *diverticulosis*, *malabsorption*, *coeliac disease*, and *irritable bowel syndrome*.

LOCATION OF THE INTESTINE

Situated below the stomach and the liver, the intestine occupies a large proportion of the central and lower part of the abdomen.

and *adenomas*, *leiomyomas*, *lipomas*, and *angiomas* in the small intestine.

intoxication

A general term for a condition resulting from *poisoning*. It customarily refers to the effects of excessive drinking (see *alcohol intoxication*). The term may also be used of *drug poisoning*; poisoning from the accumulation of the by-products of *metabolism* in the body; or the effects of industrial poisons.

intra-

A prefix that means "within", as in the term "*intramuscular*" (within a muscle). (See also *inter*-.)

intra-articular cartilage

See *hyaline cartilage*.

intracavitary therapy

Treatment of a cancerous tumour in a hollow organ by placing a radioactive implant or *anticancer drugs* within the cavity of the organ.

Intracavitary *radiotherapy* is a type of brachytherapy (the practice of implanting radioactive wires or grains close to the tumour) that is mainly used to treat cancers of the uterus and cervix (see

uterus, cancer of; cervix, cancer of). Implants of radioactive material (usually in the form of artificial radioisotopes in small tubes) are placed near the tumour and left there for a period of time. This varies from hours to days depending on the type of radioactive substance used and the type of tumour being treated.

Intracavitary *chemotherapy* may be used to treat a malignant effusion (a collection of fluid that contains cancerous cells) that has developed in the chest or abdomen. Treatment slows the rate at which the fluid returns after it has been drained. Intracavitary chemotherapy is also used to treat cancers of the bladder. The drugs are introduced into the cavity through a *catheter* (flexible tube) and may either be left in place or drained off after a certain period of time.

intracerebral haemorrhage

Bleeding into the tissue of the brain from a ruptured blood vessel. Intracerebral haemorrhage is one of the three principal mechanisms by which a *stroke* can occur.

CAUSES

This disorder mainly affects middle-aged or elderly people and is usually due to *atherosclerosis* (accumulation of fatty deposits in the walls of the arteries). Untreated *hypertension* (high blood pressure) increases the risk of intracerebral haemorrhage.

SYMPOTMS

The ruptured artery is usually in the *cerebrum* (the main mass of the brain). The escaped blood seeps out, damaging brain tissue. The symptoms are sudden headache, weakness, and confusion, and often loss of consciousness. Speech loss, facial paralysis, or one-sided muscle weakness may develop, depending on the area affected.

TREATMENT AND OUTLOOK

Surgery is usually impossible; treatment is aimed at life-support and the reduction of blood pressure. Large haemorrhages are usually fatal. For the survivor of an intracerebral haemorrhage, rehabilitation and outlook are the same as for any type of stroke.

intracranial aneurysm

The abnormal dilation of an artery occurring anywhere inside the area enclosed by the *cranium* (skull bones). Intracranial aneurysms may cause no symptoms. However, they can suddenly

enlarge or rupture, causing *subarachnoid haemorrhage* or *stroke*, which are potentially fatal. (See also *aneurysm; berry aneurysm*.)

intracranial hypertension, benign

A condition in which *intracranial pressure* is substantially raised. The cause of the condition is unknown, but it often occurs in obese young women with menstrual irregularities. Rarely it is caused by drugs, including *corticosteroid drugs*. Symptoms may include headache, vomiting, and visual disturbance. The condition is not fatal but can damage the *optic nerves*, leading to permanent visual loss. Treatment is with *diuretic drugs*; occasionally, excess *cerebrospinal fluid* may be diverted by way of a surgically inserted *shunt* (artificial passage).

intracranial pressure (ICP)

Pressure exerted by *cerebrospinal fluid* (fluid that cushions and nourishes the brain and spinal cord) around the brain. ICP can be assessed during a *lumbar puncture*. Following serious head injury or some types of *neurosurgery*, ICP may be monitored continuously using a transducer that is inserted through the skull.

Raised ICP may be due to a *brain tumour, head injury, meningitis*, or benign *intracranial hypertension*. Untreated, it can result in permanent neurological damage and may be serious and, in some cases, life-threatening.

intracranial tumour

Any tumour that develops within the skull.

intractable

A term used to describe any condition that does not respond to treatment.

intracytoplasmic sperm injection (ICSI)

A treatment for male *infertility* in which a single sperm is collected from a sample of semen and injected into an *ovum* (egg). The ovum is then placed in the woman's uterus (see *in vitro fertilization*).

intradermal

A medical term meaning "into or within the skin". For example, an intradermal injection is made into the skin, whereas a *subcutaneous injection* is made into the layer of fat under the skin.

intradermal naevus

A type of pigmented *naevus* (skin blemish) formed by groups of *melanocytes* (pigment-producing cells) within the dermis (the thick inner layer of the skin). An intradermal naevus is usually raised and may range in colour from dark brown to pink. They are noncancerous and may disappear spontaneously. (See also *junctional naevus*.)

intramuscular

A medical term meaning "within a muscle", as in an intramuscular injection, in which a drug is injected deep within a muscle.

intraocular pressure

The pressure within the eye that helps to maintain the shape of the eyeball. Normal intraocular pressure is produced by a balance between the rate of production and removal of aqueous *humour*, the watery fluid that fills the front of the eyeball. Aqueous humour is continually produced from the *ciliary body* and exits from the drainage angle (a network of tissue between the iris and cornea). If drainage is impeded, intraocular pressure builds up; this condition is called *glaucoma*. If the ciliary body is damaged (as a result of prolonged inflammation), insufficient aqueous fluid may be produced and the eyeball may become soft.

intrauterine contraceptive device

See *IUD*.

intrauterine growth retardation

Poor growth in a *fetus* (an unborn baby within the uterus). Intrauterine growth retardation usually results from a failure of the *placenta* to provide adequate nutrients (which is often related to *pre-eclampsia*) or sometimes from a fetal defect. Severe maternal disease, such as chronic *kidney failure*, can reduce fetal growth. If the mother smokes during pregnancy, this may also reduce the growth and birth weight. Problems in the fetus, such as an intrauterine infection or *genetic disorder*, can also impair growth.

Intrauterine growth retardation may be suspected on *antenatal* examination; *ultrasound scanning* may be performed to assess the problem.

The underlying cause is treated, if possible. If the baby's growth is slowing, *induction of labour* or a *caesarean*

section may be necessary. Most babies whose growth was retarded in the uterus gain weight rapidly after delivery. If an intrauterine infection or genetic disorder was the cause, however, poor growth may continue after birth.

intravenous

A term meaning "within a vein", as in intravenous infusion (slow introduction of a substance into a vein) and intravenous injection (rapid introduction of a substance into a vein).

intravenous infusion

The slow introduction of fluid into the bloodstream through a cannula (thin plastic tube) inserted into a vein. An intravenous injection is given over several hours or days and is commonly known as a drip. The procedure is used to give blood (see *blood transfusion*) or, more commonly, fluids or essential salts. Other uses of intravenous infusion include providing nutrients to people who are unable to digest food (see *feeding, artificial*) as well as the administration of certain drugs. A machine known as an infusion pump may be used to control the amount of the drug or fluid being infused.

intravenous urography

An X-ray procedure, commonly abbreviated to IVU, that is used to give a clear image of the *urinary tract*.

The procedure involves intravenous injection of a *contrast medium* (a substance that is opaque to X-rays) into the arm. The medium is carried in the blood to the urinary system, where it passes through the kidneys, ureters, and bladder to be excreted in the urine. X-rays taken at intervals show outlines of the urinary system.

IVU reveals abnormalities such as tumours and obstructions, and signs of kidney disease.

intraventricular haemorrhage

Bleeding into the ventricles (the fluid-filled cavities of the brain). Premature babies are at greater risk because the nearby blood vessels are underdeveloped and fragile, but the bleeding may occur in babies carried to full term.

There may be no obvious signs that a haemorrhage has occurred; alternatively, the baby may be pale and limp. *Seizures* may also occur.

Ultrasound scanning of the baby's brain through the fontanelle (a gap in

the baby's skull) is used to check for bleeding. Intraventricular haemorrhage may cause no long-term problems. In some cases, however, it may lead to disability or *hydrocephalus* (a buildup of fluid around the brain). In the most severe cases, it may be life-threatening.

intrinsic asthma

The name sometimes given to a type of *asthma* that is not associated with an identifiable allergic trigger, such as pollen. (See also *allergy; hypersensitivity*.)

intrinsic factor

A chemical produced by the stomach lining that is necessary for the absorption of vitamin B_{12} . A lack of intrinsic factor leads to a deficiency in vitamin B_{12} ; this problem, in turn, results in *pernicious anaemia*.

introitus

A general term for the entrance to a body cavity or space. The word is most commonly used for the vagina.

introspection

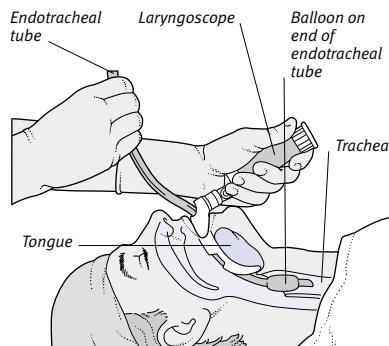

The contemplation or analysis of one's own thoughts, feelings, and other mental processes. (See also *insight*.)

introvert

A person who is more concerned with his or her inner world than the external or social environment. Introverts prefer to work alone, are shy and quiet, and become withdrawn when under stress. (See also *extrovert; personality*.)

intubation

A term most commonly used to refer to the process of passing an *endotracheal* (breathing) *tube* into the trachea (wind-

Endotracheal intubation

Guided by an anaesthetist, the endotracheal tube is passed through the patient's mouth and down the throat into the trachea.

pipe). Endotracheal intubation is carried out if mechanical *ventilation* is needed to deliver oxygen into the lungs.

The anaesthetist looks down the patient's throat with a laryngoscope (viewing instrument) to identify the vocal cords. The tube is then passed through the mouth or nose and down the throat between the vocal cords and trachea.

The term "intubation" is also used to refer to the placement of a gastric or intestinal tube in the stomach for purposes of suction or the giving of nutrients (see *feeding, artificial*).

intussusception

A condition in which part of the intestine telescopes in on itself, forming a tube within a tube, usually resulting in intestinal obstruction (see *intestine, obstruction of*). The condition usually affects the last part of the small intestine, where it joins the large intestine.

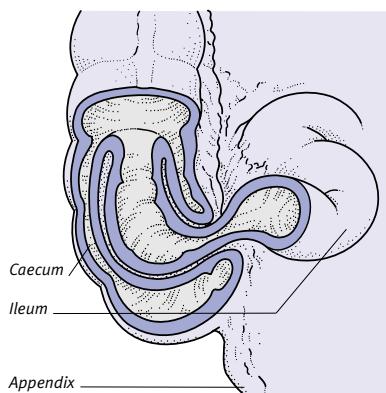

CAUSES

In some cases there is an association with a recent infection. In other cases, it may start at the site of a *polyp* or *Meckel's diverticulum* (a pouch-like projection from the ileum).

SYMPTOMS AND COMPLICATIONS

Intussusception occurs most commonly in children under the age of two. An affected child usually develops severe abdominal colic; vomiting is common, and blood and mucus are often found in the faeces.

In severe cases of intussusception, the blood supply to the intestine becomes blocked. *Gangrene* (tissue death), followed by *peritonitis* (inflammation of the abdominal lining) or *perforation* (rupture), may result.

Intussusception

This disorder is characterized by part of the intestine telescoping in on itself. The problem usually occurs at the junction between the ileum and the caecum.

TREATMENT

In some cases, an *enema* can be used to force the abnormal area of intestine back into a normal position. In other cases, surgery may be necessary to reposition the intestine.

invasive

A term used to describe anything that forcibly enters or spreads through the body. The word "invasive" is usually applied to cancerous tumours or harmful microorganisms that tend to spread throughout body tissues. It can also be used to refer to surgery. In an "invasive" medical procedure, the body tissues are penetrated by an instrument during surgery. (See also *minimally invasive surgery; noninvasive*.)

inverted nipple

An indrawing of the *nipple*. The condition can be longstanding or may develop in later life as a result of changes in the breast tissue. Possible causes include normal changes associated with aging or, in some cases, an underlying cancer.

in vitro

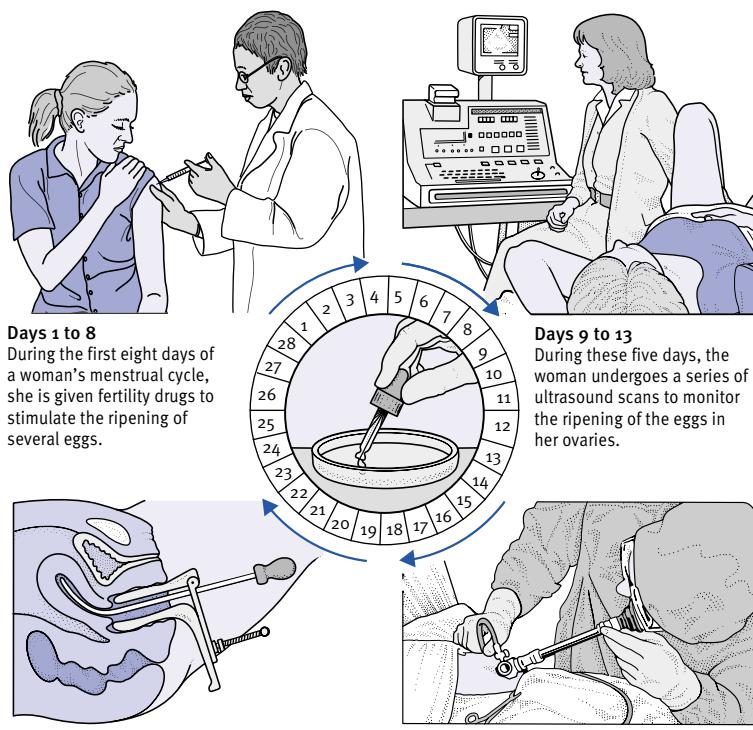

The performance of biological processes in a laboratory rather than within the body. The term literally means "in glass".

in vitro fertilization (IVF)

A technique used to treat *infertility* when its cause cannot be determined or treated or if there is a blockage in a fallopian tube. IVF is also used to treat couples affected by a *genetic disorder* because the

PROCEDURE FOR IN VITRO FERTILIZATION

Fertilization of eggs outside a woman's body can be performed to treat some types of infertility. One such technique used is in vitro fertilization; the main stages involved in this procedure are illustrated below.

Days 16 to 17
About two days later, the eggs are examined to see if they have been fertilized and have started to develop into embryos. If they have, two or three of the best embryos are introduced into the woman's uterus through the vagina. Further embryos may be frozen and stored.

Days 14 to 15
Immediately before ovulation (which may be induced with drugs), ripe eggs are removed by laparoscopy (above) or by ultrasound-guided needle aspiration through the vagina or the abdomen. The eggs are mixed with the man's sperm in a dish (above, centre), which is then put in an incubator.

embryo can be tested for abnormalities before implantation. IVF involves the surgical removal of an *ovum* (egg) from the ovary and its fertilization outside the body.

HOW IT IS DONE

The woman is given a course of *fertility drugs* to stimulate the release of mature ova, followed by *ultrasound scanning* to check the ova. The ova are collected immediately before ovulation using the guidance of ultrasound, either by *laparoscopy* or via the vagina under sedation. They are then mixed with sperm – usually from the partner, but sometimes from a donor – in the laboratory and are incubated at body temperature for about 48 hours to allow fertilization to take place. Two, or sometimes more, fertilized ova are introduced into the woman's uterus through a thin tube fed through the cervix. If they become safely implanted in the uterine wall, the pregnancy usually continues normally.

Many attempts at IVF may be needed before a successful pregnancy is achieved. Modifications of the technique, such as *gamete intrafallopian transfer* (GIFT), are technically simpler than the original method. (See also *intracytoplasmic sperm injection*.)

in vivo

Literally “in the living organism”; biological processes occurring within the body. (See also *in vitro*.)

involuntary movements

Uncontrolled movements of the body. These movements occur spontaneously and may be slow and writhing (see *athetosis*); rapid, jerky, and random (see *chorea*); or predictable, stereotyped, and affecting one part of the body, usually the face (see *tic*). They may be a feature of a disease (for example, *Huntington's disease*) or a side effect of certain drugs used to treat psychiatric conditions.

involuntary muscle

An alternative name for smooth *muscle*, which lines the walls of internal body structures such as the blood vessels, airways, and digestive tract.

involution

A term meaning a return to normal size; it is most commonly used to refer to the shrinkage of the enlarged *uterus* following *childbirth*.

iodine

A *trace element* essential for formation of the *thyroid hormones*, triiodothyronine (T3) and thyroxine (T4), which control the rate of *metabolism* (internal chemistry) as well as growth and development of the body.

Iodine must be obtained from the diet; it is found in seafood and dairy products, as well as in vegetables grown in soil containing iodides. Dietary shortage may lead to enlargement of the thyroid gland known as goitre or *hypothyroidism*. A deficiency in newborn babies can, if left untreated, lead to mental deficiency and incomplete physical development known as *cretinism*. Shortages are very rare in developed countries due to bread and table salt being fortified with iodide or iodate.

Radioactive iodine is sometimes used to reduce thyroid gland activity in cases of thyrotoxicosis and in the treatment of thyroid cancer. Iodine compounds are used as antiseptics, in radiopaque contrast media in some X-ray procedures (see *imaging techniques*), and in some cough remedies.

ion

A particle that carries an electrical charge; positive ions are called cations and negative ions anions. Many vital body processes, such as the transmission of nerve impulses, depend on the movement of ions across cell membranes. Sodium is the principal cation in the fluid that bathes all cells (extracellular fluid), affecting the flow of water into and out of cells (see *osmosis*), thereby influencing the concentration of body fluids.

The acidity of the blood and other body fluids is dependent on the level of hydrogen cations, which are produced by metabolic processes. To prevent the fluids from becoming too acidic, hydrogen cations are neutralized by bicarbonate anions in the extracellular fluid and the blood, and by phosphate anions inside cells (see *acid-base balance*).

ionizer

A device that produces *ions*. Some people believe that use of an ionizer, which produces negative ions, reduces

IMPORTANT IONS AND THEIR ROLES

Types of ion	Name	Major roles in body
Cations (positively charged ions)	Ammonium (NH_4^+)	Acid–base balance; produced by protein metabolism
	Calcium (Ca^{2+})	Nerve conduction; muscle contraction; blood clotting; bone and tooth formation; heart muscle contraction
	Hydrogen (H^+)	Acid–base balance; component of stomach acid
	Magnesium (Mg^{2+})	Nerve conduction; muscle contraction; bone and tooth formation; enzyme activation; protein metabolism
	Potassium (K^+)	Nerve conduction; muscle contraction; water balance; acid–base balance; heart rhythm
	Sodium (Na^+)	Nerve conduction; muscle contraction; water balance; acid–base balance
Anions (negatively charged ions)	Bicarbonate (HCO_3^-)	Acid–base balance; neutralizes stomach acid
	Chloride (Cl^-)	Acid–base balance; water balance; component of stomach acid
	Phosphate (PO_4^{3-})	Acid–base balance; bone and tooth formation; protein metabolism; energy metabolism; structure of cell membranes

symptoms, such as headaches and fatigue that may result from a buildup of the positive ions generated by electrical machines.

ionizing radiation

A type of *radiation*.

ipecacuanha

A drug (also called ipecac) previously used to induce vomiting in the treatment of types of *poisoning*.

ipratropium bromide

A *bronchodilator* drug used in the treatment of *breathing difficulties*.

IQ

The abbreviation for intelligence quotient, which is an age-related measure of intelligence (see *intelligence tests*).

iridectomy

A procedure performed on the eye to remove part of the *iris*. The most common type of iridectomy, known as a "peripheral iridectomy", is usually performed to treat acute *glaucoma*. A small opening is made, surgically or with a laser, near the outer edge of the iris to form a channel through which *aqueous humour* can drain.

iridocyclitis

Inflammation of the *iris* and *ciliary body*. Iridocyclitis is more usually known as "anterior *uveitis*". (See *eye, disorders of*).

iridotomy

A surgical procedure performed on the eye, in which an incision is made in the *iris* using a knife or a laser. (See also *iridectomy*).

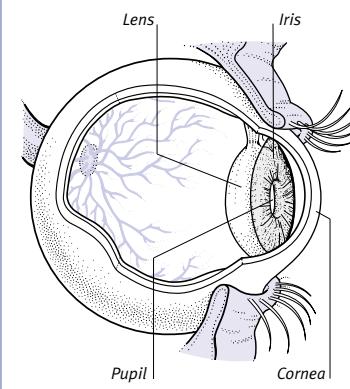

iris

The coloured part of the eye. The iris is made up of a loose framework of transparent *collagen* and two sets of muscle fibres (one radial and one circular) that lies behind the *cornea* and in front of the *lens*. It is connected at its outer edge to the ciliary body and has a central aperture, the *pupil*, through which light enters the eye and falls on the *retina*. The iris constantly contracts and dilates to alter the size of the pupil, in order to control the amount of light that passes through it and so falls on the retina.

The colour of the iris is inherited from the parents (see *inheritance*) and is determined principally by the amount

LOCATION OF THE IRIS

The iris lies behind the cornea and in front of the lens. The outer edge is connected to a ring of muscle called the ciliary body (not shown). At the centre is an aperture called the pupil.

of *melanin* (dark pigment) in its tissues. Brown eyes contain a high level of melanin. Blue and grey eyes contain very little melanin, their colour comes instead from the collagen tissues themselves. Hazel and green eyes contain moderate levels of melanin; their colour comes partly from the pigment and partly from the collagen tissues. Flecks of colour in the iris are due to scattered light reflected off blood vessels and muscle tissue. It is possible for people to have eyes of different colours (a fairly rare condition called heterochromia iridum). People with *albinism* have no melanin in their bodies and therefore the colour is governed by the tissues. Such people have light blue or even pink eyes.

iritis

An inflammation of the *iris*, now often termed an "anterior *uveitis*".

iron

A mineral that is essential for the formation of certain *enzymes*, *haemoglobin* (the oxygen-carrying pigment in red blood cells), and *myoglobin* (the oxygen-carrying pigment in muscle cells). Iron is found in foods such as liver, cereals, fish, green leafy vegetables, nuts, and beans. During pregnancy, iron supplements may be required. Iron deficiency leading to anaemia (see *anaemia, iron deficiency*) is usually caused by abnormal blood loss, such as

from a *peptic ulcer* or particularly heavy periods but may also be due to diet.

Iron supplements may cause nausea, abdominal pain, constipation, or diarrhoea and may colour the faeces black. Excessive iron in the tissues is a feature of *haemochromatosis*, which commonly results in *cirrhosis*, or other forms of organ damage.

iron-deficiency anaemia

See *anaemia, iron-deficiency*.

iron lung

A large machine formerly used to maintain breathing, especially in people paralysed by *poliomyelitis*. An iron lung consisted of a chamber that enclosed the patient's chest. The air pressure in the chamber could then be controlled in order to force air into and out of the lungs. The iron lung has been replaced by more efficient means of maintaining breathing (see *ventilation*).

irradiation

See *radiation hazards; radiotherapy*.

irradiation of food

Treatment of food with ionizing *radiation* in order to kill bacteria, moulds, insects, and other parasites. Irradiation improves the keeping qualities of food and is a means of controlling some types of *food poisoning*. It does not, however, destroy bacterial toxins and may destroy *vitamins*. Irradiation does not render food radioactive, and there is no evidence that it poses a risk to human health.

irrigation, antral

See *antral irrigation*.

irrigation, wound

Cleansing of a dirty or contaminated wound by washing it out repeatedly with a medicated solution or sterile saline solution.

irritable bladder

Intermittent, uncontrolled contractions of the muscles in the *bladder* wall that may cause urge incontinence (see *incontinence, urinary*).

Irritable bladder can occur if there is a urinary tract infection (see *cystitis*); a catheter present within the bladder; a bladder stone (see *calculus, urinary tract*); or an obstruction to the outflow of urine by an enlarged *prostate gland*, however often the cause of discomfort

is not known. In some cases, symptoms may be relieved by *antispasmodic drugs*; other treatment is directed at any underlying cause. Bladder training may also be used.

irritable bowel syndrome (IBS)

A combination of intermittent abdominal pain and constipation, diarrhoea, or bouts of each, that occurs in the absence of other diagnosed disease.

CAUSE AND INCIDENCE

The precise cause of IBS is unknown, but *anxiety* and *stress* tend to exacerbate the condition. IBS affects about one in five people at some time in life and accounts for more referrals to gastroenterologists than any other disorder. It is twice as common in women as in men and the disorder is generally found to begin in early or middle adulthood.

SYMPOTMS AND SIGNS

Symptoms of IBS include intermittent, cramplike pain in the abdomen; abdominal distension, often on the left side; transient relief of pain by bowel movement or passing wind; a sense of incomplete evacuation of the bowels; excessive wind; passage of mucus; diarrhoea; constipation; and nausea. Some people also have symptoms unrelated to the digestive tract, such as headache, back pain, and tiredness.

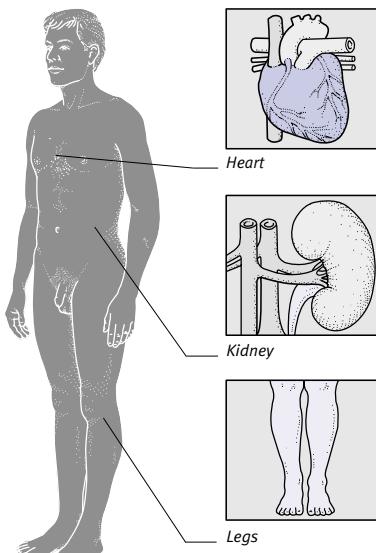

Symptoms are typically intermittent, and usually recur throughout life, though they may become less frequent and severe with time. The condition is unlikely to lead to complications.

DIAGNOSIS AND TREATMENT

There is no single test to diagnose IBS as opposed to another disorder of the digestive tract. In order for a diagnosis of IBS to be made, a patient must have had continuous or recurrent abdominal pain or discomfort for at least 12 weeks accompanied by at least two of the following features: relief of pain on defaecation; onset of pain associated with a change in stool frequency; and onset of pain associated with a change in stool consistency.

IBS can sometimes be controlled through a change in diet and use of relaxation techniques. An individual may need to experiment to find the approach that works best.

If constipation is the main problem, a high-fibre diet or bulk-forming agents (see *laxative drugs*), such as *bran* or *methylcellulose*, may be helpful. Short courses of *antidiarrhoeal drugs*

Symptoms of ischaemia

Ischaemia (insufficient blood supply) of the heart causes the chest pain of *angina pectoris*. Ischaemia of blood vessels in the legs may cause a cramplike pain during exercise. The condition may also affect the kidneys, causing kidney failure, or the brain (not shown), resulting in a stroke.

may be given for persistent diarrhoea. *Antispasmodic drugs* may be prescribed to relax the contractions of the digestive tract and relieve abdominal pain. *Hypnosis*, *psychotherapy*, and *counselling* have proved effective in some cases.

ischaemia

Insufficient blood supply to a specific organ or tissue. It is usually caused by a disease of the blood vessels, such as *atherosclerosis*, but may also result from injury, constriction of a blood vessel due to spasm of the muscles in the vessel wall, or an inadequate blood flow due to inefficient pumping of the heart. Symptoms displayed depend on the area affected.

Treatment may include *vasodilator drugs* to widen the blood vessels or, in more severe cases, an *angioplasty* or *bypass operation*.

ischaemic attack

See *transient ischaemic attack*.

ischaemic colitis

A form of *colitis* (inflammation of the colon, the main part of the large intestine) caused by an interruption of the blood supply to the colon. Ischaemic colitis most commonly affects people over

50 years old. People with diseases affecting blood vessels elsewhere in the body, such as *stroke* or *peripheral vascular disease*, are more likely to be affected. Other risk factors include a history of *congestive heart failure* or *diabetes mellitus*; surgery that has resulted in damage to the colon's blood supply; and treatment of the abdomen with *radiotherapy*.

SYMPTOMS AND COMPLICATIONS

Like other forms of colitis, ischaemic colitis may cause abdominal pain, diarrhoea (which may contain blood), fever, and vomiting. A longstanding reduction in the blood supply may lead to the formation of a stricture (narrowed area) in the affected part of the colon. Sudden total loss of blood supply, due to *thrombosis* or to an *embolism*, can cause *gangrene* (tissue death) of the colon.

DIAGNOSIS AND TREATMENT

The condition may be diagnosed by viewing the colon (see *colonoscopy*; *sigmoidoscopy*) and by taking a *biopsy* (sample of colon tissue). *Angiography* may also be performed to locate any blocked blood vessels.

In mild ischaemia, treatment with drugs used to treat *heart failure* and *hypertension* in combination with *lipid-lowering drugs* and, in some cases, *antiplatelet* or *anticoagulant drugs* is often sufficient, but acute ischaemia may require surgery in order to remove any blockages in the blood vessels. Areas of colon that have been irreparably damaged must be removed before *peritonitis* and *gangrene* (tissue death) develop (see *colectomy*).

ischaemic necrosis

The death of tissue as a result of an inadequate blood supply (see *necrosis*).

ischaemic optic atrophy

See *optic atrophy*.

ischium

One of the bones that form the lower part of the *pelvis*.

islets of Langerhans

Clusters of *endocrine* (hormone-producing) cells within the *pancreas*. The islets of Langerhans contain at least four different types of cells, which secrete hormones that control the level of *glucose* in the body. One type of cell secretes *insulin*, which lowers the blood glucose level; another secretes *glucagon*, which raises the blood glu-

cose level; a third secretes a hormone called somatostatin, which inhibits the secretion of insulin; and a fourth, about which relatively little is known, secretes a pancreatic polypeptide (a protein molecule).

One common disorder affecting the islets of Langerhans is type 1 *diabetes mellitus*, in which the insulin-secreting cells are destroyed. Other, less common disorders include the growth of tumours in particular groups of cells, leading to an excess of the hormone produced by those cells (see *glucagonoma*; *insulinoma*).

Isogel

A brand name for ispaghula husk, a bulk-forming agent used as a *laxative drug*. Isogel is also used to control some types of *diarrhoea*.

isoimmunization, Rhesus

See *Rhesus isoimmunization*.

isolation

Nursing procedures (also called barrier nursing) designed to prevent a patient from infecting others or from being infected. The patient is usually isolated in a single room.

Complete isolation is used if a patient has a contagious disease, such as *Lassa fever*, that can be transmitted to others by direct contact and airborne germs. In this case, all bedding, equipment, and clothing are either sterilized or incinerated after use. Partial isolation is carried out if the disease is transmitted in a more limited way (by droplet spread, as in *tuberculosis*, for example).

Reverse isolation, also called reverse barrier nursing, is used to protect a patient whose resistance to infection is severely lowered by a disease or treatment such as *chemotherapy*. The air supply to the room is filtered and all staff and visitors must wear caps, gowns, masks, and gloves. Occasionally, long-term reverse isolation may be required for patients who have severe combined immunodeficiency (see *immunodeficiency disorders*).

isometric

A term used for a system of *exercise* that involves no body movement, and in which muscles build up strength by working against resistance. The resistance is provided by either a fixed object or an opposing set of muscles. (See also *isotonic*).

isoniazid

An *antibacterial drug* that is used in the treatment of *tuberculosis*. Isoniazid is given in combination with other anti-tuberculous drugs, usually for a minimum of six months.

isoprenaline

A drug that is used on rare occasions as an emergency treatment of *heart block* or severe *bradycardia* (an abnormally slow heart rate). Isoprenaline was previously used to treat *asthma*, but it has now been replaced by drugs with fewer side effects.

isosorbide

A long-acting *nitrate drug* that acts as a vasodilator drug (by widening blood vessels). Isosorbide is used to reduce the severity and frequency of *angina pectoris* (chest pain caused by an impaired blood supply to the heart muscle). Isosorbide is also given to treat severe *heart failure*. There are two forms of isosorbide: mononitrate and dinitrate. Isosorbide dinitrate is converted by the body into isosorbide mononitrate, which is the active form of the drug.

Side effects of isosorbide include headache, hot flushes, and dizziness. In addition, tolerance to the drug may develop especially in patients who are using long-acting preparations or patches; a change in the dosage, frequency, or timing, or changing to a different drug, may be required.

isotonic

Having the same tension. It is used to define a system of *exercise*, such as weight lifting, in which muscle tension is kept constant as the body works against its own, or an external, weight. The term "isotonic" also describes fluids, such as intravenous fluids or drinks, with the same osmotic pressure (see *osmosis*) as the blood. (See also *isometric; hypotonic solutions*.)

isotope

Any one of the different atoms of a chemical element. Different isotopes of an element have the same number of protons (positively charged particles) but different numbers of neutrons (neutral particles) in their nucleus, and therefore a different atomic weight.

Radioactive isotopes are unstable and break down into more stable forms, with the release of electromag-

netic *radiation*. This radiation release means that such isotopes may be used in some medical procedures, such as *radiotherapy* for cancer and imaging tests such as *radionuclide scanning*.

isotope scanning

See *radionuclide scanning*.

isotretinoin

A drug derived from *vitamin A* used in the treatment of *acne*. Isotretinoin works by reducing the formation of sebum (natural skin oils) and keratin (a tough protein that is the major component of the outer layer of skin).

Isotretinoin can be used as a topical gel to treat mild to moderate cases of acne, or it may be taken orally in the treatment of severe, scarring acne that is unresponsive to other treatments. Side effects of topical treatment include inflammation and peeling of the skin; sunlight should be avoided. Isotretinoin should only be taken orally under medical supervision. In this form, it may cause drying of the skin and the mucous membranes, nosebleeds, sore eyes, and disorders of the blood.

Isotretinoin may damage a developing fetus; pregnancy must be avoided during treatment and for at least one month after taking the drug. Regular blood tests are recommended to check for complications.

ispaghula

A bulk-forming *laxative drug* that is used to treat *constipation*, *diverticular disease*, and *irritable bowel syndrome*. As ispaghula travels through the intestine, it absorbs water, thereby softening and increasing the volume of the faeces. Ispaghula is also used in people who have chronic, watery *diarrhoea* and in those patients who have had a *colostomy* or an *ileostomy* to control the consistency of faeces.

Adverse effects include flatulence, abdominal distension, and discomfort.

isthmus

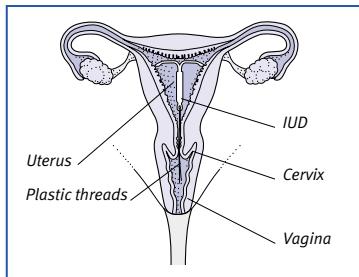

A narrow connecting structure or tissue between two larger body parts, such as the portion of tissue connecting the two lobes of the *thyroid gland*.

Istin

A brand name for *amlodipine*, a *calcium channel blocker drug* used in the treatment of disorders such as *angina pectoris* (chest pain due to insufficient blood

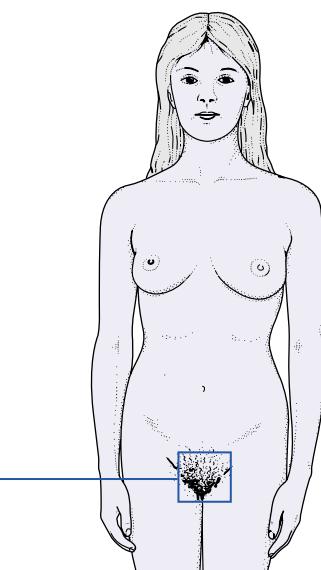

THE IUD (INTRAUTERINE CONTRACEPTIVE DEVICE)

The IUD, also known as the IUCD, is a small plastic contraceptive device inserted into the uterus through the cervix. IUDs are thought to work by preventing the implantation of fertilized eggs in the uterus. All types of IUD can be fitted, by specially trained healthcare personnel, in family planning clinics, hospitals, or general practitioners' surgeries.

Site of an IUD

An IUD is inserted into the uterus. Most types have two arms that hold them in position. The base of the IUD has one or two plastic threads

that extend through the cervix to the vagina. The threads enable the user to check that the device is in place.

supply to the heart muscle) and *hypertension* (high blood pressure).

itching

Known medically as pruritus, an intense irritation or tickling feeling in the skin.

TYPES AND CAUSES

Generalized itching may result from excessive bathing, which removes the natural oils from the skin and may leave the skin excessively dry. Some people experience general itching after taking certain drugs. Many elderly people suffer from dry, itchy skin, especially on their backs. Itching commonly occurs during pregnancy.

Conditions, including *chickenpox*, *urticaria* (nettle rash), and *eczema*, produce itching. Generalized skin itchiness can be a result of *diabetes mellitus*, *kidney failure*, *jaundice*, and *thyroid* disorders.

Pruritus ani (itching around the anal region) occurs with *haemorrhoids* and *anal fissure*. *Threadworm infestation* is the most likely cause of anal itching in children. *Pruritus vulvae* (itching of the external genitalia in women) may be due to the condition *candidiasis*, hormonal changes, or to use of spermicides or vaginal ointments and deodorants. *Insect bites*, *lice*, and *scabies* infestations cause intense itching.

TREATMENT

Specific treatment for itching depends on the underlying cause. Cooling and soothing lotions, such as *calamine*, may help to relieve irritation; emollients (substances that moisten and soften the skin) may reduce dryness.

itis

A suffix meaning "inflammation of". Virtually every organ or tissue in the body can suffer inflammation, so "itis" is a very common word ending in medicine. Examples of its use are *bronchitis* (inflammation of the bronchi) and *hepatitis* (inflammation of the liver).

ITP

An abbreviation for *idiopathic thrombocytopenic purpura*.

itraconazole

A type of *antifungal drug*.

IUCD

An abbreviation for intrauterine contraceptive device (see *IUD*).

IUD

An abbreviation for intrauterine contraceptive device. An IUD, also known as an IUCD or coil, is a device inserted

into the uterus for *contraception*. Most IUDs are plastic devices that have copper incorporated to improve their effectiveness. One type of IUD releases small amounts of *progestogen hormone* and is sometimes known as an *IUS*.

IUDs are believed to inhibit the implantation of a fertilized egg in the wall of the uterus (see *implantation, egg*).

HOW IUDS ARE USED

An IUD is inserted through the vagina and cervix into the uterine cavity. Once in position, it provides immediate protection. Most IUDs have one or two plastic strings attached to make removal easier and to indicate their presence. IUDs usually need to be replaced every three to eight years depending on the type.

WHO SHOULD USE IUDS

Women who have been pregnant are less likely to have complications than women who have never been pregnant. For example, they may feel less pain on insertion and have lighter menstrual flow and lower expulsion rates. IUDs are usually not recommended for women with *fibroids* or an irregular uterine cavity. If menstrual flow is heavy, an IUS may be recommended instead of an IUD.

RISKS AND COMPLICATIONS

A rare complication of the use of IUDs is perforation of the uterus, which most commonly occurs at the time of insertion. Rarely, pregnancy can occur with an IUD in place; however, an IUD seldom causes problems and it can be removed early in pregnancy. IUDs increase the risk of PID, which can lead to permanent infertility.

IUS

An abbreviation for intrauterine system. The IUS is a contraceptive device that fits inside the uterus, like an *IUD*. It contains the *progestogen hormone* levonorgestrel, which is released continuously over three to five years. The IUS acts by thinning the uterine lining and thickening cervical mucus. It also makes menstrual periods lighter, so may be used for women with heavy periods (see *menorrhagia*). One widely used brand of IUS is the *Mirena*.

IVF

See *in vitro fertilization*.

IVU

The abbreviation for *intravenous urography* (an X-ray imaging technique for visualizing the urinary tract).

J

Jaccoud's arthropathy

Also called Jaccoud's arthritis or Jaccoud's syndrome, a rare form of chronic arthritis associated with systemic *lupus erythematosus*. The disorder causes fibrous changes in the joint capsules and tendons at the base of the fingers, leading to pain and swelling.

Jacksonian seizures

A temporary brain disturbance in which *seizures* begin in one part of the body, such as a limb or the face, and then spread to other areas or even the whole body (a progression called the march of the seizure). The person usually retains consciousness but may have *amnesia* (memory loss). (See also *epilepsy*.)

Jahnke's syndrome

A form of *Sturge-Weber syndrome* in which there is malformation of blood vessels in the face and brain but without the *glaucoma* (increased fluid pressure in the eye) that is usually associated with the syndrome.

Jakob-Creutzfeldt disease

See *Creutzfeldt-Jakob disease*.

Japanese B encephalitis

An epidemic, mosquito-borne form of *encephalitis* (brain inflammation) occurring in Japan, India, and parts of southeast Asia. In most cases the infection causes no symptoms; however, some people develop severe encephalitis leading to paralysis, seizures, coma, and death. Immunization is available for those travelling to high-risk areas.

jargon aphasia

A form of *aphasia* (loss of language skills) in which the affected person cannot form grammatical sentences but utters meaningless phrases composed of jumbled words or neologisms (made-up words). Jargon aphasia may be due to a lesion in the dominant temporal lobe of the *brain*, or, rarely, may be a sign of *schizophrenia*.

jaundice

Yellowing of the skin and whites of the eyes, caused by an accumulation of the yellow-brown pigment *bilirubin* in blood and tissues. Jaundice is the chief sign of many disorders of the *liver* and *biliary system*. Many otherwise healthy babies are affected briefly by jaundice soon after birth (see *jaundice, neonatal*).

TYPES AND CAUSES

Bilirubin is formed from *haemoglobin* (the oxygen-carrying pigment in red blood cells) when old red cells are broken down, mainly by the *spleen*. It is absorbed by the liver, where it is made soluble in water and excreted in *bile*.

There are three main types of jaundice: haemolytic, hepatocellular, and obstructive. In haemolytic jaundice, too much bilirubin is produced for the liver to process. This condition results from excessive *haemolysis* (breakdown of red blood cells), which can have many causes (see *anaemia, haemolytic*).

In hepatocellular jaundice, bilirubin accumulates because it is prevented from passing from liver cells into the bile. This form of jaundice is usually due to acute *hepatitis* (inflammation of the liver) caused by taking certain drugs or by *liver failure*.

In obstructive jaundice, also called cholestatic jaundice, bile cannot leave the liver because of *bile duct obstruction*, which may be caused by gallstones or due to a tumour anywhere in the duct. Obstructive jaundice can also occur if the bile ducts are underdeveloped (as in *biliary atresia*) or have been destroyed by disease. *Cholestasis* (stagnation of bile in the liver) then occurs and bilirubin overflows into the blood.

DIAGNOSIS AND TREATMENT

Blood tests, and possibly also a *liver biopsy* (removal of a sample of tissue for analysis), may be performed to identify the cause of the jaundice. Investigation of the bile duct may be carried out using such imaging techniques as *ERCP* and *MRI*. Treatment is for the underlying cause.

jaundice, neonatal

Yellowing of the skin and whites of the eyes in newborn babies, due to accumulation of the yellow-brown bile pigment *bilirubin* in the blood. Neonatal jaundice usually results from the *liver* being too immature to excrete bilirubin efficiently. The condition, which tends to be more common in breast-fed babies, is usually harmless and disappears within a week.

In rare cases, severe or persistent neonatal jaundice can be caused by the blood disorder *haemolytic disease of the newborn*; the genetic condition *G6PD deficiency*; *hepatitis* (inflammation of the liver); *hypothyroidism* (underactivity of the thyroid gland); *biliary atresia* (abnormal formation or absence of the bile ducts); or infection.

Jaundiced babies usually require extra fluids and may be treated with *phototherapy* (light therapy) or, in severe cases, exchange transfusion (see *blood transfusion*). If severe neonatal jaundice is not treated promptly, *kernicterus* (a form of brain damage) may occur.

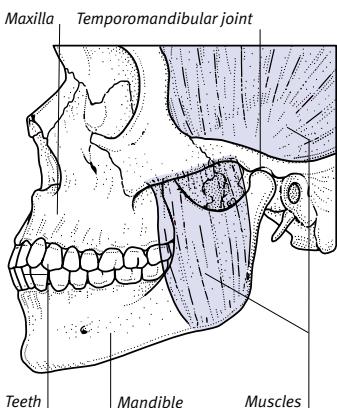

jaw

The mobile bone of the face, also called the mandible (or lower jaw). The term sometimes includes the *maxilla* (upper jaw), the bone that extends from the inner rims of the eyes to the mouth.

The mandible bears the lower teeth on its upper surface, and is connected to the base of the skull at the *temporomandibular joints*. Muscles attached to the jaw move the bone to enable chewing, biting, and side-to-side and downward motions.

ANATOMY OF THE JAW

The U-shaped jaw bone (mandible) joins the skull in front of the ears, at the temporomandibular joint. The jaw can move in several directions to enable biting and chewing.

jaw, dislocated

Displacement of the lower *jaw* from one or both *temporomandibular joints* (which connect the jaw to the base of the skull), usually due either to a blow or to yawning. There is usually pain in front

of the ear on the affected side, and the jaw projects forwards. The mouth cannot be fully closed, which makes eating and speaking difficult. Surgery may be performed to stabilize the joint, but dislocation tends to recur.

jaw, fractured

A fracture of the *jaw* bone, most often caused by a direct blow. A minor fracture may cause tenderness and pain on biting. In severe injuries, jaw movement may be limited, and there may be loss of feeling in the lower lip.

Minor fractures are normally left to heal on their own. Severe fractures with bone displacement, however, require surgery and immobilization of the jaw (see *wiring of the jaws*).

JC virus

A type of virus called a polyomavirus. JC virus does not usually cause symptoms in healthy adults but can be dangerous in people with a depressed immune system due to diseases such as *leukaemia*, *lymphoma*, or *AIDS*. In such cases, JC virus causes a brain disease called progressive multifocal leucoencephalopathy, which leads to dementia.

jealousy, morbid

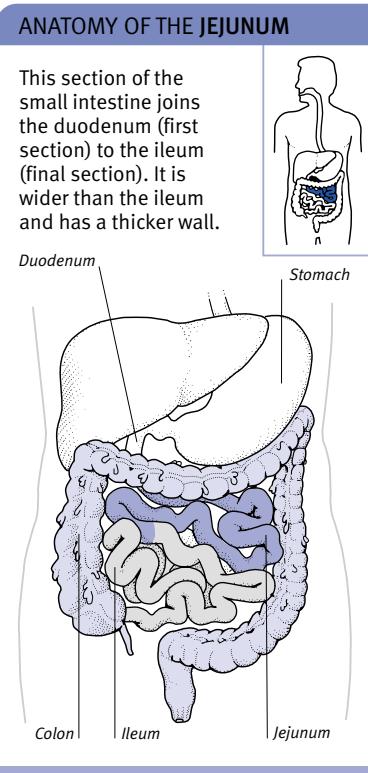

Preoccupation with the potential sexual infidelity of one's partner. The sufferer, most often a man, becomes convinced that his partner is having an affair. Morbid jealousy is usually caused by a *personality disorder*, *depression*, or *paranoia*, but may also result from *alcohol dependence* or organic brain syndrome (see *brain syndrome, organic*).

jejunal biopsy

A diagnostic test in which a small piece of tissue is removed from the lining of the *jejunum* (middle section of the small intestine) for microscopic examination. It is especially useful in the diagnosis of *coeliac disease*, *intestinal lymphoma*, and other causes of *malabsorption*. The biopsy is taken through an *endoscope* introduced via the mouth, or with a device called a Crosby capsule, which is attached to a thread and swallowed.

jejunum

The middle, coiled section of the small *intestine*, joining the *duodenum* to the *ileum*. The main functions of the jejunum are to digest food and absorb nutrients. It may be affected by *coeliac disease*, *Crohn's disease*, and *lymphoma*.

jellyfish stings

Injections of venom from the stinging cells of jellyfish, which belong to a group of marine animals called cnidarians. In most instances of jellyfish stings, there is only mild pain or itching, but some jellyfish venom causes vomiting, breathing difficulties, and collapse. Dangerous species live mainly in tropical waters. *Antivenoms* may be used to treat severe cases.

jerky nystagmus

A form of *nystagmus* (involuntary eye movement) in which the eyes move slowly in one direction, then dart back.

jet-lag

Fatigue and disruption of the sleep-wake cycle, caused by disturbance of normal body *biorhythms* as a result of flying across different time zones.

jigger

An alternative name for a *chigoe*, which is also sometimes known as a sand flea.

jogger's nipple

Soreness of the nipple caused by friction from clothing, usually during such sports as jogging or long-distance run-

ning. Covering the nipple with a bandage or a layer of petroleum jelly reduces rubbing.

joint

The junction between two or more bones. Many joints are highly mobile, while others are fixed or allow only a small amount of movement (see *Types of joint* box opposite).

STRUCTURE

In all types of joint, the bones are held together by soft tissues. In fixed joints, such as those in the skull, the bones are firmly secured by fibrous tissue. In semi-mobile joints (such as those in the spine), the bones are connected by cartilage, which allows limited movement. Mobile joints (such as those in the limbs) are supported by strong *ligaments*. They are moved by *muscles*, which are attached to the bones by *tendons*. Each mobile joint is also sealed within a tough, fibrous capsule.

TYPES

There are several types of mobile joint, each allowing a specific form of movement. Hinge joints, such as those in the fingers, knees, and elbows, principally allow bending and straightening. Pivot joints, such as the joint between the first and second vertebrae (see *vertebra*), allow rotation only. Ellipsoidal joints, such as the wrist, allow all types of movement except pivotal. Ball-and-socket joints, such as the shoulder and hip, allow movement in all directions.

DISORDERS

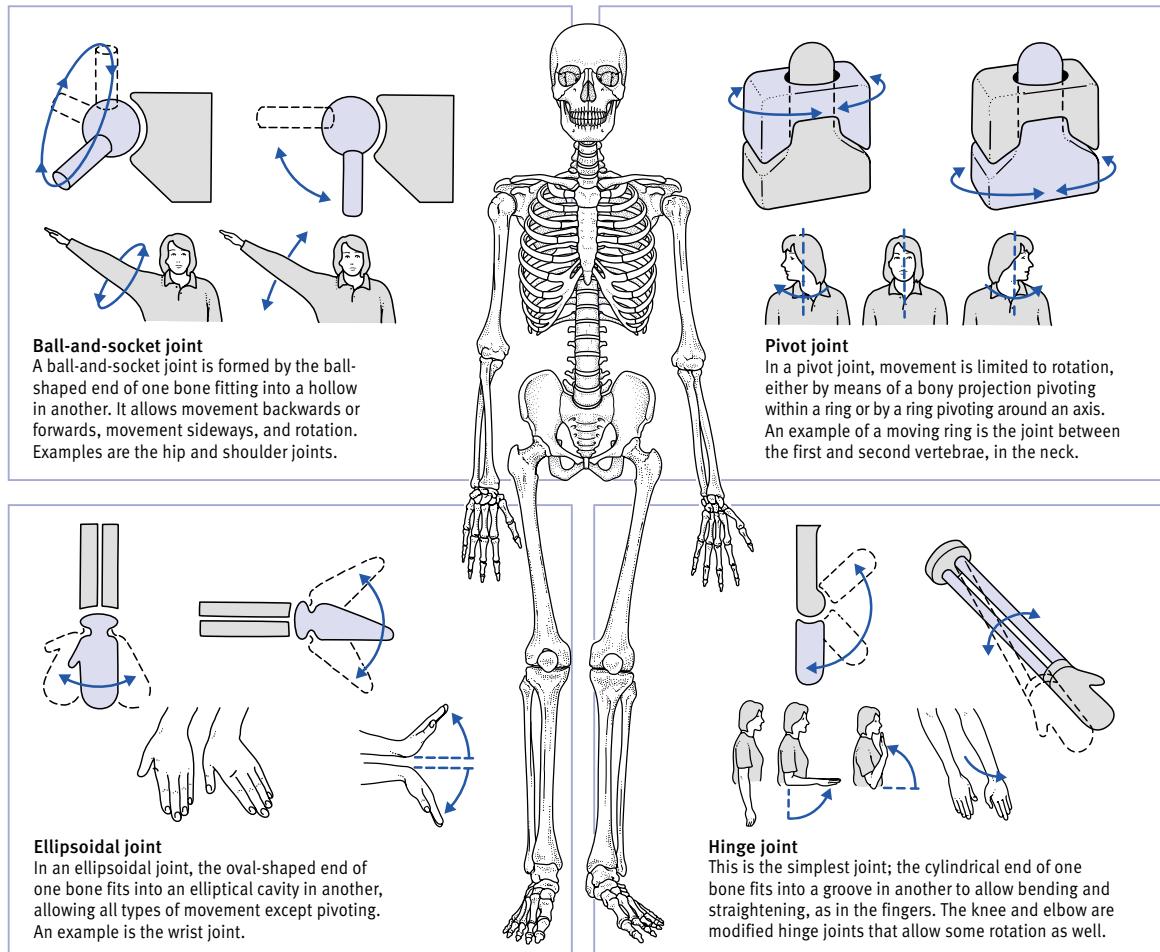

Common joint injuries include *sprains* (minor tears) or rupture of ligaments; damage to cartilage; and tearing of joint capsules. Such injuries may be caused by sudden twisting or wrenching movements, often during sport or vigorous exercise, or in a fall. Separation of the bone ends (see *dislocation*, *joint*), and partial displacement (see *subluxation*), are also usually caused by injury, but are occasionally present from birth. Rarely, the bone ends are fractured, which may cause bleeding into a joint (*haemarthrosis*). Joint *effusion* (build-up of fluid in a joint) is usually due to *synovitis* (inflammation of the joint lining).

One of the main diseases of the joints is *arthritis*, which causes pain, stiffness, inflammation, and degeneration of the joints. Other joint disorders include *bursitis* (inflammation of a fluid-filled cushion around a joint); distortion or rupture of an intervertebral disc (see *disc, slipped*); *gout*; and *bunions*.

TYPES OF JOINT

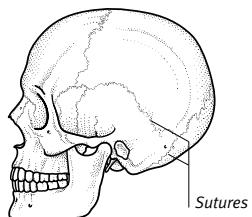

There are several types of joint. Some are fixed (such as the skull joints), some allow only a little movement (the vertebral joints, for example), and some are mobile. Of the mobile joints,

ball-and-socket have the widest range of movement. Pivot joints allow rotation only. Ellipsoidal joints allow movement in most directions. Hinge joints mainly allow bending.

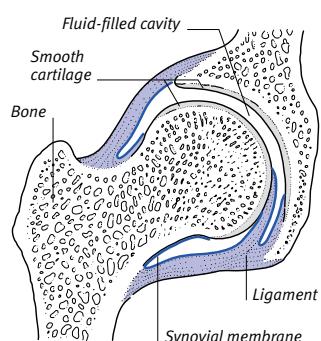

STRUCTURE OF A FIXED JOINT

Fixed joints are firmly secured by fibrous tissue. The joints between the bones of the skull (known as sutures) are an example.

STRUCTURE OF A MOBILE JOINT

The surfaces of the bone ends are coated with very smooth cartilage to reduce friction as they move against each other. The ends are sealed within a tough fibrous capsule; this is lined with synovial membrane, which produces a sticky lubricating fluid. The joint is surrounded by strong ligaments that support it and prevent excessive movement. Its movement is controlled by muscles that are attached to bone by tendons on either side of the joint. Most mobile joints have at least one bursa (fluid-filled sac) nearby, which cushions a pressure point.

joint replacementSee *arthroplasty*.**Joubert's syndrome**

An autosomal recessive *genetic disorder*, present from birth, in which part of the cerebellum, an area located at the back of the brain, fails to develop properly. Affected children have impaired balance and coordination; abnormal breathing patterns; hypotonia (decreased muscle tone); and, sometimes, *seizures*.

joule

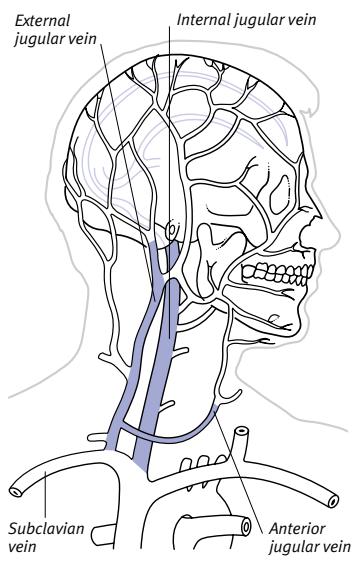

The international unit of *energy*, work, and heat. Approximately 4,200 joules (symbol J) or 4.2 kilojoules (kJ) equal 1 kilocalorie (kcal); 1 kJ is equal to about 0.24 kcal. (See also *calorie*.)

jugular vein

One of three veins on each side of the neck (the internal, external, and anterior jugular veins) that return deoxygenated blood from the head to the heart. The internal jugular vein, the largest of the three, arises at the base of the skull and travels down the neck alongside the *carotid arteries*, before passing behind the *clavicle* (collarbone), where it joins the subclavian vein (the large vein that drains blood from the arms).

ANATOMY OF THE JUGULAR VEINS

There are three jugular veins on each side of the neck that return blood from the head to the heart.

**jugular venous pressure**

An assessment of the pressure within the internal *jugular vein*, one of the three major veins on each side of the neck that carry deoxygenated blood to the right atrium of the *heart*. *Heart failure* can cause raised jugular venous pressure.

junctional naevus

A pigmented *naevus* formed by a cluster of melanocytes (pigment-producing cells) in the skin, at the junction between the epidermis (outer layer) and the dermis (inner layer). The naevus looks like a flat, non-hairy, brown mole. (See also *intradermal naevus*.)

Jungian theory

The Swiss psychiatrist Carl Gustav Jung (1875–1961) theorized that certain ideas called archetypes, inherited from experiences in humanity's distant past, existed in the unconscious and controlled the way a person viewed the world. Jung called these shared ideas the "collective unconscious". Jungian therapy was aimed at putting people in touch with this source of ideas, particularly through the interpretation of dreams. Jung also postulated two basic types of personality: the extrovert and the introvert.

juvenile arthritisSee *juvenile chronic arthritis*.**juvenile chronic arthritis**

A rare form of *arthritis* (joint inflammation) affecting children. Juvenile chronic arthritis occurs more often in girls, and usually develops between two and four years of age or around puberty.

TYPES

There are three main types, all of which cause joint pain, swelling, and stiffness. The most common form is pauciarticular juvenile arthritis, which affects four joints or fewer and usually occurs in very young girls. Polyarticular juvenile arthritis affects five or more joints, and is more common in girls. *Still's disease* (systemic onset juvenile arthritis) affects both boys and girls. It starts with fever, rash, enlarged lymph nodes, abdominal pain, and weight loss. These symptoms last for several weeks. The joint problems may not develop for some months.

COMPLICATIONS

Possible complications include short stature, *anaemia*, *pleurisy* (inflammation of the membranes around the lungs), *pericarditis* (inflammation of the mem-

brane around the heart), and enlargement of the *liver* and *spleen*. *Uveitis* (inflammation of parts of the eye) may develop. Rarely, *amyloidosis* (in which an abnormal protein is deposited in body organs) or *kidney failure* may develop.

DIAGNOSIS

Diagnosis is based on the symptoms, together with the results of *X-rays* and *blood tests*; it is made only if the condition lasts for longer than three months.

TREATMENT AND OUTLOOK

Treatment may include *antirheumatic drugs*, *corticosteroid drugs*, *nonsteroidal anti-inflammatory drugs*, or *aspirin*. Splints may be worn to rest inflamed joints and to reduce the risk of deformities. *Physiotherapy* reduces the risk of muscle wasting and deformities. The arthritis usually clears up after several years, but in some children it persists into adult life.

juvenile muscular atrophy

A form of muscle atrophy (wasting and weakness) that occurs in children and adolescents, and is caused by an autosomal recessive *genetic disorder*. Muscle atrophy is most obvious in the legs, and later the arms. Respiratory muscles may also be involved. Most affected children eventually become wheelchair bound.

juvenile-onset diabetes

A form of type 1 (insulin-dependent) *diabetes mellitus* that develops suddenly in childhood or adolescence.

juvenile osteoporosis, idiopathic

A rare form of osteoporosis (loss of bone density) that occurs in children of eight to 14 years. Idiopathic juvenile osteoporosis causes leg and back pain; *kyphosis* (curvature of the upper spine); walking difficulty; and an increased susceptibility to fractures. The disorder usually begins suddenly and often disappears spontaneously after two to four years. Treatment is aimed at preventing fractures and maintaining mobility.

K

kala-azar

A form of the parasitic disease *leishmaniasis*, which is spread by sandflies. Kala-azar occurs in parts of Africa, India, the Mediterranean, and South America.

Kallmann's syndrome

An inherited condition in which there is a deficiency of gonadotrophin-releasing hormone (GnRH). This hormone, which is produced in the hypothalamus, is responsible for regulating the release of other hormones in the pituitary gland that in turn stimulate the testes. The deficiency of GnRH delays or sometimes prevents normal sexual development at puberty. The condition is also associated with colourblindness and a lack of sense of smell. Kallmann's syndrome is treated with hormones that replace GnRH.

kaolin

An *aluminium* compound used as an ingredient in some *antidiarrhoeal drugs*. Kaolin is an adsorbent and is taken by mouth to treat the diarrhoea and vomiting caused by food poisoning and other digestive disorders.

Kaposi's sarcoma

A cancerous tumour arising from blood vessels in the skin or, less commonly, in internal organs. Almost all cases of Kaposi's sarcoma occur in people who have *AIDS*. Several tumours are often present, appearing as pinkish-purple, raised areas of skin. The tumours can spread rapidly over the body; they usually develop first on the feet and the ankles, spread up the legs, then occur on the hands and the arms. Internal tumours, such as those affecting the gastrointestinal and respiratory tracts, may cause severe bleeding.

Skin tumours may be treated with *radiotherapy*. *Anticancer drugs* may be used if the skin is widely affected, or for internal tumours. *Antiretroviral drugs* often control the cancerous growths and may shrink them.

Kaposi's varicelliform eruption

A generalized, serious skin eruption, consisting of pus-filled blisters, caused by a viral infection in areas of pre-existing atopic *dermatitis*. The disorder is also known as *eczema herpeticum*. The viruses usually responsible are herpes simplex virus (HSV-1 and HSV-2) and coxsackievirus.

Kartegener's syndrome

An inherited disorder in which the heart is situated on the right instead of the left side of the chest (a condition known as dextrocardia). This is associated with abnormal functioning of the cilia (hair-like projections) lining the airways, which impairs clearance of mucus and results in *bronchiectasis* and *sinusitis*.

karyotype

The characteristics of *chromosomes*, in terms of number, size, and structure, in an individual or a species. The term "karyotype" is also applied to a diagram of chromosome pairs arranged in their assigned numerical order.

Kawasaki disease

A rare, acute illness of unknown cause that most commonly affects children under two years of age. The disease is characterized by fever lasting one to two weeks; conjunctivitis; dryness and cracking of the lips; swollen *lymph nodes* in the neck; reddening of the palms and soles; and a generalized rash. By the end of the second week of illness, the skin at the tips of the fingers and toes peels and other symptoms subside. The heart muscle and *coronary arteries* are affected in some cases.

High doses of gamma-globulin (see *immunoglobulin infections*) and *aspirin* may be given in order to prevent associated heart complications. The majority of children recover completely.

Keller's operation

A type of surgery sometimes used to treat *hallux valgus* (a deformity of the big toe). The operation involves cutting away a piece of bone from the base of the first joint of the toe. Fibrous tissue forms in the gap, although the toe is left shorter. (See also *bunion*.)

keloid

A raised, hard, irregularly shaped, itchy scar on the skin due to a defective healing process in which too much *collagen* (a tough, fibrous protein) is produced, usu-

ally after a skin injury. Keloids can develop anywhere on the body, but the breastbone and shoulder are common sites. Black people are affected more commonly than white people. After several months, most keloids flatten and cease to itch.

Injection of *corticosteroid drugs* into the keloid may reduce itchiness more quickly and cause some shrinkage.

Keloid on the earlobe

This large overgrowth of scar tissue has formed on the earlobe after the ear was pierced. Black people are particularly susceptible to keloids.

keratin

A fibrous *protein* that is the main constituent of the tough outermost layer of the *skin*, *nails*, and *hair*.

keratitis

Inflammation of the *cornea* (the transparent front part of the eyeball). It often takes the form of a *corneal ulcer* and may result from injury, contact with chemicals, or an infection. Symptoms of keratitis include pain and excessive watering of the eye, blurring of vision, and *photophobia* (abnormal sensitivity to bright light).

Noninfective keratitis is treated by keeping the affected eye covered until it has healed. Drugs such as antibiotics may be given to treat infective keratitis. (See also *disciformis keratitis*.)

keratoacanthoma

A type of harmless skin nodule that commonly occurs in elderly people, most often on the face or arm. The cause is unknown, but many years of exposure to strong sunlight or long-term use of *immunosuppressant drugs* may be contributory factors. Initially, the nodule resembles a small wart, but it grows to 1–2 cm across in about eight weeks. Although the nodule usually disappears gradually after this time, surgical removal is often recommended to prevent scarring.

keratoconjunctivitis

Inflammation of the *cornea* (the transparent front part of the eyeball) that is associated with *conjunctivitis* (inflammation of the conjunctiva, the membrane covering the eyeball). The most common form of the disorder, epidemic keratoconjunctivitis, is caused by a virus and is highly infectious. The inflammation is often severe and in some cases may destroy the surface of the conjunctiva. Tiny, opaque spots develop in the cornea that may interfere with vision and persist for some months.

There is no specific treatment, but corneal spots may be minimized by using eye-drops containing *corticosteroid drugs*.

keratoconjunctivitis sicca

Persistent dryness of the *cornea* (the transparent front part of the eyeball) and the *conjunctiva* (the membrane covering the eyeball) caused by deficiency in tear production. The condition is associated with *autoimmune disorders* such as *rheumatoid arthritis*, *Sjögren's syndrome*, and *systemic lupus erythematosus*, all of which can damage the tear glands. Prolonged dryness may lead to blurred vision, itching, grittiness, and, in severe cases, the formation of a *corneal ulcer*. The most effective treatment is frequent use of artificial tears (see *tears, artificial*).

K

keratoconus

An inherited disorder of the *eye*, in which the *cornea* (the transparent front part of the eyeball) becomes gradually thinned and conical. The condition affects both eyes and usually develops around puberty, giving rise to increasing *myopia* (short-sightedness) and progressive distortion of vision that cannot be fully corrected by glasses. Hard *contact lenses* improve vision in the early stages, but later it is generally necessary to perform a *corneal graft* to restore normal vision permanently.

keratolytic drugs

Drugs that loosen and remove the tough outer layer of *skin*. Keratolytic drugs, which include *urea* and *salicylic acid* preparations, are used to treat skin and scalp disorders, such as *warts*, *acne*, *dandruff*, and *psoriasis*.

keratomalacia

A progressive disease of the *eye*, caused by severe *vitamin A* deficiency, in which the cornea (the transparent front part of the eyeball) becomes opaque and ulcerated. Perforation of the cornea is also

common, often leading to loss of the eye through infection. The disorder usually occurs only in severely malnourished children and is a common cause of blindness in developing countries.

In the early stages, the damage can be reversed by treatment with large doses of vitamin A but, if the condition is left untreated, blindness is usually inevitable.

keratopathy

A general term used to describe a variety of disorders of the *cornea* (the transparent front part of the eyeball).

TYPES

Actinic keratopathy is a painful condition in which the outer layer of the cornea is damaged by *ultraviolet light* emitted from the sun, reflected from surfaces such as snow (in which case the problem is called snow-blindness), or given off by artificial sources such as sunbeds or arc-welding torches.

Exposure keratopathy is corneal damage due to loss of the protection afforded by the tear film and blink reflex. It may occur in conditions in which the eyelids inadequately cover the cornea, including severe *exophthalmos*, *facial palsy*, and *ectropion*.

keratoplasty

See *corneal graft*.

keratosis

A skin growth that is caused by an overproduction of the tough, fibrous protein *keratin*. Keratoses occur mainly in elderly people.

TYPES

Seborrhoeic keratoses are harmless growths that occur mainly on the trunk. They range in appearance from flat, dark-brown patches to small, wartlike protrusions. The growths do not need treating unless they are unsightly.

Solar keratoses are small, wartlike red or flesh-coloured growths that appear on exposed parts of the body as a result of overexposure to the sun over many years. Rarely, they may develop into skin cancer, usually *squamous cell carcinoma*.

TREATMENT

Seborrhoeic keratoses can be removed by curettage (scraping away). Surgery is required for solar keratoses that have become cancerous, however.

keratosis pilaris

A common condition, usually occurring in adolescents, in which patches of rough skin appear on the upper arms,

thighs, and buttocks. The openings of the hair follicles become enlarged by plugs of *keratin* (a tough, fibrous protein), and hair growth may be distorted.

The condition is not serious and usually clears up on its own. In severe cases, applying a mixture of salicylic acid and soft paraffin and scrubbing with a loofah may help.

keratotomy, radial

An uncommon procedure in which radiating incisions are made in the *cornea* (the transparent front part of the eyeball) up to, but not through, its innermost layer, in order to reduce *myopia* (short-sightedness). Radial keratotomy has been largely replaced by laser procedures, such as *LASIK*, which carry less risk of permanent damage to the eye.

kerion

A red, painful swelling, oozing fluid, that appears on the scalp due to infection with scalp ringworm (see *tinea*). Treatment with oral *antifungal drugs* needs to be continued for several weeks before the scalp heals. The disorder may leave scarring and an area of permanent hair loss.

kernicterus

The abnormal accumulation of the pigment *bilirubin* in the brain of a newborn baby, as a result of severe *jaundice*. Kernicterus causes permanent brain damage, but the effective treatment of jaundice in newborn babies has made the condition rare.

ketamine

A general *anaesthetic* administered by injection. It is mainly given to children undergoing painful procedures, such as *bone marrow biopsy*. Ketamine may be abused for its stimulant effect.

ketoacidosis

A combination of *acidosis* and *ketosis*. (See also *diabetic ketoacidosis*.)

ketoconazole

An *antifungal drug* used to treat *fungal infections* of the gut, skin, and finger nails, and *candidiasis* (thrush) of the mouth or vagina. It is also used as a shampoo to treat dandruff. Adverse effects include nausea and rash.

ketone

Any of a group of chemicals related to acetone (which is found in solvents such as nail polish remover). Certain

ketones are produced during the *metabolism* of fats; if excessive amounts build up in the body, they cause *ketosis*.

ketoprofen

A type of nonsteroidal *anti-inflammatory drug* (NSAID) that is prescribed as an *analgesic drug* (painkiller) for injuries to soft tissues, such as muscles and ligaments. Ketoprofen also reduces joint pain and stiffness in arthritic conditions. It may cause abdominal pain, nausea, indigestion, and an increased risk of *peptic ulcer*.

ketosis

A potentially serious condition in which excessive amounts of chemicals called *ketones* accumulate in the body. Ketones are normal products of fat *metabolism*, but are produced in excess when body cells cannot use *glucose* as an energy source. This occurs in starvation, in prolonged vomiting, and in untreated *diabetes mellitus* (see *diabetic ketoacidosis*) when a lack of insulin prevents glucose from entering cells. Symptoms include sweet, acetone-smelling breath, loss of appetite, nausea, and abdominal pain. Ketosis may eventually result in confusion, unconsciousness, and death. Treatment is of the underlying cause.

keyhole surgery

Another name for *minimally invasive surgery*.

kidney

Either of the two organs that filter the blood and excrete waste products and excess water as *urine*. The kidneys are situated at the back of the abdominal cavity, on either side of the spine.

STRUCTURE

Each kidney is surrounded by a fibrous capsule and is made up of an outer layer (cortex) and an inner layer (medulla). The cortex contains specialized capillaries (tiny blood vessels) called glomeruli; these vessels, together with a series of tubules, make up the *nephrons*, the filtering units of the kidney. Urine, the waste product from filtering, passes through tubules to the medulla, collects in an area called the renal pelvis, then travels through tubes called ureters to the bladder.

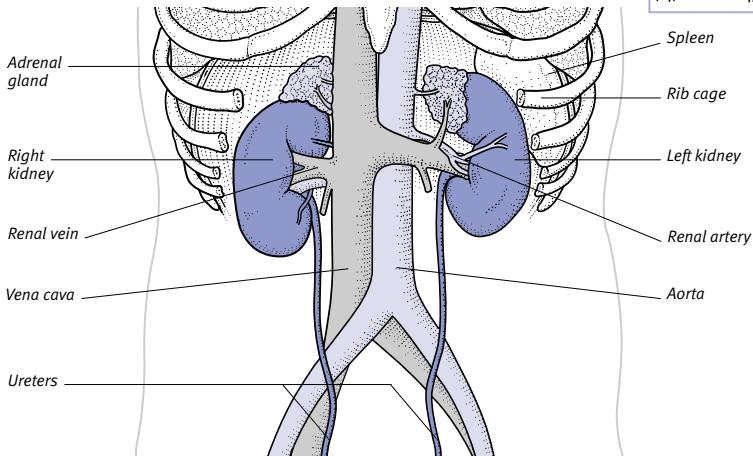

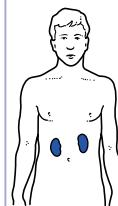

FUNCTIONS

The nephrons filter blood under pressure and then selectively reabsorb water and certain other substances into the blood. Urine is formed from substances that are not reabsorbed (see illustrated box: the function of the kidney).

LOCATION OF THE KIDNEYS

The kidneys are situated at the back of the abdominal cavity, just above the waist, on either side of the spine. The right kidney lies below the liver (not shown), and the left kidney lies below the spleen. Each kidney

is connected to the bladder by a ureter. The renal arteries, which supply the kidneys, arise directly from the aorta, and the renal veins join on to the inferior vena cava. The two adrenal glands sit on top of each kidney.

The kidneys also regulate the body's fluid balance. To do this, they excrete excess water, and when water is lost from the body (for example, as a result of sweating), they conserve it (see *ADH*). In addition, they control the body's *acid-base balance* by adjusting urine acidity. Lastly, the kidneys produce hormones involved in the regulation of red blood cell production and *blood pressure*.

kidney biopsy

A procedure in which a small sample of *kidney* tissue is removed and examined under a microscope. Kidney biopsy is performed to investigate and diagnose serious disorders such as *glomerulonephritis*, *proteinuria*, *nephrotic syndrome*, and *acute kidney failure*, or to assess the kidneys' response to treatment.

There are two basic techniques: percutaneous needle biopsy, in which a hollow needle is passed through the skin into the kidney under local anaesthesia; and open surgery under general anaesthesia.

kidney cancer

A cancerous tumour of the *kidney*. Most kidney cancers originate in the kidney itself, but in rare cases cancer spreads to the kidney from another organ.

TYPES

There are three main types of cancer that affect the kidney: renal cell carcinoma, nephroblastoma, and transitional cell carcinoma.

Renal cell carcinoma

Also known as hypernephroma or adenocarcinoma, this is the most common type of kidney cancer. It usually occurs in people over the age of 40 and affects twice as many men as women. A common symptom is blood in the urine. There may also be pain in the back, a lump in the abdomen, fever, or weight loss. The cancer often spreads to the lungs, bones, liver, and brain.

Nephroblastoma

Nephroblastoma (also called Wilms' tumour) is a fast-growing tumour that mainly affects children under five years old. Nephroblastoma sometimes runs in families, but its cause is unknown. Symptoms may include swelling of the abdomen, abdominal pain or discomfort, and, occasionally, blood in the urine. Nephroblastoma may spread to the lungs, liver, and brain.

Transitional cell carcinoma

This type of kidney cancer arises from cells lining the renal pelvis (the urine-collecting system within the kidney); it is most common in smokers or in people

DISORDERS OF THE KIDNEY

The kidneys are susceptible to a wide range of disorders. Only one normal kidney is needed for good health, however, so disease is rarely life-threatening unless it affects both kidneys and is at an advanced stage. *Hypertension* (high blood pressure) can be both a cause and an effect of kidney damage. Other effects of serious damage include *nephrotic syndrome* and *kidney failure*.

Congenital and genetic disorders

Congenital abnormalities, such as *duplex kidney* (in which a kidney is partially duplicated) and *horseshoe kidney* (in which the two kidneys are joined at their base), are fairly common and usually harmless. Serious inherited disorders include *polycystic kidney disease* (see *kidney, polycystic*), in which multiple cysts develop on both kidneys; and *Fanconi's syndrome* and *renal tubular acidosis*, in which the kidney tubules function abnormally so that certain substances are inappropriately lost in the urine.

Impaired blood supply

Various conditions may cause damage to, or lead to blockage of, the blood vessels within the kidneys, impairing

blood flow. Such conditions include *shock*, *haemolytic-uraemic syndrome*, *polyarteritis nodosa*, *diabetes mellitus*, and *systemic lupus erythematosus*. Impaired blood flow through the kidneys can lead to tissue damage, hypertension, and kidney failure.

Autoimmune disorders

Glomerulonephritis includes a group of autoimmune disorders (in which the immune system attacks the body's own tissues) that cause the filtering units of the kidneys to become inflamed and unable to function normally.

Drugs

Allergic reactions to drugs, prolonged treatment with *analgesic drugs* (pain-killers), and some *antibiotics* can damage kidney tubules.

Tumours

Noncancerous *kidney tumours* are rare; *kidney cancer* is uncommon.

Metabolic disorders

Diabetes mellitus is the commonest cause of kidney failure in developed countries. Other metabolic disorders, such as

hyperuricaemia, may cause kidney stones to form (see *calculus, urinary tract*).

Infection

Infection of the kidney is called *pyelo-nephritis* and can be a complication of *cystitis*. A predisposing factor to infection is obstruction of urine flow through the urinary tract due to a kidney or ureteral stone, tumour, or congenital defect.

Other disorders

Hydronephrosis (a kidney swollen with urine) is caused by obstruction of the urinary tract. *Crush syndrome* is a condition in which kidney function is disrupted by proteins released into the blood from damaged muscle.

INVESTIGATION

Kidney disorders are investigated by *kidney imaging* techniques such as *ultrasound scanning*, *urography*, *angiography*, and *CT scanning* or *MRI*; by *kidney biopsy* (removal of a small amount of tissue for analysis); by *blood tests*; and by *kidney function tests* such as *urinalysis*.

who have taken certain *analgesic drugs* for a long time. Blood in the urine is a common symptom; *hydronephrosis* (distension of the kidney with urine) may occur due to blockage of the ureter.

DIAGNOSIS, TREATMENT, AND OUTLOOK

The doctor will conduct a physical examination and test a urine sample for the presence of blood. Diagnosis can be confirmed by *ultrasound scanning*, *CT scanning*, *MRI*, or intravenous *urography*.

All types of kidney cancer require surgical removal of the affected kidney and sometimes also of the *ureter*. Any remaining cancerous cells are destroyed using *radiotherapy* and/or treatment with *anticancer drugs* (for example, *interleukin* or *medroxyprogesterone* are given to treat some cases of renal cell carcinoma).

Survival rates vary, depending on the type of cancer and how early treatment is commenced. In the case of nephroblastoma, about four in every five affected children survive; cure rates for this form of kidney cancer are relatively high even if it has spread by the time diagnosis is made.

kidney cyst

A fluid-filled sac in the *kidney*. Cysts commonly develop in people over 50, and can occur either singly or multiply in one or both kidneys. Most cysts occur for no known reason, are noncancerous, and do not usually produce symptoms unless they become large enough to cause lower back pain due to pressure on surrounding tissues. Large numbers of kidney cysts, however, may be associated with *polycystic kidney disease* (see *kidney, polycystic*), which often leads to *kidney failure*.

Simple cysts do not usually require treatment. For cases in which the cysts are painful or recurrent, however, aspiration (withdrawal of fluid) or surgical removal may be carried out.

kidney, duplex

See *duplex kidney*.

kidney failure

A reduction in the function of the kidneys. Kidney failure causes waste products such as urea and excess fluid

to accumulate in the body, and also produces other chemical imbalances in the blood and body tissues.

TYPES

Kidney failure can be acute or chronic. In the acute form, kidney function often returns to normal once the underlying cause has been discovered and treated. In chronic kidney failure, however, kidney tissue is progressively damaged over several months or years. This condition may develop into end-stage kidney failure, a life-threatening condition in which kidney function is usually irreversibly lost.

CAUSES

Causes of acute kidney failure include a severe reduction in blood flow to the kidneys, as occurs in *shock*; an obstruction to urine flow, for example due to a bladder tumour; or certain rapidly developing types of kidney disease, such as *glomerulonephritis*.

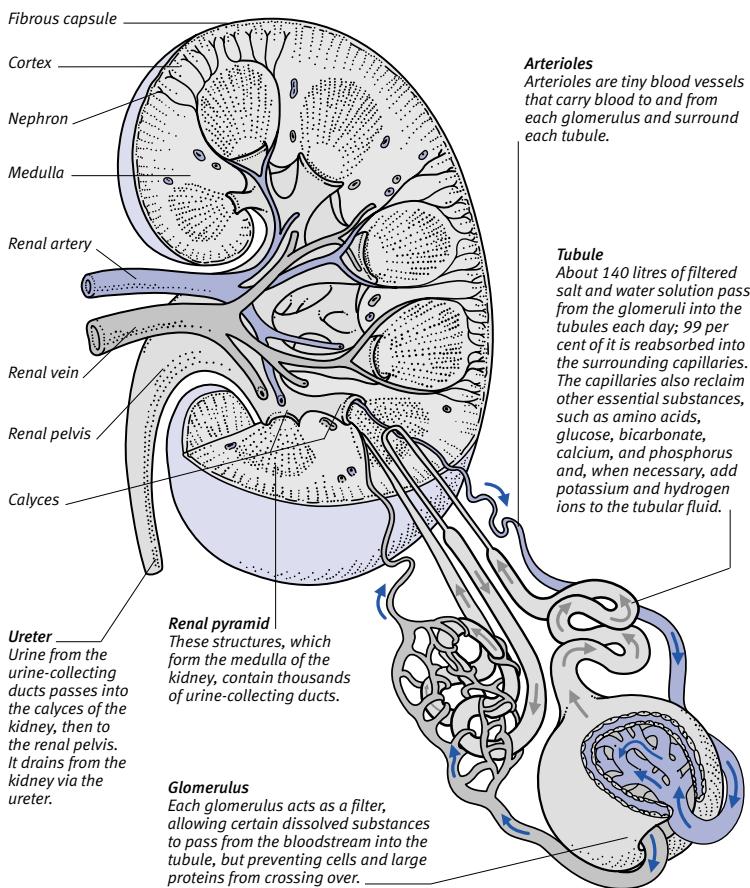

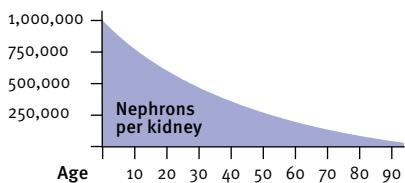

Chronic kidney failure can be the result of a disease that causes progressive damage to the kidneys, such as *polycystic kidney disease* (see *kidney*,

THE FUNCTION OF THE KIDNEYS

The kidneys' main function is to filter the blood. This activity is essential in regulating the body's fluid balance and acid-base balance. Each kidney has about 1 million nephrons, where the filtering takes place. A nephron consists of a knot of capillaries, which is called a glomerulus, and a tubule, where urine is formed. Urine drains out of the kidney via the ureter; the normal daily output is 1 to 2 litres.

RENAL FUNCTION AND AGE

The efficiency of the kidneys diminishes with age as the number of functional nephrons is reduced.

(examination of a tissue sample) and *intravenous urography* (taking X-rays of the urinary tract), may be carried out to identify the cause of the kidney failure if this is not already obvious.

If acute kidney failure is due to a sudden reduction in blood flow, blood volume and pressure can be normalized by saline *intravenous infusion* or *blood transfusion*. If there is an obstruction in the urinary tract, surgery may be needed. Acute kidney disease may be treated with *corticosteroid drugs*. Treatment may also involve *diuretic drugs* and temporary *dialysis* (artificial purification of the blood).

A high-carbohydrate, low-protein diet with controlled fluid and salt intake is important in the treatment of acute and chronic kidney failure, because this reduces the workload on the kidneys.

For end-stage kidney failure, long-term dialysis or a *kidney transplant* is the only effective treatment.

Kidney function tests

Tests that are performed to investigate *kidney disorders*. *Urinalysis* is a simple test in which a urine sample is examined under a microscope for blood cells, pus cells, and casts (cells and mucous material that accumulate in the tubules of the kidneys and pass into the urine). Urinalysis is used to test for substances, such as proteins, that leak into the urine when the kidneys are damaged. Kidney function can be assessed by measuring the concentration in the blood of substances that the kidneys normally excrete, such as *urea* and *creatinine*; by creatinine clearance, in which levels of creatinine in the blood are compared with creatinine excreted in urine over 24 hours; and by *kidney imaging* with radioisotopes.

Kidney imaging

Techniques for visualizing the *kidneys*, usually performed for diagnosis.

Ultrasound scanning is often the first investigation and can be used to identify kidney enlargement, a cyst or tumour, and the site of any blockage. Conventional *X-rays* show the outline of the kidneys and most kidney stones, while *intravenous urography* shows the internal anatomy of the kidney and ureters. *Angiography* is used to image blood circulation through the kidneys. *CT scanning* and *MRI* provide detailed cross-sectional images of kidney tissue and the urine-collecting system, and can show abscesses or tumours.

polycystic), *diabetes mellitus*, and *hypertension* (high blood pressure), or from longstanding obstruction to urine flow.

SYMPOMTS

The most obvious symptom of acute kidney failure is oliguria (a reduced volume of urine). Urea and other waste products build up in the blood and tissues causing drowsiness, nausea, and breathlessness.

Symptoms of chronic kidney failure develop more gradually, and may include nausea, loss of appetite, and weakness. The kidney damage leads to conditions such as *anaemia* and *hyperparathyroidism*.

DIAGNOSIS AND TREATMENT

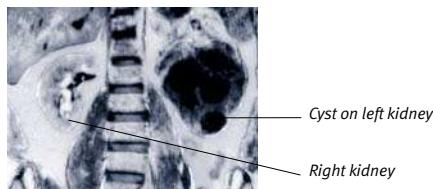

A person with suspected kidney failure will initially need blood and urine tests. Other tests, such as *kidney biopsy*

KIDNEY IMAGING

The various kidney imaging techniques can provide different types of information to help doctors investigate and diagnose kidney disorders.

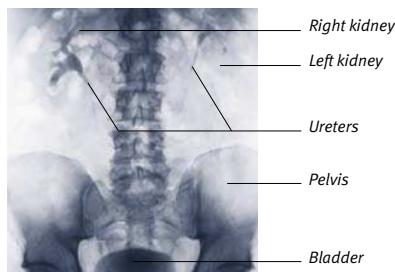

MRI and CT scanning

These techniques produce cross-sectional images of body tissues, displayed as computer-generated pictures. They clearly show structural abnormalities such as tumours and cysts. This MRI scan of the abdomen shows a polycystic kidney (on the right of the image).

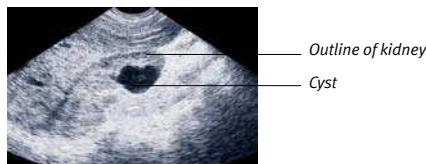

IVU (Intravenous urography)

This is a type of X-ray in which fluid containing a contrast medium (a substance opaque to X-rays) is introduced into the urinary system, then X-rays are taken. The images show how the fluid moves through the kidneys, ureters, and bladder, and can show up any obstructions, such as stones in the urinary tract.

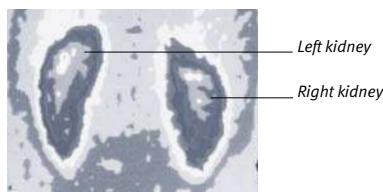

Ultrasound scanning

This is a quick technique, which provides clear images of the structure of the kidney. It can reveal fluid-filled structures such as cysts, which can be clearly differentiated from the kidney tissue surrounding them.

Radionuclide scanning

This produces coloured images to show the functioning of the kidneys. (This scan is taken from the back.) Areas that are brighter than normal show overactive cells, as in a tumour; colours that are less intense than normal show underactivity, as in kidney failure.

Two types of *radionuclide scanning* are used: DMSA and DTPA scanning. DMSA is given by intravenous injection and binds to cells in the kidney tubules, giving a single, static picture of the kidneys. DTPA, also given intravenously, is filtered in the kidneys and passes out in the urine. Pictures taken at intervals record its clearance by the kidney, providing an indicator of kidney function.

Kidney, polycystic

An inherited disorder in which both kidneys develop numerous cysts that gradually enlarge until most of the normal tissue is destroyed. Polycystic kidney disease is distinguished from multiple simple *kidney cysts*, which occur commonly with increasing age.

TYPES

There are two types of polycystic disease. The most common type usually appears in middle age, producing abdominal swelling, pain, and blood in the urine. As the disease progresses, *hypertension* (high blood pressure) and *kidney failure* may result.

The second type of polycystic disease, which is rare, causes enlargement of the kidneys and kidney failure in infants and young children.

TREATMENT AND PREVENTION

There is no effective treatment for preserving kidney function in either type of the condition, but symptoms of kidney failure can be treated by *dialysis* (artificial purification of the blood) and *kidney transplant*.

People with a family history of this disease may need *genetic counselling* before starting a family. The adult form is an *autosomal dominant disorder* and an affected parent has a 50 per cent chance of passing on the defective gene. If both parents carry the gene for the juvenile form (*autosomal recessive disorder*), their fetus can be examined using *ultrasound scanning* to detect kidney enlargement.

Kidney stone

See *calculus, urinary tract*.

Kidney transplant

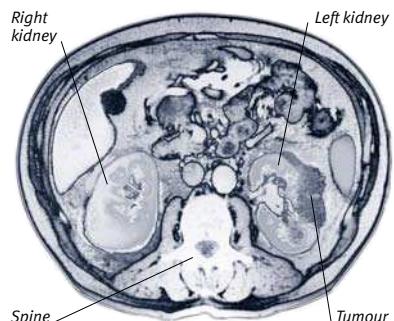

An operation in which a person with chronic *kidney failure* receives a healthy kidney from a living or, more commonly, a dead donor. One donor kidney can maintain the health of the recipient.

The new kidney is placed in the *pelvis* through an incision in the abdomen and carefully positioned so that it can be connected easily to a nearby vein and artery and to the *bladder*. The diseased kidneys may be left in place.

The transplant removes the need for *dialysis* (artificial purification of blood) and often allows a return to a normal lifestyle. The procedure is more straightforward than transplantation of other organs. Unless the donor is an identical twin, *immunosuppressant drugs* are given to avoid rejection of the kidney.

Kidney tumours

Growthths in the *kidney*. Kidney tumours may be cancerous (see *kidney cancer*) or noncancerous. The latter type, which include *fibromas*, *lipomas*, and *leiomyomas*, are often symptomless, although a *haemangioma* (composed of a collection of blood vessels) may grow very large and cause blood to appear in the urine.

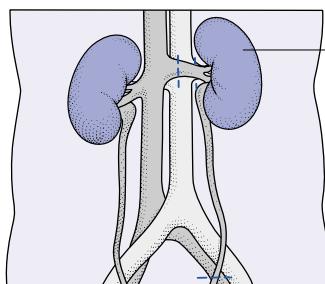

CT scan of a kidney tumour

In this scan, the body is seen from below, with the spine at the base of the image. The kidneys are the round shapes on either side. A tumour (dark mass) can be seen on the left kidney (right of image).

PROCEDURE FOR A KIDNEY TRANSPLANT

A kidney transplant is performed when a person's kidneys have lost almost all of their normal function (so-called end-stage kidney failure). Just one healthy donor kidney can allow a patient to have a normal lifestyle. The donated kidney comes from a close relative of the patient, or from any person who consented to medical use of his or her organs after death. To prevent rejection of the kidney by the recipient's *immune system*, the tissue-type and blood group of recipient and donor must be a close match (see *Transplant surgery*).

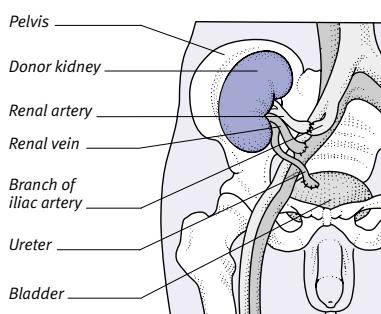

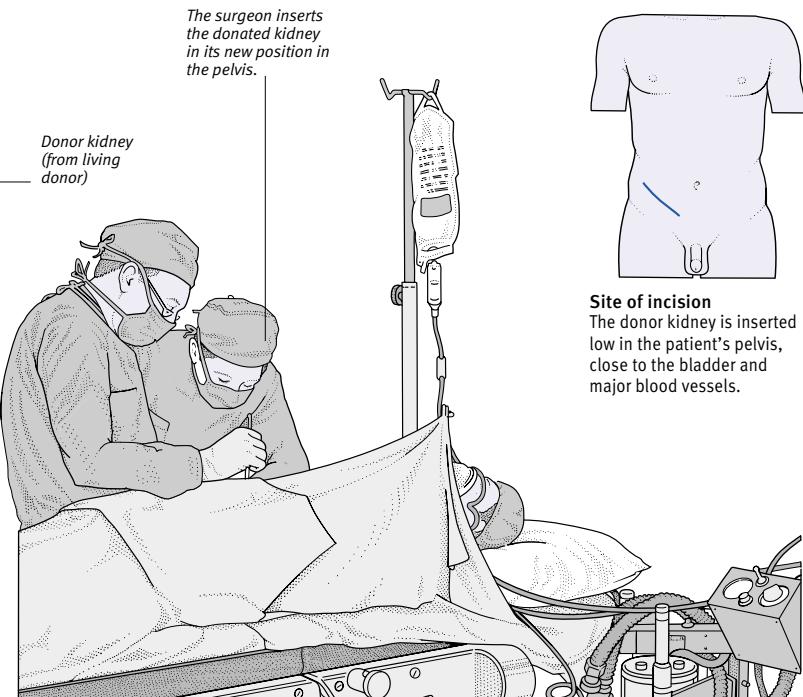

1 The donor kidney is removed. Usually the left kidney is removed from living donors, because it has a longer vein than the right and is easier to remove safely. With donation from people who have died (cadavers), both kidneys are used and each kidney usually goes to a separate recipient. Kidneys from a cadaver can be maintained for transplantation by a machine that passes a cooling saline solution through them. Donor organs may need to be transported over long distances, and occasionally to other countries, to reach the recipient.

2 After removal, a donor kidney is flushed with chilled saline solution in order to preserve the tissues and internal structures. The donor kidney should be transplanted as soon as possible, but there is a reasonable success rate even if transplantation is delayed for up to 48 hours.

DIALYSIS AND TRANSPLANTATION

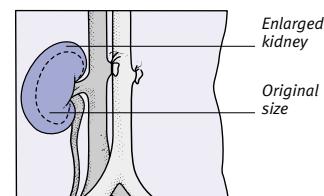

A significant proportion of patients with end-stage kidney failure are suitable for a kidney transplant, but many have to remain on dialysis for some time until a suitable donor kidney becomes available. A computer system is used to match donors with the most suitable recipients. The number of available donor kidneys is considerably less than the number of people waiting for a transplant.

3 The donor kidney is usually placed in the pelvis. The renal artery and vein of the donor kidney are joined to a convenient artery (usually a branch of the external iliac artery) and vein of the recipient. The lower end of the donor ureter is connected to the recipient's bladder. The donor kidney usually begins working immediately after transplantation into the recipient.

THE DONOR (AFTER THE OPERATION)

The health of the donor is not affected by having a kidney removed because the body can work efficiently with just one. The remaining kidney enlarges to increase its capacity and takes over full function.

K

A biopsy of the tumour may be needed to confirm that it is not cancerous. Treatment is usually not needed for noncancerous tumours unless they are large or painful.

Kiel classification

A system that is used for ranking non-Hodgkin's lymphoma (see *lymphoma, non-Hodgkin's*), any of several cancerous tumours of the lymphoid tissues in which the cells divide unchecked. The cancer is classified as high-grade or low-grade according to the type of cell and how rapidly the cells are dividing. Once widely used, Kiel classification has now been replaced by *WHO* classification.

Kienböck disease

Death of tissue cells (see *necrosis*) in the wristbone known as the lunate bone. The disorder, characterized by pain and stiffness in the wrist, is caused by an inadequate blood supply, often the result of an undiagnosed or unsuccessfully treated fracture. Treatment usually consists of resting the joint; in a few cases, surgery is needed.

killer T-cell

A type of white blood cell, also known as a cytotoxic T-lymphocyte or a CD8 lymphocyte, that has an important role in the *immune system*. Killer T-cells destroy an abnormal, cancerous, or virus-infected cell after a foreign *antigen* on its surface has been recognized by *helper T-cells*. (See also *natural killer cells*.)

kilocalorie

The unit of energy equal to 1,000 *calories*, abbreviated to kcal. In dietetics, a kilocalorie is sometimes referred to simply as a calorie (or C).

kilojoule

The unit of energy equal to 1,000 joules, abbreviated to kJ. One kcal (see *kilocalorie*) equals 4.2 kJ.

kinky-hair disease

A genetic disorder, also called Menkes' syndrome, in which body cells do not absorb sufficient copper. The condition is present from birth. It causes brittle, kinky hair; hypotonia (abnormal muscle slackness); feeding difficulties; seizures; and degeneration of brain tissue. Affected children die after a few years.

Kinky-hair disease is an *X-linked disorder*; it affects only male babies, but females may carry the gene. People

with a family history of the disorder may wish to consider genetic counselling before having children.

kiss of life

A common name for *artificial respiration*.

Klebsiella

A genus of rod-shaped bacteria that is commonly found in the human intestine. They may cause pneumonia, lung abscess, or *peritonitis* in people with *ascites* (excess fluid in the peritoneal cavity) due to liver disease. One type, *KLEBSIELLA GRANULOMATIS*, is the cause of the sexually transmitted infection granuloma inguinale or donovanosis, which is common in the tropics and produces a rash and ulceration of the genital area.

kleptomania

A recurring inability to resist impulses to steal, often without any desire for the stolen objects. The condition is usually a sign of an immature personality. It is sometimes associated with *depression*, and may also result from *dementia* or some forms of *brain damage*.

Klinefelter's syndrome

A *chromosomal abnormality* in which a male has one, or occasionally more, extra X chromosomes in his cells, giving

ing a complement of XXY instead of XY. The risk of a baby having the condition increases with maternal age.

SYMPTOMS AND SIGNS

Features of the syndrome vary in severity and may not become apparent until the child reaches puberty, when *gynaecomastia* (breast enlargement) occurs and the testes remain small. Affected males are usually infertile (see *infertility*). They tend to be tall and thin with a female body shape and absence of body hair. Incidence of learning difficulties is higher in people with Klinefelter's syndrome than in the general population.

TREATMENT

There is no cure, but hormonal treatment can induce signs of puberty (see *sexual characteristics, secondary*) such as the growth of facial hair, and surgery may be used to correct gynaecomastia.

Klippel–Fiel syndrome

A condition characterized by an abnormally short neck, due to fused cervical vertebrae. Affected people have restricted neck movement and a low hairline.

Klippel–Trenaunay–Weber syndrome

A rare condition, usually affecting a limb, in which massive malformation of blood vessels (including both arteries and veins) leads to overgrowth of the affected area.

Klumpke's paralysis

Paralysis of the lower arm, with wasting of the small muscles in the hand, and numbness of the fingers (but not the thumb) and the inner forearm.

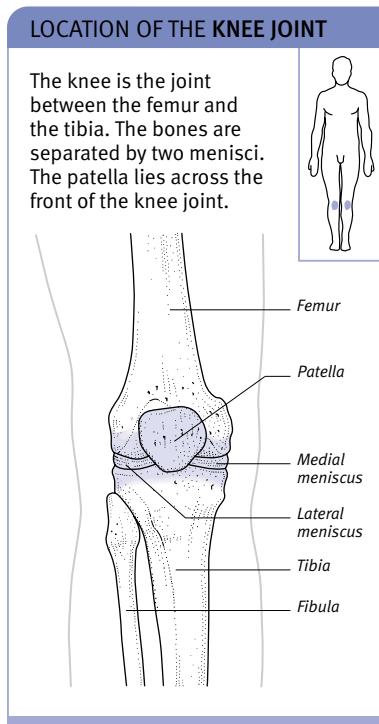

Klumpke's paralysis is caused by injury to the eighth cervical and first thoracic nerves (two of the *spinal nerves*) in the brachial plexus (the network of nerves located behind the shoulderblade), which usually results from injury to the shoulder.

knee

The hinge *joint* between the *femur* (thighbone) and *tibia* (shin). The *patella* (kneecap) covers the front of the joint.

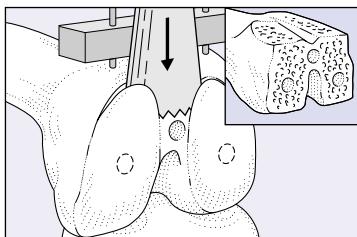

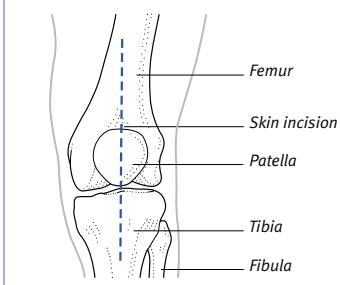

STRUCTURE

Two protective discs of cartilage called *menisci* (see *meniscus*) cover the surfaces of the femur and tibia to reduce friction. Bursas (fluid-filled sacs) located above and below the patella, and behind the knee, cushion the joint. External ligaments on either side of the knee provide support, and cruciate ligaments within

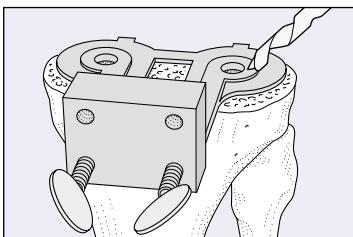

PROCEDURE FOR A KNEE REPLACEMENT

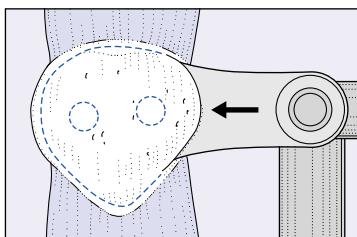

This procedure is carried out to replace a diseased or eroded knee joint. The surgeon usually makes a long, straight incision, cutting through the joint capsule and synovial membrane, then pushes aside the patella to reach the joint. Special instruments are used to make precise measurements and cut away areas of bone so that the artificial knee replacement components will fit and move correctly.

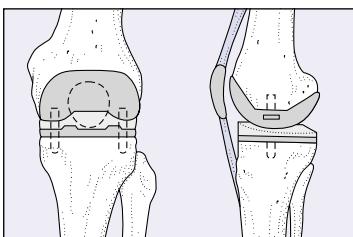

1 The lower end of the femur (thigh-bone) is shaped and holes are drilled into it to accept the femoral component of the prosthesis (see inset). Accuracy is achieved by using the surgical equivalent of a mitre box.

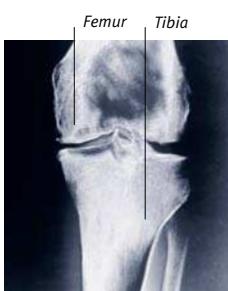

2 The upper end of the tibia (shin-bone) is shaped, and holes are drilled into it to accept the tibial component of the prosthesis. The cutting and drilling of the bone are again carried out using the special orthopaedic instruments.

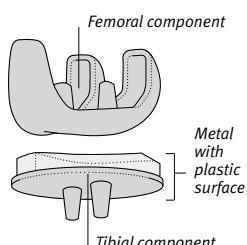

3 Often the patella is left undamaged, but repairs may be carried out to its surface. In this case, the back part of the patella is cut away to leave a flat surface. Small holes are then drilled into this surface to accept the patellar component of the artificial joint.

4 After achieving a satisfactory fit using trial components, the three parts of the final prosthesis are then cemented in place. Any excess cement is then removed from around the new joint and a final check is made of the joint movements.

X-ray of arthritic knee
Severe wear and tear of the bone and cartilage can easily be seen on this knee X-ray.

Knee prosthesis
The main artificial components fit over the femur and tibia (the patellar component is not shown). The prostheses come in different types and sizes.

X-ray of artificial knee
This X-ray shows the three components of the prosthesis in position after surgery.

the joint prevent overstraightening and overbending. The quadriceps muscles, at the front of the thigh, straighten the knee, and the hamstring muscles at the back of the thigh bend it.

DISORDERS

Injuries of the knee are common, and include ligament sprains, torn meniscus, *dislocation* of the patella, and *fracture* of any of the bones. A painful inflammatory condition, *chondromalacia patellae*, is common in adolescents, and *knock-knee* and *bowleg* are common temporary defects in children.

kneecap

See *patella*.

knee-jerk reflex

An involuntary response, also known as a patellar reflex, that occurs when the tendon just below the kneecap (patella) is tapped. The tendon stretches and the thigh muscles contract, straightening the knee. (See also *reflex*.)

knee-joint replacement

Surgery to replace a diseased knee joint with an artificial one, usually made of metal or plastic. Knee-joint replacement is most commonly carried out on older people whose knees are severely affected by the inflammatory conditions *osteoarthritis* or *rheumatoid arthritis*.

Kniest syndrome

A very rare inherited disorder due to abnormal collagen (a protein in bone, cartilage, and connective tissue). It causes severe dwarfism (see *short stature*) with curvature of the spine (*kyphoscoliosis*).

knock-knee

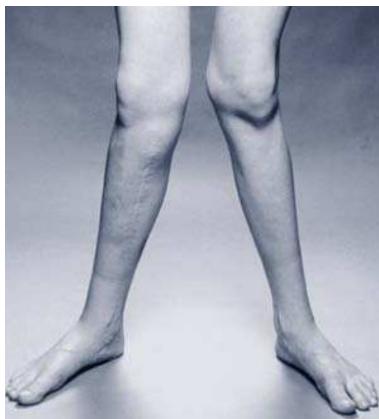

Inward curving of the legs so that the knees touch, causing the feet to be positioned further apart than normal.

CAUSES

Knock-knee is common in children between the ages of three and five and may be part of normal development. In some children, knock-knee may be caused by *rickets*, a disease that softens the bones. In adults, causes include *osteoarthritis* and *rheumatoid arthritis* of the knee. A leg *fracture* that has not healed correctly may also cause knock-knee in children or adults.

TREATMENT

In children, the condition usually disappears by about seven years. Knock-knee that persists, or is due to a disorder, may require *osteotomy*, a surgical procedure

**The appearance of knock-knee**

This condition is common in young children but almost always disappears by the age of seven.

in which the *tibia* (shin) is cut and realigned to straighten the leg. In adults, *knee-joint replacement* may be needed.

knuckle

The name for a *finger* joint.

Koch's bacillus

Another name for *MYCOBACTERIUM TUBERCULOSIS*, the microorganism responsible for *tuberculosis*.

Koebner's phenomenon

A reaction in people with skin disorders such as *psoriasis* and *lichen planus*. New lesions develop, often due to scratching.

koilonychia

A condition in which the *nails* are brittle and thin, and become spoon-shaped. It may be congenital, and may be associated with iron-deficiency *anaemia* or the skin disease *lichen planus*.

**The appearance of koilonychia**

In koilonychia, the nails look fragile and are flattened in the middle and elevated at the ends.

Konakion

A brand name for the *vitamin K* supplement *phytomenadione*, given routinely to newborn babies to prevent bleeding.

Koplik's spots

Tiny spots that appear in the mouth during the incubation period of *measles*.

Korsakoff's psychosis

See *Wernicke-Korsakoff syndrome*.

Krabbe's disease

A very rare inherited metabolic disorder (see *metabolism, inborn errors of*) that causes death in early childhood. Krabbe's disease is caused by deficiency of an *enzyme* (a substance that promotes a biochemical reaction) called galactocerebrosidase. The deficiency leads to the accumulation of toxic chemicals within cells of the nervous system. Symptoms, including *seizures*, deteriorating vision, deafness, and muscle weakness, usually begin to develop by nine months.

kraurosis vulvae

See *vulvitis*.

kuru

A rare, fatal infection of the brain that affects some inhabitants of New Guinea. Kuru is caused by a "slow" virus, or *prion*, which has a long incubation period and is spread by cannibalism. Signs include progressive difficulty in controlling movements and *dementia*.

The study of scrapie in sheep led to the identification of prions, which also play a role in Creutzfeldt-Jakob disease and BSE. (See also *slow virus diseases*).

Kveim test

A skin test used to diagnose *sarcoidosis* (tissue inflammation). It involves injecting Kveim antigen (a protein from the spleens of people with sarcoidosis) into the skin, then taking biopsies from the injection site four to six weeks later to see if nodules of sarcoid tissue have developed. The test has largely been replaced by analysis of lung tissue taken during *bronchoscopy* (examination of the airways with a viewing tube) or biopsy of other affected tissue.

kwashiorkor

A severe form of *malnutrition* in young children that occurs principally in poor rural areas in the tropics.

SYMPTOMS AND COMPLICATIONS

Affected children have stunted growth and a puffy appearance due to oedema (accumulation of fluid in the tissues). The liver often enlarges, dehydration may develop, and the child loses resistance to infection, which may have fatal

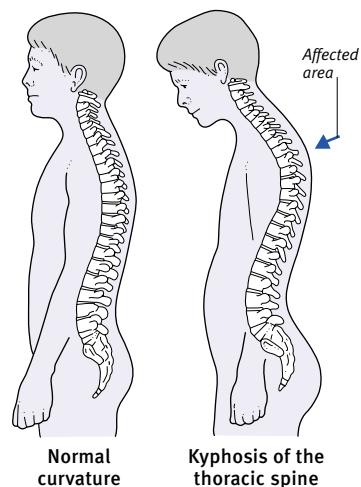

consequences. The advanced stages are marked by jaundice, drowsiness, and a fall in body temperature.

TREATMENT

Initially, the child is fed small, frequent amounts of milk, and vitamin and mineral tablets. A nutritious diet is then gradually introduced. Most treated children recover, but those under two years may have permanently stunted growth.

kyphoscoliosis

A combination of the two types of spinal curvature: *kyphosis* and *scoliosis*.

**The appearance of kyphosis**

In kyphosis, the thoracic part of the spine is excessively curved (as indicated by the arrow, above), producing a humped appearance.

kyphosis

Excessive outward curvature of the *spine*. Kyphosis usually affects the spine at the top of the back, resulting in a hump or pronounced rounding of the back. When kyphosis is combined with a curvature of the spine to one side (*scoliosis*), it is known as kyphoscoliosis.

The condition may be caused by a variety of *spine disorders*, or a *congenital* abnormality. Treatment is of the underlying disorder, but is rarely successful.

L

Laband's syndrome

An autosomal dominant *genetic disorder* affecting tissues throughout the body. It causes bone deformities; overly flexible joints; clubbing of the fingers, and missing nails. Other features include a bulbous nose, overgrowth of the gums, thickened ears, and an enlarged liver and spleen. Some people may also have *learning difficulties*.

labetolol

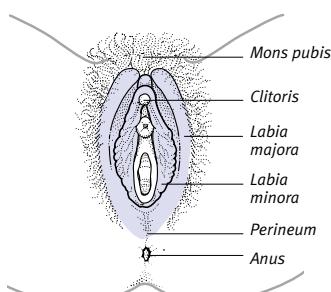

A *beta-blocker drug* that is used to treat *hypertension* (high blood pressure) and *angina pectoris* (chest pain caused by an impaired blood supply to the heart). Possible adverse effects include indigestion and nausea; in rare cases, the drug may cause *depression* and, in men, temporary *impotence*.

labia

The folds of skin of the *vulva* that protect the vaginal and urethral openings. There are two pairs of labia. The outer pair, the *labia majora*, are fleshy folds that contain sweat glands and grow hair. They cover the smaller, hairless inner folds, the *labia minora*, which meet to form the hood of the *clitoris*.

LOCATION OF THE LABIA

The *labia majora* extend forwards from the perineum and fuse at the front at the *mons pubis*. The *labia minora* lie within.

labile

A term meaning "unstable" or "likely to undergo change".

labour

See *childbirth; induction of labour*.

labour pains

Painful muscle contractions in the *uterus* during *childbirth*. The contractions dilate (widen) the *cervix* and then move the baby through the birth canal for delivery.

labyrinth

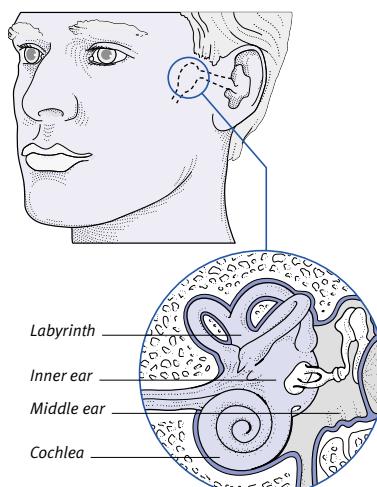

The collective term for the structures of the inner *ear*. The first part of the labyrinth is the *cochlea*, which contains the mechanisms that enable *hearing*. Situated behind the cochlea are two sacs (the *saccule* and the *utricule*) and three fluid-filled semicircular canals, all of which are concerned with *balance*.

labyrinthitis

Inflammation of the *labyrinth*, in the inner ear. The disorder is almost always caused by bacterial or viral infection. Viral labyrinthitis may develop during illnesses such as influenza. The bacterial form is a complication of *otitis media* (middle-ear infection).

SYMPOTMS

The main symptom of labyrinthitis is *vertigo*. Nausea, vomiting, *nystagmus* (abnormal, jerky movements of the eye), *tinnitus* (ringing in the ears), and hearing loss may also occur.

Mechanism of labyrinthitis

In labyrinthitis, inflammation of the fluid-filled chambers (labyrinth) of the inner ear causes disruption of the individual's sense of balance. The inflammation is usually caused by viral or bacterial infection.

TREATMENT

Viral labyrinthitis clears up on its own, but symptoms may be relieved by *antihistamine drugs*. Bacterial labyrinthitis needs immediate treatment with *antibiotic drugs*, otherwise permanent *deafness* or *meningitis* (inflammation of the membranes covering the brain) may result.

laceration

A torn, irregular *wound*.

lacrimal apparatus

The system in the eye that produces and drains *tears*. The lacrimal apparatus includes the main and accessory lacrimal glands and nasolacrimal drainage duct (see *lacrimal apparatus* box, overleaf).

The main lacrimal glands lie just within the upper and outer margin of the eye orbit and drain onto the *conjunctiva* (the transparent membrane covering the white of the eye and the inside of the eyelids). They secrete tears during crying and when the eye is irritated.

The accessory glands lie within the conjunctiva, and maintain the normal tear film, secreting it directly onto the conjunctiva; the fluid is spread across the eye surfaces by blinking.

Tears drain from the eye through the lacrimal puncta, tiny openings towards the inner ends of the upper and lower eyelids. The puncta are connected by narrow tubes to the lacrimal sacs, which lie within the lacrimal bones on the sides of the nose. Leading from the sacs are the nasolacrimal ducts, which open inside the nose.

lactamase

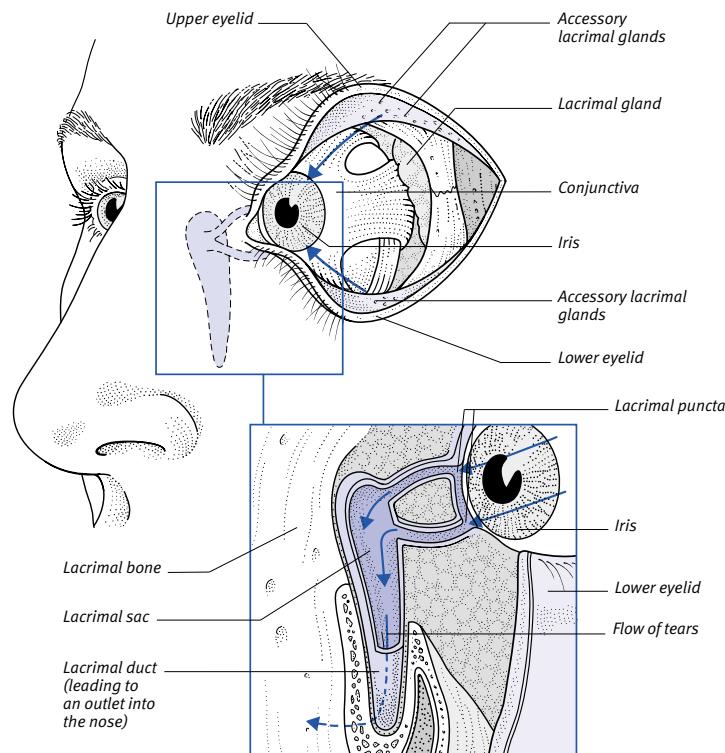

An enzyme, also called penicillinase or beta-lactamase, that is produced by *STAPHYLOCOCCUS* bacteria (see *staphylococcal infections*). Lactamase inactivates *antibiotic drugs* of the penicillin and cephalosporin groups, making them ineffective against the bacteria.

lactase deficiency

A condition in which there is an absence of *lactase*, an enzyme that breaks down *lactose* (milk sugar), in the cells of the small intestine. Lactase deficiency reduces ability to digest lactose. This is called *lactose intolerance* and usually appears in adolescence or adulthood; rarely, it is present at birth (especially in premature babies). Lactase deficiency may also occur temporarily after *gastroenteritis* or treatment with antibiotics, particularly in young children.

FUNCTIONS OF THE LACRIMAL APPARATUS

Tear production must be sufficient to compensate for evaporation and maintain the tear film. Accessory lacrimal glands in the conjunctiva perform this function. The main lacrimal glands secrete tears when excess fluid is required. Surplus tears drain into the nose through the lacrimal puncta, lacrimal sac, and lacrimal duct.

SYMPTOMS

The undigested lactose ferments in the intestines, causing symptoms such as abdominal cramps, bloating, *flatulence*, and *diarrhoea*.

DIAGNOSIS AND TREATMENT

The condition may be diagnosed by testing faeces for the presence of lactose. Alternatively, an *exclusion diet* may be used, in which consumption of dairy products is stopped for a few days and then resumed to see if this causes any changes in the symptoms.

Treatment is with a lactose-free diet. Some people are able to tolerate small amounts of dairy produce but others must avoid dairy products completely, including milk, yoghurt, cream, butter, and cheese. It is possible to obtain milk products in which lactose has already been broken down, and enzyme supplements containing lactase, which can be added to milk, or eaten with food.

lactation

The production and secretion of breast milk (see *breast-feeding*).

lactic acid

A weak acid that is produced when body cells break down glucose by *anaerobic* metabolism (chemical processes that do not require oxygen) to generate energy. Lactic acid is produced by muscles during vigorous exercise and is one of the factors that contribute to *cramp*.

Lactic acid is also produced in body tissues when they receive insufficient oxygen through impairment of their blood supply. This situation may be the result of a *myocardial infarction* (heart attack) or *shock*.

Normally, lactic acid is removed from the bloodstream by the liver. If this does not happen, the lactic acid accumulates in the body and causes a condition known as *lactic acidosis*.

lactobacillus

A type of rod-shaped *bacteria* found in fermented plant and dairy products. Some types of *lactobacilli* colonize the human intestine and the vagina, where they prevent the overmultiplication of harmful bacteria.

lactose

One of the sugars present in milk; a di-saccharide *carbohydrate*.

lactose intolerance

The inability to digest *lactose* (see *lactase deficiency*).

lactulose

An osmotic *laxative drug* that is used to treat *constipation*.

Lafora-body disease

A degenerative disease of the nervous system that causes *epilepsy*. The disease is an autosomal recessive *genetic disorder* that first appears in childhood or adolescence, often with *seizures*. Subsequent signs include impaired movement and coordination, and *dementia*. There is no treatment. Death usually occurs within 10 years of onset.

Lambert–Eaton syndrome

A neuromuscular disorder in which nerve cells fail to release sufficient amounts of the *neurotransmitter* acetylcholine. It is often associated with the type of lung cancer known as *small cell carcinoma*. The main symptom is profound muscle weakness in the trunk and limbs.

lambliasis

Another name for *giardiasis*.

laminectomy

The partial surgical removal of one of the laminae (the bony arches on each *vertebra*). Laminectomy is performed as the first stage of spinal canal decompression (see *decompression, spinal canal*) or in the treatment of a prolapsed disc (see *disc prolapse*).

Lamisil

A brand name for the antifungal drug *terbinafine*.

lamivudine

A *reverse transcriptase inhibitor* drug used in the treatment of *HIV* infection, to slow the progression of the illness. It is always prescribed in combination with another drug for HIV, to prevent the

virus from becoming resistant to it. Often, when treatment is started, three drugs are used: two reverse transcriptase inhibitors and a third drug from another class, such as a *protease inhibitor*. Lamivudine may also be used to treat longstanding *hepatitis B* infections.

Nausea, vomiting, and diarrhoea are the most common side effects; others include a cough, headache, and pins and needles. Side effects such as fever, rash, hair loss, jaundice, or sore throat should be reported to a doctor. If severe abdominal pain develops, the person should seek urgent medical help.

lamotrigine

An *anticonvulsant drug* used either alone or in combination with other anticonvulsants in the treatment of *epilepsy*. Lamotrigine can cause various minor side effects such as rash, nausea, headache, and blurred vision. Rarely, serious skin reactions may occur, particularly in children. In addition, there may be flu-like symptoms, bruising, sore throat, and facial swelling, which should be reported to a doctor promptly.

lance

To incise (cut into) using a *lancet* or a surgical *scalpel*.

lancet

A small, pointed, double-edged knife used to open and drain lesions, such as boils and abscesses.

Landouzy–Dejerine dystrophy

See *facioscapulohumeral dystrophy*.

language disorders

Problems affecting a person's ability to communicate and/or comprehend the spoken and/or the written word (see *speech; speech disorders*).

lanolin

A mixture of purified water and a yellow, oily substance that is obtained from sheep's wool. Lanolin is used as an *emollient* in the treatment of dry skin and mild *dermatitis*. In occasional cases, lanolin may cause an allergic reaction.

Lanoxin

A brand name for the digitalis drug *digoxin*.

lansoprazole

A drug used to treat disorders that are caused by excess stomach acid, such as *peptic ulcer* and *acid reflux*. Lansoprazole belongs to a group of drugs known as *proton pump inhibitors*. These drugs work by inhibiting the production of stomach acid.

Common side effects of lansoprazole include abdominal pain, constipation, diarrhoea, headache, fatigue, and dizziness. More serious side effects include muscle or joint pain, swollen hands and feet, and excessive bruising; all of these symptoms should be reported to a doctor. If a rash, itching, wheezing, or

breathing difficulties develop, the affected individual should stop using the drug immediately and seek urgent medical help.

lanugo hair

The fine, soft, downy hair that covers a *fetus*. Lanugo hair first appears in the fourth or fifth month of gestation and usually disappears by the ninth month. It can still be seen in some premature babies.

Lanugo hair sometimes reappears in adults who have cancer. It may also occur in those with the eating disorder *anorexia nervosa* or be a side effect of certain drugs, especially *ciclosporin*.

laparoscopy

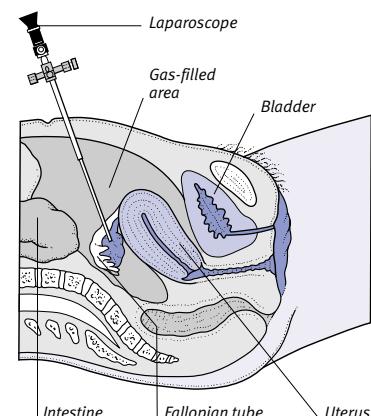

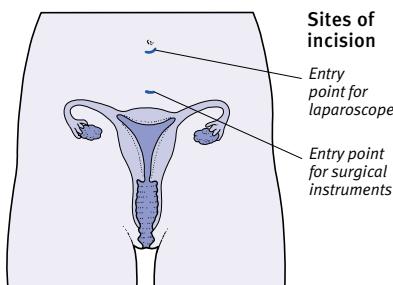

Examination of the interior of the abdomen using a viewing instrument called a laparoscope, which is a type of *endoscope*. Laparoscopy is carried out in order to investigate the possible causes of abdominal pain, such as *appendicitis*. The procedure is also used in *gynaecology* for the diagnosis of disorders and investigation of infertility. Laparoscopy is also used to perform *minimally invasive surgery* such as *appendectomy*, *cholecystectomy*, and female sterilization (see *sterilization, female*).

laparotomy

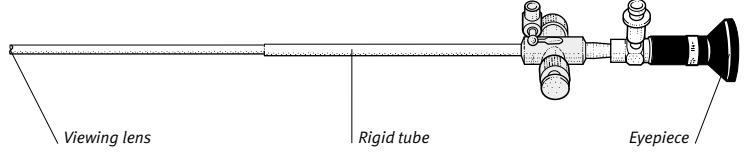

Any operation in which the abdomen is opened either for diagnostic purposes or for surgical treatment.

PROCEDURE FOR LAPAROSCOPY

A hollow needle is inserted into the abdomen just below the navel (under anaesthesia), and carbon dioxide gas is pumped through to expand the abdominal cavity. The laparoscope is inserted through another incision to view the internal organs. The gas is removed afterwards but small amounts may remain for a day or two and cause some discomfort.

THE LAPAROSCOPE

Gynaecological laparoscopy
Laparoscopy is used in diagnosis and is also sometimes used for removing ova for in vitro fertilization. Laparoscopy is commonly used to perform female sterilization.

Largactil

A brand name for the antipsychotic and anti-emetic drug *chlorpromazine*.

large intestine

The last section of the *gastrointestinal tract*. It begins at a pouch called the *caecum* (from which the *appendix* hangs). The main part, the *colon*, has four sections: the ascending, transverse, descending, and sigmoid colon. The intestine ends at the *rectum*, which is connected to the *anus*.

The large intestine processes the remains of food after nutrients have been extracted. It reabsorbs water, vitamins, and mineral salts into the bloodstream, and expels the waste material as *faeces*.

Lariam

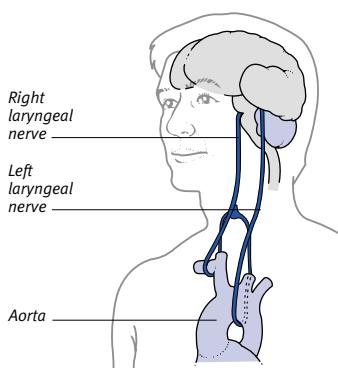

The brand name for the antimalarial drug *mefloquine*.

larva migrans

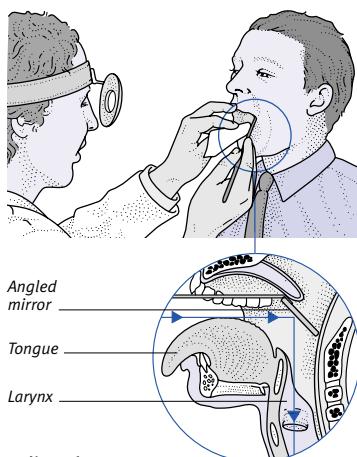

Infections that are characterized by the presence of the larval (immature) forms of certain parasitic worms in the body. Visceral larva migrans (*toxocariasis*) is caused by a type of worm that normally parasitizes dogs. Cutaneous larva migrans (creeping eruption) is caused by a form of *hookworm infestation*; the larvae penetrate the skin and move around, leaving intensely itchy red lines that are sometimes accompanied by blistering. Both types of larva migrans can be treated with *anthelmintic drugs*.

LOCATION OF LARYNGEAL NERVES

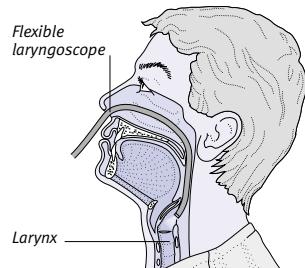

Both nerves leave the brain at the base of the skull and pass down the neck. One hooks around an artery behind the right clavicle, the other hooks around the aorta; both return to the larynx.

**PROCEDURE FOR LARYNGOSCOPY**

There are two techniques for examination of the larynx. The patient's throat is examined with the use of a mirror in indirect laryngoscopy. In direct laryngoscopy, the patient's throat is viewed with an instrument called a laryngoscope. If a flexible laryngoscope is used, only local anaesthesia is needed; if a rigid laryngoscope is used, general anaesthesia is required.

INDIRECT LARYNGOSCOPY**Indirect laryngoscopy**

The patient sticks out his or her tongue and the doctor rests an angled mirror on the soft palate. A lamp or mirror on the doctor's head illuminates the larynx, which is visible in the angled mirror.

DIRECT LARYNGOSCOPY**Flexible laryngoscope**

A flexible laryngoscope is passed down the throat via the nostril; a rigid laryngoscope is passed via the mouth.

View of larynx

This view was obtained with a laryngoscope. The vocal cords are at the centre and the epiglottis forms the arc at the top.

**laryngeal nerve**

One of a pair of *nerves* that carry instructions from the *brain* to the *larynx* (voicebox) and send sensations from the larynx to the brain.

laryngeal nerve palsy

Paralysis of one or both of the *laryngeal nerves*. Laryngeal nerve palsy may be caused by disorders that cause pressure on the nerve, such as an *aneurysm* (localized swelling) in the aorta or a tumour in the thyroid gland, oesophagus, or lung. The condition may also result from infections or poisoning affecting the nerves, or damage during surgery on the thyroid gland, lung, or heart. Laryngeal nerve palsy causes complete or partial *vocal cord* paralysis, resulting in varying degrees of voice loss.

laryngeal stridor

A form of *stridor* (an abnormal, high-pitched sound during breathing) that emanates from the *larynx* (voicebox). It may occur if the larynx is inflamed, or partially blocked by an inhaled object. The condition may also appear at birth,

or soon after, when it is known as congenital stridor; the cause is thought to be abnormal softness of the cartilage in the larynx (laryngomalacia).

Congenital laryngeal stridor rarely causes serious problems and usually corrects itself as the baby grows. However, medical or surgical treatment may be needed if the condition interferes with breathing.

laryngectomy

Surgical removal of all or part of the *larynx* (voicebox) to treat advanced cancer (see *larynx, cancer of*). If the entire larynx is removed, a stoma (opening) is then made in the trachea (windpipe), through which the patient will breathe. After the operation (called a tracheotomy) normal speech is no longer possible, but many patients learn to speak using *oesophageal speech*. There are also electronic devices available that help to generate speech.

laryngitis

Inflammation of the *larynx* (voicebox) that may be acute, lasting only a few days, or chronic, persisting for a long period.

CAUSES

Acute laryngitis is usually caused by a viral infection, such as a cold. It can also be due to an *allergy* or straining the laryngeal muscles. Chronic laryngitis may be caused by overusing the voice; violent coughing; irritation from tobacco smoke or fumes; or damage during surgery. Alcohol, particularly spirits, may aggravate laryngitis.

SYMPOTMS

Hoarseness is the most common symptom and may progress to loss of voice. Throat pain or discomfort and a dry, irritating cough may also occur. Laryngitis due to a viral infection is often accompanied by fever and a general feeling of illness.

TREATMENT

Treatment depends on the cause. Acute laryngitis due to a viral infection usually disappears by itself. There is no treatment for chronic laryngitis other than resting the voice, taking mild analgesic drugs (painkillers) if needed, using steam inhalation, and avoiding tobacco smoke and alcohol. If hoarseness persists for more than two weeks, medical advice should be sought in order to exclude the possibility of laryngeal cancer (see *larynx, cancer of*). In some cases, chronic laryngitis responds to speech therapy.

laryngoscopy

Examination of the *larynx* (voicebox) using a mirror held against the back of the palate (indirect laryngoscopy), or a rigid or flexible viewing tube known as a laryngoscope (direct laryngoscopy).

Laryngoscopy is performed to investigate pain in the throat; difficulty in swallowing; persistent hoarseness; and

abnormal noises during breathing (such as *stridor*). Indirect laryngoscopy can show clear abnormalities, such as inflammation, paralysis of the vocal cords (see *laryngeal nerve palsy*), *singer's nodes*, or tumours. Direct rigid laryngoscopy is usually performed under general anaesthesia, and direct flexible laryngoscopy is usually carried out using local anaesthesia. These techniques enable doctors to examine the tissues of the larynx more closely, as well as to take a *biopsy* (sample of tissue) or remove foreign bodies or benign tumours.

laryngotracheobronchitis

Inflammation of the *larynx* (voicebox), *trachea* (windpipe), and *bronchi* (main airways to the lungs), caused by a viral or a bacterial infection. The disorder is usually mild but in some cases can be life-threatening. It is a common cause of *croup* in young children.

larynx

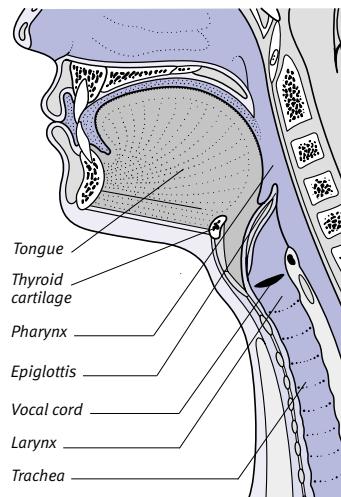

The organ in the throat responsible for voice production, commonly called the voicebox. It lies between the *pharynx* (throat) and the *trachea* (windpipe).

STRUCTURE AND FUNCTION

The larynx consists of areas of *cartilage*, the largest of which is the thyroid cartilage, which projects forwards to form the Adam's apple. Below the thyroid cartilage is the cricoid cartilage, which joins it to the trachea. Situated on the back of the cricoid cartilage are two pyramid-shaped structures called the arytenoid cartilages. The inside of the larynx is lined with mucous membrane.

LOCATION OF THE LARYNX

The larynx, commonly called the voicebox, is situated deep in the throat between the pharynx and the trachea (windpipe).

Within the larynx, stretching between the thyroid and arytenoid cartilages, are two fibrous sheets of tissue called the *vocal cords*. The cords vibrate to produce vocal sounds when air from the lungs passes through them. These vibrations are modified by the tongue, mouth, and lips to produce *speech*.

Attached to the top of the thyroid cartilage is the *epiglottis*, which is a leaf-shaped flap of cartilage that closes

DISORDERS OF THE LARYNX

Disorders of the *larynx* (voicebox) usually cause *hoarseness*; other symptoms of a disorder include breathing difficulties, *stridor* (an abnormal sound during breathing), sore throat, and coughing.

Inflammation

Laryngitis (inflammation of the larynx) is the most common laryngeal disorder in adults. *Croup* (inflammation of the airways) is common in young children, up to the age of about four. Much rarer is *epiglottitis* (inflammation of the epiglottis, the flap of cartilage that covers the larynx).

Congenital defects

Rarely, a baby is born with a soft, limp larynx and epiglottis, a condition called *laryngomalacia*. This defect causes noisy breathing (see *laryngeal stridor*).

Tumours

Various kinds of noncancerous tumour may develop on the vocal cords. The most common is a *polyp* (a noncancerous swelling caused by smoking, an infection such as influenza, or straining the voice). Warts and small noncancerous growths called *singer's nodes* can also occur on the vocal cords. The larynx may also develop cancerous tumours

(see *larynx, cancer of*), which may cause persistent hoarseness.

Other disorders

Lesions, infection, or other disorders affecting the throat tissues, or surgery on the throat, may damage the nerves supplying the larynx. As a result, one or both of the vocal cords may become paralysed (see *laryngeal nerve palsy*).

INVESTIGATION

Disorders of the larynx are investigated by *laryngoscopy*. Sometimes a *biopsy* sample is taken.

over the larynx to prevent food and liquid from passing into the trachea during swallowing.

larynx, cancer of

A cancerous tumour of the *larynx* (voice-box). In more than half of the cases, the tumour develops on one of the *vocal cords*; in the remainder, tumours arise just above or below the cords.

CAUSES

The exact causes are not known, but smoking and high alcohol consumption are known risk factors.

SYMPOTMS

Hoarseness is the main symptom, particularly when the tumour originates on the *vocal cords*. At an advanced stage, symptoms may include difficulty in breathing and swallowing, and coughing up blood. The cancer may have spread to the *lymph nodes* in the neck; if so, the nodes will be enlarged.

DIAGNOSIS AND TREATMENT

If *laryngoscopy* reveals a tumour on the larynx, a *biopsy* (tissue sample) is taken. If the tumour is small, *radiotherapy* or *laser treatment* may be used to destroy it. For unresponsive or large tumours, partial or total *laryngectomy* (removal of the larynx) may be considered.

laser

A device that produces an intense beam of light. Lasers have many medical uses (see *laser treatment*).

laser treatment

Use of a *laser* beam in a variety of medical procedures. Lasers can cut through tissues, seal blood vessels, and destroy abnormal cells. They can be focused precisely so that tissues surrounding an operation site are not damaged.

TYPES

There are many different medical laser systems, and they can be operated in a variety of ways. Some emit light in brief bursts and are known as pulsed lasers; others emit a steady beam and are called continuous wave lasers.

One of the most commonly used devices is the carbon dioxide (CO_2) laser, which can be operated in either continuous or pulsed mode. Of all lasers, the CO_2 laser has an action most similar to that of a conventional scalpel. It is used both for internal surgery, including excision of brain tumours, and for skin treatments, such as the removal of noncancerous moles and scarring, and the reduction of wrinkles.

The argon continuous laser emits a light that is easily absorbed by the blood, causing it to clot. This laser has applications in ophthalmology (particularly in the treatment of abnormalities in the *retina* as a result of *diabetes mellitus*), surgery on the inner ear, and reduction of birthmarks such as port-wine stains. Another versatile laser is the yttrium-aluminium-garnet (YAG) system for treatments such as dentistry, hair and tattoo removal, and lithotripsy (breaking up of kidney stones). Tattoo removal and other dermatological treatments are also often carried out with a system known as the ruby laser, the light from which is strongly absorbed by the pigment melanin in hair and skin.

LASIK

The abbreviation for laser-assisted in-situ keratomileusis, a type of eye surgery in which a *laser* is used to reshape the *cornea* (transparent front part of the eye). LASIK is performed to correct refractive errors (see *refraction*) such as shortsightedness (see *myopia*) and *astigmatism*. A flap is cut partway through the cornea, some of the area beneath is removed by laser, and the flap is replaced.

Lasix

A brand name for the diuretic drug *furosemide* (frusemide).

Lassa fever

A serious infectious disease caused by a rodent-borne virus. Lassa fever, which is transmitted through contact with the urine, faeces, or saliva of rodents, is largely confined to West Africa. Symptoms appear after an incubation period of three to 21 days with fever, headache, muscular aches, and a sore throat. Later, severe diarrhoea and vomiting develop. In extreme cases, the condition leads to fatal heart or kidney failure. Treatment of Lassa fever is with the antiviral drug *ribavirin*, and *serum* containing *antibodies* to the virus.

Lassar's paste

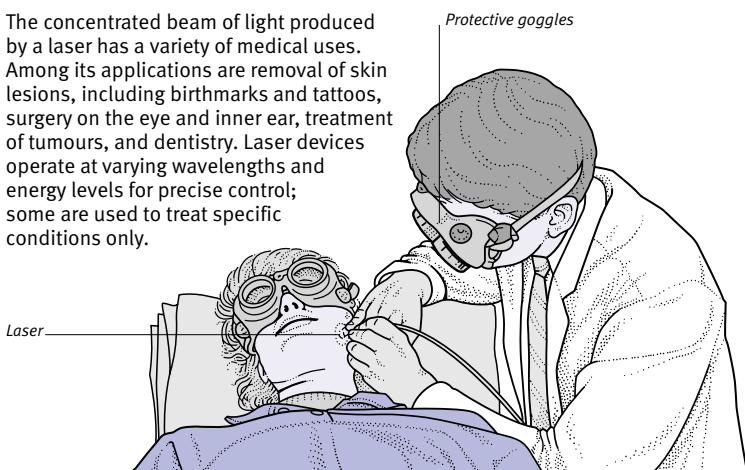

A traditional skin preparation that is used in scaling conditions such as *psoriasis*. Lassar's paste contains *salicylic acid* and *zinc oxide*. Sometimes, *dithranol* is added to the paste.

lassitude

A term describing a feeling of *tiredness*, weakness, or exhaustion.

USE OF A LASER

The concentrated beam of light produced by a laser has a variety of medical uses. Among its applications are removal of skin lesions, including birthmarks and tattoos, surgery on the eye and inner ear, treatment of tumours, and dentistry. Laser devices operate at varying wavelengths and energy levels for precise control; some are used to treat specific conditions only.

Before treatment

After treatment

Removing skin blemishes

These photographs, which were taken before and after laser treatment, show the removal of a port-wine stain (a type of haemangioma). In some cases, treatment is less successful, leaving scars.

latanoprost

A *prostaglandin* drug used as eye-drops in the treatment of the eye condition *glaucoma* (increased pressure of fluid within the eyeball).

lateral

Relating to, or situated on, one side. "Bilateral" means "on both sides".

lateral cutaneous nerve entrapment

Compression of the thigh's lateral cutaneous nerve, which supplies the skin of the front and outer areas of the thigh. The nerve passes underneath the inguinal ligament (the fibrous band of tissue that extends across the crease of the groin); if, for any reason, the ligament puts pressure on the nerve the result is a burning, tingling sensation and sometimes a condition known as *meralgia paraesthetica* (numbness in the thigh). In many cases, the problem is due to obesity. It may also result from over-stretching of the hip joint, for example, when playing sport, or wearing constricting clothes around the hips.

There is no specific treatment. In obese people, weight loss may help to relieve the symptoms. Rarely, surgery is performed to try to reduce the pressure on the nerve.

latex fixation test

Also called the latex agglutination test, a procedure that is performed on body fluids, such as urine, blood, and saliva, in order to detect the presence of particular infections. Tiny beads of latex are coated with *antibodies* (proteins produced by the immune system) against a certain infectious organism and then added to a sample of body fluid. If the organism is present in the sample, it reacts with the antibodies on the beads, causing them to clump together.

latissimus dorsi

A large, flat, triangular *muscle* in the back. One end of the muscle is fixed to the lower chest vertebrae and the back of the *pelvis*, while the other end of the muscle is joined to the top of the *humerus* (upper arm bone). Contraction of the latissimus dorsi muscle moves the arm downwards and backwards.

laudanum

A solution of *opium*, formerly used as a sedative and painkiller and in the treatment of diarrhoea.

laughing gas

The popular name for *nitrous oxide*, used with oxygen in general *anaesthesia*.

Laurence–Biedl–Moon syndrome

A rare inherited disorder characterized by obesity, *retinitis pigmentosa* (degeneration of the retina that may lead to blindness), *learning difficulties*, *polydactyly* (extra digits), and *hypogonadism* (underactivity of the ovaries or testes). (See also *genetic disorders*.)

lavage, gastric

Washing out the stomach with water, usually to remove toxins. The person is laid on one side, with the head lower than the stomach. One end of a lubricated, flexible tube is passed down the *oesophagus* (gullet) into the stomach. The other end is attached to a funnel. Water is poured into the tube until the stomach is full, then the funnel end is lowered, allowing the stomach contents to drain into a bucket. The procedure is repeated until the water runs clear.

Lavage is not used if a corrosive poison has been swallowed because of the risk that the tube may perforate tissues in the oesophagus or stomach.

laxative drugs

COMMON DRUGS

BULK-FORMING • Ispaghula • Methylcellulose

• Sterculia

STIMULANT • Bisacodyl • Co-danthramer

• Co-danthrusate, • Docusate sodium • Senna

• Sodium picosulfate

LUBRICANT • Docusate sodium

• Liquid paraffin

OSMOTIC • Lactulose • Magnesium citrate

• Magnesium hydroxide • Magnesium

sulphate • Sodium acid phosphate

A group of drugs used to treat *constipation* by making faeces pass through the intestines more quickly and easily. Laxatives are also given to people with *haemorrhoids* (piles), to prevent straining during defecation. In addition, they may be used to clear the intestine before investigative procedures such as *colonoscopy* or barium *enema*, or before abdominal surgery.

TYPES

There are various types of laxative, all of which work on the large intestine, either by increasing the speed with which faeces pass through the bowel, or by increasing their bulk and/or water content. Bulk-forming laxatives are not

absorbed as they pass through the digestive tract. They contain particles that absorb many times their own volume of water, thereby increasing the volume and softness of the faeces and making them easier to pass. Stimulant laxatives prompt the intestinal wall to contract more strongly and speed up the elimination of faeces. Lubricant laxatives soften and facilitate the passage of faeces. Osmotic laxatives cause water to be retained in the intestine, thus increasing the softness and volume of the faeces.

POSSIBLE ADVERSE EFFECTS

If they are used in excess, laxative drugs may cause abdominal cramps, diarrhoea, flatulence, and disturbances in body chemistry. Lubricants may prevent the fat-soluble vitamins (A, D, E, and K) from being absorbed in the intestine. Prolonged use of stimulant laxatives may lead to dependence on them for normal bowel function. For these reasons, laxatives should be used only if absolutely necessary, and for as little time as possible. When taken to relieve constipation, their use should be discontinued as soon as normal bowel movements have resumed. If constipation lasts for more than a week, a doctor should be consulted.

lazy eye

A term for the visual defect that commonly results from squint (see *amblyopia*).

LDL

See *low density lipoprotein*.

lead poisoning

Damage to the *brain*, *nerves*, red *blood cells*, and digestive system caused by inhaling lead fumes or swallowing lead salts. Acute poisoning, which occurs when a large amount of lead is taken into the body over a short period of time, is sometimes fatal but is rare. Chronic poisoning can be caused by exhaust fumes from vehicles running on leaded petrol, or by old paint or water pipes containing lead.

SYMPTOMS AND SIGNS

Symptoms of acute poisoning include severe, colicky abdominal pain, diarrhoea, and vomiting. There may also be *anaemia*, appetite loss, and, in chronic lead poisoning, a blue, grey, or black line along the gum margins.

Chronic poisoning can have especially severe effects on children: it can damage the brain and nervous system, leading to behavioural and learning

difficulties, and cause kidney problems and hearing difficulties. In adults, it can harm the kidneys, and the nervous and digestive systems.

DIAGNOSIS AND TREATMENT

Lead poisoning may be confirmed by blood and urine tests. *Chelating agents*, such as *penicillamine*, may be prescribed; they bind to the lead and enable the body to excrete it at a faster rate.

learning

The process by which knowledge or abilities are acquired, or by which behaviour is modified.

Various theories about learning have been proposed. Behavioural theories emphasize the role of *conditioning*, and cognitive theories are based on the concept that learning occurs through the building of abstract "cognitive" models, using mental capacities such as insight, *memory*, *intelligence*, and understanding. No one theory, however, can account for the complexities of learning.

learning difficulties

Problems with *learning*, which result from a range of mental and physical problems. Possible causes include *deafness*, *speech disorders*, and disorders of *vision*, as well as genetic and chromosomal problems. Learning difficulties may be either general or specific.

In general learning difficulties, all aspects of mental and physical functioning may be affected. Depending on the severity of the problem, a child with general learning difficulties may need to be educated in a special school.

Specific learning difficulties include *dyslexia* (difficulty in reading and/or writing), *dyscalculia* (inability to solve mathematical problems), and *dysgraphia* (a writing disorder). An affected child has problems in a particular area of learning but has normal intelligence. Treatment includes correction of any physical problems that interfere with learning, such as vision or hearing problems, and specialized teaching.

learning disability

A *learning difficulty*.

Leber's hereditary optic atrophy

See *optic atrophy*.

lecithin

A *phospholipid* (fatty substance) that is an important component of cell membranes. Lecithin is found in foods such

as egg yolk, offal, and whole grains, and can be extracted from soya to be used as an emulsifier in processed foods. (See also *nutrition*.)

leech

A type of bloodsucking worm with a flattened body and a sucker at each end. Leeches of various types mainly inhabit tropical forests and waters. They bite painlessly, introducing their saliva into the wound before sucking blood. Leech saliva contains an anticoagulant substance called *hirudin*, which may cause the wound to bleed for hours.

Use of leeches to drain blood

Leeches such as this are used in medicine (to drain a *haematoma* from the outer ear following injury, for example). The bites are painless, but the saliva contains an anticoagulant agent, and the wound may bleed for several hours.

Leeches are sometimes used in medicine in order to drain a *haematoma* (collection of blood) from a wound. In addition, sometimes leeches are used in an effort to improve the circulation in tissues after surgery.

left atrium

The upper left chamber of the *heart*. In each heartbeat, the left atrium fills with oxygenated blood, which travels from the lungs via the pulmonary veins. The *mitral valve* then opens, allowing blood to be squeezed into the *left ventricle*, to be pumped around the body.

left bundle branch block

See *heart block*.

left ventricular failure

A disorder in which the left ventricle fails to empty normally, despite increased pressure from the blood within it. (See also *heart failure*.)

leg, broken

See *femur*, *fracture of*; *fibula*; *tibia*.

Legg-Calvé-Perthes' disease

See *Perthes' disease*.

legionnaires' disease

A form of *pneumonia* that is caused by *LEGIONELLA PNEUMOPHILA*, a bacterium that breeds in warm, moist conditions and stagnant water. Legionnaires' disease can occur in outbreaks. The source of infection is often an air-conditioning system in a large public building; the disease is contracted by the inhalation of droplets of contaminated water.

The first symptoms include headache, muscular and abdominal pain, diarrhoea, and a dry cough. Over the next few days, pneumonia develops, resulting in high fever, shaking chills, coughing up of thick *sputum* (phlegm), drowsiness, and sometimes *delirium*. Liver and kidney damage may occur.

Treatment is with antibiotic drugs such as *clarithromycin* and *rifampicin*. The majority of people recover but mortality rates are higher among the elderly.

leg, shortening of

Shortening of the leg is usually caused by faulty healing of a fractured *femur* (thigh-bone) or *tibia* (shin). Other causes are an abnormality present from birth, surgery on the leg, or muscle weakness associated with *poliomyelitis* or another neurological disorder.

legs, restless

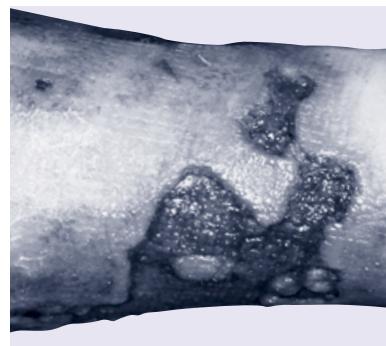

See *restless legs*.

leg ulcer

An open sore on the leg that is slow to heal, usually resulting from poor blood circulation in the area.

TYPES

There are two main types of leg ulcer: venous (also called gravitational or stasis) and arterial. Venous ulcers are by far

Venous ulcer on the leg

This type of ulcer, also known as a *stasis ulcer*, is caused by impaired drainage of blood from the leg by the veins. It is usually accompanied by oedema (fluid accumulation) in the lower leg.

the most common and occur mainly near the ankles and on the lower legs. They are caused by valve failure in veins and usually appear in conjunction with *varicose veins*.

Arterial ulcers, which form on the foot, are caused by poor blood flow through arteries. These ulcers are most likely to occur in people with *diabetes mellitus* and *sickle cell anaemia*.

TREATMENT

Treatment depends on the cause of the ulcer. The affected area should be bandaged in order to prevent infection, reduce swelling, and improve the circulation. If an ulcer is exuding pus, a dressing is applied under bandages and changed every few days. Measures such as exercising regularly, wearing support stockings, and keeping the leg raised when sitting may also help to improve circulation. A leg ulcer may take several months to heal, however, and the problem often recurs. In rare cases, a skin graft is necessary.

leiomyoma

A noncancerous tumour of smooth muscle. Leiomyomas, also called *fibroids*, usually occur in the *uterus*. More rarely, they develop in the walls of blood vessels in the skin, forming tender lumps. Leiomyomas may require surgical removal if they cause symptoms.

leiomyosarcoma

Also known as LMS, leiomyosarcoma is a cancerous tumour of the smooth muscle. Leiomyosarcomas most commonly occur in the stomach, small intestine, bladder, uterus, and prostate and are among the most common types of *sarcoma* (connective tissue cancer) of soft tissue. Leiomyosarcomas mainly affect adults; they are rare in children.

Treatment of a leiomyosarcoma is with surgery, to remove the tumour and surrounding tissue, and chemotherapy and/or radiotherapy if the tumour cannot be removed completely.

leishmaniasis

Any of a variety of diseases caused by single-celled *parasites* called leishmania. These parasites are harboured by dogs and rodents and are transmitted by the bites of sandflies.

TYPES

The most serious form of leishmaniasis is called kala-azar or visceral leishmaniasis. This disease is prevalent in some parts of Asia, Africa, and South Amer-

ica, and also occurs in some Mediterranean countries. In addition, there are several types of cutaneous leishmaniasis, some of which are prevalent in the Middle East, North Africa, and the Mediterranean.

SYMPOTMS

Kala-azar causes persistent fever, enlargement of the *spleen*, *anaemia*, and, later, darkening of the skin. The illness may develop any time up to two years after infection, and, if untreated, may be fatal. The cutaneous forms of the disease have the appearance of a persistent ulcer at the site of the sandfly bite.

TREATMENT

All varieties of leishmaniasis can be treated with drugs, such as sodium stibogluconate, given by intramuscular or intravenous injection.

People visiting areas in which leishmaniasis occurs should take measures to minimize the risk of *sandfly bites*.

Leishmaniasis ulcer

This skin ulcer, which has developed at the site of a sandfly bite, is typical of the lesions found on the skin of people who are suffering from cutaneous leishmaniasis.

lens

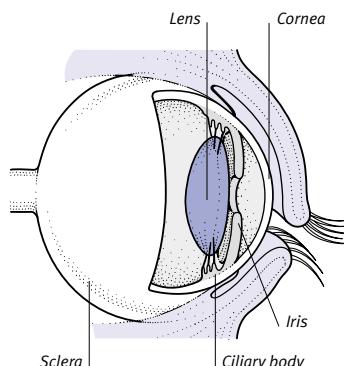

The internal part of the eye that is responsible for focusing; also called the crystalline lens (to distinguish it from the *cornea*, which is also a form of lens). The lens is a disc of elastic, transparent tissue situated behind the *iris* and suspended on delicate fibres from the *ciliary body*. It is slightly less convex on the front surface than on the back.

The lens directs light precisely on to the retina (the layer of light-sensitive cells lining the eyeball). The muscles of the ciliary body act on it to change its curvature and thus alter its focus, so that near or distant objects can be seen sharply (see *accommodation*).

One common disorder that may affect the lens is *cataract* (a condition in which the lens tissue gradually turns opaque, restricting sight). Other possible problems are *lens dislocation* and *aphakia* (absence of the lens).

LOCATION OF THE LENS

This elastic, transparent structure lies behind the iris and is suspended on delicate fibres from the ciliary body. Its full name, the crystalline lens, differentiates it from the cornea (which also acts as a lens).

lens dislocation

Displacement of the crystalline lens from its normal position in the eye. Lens dislocation is almost always due to an injury that ruptures the fibres connecting the lens to the *ciliary body*. In people with the genetic disorder *Marfan syndrome*, these fibres are particularly weak; lens dislocation is common in such individuals.

A dislocated lens may produce severe visual distortion or double vision. If it slips forwards, it may cause a form of *glaucoma* (increased pressure within the eyeball) if drainage of fluid from the front of the eye is affected. If glaucoma is severe, the lens may need to be removed. (See also *aphakia*.)

lens implant

A plastic *prosthesis* (artificial substitute) used to replace the removed opaque lens in *cataract surgery*.

lentigo

A flat, brown area of skin that is also known as an age spot or liver spot. Lentigines (the plural of lentigo) are similar to freckles, except that they occur on both covered and exposed areas of skin and do not fade in winter. They are usually harmless and need no treatment. Any raised, darker brown areas within a lentigo need to be investigated, however, because they could develop into malignant melanomas (see *melanoma, malignant*).

leprosy

See *Hansen's disease*.

leptin

A *protein* that has a role in the regulation of fat storage by the body.

leptospirosis

A rare disease that is caused by a type of *spirochaete* bacterium harboured by rodents and excreted in their urine. It is usually transmitted to humans by contact with contaminated water or soil.

Symptoms of leptospirosis develop one to three weeks after infection. They include fever, chills, intense headache, severe muscle aches, and a skin rash. If the disease is left untreated, the nervous system may also be affected, often producing signs of *meningitis* (inflammation of the membranes covering the brain). The most severe form of leptospirosis is known as Weil's disease; it causes widespread internal bleeding, as well as kidney and liver damage.

Antibiotic drugs are effective but the recovery of kidney and liver function may be slow.

lesion

An all-encompassing term for any abnormality of structure or function in any part of the body. The term may refer to a wound, infection, tumour, abscess, or chemical abnormality.

lethargy

A feeling of *tiredness*, drowsiness, or lack of energy.

leucocyte

An alternative spelling for leukocyte, a type of *blood cell*.

leukaemia

Any of several types of cancer in which there is a disorganized proliferation of abnormal white *blood cells* in the bone marrow. This increase in white cells interferes with production of normal blood cells in the marrow. A reduced number of red blood cells leads to *anaemia*, while a reduction in normal white cells increases the body's susceptibility to infection. Inadequate numbers of platelets may cause abnormal bleeding (see *thrombocytopenia*). Also, organs such as the liver, spleen, lymph nodes, or brain may cease to function properly if they become infiltrated by abnormal cells.

Leukaemias are classified as *acute* or *chronic* (acute types generally develop

faster than chronic). They are also classified according to the type of white cell that is proliferating abnormally. If the abnormal cells are *lymphocytes* or lymphoblasts (precursors of lymphocytes), the leukaemia is called lymphocytic or lymphoblastic leukaemia. If the abnormal cells are derived from other types of white cell or their precursors, the disease is called myeloid, myeloblastic, or granulocytic leukaemia. (See also *leukaemia, acute*; *leukaemia, chronic lymphocytic*; *leukaemia, chronic myeloid*.)

leukaemia, acute

A type of *leukaemia* in which excessive numbers of immature white blood cells called blasts are produced in the bone marrow. If left untreated, acute leukaemia can cause death within a few weeks or months.

TYPES

The abnormal cells may be of two main types: lymphoblasts (immature *lymphocytes*) in acute lymphoblastic leukaemia, or ALL, and myeloblasts (immature forms of other types of white blood cell) in acute myeloblastic leukaemia, or AML.

CAUSES

In most cases, the cause of acute leukaemia is unknown. However, exposure to certain chemicals (such as benzene) or high levels of radiation may be a risk factor. Previous treatments for cancer may also increase the risk of leukaemia developing. Inherited factors are thought to play a part; there is increased incidence in individuals who have certain genetic disorders (such as *Fanconi's anaemia*) and chromosomal abnormalities (such as *Down's syndrome*). In addition, people who have blood disorders such as aplastic anaemia (see *anaemia, aplastic*) or primary *polycythaemia* are at increased risk because their bone marrow is already abnormal.

SYMPTOMS AND SIGNS

The symptoms and signs of acute leukaemia are due to the abnormal white cells crowding the bone marrow and infiltrating the bloodstream and body tissues (see *Leukaemia* box, opposite). They include bleeding gums, headache, easy bruising, bone pain, enlarged lymph nodes, and symptoms of *anaemia*, such as *tiredness*, pallor, and breathlessness on exertion. There may also be repeated chest or throat infections.

DIAGNOSIS AND TREATMENT

Blood tests (and, in some cases, tests on the cerebrospinal fluid, which surrounds the brain and spinal cord) may

reveal the presence of abnormal white cells, but diagnosis is confirmed by a *bone marrow biopsy*.

Treatment is divided into two phases: remission induction to control the disease, and consolidation, which prevents the disease from recurring. Procedures include transfusions of blood and platelets; the use of *anticancer drugs* to kill abnormal cells in the bone marrow; and possibly *radiotherapy* to destroy any abnormal cells in the brain. A *bone marrow transplant* or *stem cell transplant* may also be required.

OUTLOOK

Chemotherapy has increased success rates, but the outlook depends on the type of leukaemia and the age of the patient. People with ALL generally respond better to treatment than those with AML, and many children with ALL can now make a full recovery. Treatment of AML is less likely to be successful in people over the age of fifty.

leukaemia, chronic lymphocytic

A type of *leukaemia* caused by a proliferation of mature *lymphocytes* (white blood cells that are normally involved in fighting infection and harmful cells). There is no cure for the disease, but it is not always fatal. The cause is unknown.

SYMPTOMS

Symptoms develop slowly, often over many years. There may be enlargement of the *liver*, *spleen*, and *lymph nodes*, persistent raised temperature, and night sweats. Recurrent infections and anaemia also are common.

DIAGNOSIS AND TREATMENT

Diagnosis is by blood tests and a *bone marrow biopsy*. In many mild cases, treatment is not needed. If symptoms become troublesome, drug treatment is started, often with *chlorambucil*.

leukaemia, chronic myeloid

Also known as chronic granulocytic leukaemia, a type of *leukaemia* caused by overproduction of granulocytes (a type of white *blood cell*) or, in particular, neutrophils (a type of granulocyte). The cause of the condition is unknown but almost all affected people have a *chromosomal abnormality* called the Philadelphia chromosome, in which part of one chromosome is attached to another.

Chronic myeloid leukaemia usually has two phases: a chronic phase, which may last for several years, and an accelerated, or acute, phase that may last for several months.

LEUKAEMIA

In all forms of leukaemia, abnormal white cells proliferate in the bone marrow and spill into the blood. There are four main types: acute lymphoblastic leukaemia (ALL), acute myeloblastic leukaemia (AML), chronic lymphocytic leukaemia (CLL), and chronic myeloid leukaemia (CML). The acute types have a rapid onset. There

is a risk of death from overwhelming infection or blood loss, but modern treatment has greatly improved survival rates, particularly in childhood leukaemias.

The chronic forms of leukaemia progress much more gradually than the acute types, but many of them are essentially incurable.

Symptoms of acute leukaemia

Symptoms are caused partly by the abnormal white cells crowding out the bone marrow (so that it fails to produce sufficient normal blood cells of all types) and partly by the invasion of other body organs by abnormal cells.

Gum bleeding

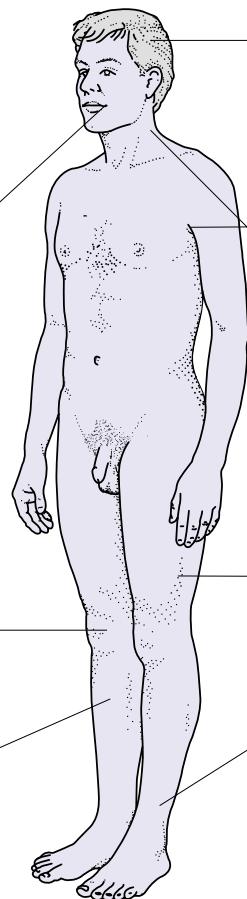

Gums may bleed as a result of insufficient production of platelet cells by the bone marrow; platelets are needed for the arrest of bleeding.

Bone tenderness

Tenderness of the bones may be felt as the bone marrow becomes packed with immature white cells.

Easy bruising and bleeding

Reduced numbers of platelets may lead to bleeding from nose and gums and bruising after mild trauma.

Headache

Headache may be caused by abnormal white cells affecting the nervous system.

Enlarged lymph nodes

The lymph nodes in the neck, armpits, and groin may be swollen with huge numbers of immature white cells. The liver, spleen, and testes may also be swollen.

Anaemia

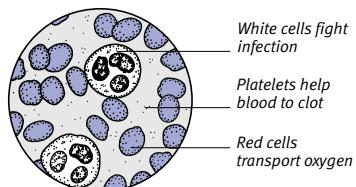

Anaemia develops if there is insufficient production of red blood cells by the bone marrow. Anaemia causes tiredness, breathlessness on exertion, and pallor.

Infections

White blood cells play a major part in the defence against infection. However, in acute leukaemia, only immature, nonfunctioning white cells are made, so the patient may suffer from repeated chest or throat infections, herpes zoster, or skin and other infections.

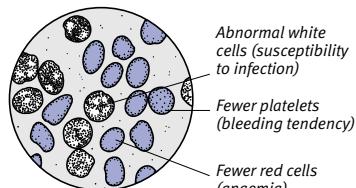

HOW LEUKAEMIA ATTACKS THE BODY

Leukaemia is a form of cancer, but with the abnormally growing cells (mutated white blood cells) forming in the bone marrow rather than grouped into a tumour in a specific area. The abnormal cells may spill into the bloodstream and infiltrate and interfere with the function of other organs. But worse, these cells "take over" the marrow and prevent it from making enough normal blood cells (including normal white cells, red cells, and platelets). This leaves the sufferer highly susceptible to serious infections, anaemia, and bleeding episodes.

Normal appearance of blood

In a normal blood smear, there are large numbers of red cells, many platelets, and a few white cells.

Appearance of blood in leukaemia

In leukaemia, the blood usually contains many abnormal white cells, and fewer red cells and platelets.

SYMPOTMS

During the chronic phase, symptoms are not always obvious, although they may include fever, night sweats, and weight loss. High numbers of white cells may cause the blood to become very thick and unable to flow through the smallest vessels, leaving tissues starved of oxygen. The results include visual disturbances, as blood vessels in the eye are affected, and abdominal pain due to the death of tissues in the spleen; *priapism* (persistent, painful erection of the penis) may also occur.

The symptoms of the accelerated phase are like those of acute leukaemia (see *leukaemia, acute*).

DIAGNOSIS AND TREATMENT

The diagnosis is made from blood tests and a *bone marrow biopsy*. Treatment of the chronic phase includes *anticancer drugs* or *alpha interferons*. A *bone marrow transplant* is also possible if a suitable donor can be found. When the disease transforms into the acute phase, the treatment is similar to that given for acute leukaemia.

leukocyte

Any type of white *blood cell*.

leukodystrophies

A rare group of inherited childhood diseases in which the *myelin* sheaths that form a protective covering around many nerves, particularly in the brain and the spinal cord, are destroyed. The leukodystrophies cause severely disabling conditions, such as impaired speech, *blindness*, *deafness*, and *paralysis*, and are always fatal.

leukoplakia

Raised white patches on the *mucous membranes* of the *mouth* or *vulva* due to tissue thickening. It is most common in elderly people and in those with *AIDS*.

CAUSES

Leukoplakia in the mouth, which most commonly occurs on the tongue, is usually due to *smoking* or to rubbing by a rough tooth or denture. It is not known what causes the condition to develop on the vulva.

SYMPOTMS AND TREATMENT

The raised patches are usually harmless and painless, but they occasionally result in a cancerous change in the affected tissue. For this reason, leukoplakia should always be reported to a doctor.

If the condition persists, the patches are removed under either general or local *anaesthesia* and the tissue is examined microscopically for any signs of malignant change. (See also *mouth cancer*, *vulva*, *cancer of*.)

leukorrhoea

See *vaginal discharge*.

leukotriene receptor antagonists

A group of *antiallergy drugs* that are used to prevent the symptoms of mild to moderate *asthma*. Leukotriene receptor antagonists, which include *montelukast* and *zafirlukast*, work by blocking the effects of leukotrienes (naturally occurring substances that are released in the lungs during an allergic reaction).

Leukotriene receptor antagonists are not *bronchodilator drugs* and will not relieve an existing asthma attack. Instead, they are usually used with bronchodilators and inhaled *corticosteroids* to reduce the frequency of attacks.

Side effects of the drugs can include gastrointestinal disturbances and headache. In addition, hypersensitivity and skin reactions may occur.

levamisole

An *anthelmintic drug* given by mouth in a single dose to eliminate *roundworm* infestation. Side effects are rare but can include mild nausea or vomiting.

levodopa

A drug used to treat *Parkinson's disease*. Levodopa is usually combined with carbidopa or benserazide, substances that enhance levodopa's effects and help to reduce its side effects, including nausea, vomiting, nervousness, and agitation.

levonorgestrel

A *progestogen drug* used in some *oral contraceptives* and, in combination with an oestrogen drug, in *hormone replacement therapy (HRT)*. Norgestrel is a related drug with a similar action.

levothyroxine

A synthetic version of the *thyroid hormone* thyroxine, which is used to treat *hypothyroidism* (underactivity of the thyroid gland). Side effects, such as rapid heartbeat and tremor, may occur if the initial dose is too high.

Lewy-body dementia

A form of *dementia* in which spherical structures called Lewy bodies develop in the brain. There may be fluctuating episodes of confusion and visual hallucinations. Falls are also common.

Leyden–Mobius muscular dystrophy

A form of *muscular dystrophy*, also called limb-girdle muscular dystrophy, that affects the areas where the limbs join the body. Leyden–Mobius muscular dystrophy can occur in either sex, and it usually appears in childhood. It causes muscle weakness and wasting in the pelvic girdle (pelvifemoral muscular dystrophy) or the shoulder girdle (scapulohumeral muscular dystrophy).

LH

The abbreviation for *luteinizing hormone*.

LH-RH

The abbreviation for *luteinizing hormone-releasing hormone*.

libido

Sexual desire. Loss of libido may be a symptom of many physical illnesses; psychological difficulties such as *and depression*; *drug abuse*; and *alcohol abuse*. (See also *sexual desire, inhibited*.)

lice

Small, wingless insects that feed on human blood. There are three species that infest humans: *PEDICULUS HUMANUS CAPITIS* (the head louse), *PEDICULUS HUMANUS CORPORIS* (the body louse), and *PHTHIRUS PUBIS* (the crab, or pubic, louse). All have flattened bodies and may measure up to 3 mm across.

HEAD LICE

Head lice live on the scalp and are spread by direct contact. (The lice prefer clean hair, and their spread is not

due to poor hygiene.) Their tiny eggs (nits) are attached to hairs close to the scalp. The bites from head lice cause intense itching.

BODY LICE

Body lice live and lay eggs on clothing next to the skin. They can transmit epidemic *typhus* and *relapsing fever*.

CRAB LICE

Crab lice live in pubic hair or, more rarely, in armpits, beards, or eyelashes; they are usually transmitted during sexual contact (see *pubic lice*).

TREATMENT

Various preparations can be applied to kill lice and their eggs. In addition, lice on clothes, bedding, and items such as hairbrushes can be killed by washing the items in very hot water.

lichenification

Thickening and hardening of areas of the *skin* caused by repeated scratching, often to relieve the intense itching of skin disorders such as *atopic eczema* or *lichen simplex*.

lichen planus

A common *skin* disease of unknown cause that usually affects middle-aged people. Small, shiny, intensely itchy, pink or purple raised spots appear on the skin of the inner wrists, forearms, or lower legs. There is often a lacy network of white spots covering the inside lining of the cheeks. The disease is treated with topical *corticosteroid drugs*.

lichen sclerosus et atrophicus

A chronic skin condition of the anogenital area. The skin is scarred and white, and the anatomy of areas such as the vaginal opening or foreskin may become distorted. Treatment is with potent topical *corticosteroid drugs*.

lichen simplex

Patches of thickened, itchy, and sometimes discoloured, skin that result from repeated scratching. Typical sites are the neck, wrist, elbow area, and ankles. Lichen simplex is most common in women and is often *stress-related*. Treatment is with oral *antihistamine drugs* and creams containing *corticosteroid drugs*, and may also involve addressing any underlying stress or anxiety.

lid lag

A momentary delay in the normal downward movement of the upper eyelids that occurs when the eye looks

down. Lid lag is a characteristic feature of *thyrotoxicosis* (overactivity of the thyroid gland), and usually occurs in conjunction with *exophthalmos* (protrusion of the eyeball).

lidocaine

A local anaesthetic (see *anaesthesia, local*) that is used to numb tissues prior to minor surgical procedures. Lidocaine is also used as a *nerve block*. The drug is commonly given by injection, but it may also be applied to the surface of the skin as an anaesthetic cream; to mucous membranes as a spray or gel; or to the eyes as eye-drops.

In addition, lidocaine may be given by intravenous injection after a *myocardial infarction* (heart attack), to suppress *ventricular tachycardia* and reduce the risk of *ventricular fibrillation* (both of which are life-threatening abnormalities in the heart rhythm).

lie

In *pregnancy*, the position of the *fetus* relative to the mother's body. Normally, by the end of pregnancy, the long (head to tailbone) axis of the fetus is parallel to that of the mother. If the fetus is lying at an angle to the mother's body, or is horizontal (transverse lie), this may cause *malpresentation* in labour: the fetus's shoulder or body, rather than the head, is positioned over the cervix and delivery by *caesarean section* is needed.

life cycle

The series of stages through which an organism passes as it begins its life, reaches maturity, reproduces, and eventually dies. The term is most often used in the context of animals that assume various forms at different stages of life, such as insects and worms.

life expectancy

The number of years for which an individual at a specified age can expect to live. Life expectancy is often measured from birth. Assuming that patterns of health and illness in a community do not change, it is possible to estimate life expectancy. The proportion of a population that reaches its natural lifespan (the number of years for which people live in the absence of disease) depends on the general health of the population; for this reason, life expectancy may be used to compare levels of general health within or between countries.

life support

The process of keeping a person alive by artificially inflating the lungs (see *ventilation*) and, if necessary, maintaining the heartbeat.

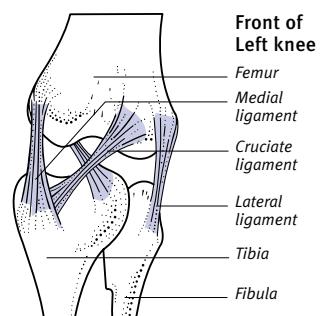

ligament

A band of tough, fibrous, partly elastic tissue that connects or supports certain body structures. Ligaments are most commonly found in *joints*; they bind the ends of the bones together and prevent excessive movement. Some ligaments are also involved in supporting various internal organs, such as the uterus, bladder, and liver.

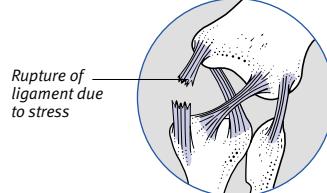

Ligaments, especially those in the ankle or knee joints may sometimes be damaged by injury. Minor ligament injuries such as *sprains* are treated with ice, bandaging, and sometimes *physiotherapy*. If a ligament has been torn (ruptured), the joint is either immobilized by a *plaster cast*, which allows healing to occur, or is repaired surgically.

FUNCTION OF LIGAMENTS

These tough, fibrous bands of tissue bind bone ends together.

Torn ligament
A common injury of football players, torn knee ligaments usually result from twisting stress when the knee is turned while weight is on that leg.

ligation

The surgical process of tying off a *duct* or a blood vessel with a *ligature* (a piece of thread or similar material). Ligation is carried out to stop bleeding from blood vessels, or to close a duct or other tubal body structure. The term is used in tubal ligation, a form of sterilization in which the fallopian tubes are tied off (see *sterilization, female*).

ligature

A length of thread or other material used for *ligation*.

lightening

A feeling that is experienced by many pregnant women at the time when the baby's head descends into the pelvic cavity. Lightening usually occurs in the final three weeks of pregnancy, and, because it leaves more space in the upper abdomen, it relieves pressure under the *diaphragm*.

lightheadedness

A general term for unsteadiness and a feeling of faintness. (See also *dizziness*; *fainting*.)

light reflex

A form of inborn *reflex* in which the pupil of the *eye* automatically responds to the amount of light falling on the eye. Normally, the pupil constricts in response to bright light, to restrict the amount of light entering the eye, and dilates (widens) in response to dim light. Abnormal light reflex can be a sign of disease in the eye or brain.

light treatment

See *phototherapy*.

lidocaine

The former name for *lidocaine*.

limb, artificial

An artificial leg or arm, known medically as a *prosthesis*, which is fitted to replace a limb that has been missing from birth (see *limb defects*) or lost as a result of *amputation*.

Prosthetic limbs enable the wearer to carry out many normal activities, such as walking. In addition, some prosthetic arms and hands contain electronic circuitry that detects and responds to impulses from the wearer's nervous system. This enables the wearer to perform complex hand and finger actions, such as gripping objects.

limb defects

The incomplete development of one or more limbs at birth. Limb defects are rare and may be inherited or form part of a *syndrome*.

In a condition called *phocomelia*, hands, feet, or tiny finger- or toe-buds are attached to limb stumps or grow directly from the trunk. The sedative drug *thalidomide*, when taken by pregnant women, is known to have caused phocomelia in fetuses.

limbic system

A ring-shaped area in the centre of the *brain* consisting of a number of connected clusters of nerve cells. The limbic system plays a role in influencing the *autonomic nervous system*, which automatically regulates body functions; the emotions; and the sense of smell. The system is extensive, and contains various different substructures including the *hippocampus*, the cingulate gyrus, and the amygdala.

limb, phantom

See *phantom limb*.

L

limited cutaneous systemic sclerosis

See *systemic sclerosis*.

limp

An abnormal pattern of *walking* in which the movements of one leg (or of the *hip* on one side of the body) are different from those of the other. If a child is limping, a doctor should be consulted within 24 hours, because the problem may result from a hip disorder that requires prompt treatment.

lintus

A bland, usually sweetened mixture taken to soothe irritation caused by an inflamed *throat*. A simple linctus contains no active drug, but linctuses are commonly used as a basis for cough suppressants (see *cough remedies*).

lindane

A drug formerly used to treat infestation by *scabies* and some types of *lice*. Lindane has now been replaced by other, less toxic drugs.

linea alba

A vertical line of fibrous tissue running down the middle of the abdominal wall. The linea alba is the site of attachment of the rectus abdominis *muscles*

and extends from the xiphoid process (the lowest part of the breastbone) to the pubic symphysis (the joint between the two pubic bones). The skin over the linea alba becomes pigmented during pregnancy (see *linea nigra*).

linea nigra

A pigmented, vertical line that appears down the front of the abdomen during *pregnancy*. The linea nigra is a visible form of the *linea alba* and often fades again after childbirth.

linear accelerator

A device for accelerating subatomic particles, such as electrons, to a speed approaching that of light so that they have extremely high energies. A linear accelerator can also be used to generate high-energy *X-rays*. High-energy electrons or X-rays are used in *radiotherapy* to treat certain cancers.

lingual

A term meaning "of the tongue", as in "sublingual drug" (a drug that is administered under the tongue).

liniment

A liquid that is rubbed on the skin to relieve aching muscles and stiff joints. Liniments may contain rubefacients (substances that increase blood flow beneath the skin), or certain drugs, such as *nonsteroidal anti-inflammatory drugs*.

linkage analysis

A type of *gene mapping*. Linkage analysis determines the presence or absence of an abnormal gene by detecting another gene located close to it on the same *chromosome*.

linkage, sex

The association of a particular *genetic disorder* with the sex chromosomes (see *sex-linked inheritance*).

linoleic acid

An essential *fatty acid* found principally in plant seed oils, such as maize oil and soya bean oil. Linoleic acid is used by the body in the synthesis of *prostaglandins* and cell membranes. Linoleic acid has to be obtained from the diet because the body cannot manufacture its own supplies.

linolenic acid

An essential *fatty acid*, found in fish oils and some plant seed oils, that is used by the body to form *prostaglandins*; linol-

enic acid can be synthesized by the body from *linoleic acid* obtained in the diet.

lint

A soft, absorbent fabric used in surgical dressings.

liothyronine

A *thyroid hormone* used as replacement therapy in *hypothyroidism* (underactivity of the thyroid gland). Liothyronine acts faster than *levothyroxine* and is cleared from the body more rapidly.

lip

One of two fleshy folds around the entrance to the mouth. The main substructure of the lips is a ring of muscle that helps to produce speech. Smaller muscles at the corners of the lips are responsible for facial expression.

Disorders of the lips include *chapped skin*, *cheilitis* (inflammation, cracking, and dryness), *cold sores*, and *lip cancer*.

lipaemia

An abnormally high level of fat in the blood. (See also *hyperlipidaemias*.)

lip cancer

A *malignant* tumour (usually a *squamous cell carcinoma*), commonly on the lower *lip*. Lip cancer is largely confined to older people, particularly those who have been exposed to a lot of sunlight and those who have smoked cigarettes or a pipe for many years.

The first symptom is a white patch that develops on the lip and soon becomes scaly and cracked with a yellow crust. The affected area grows and eventually becomes ulcerated. In some cases, the cancer spreads to the *lymph nodes* in the jaw and neck.

Lip cancer is diagnosed by *biopsy* (taking a sample of the lip tissue for microscopic examination). Treatment is surgical removal, *radiotherapy*, or a combination of both.

lipectomy, suction

A type of *body contour surgery*, commonly known as liposuction, in which excess fat is sucked out through small skin incisions, using a cannula (thin tube) attached to a vacuum device.

lipid disorders

Metabolic disorders that result in abnormal amounts of *lipids* (fats) in the body. The most common lipid disorders are the *hyperlipidaemias*, which are charac-

terized by high levels of lipids in the blood. Hyperlipidaemia can cause *atherosclerosis* (narrowing of the arteries by deposits of fatty material) and *pancreatitis* (inflammation of the pancreas). There are also some very rare lipid disorders, such as *Tay-Sachs disease*, that are due solely to heredity.

lipid-lowering diet

A diet containing low levels of *cholesterol* and of saturated fats (which are found in meat and whole-milk dairy products). By lowering the blood levels of *lipids*, such diets help to prevent *atherosclerosis* (the accumulation of fatty deposits on the walls of arteries).

lipid-lowering drugs

COMMON DRUGS

FIBRATES • Bezafibrate • Ciprofibrate

• Fenofibrate • Gemfibrozil

STATINS • Atorvastatin • Fluvastatin

• Pravastatin • Simvastatin

NICOTINIC ACID AND DERIVATIVES • Acipimox

• Nicotinic acid

DRUGS THAT BIND TO BILE SALTS • Colestipol

• Colestyramine

OTHER DRUGS ACTING ON THE LIVER • Omega-3

marine triglycerides

OTHER DRUGS • Ispaghula

A group of drugs that are used to treat, or provide protection against, *hyperlipidaemia* (abnormally high levels of the fatty substances *cholesterol* and *triglycerides* in the blood). These drugs help to prevent, or slow the progression of, severe *atherosclerosis* (narrowing of the arteries due to deposits of fatty material) and *coronary artery disease*.

HOW THEY WORK

Most groups of lipid-lowering drugs act on the liver to inhibit the processes by which *fatty acids* are converted into *lipids*. Statins cause the liver to produce less cholesterol, while fibrates and nicotinic acid reduce the formation of both cholesterol and triglycerides. Omega-3 marine triglycerides reduce the levels of triglycerides.

Drugs that bind to bile salts reduce the absorption of these salts (which contain high levels of cholesterol) from the small intestine into the bloodstream. The lowered blood levels of bile salts stimulate the liver into converting more cholesterol into bile salts.

POSSIBLE ADVERSE EFFECTS

Drugs that bind to bile salts may cause constipation, and sometimes nausea and diarrhoea, as a result of the increased

amount of bile in the digestive tract. They may also reduce the absorption of fat-soluble vitamins.

Fibrates may cause an increased susceptibility to *gallstones*, while statins need to be used with care in people who have a history of liver disease. Rarely, combinations of drugs that act on the liver may cause a painful muscle condition called *rhabdomyolysis*.

lipidosis

Any disorder involving the *metabolism* (chemical transformation) of *lipids* in body cells. An example of a lipidosis is *Gaucher's disease*, which causes a build-up of fatty deposits in the liver, spleen, bone marrow, and sometimes the brain.

lipids

A general term for *fats and oils*. Lipids include triglycerides (simple fats), phospholipids (important constituents of cell membranes and nerve tissue), and sterols, such as *cholesterol*.

lipoatrophy

Wasting of the subcutaneous fat layer, which lies just beneath the skin. This condition may be associated with *lipodystrophy* and also sometimes occurs at sites of insulin injections in people with *diabetes mellitus*.

lipodystrophy

A type of disorder in which the metabolism (chemical transformation) of fat in the body is disturbed, leading to abnormalities in body fat distribution.

TYPES

One type of lipodystrophy occurs in people undergoing treatment with protease inhibitor drugs for *HIV*; it causes wasting of the limbs, buttocks, and face, but excessive fat deposits in the abdominal cavity, chest or breasts, back, and neck. Affected people also have raised levels of *lipids* in the blood.

Another form, total lipodystrophy, is due to an autosomal recessive genetic disorder. In this disorder, loss of fat over the whole body is associated with raised basal metabolic rate, hirsutism (excessive body hair), liver enlargement, and insulin-resistant *diabetes mellitus*.

lipoma

A common noncancerous tumour of fatty tissue. Lipomas are slow-growing, soft swellings that may occur anywhere on the body, most commonly on the thigh, trunk, or shoulder. They are pain-

less and harmless, but may be surgically removed for cosmetic reasons.

lipoprotein

A small particle that is made up of a fatty core surrounded by a water-soluble form of fat (known chemically as a phospholipid) and a protein (apo-protein). Lipoproteins are the form in which fats are transported in the bloodstream.

liposarcoma

A rare cancer of fatty tissue that most commonly develops during late middle age. Liposarcomas produce firm swellings, usually in the abdomen or the thigh. The tumours can generally be removed by surgery but tend to recur.

Lipostat

The brand name for the lipid-lowering drug *pravastatin*.

liposuction

The popular term for suction lipectomy (see *lipectomy, suction*).

lip-reading

A way of understanding speech by interpreting movements of the mouth and tongue. Lip-reading is often used by people who are deaf.

liquid paraffin

A lubricant *laxative drug* obtained from petroleum. It can cause anal irritation, and prolonged use may impair the absorption of vitamins from the intestine into the blood. It has largely been superseded by docusate sodium.

liquor

A medical term for a liquid, particularly a water-based solution, that contains a medicinal substance. The term is also used to describe body fluids, such as *amniotic fluid*.

liquorice

The dried root of the liquorice plant (*GLYCYRRHIZA GLABRA*) used as a sweetener; a liquorice derivative is used to treat *peptic ulcers*; and it is used as an *expectorant* (a medication that encourages coughing up of *sputum* from the airways).

lisinopril

An *ACE inhibitor drug* commonly used to treat *hypertension* (high blood pressure) and *heart failure*. The first dose of lisinopril may cause a rapid fall in blood pressure,

especially in someone who is also taking a *diuretic*; a person should lie down for a couple of hours after taking it. The drug may also produce various minor side effects, such as a persistent dry cough or a disturbance in taste sensation.

lisp

A common *speech disorder* caused by protrusion of the tongue between the teeth so that the "s" sound is replaced by "th". In most cases, there is no physical cause, but sometimes it is due to a cleft palate (see *cleft lip and palate*).

Unless there is an underlying cause, lisping usually disappears by the age of about four. If it persists beyond this time, speech therapy may be needed.

listeriosis

An infection that is common in animals and also affects humans.

CAUSE

Listeriosis is caused by the bacterium *LISTERIA MONOCYTOGENES*, which is widespread in the environment, especially in soil. Possible sources of human infection with listeriosis include soft cheese, ready-prepared coleslaw and salads, and improperly cooked meat.

SYMPTOMS

In most otherwise healthy adults, the only symptoms may be fever, aching muscles, diarrhoea, and abdominal pain. However, in elderly people, those with reduced immunity, and newborn babies, listeriosis can be life-threatening. *Pneumonia*, *septicaemia* (blood poisoning), and *meningitis* (inflammation of the membranes covering the brain) may develop. In pregnant women, infection may cause a miscarriage or stillbirth.

DIAGNOSIS AND TREATMENT

The condition is diagnosed by *blood tests* and analysis of other body fluids, such as cerebrospinal fluid. Treatment is with *antibiotic drugs* such as *ampicillin* and *gentamicin*.

lithium

A mood-stabilizing drug used in the long-term treatment of *mania* and *manic-depressive illness*, and to help prevent recurrence of severe depression. Side effects include nausea, vomiting, tremor, and excessive thirst. The dosage must be monitored by regular blood tests to prevent serious adverse effects. High levels of lithium may cause blurred vision, drowsiness, rash, and possibly *hypothyroidism* and kidney damage. Side effects should be reported promptly to a doctor.

lithotomy

Surgical removal of a *calculus* (stone) from the *urinary tract*. The procedure is performed only for large stones; smaller stones are usually crushed and removed using *cystoscopy*, or pulverized ultrasonically by *lithotripsy*.

lithotomy position

A position in which a patient lies on his or her back with the hips and knees bent and the legs wide apart; the feet may be supported on firm surfaces or in stirrups. Once used for *lithotomy* (removal of bladder stones), the position is now widely used for *pelvic examinations* and some types of surgery.

lithotripsy

The use of highly concentrated shock waves or ultrasonic waves to break up *calculi* (stones) inside the kidneys, upper *ureters*, and *gallbladder* so that they can be comfortably excreted.

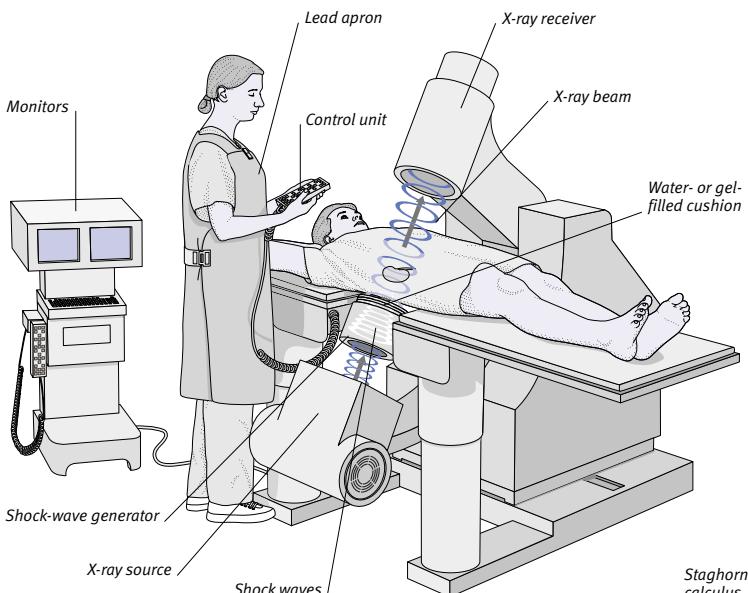

The most common type is extracorporeal shock-wave lithotripsy (ESWL), which is performed to break up small stones. ESWL uses a machine called a *lithotripter*, which produces shock waves that are transmitted into the body through a water- or gel-filled cushion placed over the organ being treated.

Ureteric colic (severe spasmodic pain in the side, occurring if the ureter is obstructed by small fragments of stone)

LITHOTRIPSY

Calculi (stones) can sometimes be broken up by lithotripsy, a procedure that uses ultrasonic or shock waves. In extracorporeal shock-wave lithotripsy (ESWL), the most common form of the treatment, no major surgery is needed. If the stones are in the kidney or ureter, fragments of the stones are passed in the urine.

EXTRACORPOREAL SHOCK-WAVE LITHOTRIPSY (ESWL)

Patient receiving ESWL

The patient is given a general or epidural anaesthetic. The lithotripter produces shock waves that are focused on the stone. The image intensifier (X-ray equipment) allows the operator to locate the stones and adjust the lithotripter to ensure that the shock waves target the stones accurately. Nearly all the energy is dissipated in the stone, shattering it. The patient then drinks liberally to flush out stone fragments. There may be some blood in the urine and abdominal bruising, but serious complications are uncommon.

Kidney stone

This X-ray shows a staghorn calculus (stone) in the left kidney (on the right in the X-ray). With lithotripsy, stones such as these can be removed without the need for surgery.

may occur after ESWL. People treated for *gallstones* may need drug treatment to aid the elimination of stone residues.

lithotripter

The machine used in extracorporeal shock-wave *lithotripsy* (ESWL) to destroy small *calculi* (stones).

Little's area

An area near the front of the nasal septum (partition between the nostrils) that is richly supplied with blood vessels and is a common site of *nosebleeds*.

Little's disease

See *spastic diplegia*.

live birth

The delivery of a baby that breathes spontaneously and has a heartbeat. Statisticians may calculate the number of live births per year per 1000 women of childbearing age (usually 15 to 44), a measure called the fertility rate, to help them assess the health and growth of a population (see *statistics, vital*).

livedo reticularis

A netlike, purple or blue mottling of the skin, usually on the lower legs, caused by enlargement of blood vessels under the skin. It is more common in people with vasculitis (inflammation of the blood vessels) and those who suffer from excessive sensitivity to cold. The condition is harmless, and tends to be worse in cold weather.

liver

The largest organ within the body, this wedge-shaped, reddish-brown structure lies in the upper right abdominal cavity, directly below the *diaphragm*.

STRUCTURE

The liver is divided into two main lobes, each consisting of many lobules. The lobules are surrounded by branches of the hepatic artery, which supplies the liver with oxygenated blood, and the portal vein, which supplies nutrient-rich blood from the small intestine. Deoxygenated blood from the liver drains into the hepatic veins. A network of ducts carries the digestive juice *bile* from the liver to the *gallbladder* and the small intestine.

FUNCTION

The liver plays a vital role in the body because it produces and processes a wide range of chemical substances (see *Disorders of the liver* box and *Structure and function of the liver* box overleaf).

The chemicals produced by the liver include important proteins for blood *plasma*, such as *albumin* and *clotting factors*. The liver also produces *cholesterol* and proteins that help the blood to carry fats around the body. In addition, liver cells secrete bile, which removes waste products from the liver and aids the breakdown and absorption of fats in the small intestine (see *biliary system*).

Another major function is the processing of nutrients for use by cells. The liver also stores excess *glucose* as glycogen. In addition, it controls the blood level of *amino acids* (the building blocks of proteins). If the level of amino acids is too high, the liver converts the excess into glucose, proteins, other amino acids, or *urea* (for excretion).

Finally, the liver helps to clear the blood of drugs and poisons. These substances are broken down and excreted in the bile.

liver abscess

A localized collection of *pus* in the *liver*. The most common cause is an intestinal infection. Bacteria may spread from areas inflamed by *diverticulitis* or *appendicitis*, and *amoebae* may invade the liver as a result of *amoebiasis*. Symptoms are high fever, pain in the upper right abdomen, and (especially in the elderly) confusion.

Ultrasound scanning usually reveals the abscess, and the organism responsible

may be identified by examination of a blood or tissue sample. The abscess can sometimes be treated by *aspiration* (sucking out the pus through a needle), but often surgery is needed.

liver biopsy

A diagnostic test in which a small sample of tissue is removed from the liver, usually under local *anaesthesia*. The main purpose of this test is to aid diagnosis of liver diseases. (See also *biopsy*.)

liver cancer

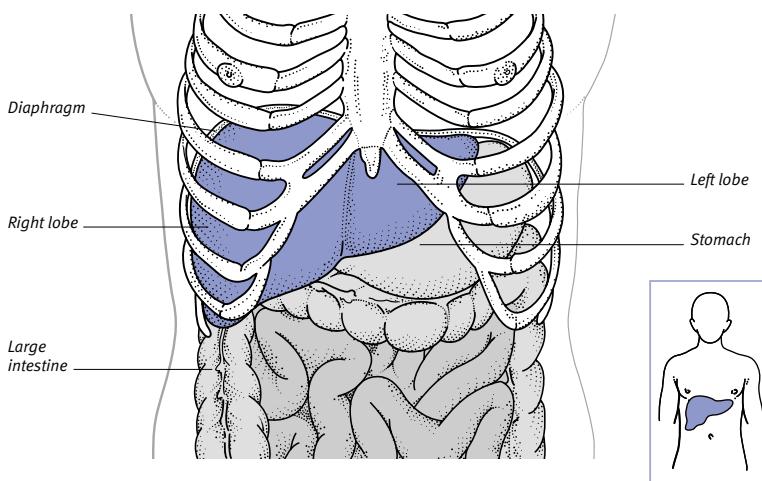

A cancerous tumour in the *liver*. The tumour may be primary (originating in the liver) or, far more commonly, secondary (having spread from elsewhere, often the stomach, pancreas, or large intestine). There are two main types of primary tumour: a *hepatocellular carcinoma*, also known as a hepatoma, which develops in the liver cells; and a *cholangiocarcinoma*, which arises from cells lining the bile ducts. Hepatocellular carcinomas are often linked to *hepatitis B* infection and to *cirrhosis*.

SYMPTOMS

The most common symptoms of any liver cancer are loss of appetite, weight loss, lethargy, and sometimes pain in the upper right abdomen. The later stages of the disease are marked by *jaundice* (yellowing of the skin and the whites of the

LOCATION OF THE LIVER

The liver is a large, red-brown organ, made up of two lobes, that occupies the upper right-hand portion of the abdominal cavity. It lies immediately beneath the diaphragm, to which its upper side is attached. Its base is in contact with the stomach, right kidney, and intestines. Tucked within a depression on the underside of the liver is the gallbladder.

DISORDERS OF THE LIVER

The most common cause of liver disease in developed countries is excessive alcohol consumption. Alcohol-related disorders (see *liver disease, alcoholic*) include *hepatitis* (liver inflammation) and *cirrhosis*. Many other types of liver disorder may occur, including infections, tumours, metabolic disorders, and congenital defects.

Liver failure (complete loss of liver function) may occur as a result of acute hepatitis, poisoning, or cirrhosis. *Jaundice* and hepatomegaly (enlargement of the liver) are common signs of liver disease.

Infection and inflammation

Hepatitis is a general term for inflammation of the liver. It can be caused by viruses (see *hepatitis, viral*) or bacteria, which may spread up the biliary system to the liver, causing *cholangitis* (inflammation of the bile duct) or *liver abscess*. Parasitic diseases, including *schistosomiasis*, *liver fluke*, *amoebiasis*, and *hydatid disease*, can also affect the liver.

Tumours

The liver is a common site for cancerous tumours that have spread

from elsewhere in the body (in which case they are known as secondary tumours of the liver). Primary tumours of the liver (those that originate in the liver) are much rarer. (See *liver cancer*.)

Metabolic disorders

Two main *metabolic disorders* affect the liver: *haemochromatosis* (in which there is too much iron in the body) and *Wilson's disease* (in which there is an excess of copper in the liver).

Congenital defects

Occasionally, defects of liver structure are present from birth. Abnormalities such as these principally affect the bile ducts. A choledochal cyst is a malformation of a main bile duct. These cysts require surgery because, in infants, they may obstruct the flow of bile, causing jaundice. *Biliary atresia*, in which the bile ducts are missing, also causes jaundice.

Poisoning and drugs

Normally, the liver can break down drugs and toxins. However, drug overdose or allergy may damage liver cells in the process, and overdose of

paracetamol can lead to severe liver damage. Poisoning by certain types of mushroom can cause acute liver failure.

Other disorders

In *Budd-Chiari syndrome*, the veins draining the liver become blocked by blood clots, which causes painful swelling of the liver. Obstruction of the portal vein is one cause of *portal hypertension* (high blood pressure in the portal vein), which can lead to *oesophageal varices* (swollen veins in the oesophagus) and *ascites* (collection of fluid in the abdomen).

Enlargement of the liver is a common symptom of *leukaemias* and *lymphomas*. *Liver failure* (complete loss of liver function) may be caused by acute hepatitis, poisoning, or cirrhosis.

INVESTIGATION

Disorders of the liver may be investigated by *liver biopsy* (removal of a tissue sample for examination), *liver-function tests*, and *liver imaging* (which includes *ultrasound scanning*, *CT scanning*, and *MRI*).

eyes, due to accumulation of the bile pigment *bilirubin*) and *ascites* (excess fluid in the abdomen).

DIAGNOSIS AND TREATMENT

Blood tests (see *liver-function tests*) may be used to assess liver function, which can be disturbed by cancer. Tumours are often detected by *ultrasound scanning*, *CT scanning*, or *MRI*; diagnosis may be confirmed by *liver biopsy* (tissue sampling).

A hepatocellular carcinoma can sometimes be cured by total removal of the tumour and a surrounding area of normal tissue. In other cases, *anticancer drugs* can help to slow the disease's progress. It is usually not possible to cure secondary liver cancer, but anticancer drugs or, in some cases, removal of a solitary *metastasis* (secondary cancerous tumour) may significantly improve the outlook.

liver, cirrhosis of

See *cirrhosis*.

liver disease, alcoholic

Damage to the *liver* resulting from excessive *alcohol* consumption. Alcohol-

related liver disease increases the risk of developing *liver cancer*.

The longer that heavy alcohol consumption goes on, the more severe the damage. The initial effect is the formation of fat globules inside liver cells, a condition called fatty liver, followed by *alcoholic hepatitis* (liver inflammation). Damage progresses to *cirrhosis* (scarring of liver tissue), resulting in severe structural damage eventually leading to loss of liver function.

Liver-function tests show a characteristic pattern of abnormalities, and *liver biopsy* (tissue sampling) may be needed to assess the severity of damage. There is no particular treatment, but abstinence from alcohol prevents further damage. Treatment for *alcohol dependence* may be required in some cases.

liver failure

Severe impairment of *liver* function that develops suddenly (acute liver failure) or at the final stages of a chronic liver disease (chronic liver failure). Because the liver breaks down toxins

in the blood, liver failure causes the levels of the toxins to rise, affecting the functioning of other organs, particularly the brain.

SYMPTOMS

Symptoms of acute liver failure develop rapidly; they may include impaired memory, agitation, and confusion, followed by drowsiness. The functioning of other organs may also become impaired, and the condition may lead to *coma* and death.

Features of chronic liver failure develop much more gradually. They include *jaundice*; itching; easy bruising and bleeding; ascites (swollen abdomen due to accumulated fluid); red palms; and, in males, *gynaecomastia* (enlarged breasts) and shrunken testes. Chronic liver failure may suddenly deteriorate into acute liver failure.

TREATMENT

Acute liver failure requires urgent hospital care. Although no treatment can repair damage that has already occurred in acute or chronic liver failure, certain measures, such as prescribing *diuretic*

drugs to reduce abdominal swelling, may be taken to reduce the severity of symptoms. Consumption of alcohol should cease in all cases.

OUTLOOK

The prognosis for sufferers of chronic liver failure varies depending on the cause, but some people survive for many years. For both chronic and acute liver failure, a *liver transplant* is necessary to increase the chances of survival.

liver fluke

Any of various species of flukes (flat-worms) that infest the *bile ducts* in the *liver*. The only significant fluke in the UK is *FASCIOLA HEPATICA*, which causes the disease *fascioliasis*.

Fascioliasis has two stages. During the first stage, young flukes migrate through the liver, causing it to become tender and enlarged; other symptoms include fever and night sweats. In the second stage, adult worms occupy the bile ducts. Their presence may lead to *cholangitis* (inflammation of the bile duct) and bile duct obstruction, which can cause *jaundice*. Treatment with an *anthelmintic drug* may be effective.

liver-function tests

Tests of blood chemistry that can detect changes in the way the *liver* is making new substances and breaking down and/or excreting old ones. The tests can also show whether liver cells are healthy or damaged (see *Liver function tests* table, overleaf).

liver imaging

Techniques that produce images of the *liver*, *gallbladder*, *bile ducts*, and blood vessels supplying the liver, to aid the detection of disease.

Ultrasound scanning is the most widely used technique for imaging the liver; *CT scanning* and *MRI* are also commonly used. *Radionuclide scanning* may reveal cysts and tumours and show bile excretion. *X-ray* imaging techniques include *cholangiography*, *cholecystography*, and *ERCP* (endoscopic retrograde cholangiopancreatography). In these procedures, a *contrast medium*, which is opaque to X-rays, is used to outline the *biliary system*. *Angiography* reveals the blood vessels in the liver.

liver palms

Redness accompanied by warmth in the palms of the hands. This combination of symptoms is often associated with chronic liver disease. (See *liver failure*.)

liver spot

See *lentigo*.

liver transplant

Replacement of a diseased *liver* with a healthy liver removed from a donor. In most cases, the donor is a dead person, but sometimes (for example, when a liver transplant is performed on a child)

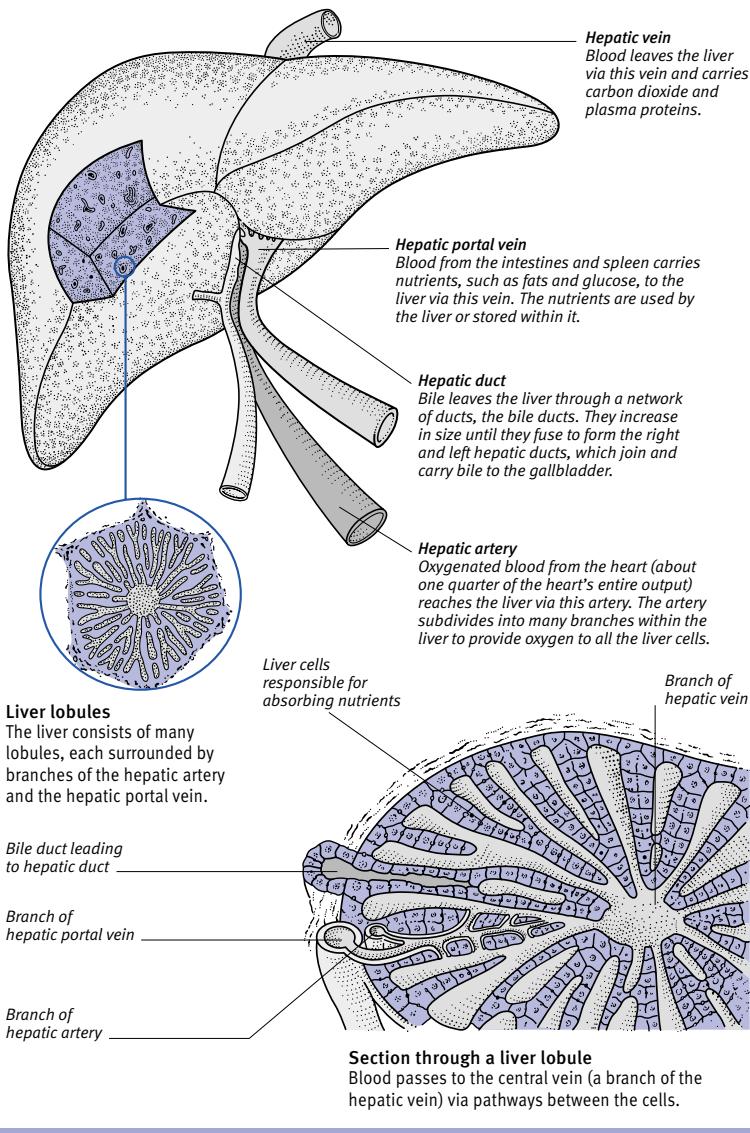

part of the liver may be donated by a living relative of the patient.

WHY IT IS DONE

Liver transplants are most successful in treating advanced liver *cirrhosis* in people with chronic *hepatitis* or primary *biliary cirrhosis*. People with primary liver cancer may be considered for a transplant if the tumour is relatively small.

STRUCTURE AND FUNCTION OF THE LIVER

The liver is a large organ with numerous functions. It absorbs nutrients from blood that has come from the intestines, and regulates the blood's glucose and amino-acid levels. It helps break down drugs and various toxins, and manufactures important proteins, such as albumin and blood coagulation factors. The liver also produces bile, which contains waste products and helps with the digestion of fats in the small intestine.

LIVER-FUNCTION TESTS	
Test	Significance
Serum bilirubin	Bilirubin is the yellow breakdown product of red blood cells that is passed to the liver and excreted in bile. It is this substance that gives the yellow colour to the skin in jaundice. High blood bilirubin levels may indicate excessive breakdown of red blood cells, obstruction to bile flow, defective processing of bile by the liver, or Gilbert's syndrome.
Serum albumin	Albumin is one of the main proteins in blood. Made by the liver, one of its actions is to hold fluid inside the blood vessels. A low level is found in many chronic liver disorders and is often associated with ascites and ankle oedema (fluid collection in the abdomen and around the ankles).
Serum alkaline phosphatase	Alkaline phosphatase is an enzyme found in the cells that line the bile ducts and also in other tissues such as bone. The blood level of this enzyme rises when there is obstruction to the flow of bile (cholestasis).
Gamma-glutamyl transpeptidase	An enzyme present in liver cells. When the flow of bile is obstructed, the blood level of this enzyme is raised, along with a raised level of alkaline phosphatase. A gamma-glutamyl transpeptidase level raised in isolation is related to alcohol intake. Its measurement can also be used as a screening test for glutamyl transpeptidase deficiency.
Serum aminotransferases (transaminases)	The aminotransferases are enzymes released from liver cells into the blood when the liver cells are damaged. The levels will be raised in any condition that damages liver cells, including poisoning, and acute and chronic hepatitis.
Prothrombin time	A normal result in this test of blood clotting depends on the presence in the blood of a protein made by the liver from a fat-soluble vitamin, vitamin K. The test result can be abnormal in two types of disorder: when the protein is not made because of liver cell damage, and when there is a blockage to bile flow in the liver, causing a lack of bile in the intestines (which interferes with fat and vitamin K absorption).

HOW IT IS DONE

During this procedure, the liver, the gallbladder, and portions of the connected blood and bile vessels are removed. The donor organs and blood vessels are then connected to the recipient's vessels.

RECOVERY PERIOD

After the transplant, the recipient is monitored in an *intensive care* unit for a few days and remains in hospital for up to four weeks. Immunosuppressant drugs to prevent rejection of the new organ must be taken for life.

live vaccine

A *vaccine* containing live but weakened (attenuated) forms of an infectious organism. Live vaccines include those for *measles, mumps, rubella, poliomyelitis*, and *tuberculosis*.

Livial

The brand name for *tibolone*, a drug that is used in the treatment of the symptoms of menopause.

lobectomy

An operation performed to cut out a *lobe* in the liver (see *hepatectomy, partial*), the lung (see *lobectomy, lung*), or the thyroid gland (see *thyroidectomy*).

lobectomy, lung

An operation to cut out one of the *lobes* of a *lung*, usually to remove a cancerous tumour in the lung.

lobotomy, prefrontal

The cutting of some of the fibres that link the brain's frontal lobes to the rest of the brain. This operation was formerly used to treat severe psychiatric disorders. It often caused harmful personality changes, however, and is now very rarely performed.

Lobstein's syndrome

See *osteogenesis imperfecta*.

lobular

A word meaning "relating to a lobule".

lobule

A smaller division of a lobe of an organ such as the *liver* or *lung*. Lobules are separated by boundaries such as septa (dividing walls).

local anaesthetic

See *anaesthesia, local*.

localized amnesia

Loss of memory for all events occurring within a particular period of time. See also *amnesia*.

localizing sign

A sign that is found during a physical examination that pinpoints the cause of a disorder.

lochia

The discharge, after childbirth, of blood and fragments of uterine lining from the area where the *placenta* was attached. The discharge is bright red for the first three or four days and then becomes paler. The amount of lochia decreases as the placental site heals, and the discharge usually ceases completely within six weeks.

locked knee

A temporary loss of the ability to move the *knee* joint. A locked knee may be the result of a torn cartilage or of small fragments of bone or cartilage in the joint (*loose bodies*).

lockjaw

A painful spasm of the jaw muscles that makes it difficult or impossible for a person to open the mouth. Lockjaw is the most common symptom of *tetanus*.

locomotor

Relating to movement from one place to another, as in locomotor *ataxia*.

locus

The medical term for a region or site in the body. In genetics, the word is used to describe the position of a gene on a chromosome.

lofepramine

A *tricyclic antidepressant* drug used in the long-term treatment of *depression*. Lofepramine is particularly helpful if the depression is accompanied by lethargy. Possible side effects include dry mouth, sweating or flushed skin, drowsiness, or blurred vision. If the drug causes constipation, difficulty in passing urine, or dizziness, a doctor should be consulted.

Löffler's syndrome

A rare form of allergic reaction affecting the lungs. Possible causes of Löffler's syndrome include drug allergy and roundworm infestation of the lungs (see *ascariasis*). The symptoms include a dry cough, fever, wheezing, shortness of breath, and chest pain. The disease often disappears spontaneously.

log-roll technique

A method of turning a casualty on to his or her back without altering the position of the spine. The technique is used if a spinal injury is suspected and resuscitation is needed (see *cardiopulmonary resuscitation*). The aim is to prevent further injury by keeping the head, trunk, and toes in a straight line.

loiasis

A form of the tropical parasitic disease *filariasis*, which is caused by an infestation by the worm *Loa loa*. The worms travel beneath the skin, producing itchy areas of inflammation known as Calabar swellings, and can sometimes be seen moving across the front of the eye. Loiasis is treated with a course of diethylcarbamazine to kill the worms.

loin

The part of the back on each side of the spine between the lowest pair of ribs and the top of the pelvis.

Lomotil

A brand-name *antidiarrhoeal drug* containing *atropine* and *diphenoxylate*.

longevity

A term meaning length of life or the condition of being long-lived.

longsightedness

See *hypermetropia*.

loop of Henlé

Part of the long renal tubule within each of the kidney's filtering units, or *nephrons*. The U-shaped loop of Henlé absorbs water and certain soluble substances back into the bloodstream.

loose bodies

Fragments of *bone*, *cartilage*, or capsule linings within a *joint*. Loose bodies may occur whenever there is damage to a joint, as in injury, *osteoarthritis*, or *osteochondritis dissecans*.

The fragments can cause a joint to lock, resulting in severe pain. *X-rays* or *arthroscopy* (viewing of the interior of a joint with an endoscope) may reveal their presence. Gentle manipulation of the joint may be required, in order to unlock it. If locking occurs frequently, the loose bodies may be removed during arthroscopy or by surgery.

loperamide

An *antidiarrhoeal drug* that slows intestinal activity and reduces the loss of water and salts from the body. It is usually used to treat sudden and recurrent bouts of diarrhoea (but not if the diarrhoea is due to infection).

Loperamide occasionally produces a rash; other rare adverse effects are abdominal cramps, and bloating. If these effects are severe, they require prompt attention from a doctor.

Lorain-Lévi syndrome

A form of *dwarfism* in which a child retains the appearance of an infant, due to insufficient secretion of growth hormone and a lack of gonadotrophin.

Lorain's disease

See *Lorain-Lévi syndrome*.

loratadine

An *antihistamine drug* used to relieve symptoms of allergic *rhinitis*, such as sneezing, runny nose, and itching eyes, and to treat allergic skin problems such as chronic *urticaria*. It is less likely to

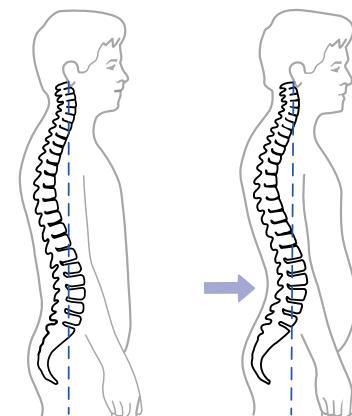

cause drowsiness than some other anti-histamines. Side effects are uncommon; they include headache, fatigue, and nausea. Fainting or palpitations (the sensation of a rapid, forceful heartbeat) may also occur; in this situation, the affected person should stop taking the drug and consult a doctor.

lorazepam

A *benzodiazepine drug* used in the treatment of *insomnia* and *anxiety*, or for premedication prior to an operation or other procedure.

lordosis

Inward curvature of the *spine*. This curvature is normally present to a minor degree in the lower back, but lordosis can become exaggerated by poor posture or by *kyphosis* (excessive curvature of the upper spine). Pronounced lordosis is usually permanent and can lead to *disc prolapse* (slipped disc) or *osteoarthritis* of the spine.

Normal and abnormal lordosis

The normal inward curvature of the spine (left) is exaggerated in abnormal lordosis (right).

losartan

An *angiotensin II antagonist drug* used to treat *hypertension* (high blood pressure). Side effects are rare and mild; they include dizziness, diarrhoea, and fatigue.

Losec

The brand name for the anti-ulcer drug *omeprazole*.

lotion

A liquid drug preparation applied to the skin. Some examples of drugs prepared as a lotion include *calamine* and *betamethasone*, both of which are used to treat skin inflammation.

Lou Gehrig's disease

The most common type of *motor neuron disease*; also known as amyotrophic lateral sclerosis (ALS).

low birthweight

See *birthweight*.

low-density lipoprotein

One of a group of proteins combined with *lipids* in the blood *plasma*. Low-density lipoproteins (LDLs) are involved in the transport of *cholesterol* in the bloodstream; they also deposit cholesterol around the body. An excess of LDLs (see *hyperlipidaemias*) is associated with *atherosclerosis* (narrowing of the arteries by deposits of fatty material). (See also *high-density lipoprotein*.)

lower back pain

See *back pain*.

Lowe's syndrome

A rare, X-linked *genetic disorder* affecting the eyes, kidneys, and brain. Lowe's syndrome is a metabolic disorder in which an *enzyme* found in cell membranes does not function. Only males are affected.

Eye problems include *glaucoma*; *cataracts*; and *nystagmus* (abnormal, jerky eye movements). The kidney dysfunction causes chemical imbalances such as *acidosis* and a form of *rickets* that is resistant to

vitamin D treatment. The brain disorders include *learning difficulties*, behavioural problems, and sometimes *seizures*.

lozenge

A medicated sweet or tablet that dissolves in the mouth, usually taken to relieve a sore mouth or throat.

LSD

The abbreviation for lysergic acid diethylamide, a synthetic *hallucinogenic drug* that is derived from the fungus *ergot*. LSD is used illegally as a recreational drug. It causes visual and sometimes auditory hallucinations (perceptions that occur with no external stimulus); it may also produce unusual emotional states such as "mystical" experiences. The user may also have abnormal thoughts, such as believing that he or she can fly unaided.

LSD sometimes produces panic and physical side effects such as nausea and dizziness. In addition, individuals who have used it frequently may experience "flashbacks" (recurrences of the hallucinations) for months or even years after their last use of the drug. LSD is not addictive but regular users rapidly develop *tolerance*.

Ludwig's angina

A rare bacterial infection that affects the floor of the mouth, usually due to an infected tooth or area of gum. Lud-

wig's angina occurs most commonly in people who tend to have poor *oral hygiene* habits.

Symptoms include fever; pain and swelling in the mouth; and difficulty in opening the mouth and swallowing. If left untreated, the disorder may cause life-threatening swelling in the throat that obstructs breathing and needs immediate treatment with *antibiotic drugs*.

lumbago

A general term for lower *back pain*. Lumbago may be due to an intervertebral *disc prolapse* (slipped disc). It may also arise if *synovium* (joint membrane) is trapped between the surfaces of a small intervertebral joint, or if there is momentary subluxation (partial dislocation) of an intervertebral joint with *sprains* of the ligaments. In many cases, however, no cause is found.

Treatment is with *analgesic drugs* (painkillers) and gentle physical activity. (See also *lumbosacral spasm*.)

lumbar

A word referring to the part of the back between the lowest ribs and the top of the pelvis. The lumbar part of the *spine* is made up of the five lumbar *vertebrae*.

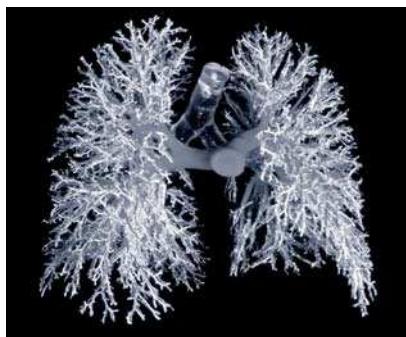

lumbar disc protrusion

See *disc prolapse*.

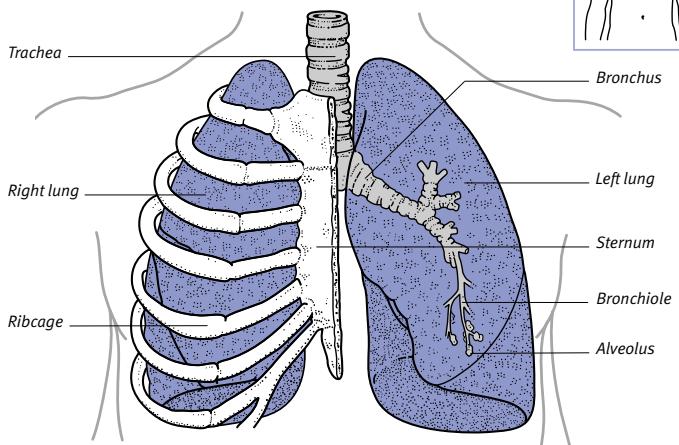

LOCATION AND STRUCTURE OF THE LUNGS

The lungs lie in the chest within the ribcage. Air entering the body through the nose and mouth travels down the trachea to the main bronchi, which divide into smaller bronchi and then into

bronchioles. These in turn lead to alveoli, where the exchange of oxygen and carbon dioxide takes place. During expiration (breathing out), air leaves the body by the same routes.

**Blood vessels in the lungs**

The tiniest "twigs" of this extensive blood vessel "tree" form into capillaries that surround the alveoli (air sacs) in the lung. Oxygen and carbon dioxide are exchanged between the alveoli and the capillaries.

lumbar lordosis

See *lordosis*.

lumbar puncture

A procedure in which a hollow needle is inserted into the lower part of the spinal canal, between two lumbar *vertebrae*, to withdraw *cerebrospinal fluid* or to inject drugs or other substances.

Lumbar puncture is usually carried out to collect a sample of cerebrospinal fluid in order to diagnose and investigate disorders of the brain and spinal cord (such as *meningitis* and *subarachnoid haemorrhage*). The procedure takes about 15 minutes and is carried out under local *anaesthesia*.

lumbosacral spasm

Excessive tightening of the muscles that surround and support the lower region of the *spine*, causing *back pain*. Treatment of lumbosacral spasm may include *analgesic drugs* (painkillers) and *muscle-relaxant drugs*.

lumbosacral spine

The area of the lower *spine* consisting of the lumbar vertebrae and the *sacrum* (the fused vertebrae that form the back of the pelvis).

DISORDERS OF THE LUNG

The lungs are continuously exposed to airborne particles, such as bacteria, viruses, and allergens, all of which can cause disease. Disorders may also arise within the lung tissue or in associated structures such as blood vessels.

Infection

Lung infections are common. These include *pneumonia* (inflammation of the lung), *tracheitis* (inflammation of the lining of the windpipe), and *croup* (a viral infection in young children).

Bronchitis and *bronchiolitis*, which are inflammatory disorders affecting the airways within the lungs, can be complications of colds or *influenza*.

The disorder *bronchiectasis* (abnormal widening of the bronchi) may be a complication of bacterial pneumonia or *cystic fibrosis*.

Allergies

Inhalation of certain substances, such as pollen, *dander* (skin cells from animals), and house mite faeces, can

lumen

The space within a tubular organ or structure such as the intestine.

lumpectomy

A surgical treatment for *breast cancer* in which only the cancerous tissue is removed, rather than the entire breast. (See also *mastectomy*; *quadrantectomy*.)

lumpy jaw

A nonmedical name for *actinomycosis*.

lunacy

An outdated term for serious mental disorder.

lung

One of the two main organs of the *respiratory system*. The lungs supply the body with the oxygen needed for *aerobic* metabolism and eliminate the waste product carbon dioxide.

STRUCTURE AND FUNCTION

Air is delivered to the lungs through the *trachea* (windpipe); this air passage divides into two main bronchi, with one *bronchus* supplying each lung. The main bronchi divide again into smaller bronchi and then into bronchioles, which lead to air passages that open out into

provokes allergic disorders in susceptible people. The most significant of these disorders is *asthma*. Another such disorder is *allergic alveolitis*, which is usually a reaction to dust of plant or animal origin.

Tumours

Lung cancer is one of the most common of all cancers; cancerous tumours may also spread to the lungs from other areas. Noncancerous tumours of the lung are far less common.

Injury

Injury to the lung, usually by penetration of the chest wall, can allow air or blood to collect between the two layers of the pleura (the membrane around each lung), and the lung may collapse (see *pneumothorax*; *haemothorax*). Injury to the interior of the lungs can be due to inhalation of toxic substances (see *asbestosis*; *silicosis*).

Other disorders

The blood supply to the lungs may be reduced by *pulmonary embolism* (a

grapelike air sacs called alveoli (see *alveolus*, *pulmonary*). Oxygen and carbon dioxide diffuse into or out of the blood through the thin walls of the alveoli.

Each lung is enclosed in a double membrane called the *pleura*; the two layers of the pleura secrete a lubricating fluid that enables the lungs to move freely as they expand and contract during breathing. (See also *respiration*.)

lung cancer

The second most common form of *cancer* in the UK (after skin cancer).

CAUSES

Smoking of tobacco is the main cause of lung cancer. Passive smoking (the inhalation of tobacco smoke by non-smokers) and environmental pollution (with radioactive minerals or asbestos, for example) are also risk factors.

TYPES

There are several types of lung cancer, each of which affects a different group of lung cells. The most common types are squamous cell carcinoma and small cell (or oat cell) carcinoma; the other main types are adenocarcinoma and large cell carcinoma.

Each form of lung cancer has a particular growth pattern and response to

condition in which a clot obstructs a blood vessel in the lung).

Oxygen intake may be severely impaired by diseases affecting the tiny air sacs in the lungs (see *alveolus*, *pulmonary*). In *emphysema*, the alveoli are destroyed, thereby reducing the area of lung tissue where oxygen is absorbed into the blood (see also *pulmonary disease*, *chronic obstructive*). *Respiratory distress syndrome* in adults occurs when fluid leaks into the alveoli from the tiny blood vessels surrounding them, thereby preventing the alveolar walls from absorbing sufficient oxygen.

INVESTIGATION

Lung disorders are investigated by *chest X-ray*, *CT scanning*, *bronchoscopy*, *pulmonary function tests*, *sputum analysis*, and *blood tests*. Sometimes, a lung *biopsy* (removal of a tissue sample) is performed.

treatment. Small cell carcinoma is the most highly malignant form of lung cancer; it grows rapidly and spreads very quickly throughout the body. In contrast, squamous cell carcinoma grows more slowly than the other forms and does not spread outside the lung until late in the course of the disease.

SYMPTOMS

The first and most common symptom of lung cancer is a persistent cough. Other symptoms include coughing up blood, shortness of breath, and chest pain. The tumour may obstruct the airway, causing *pneumonia* (inflammation in the lung), or involve the pleura (the double-layered membrane covering the lung), causing an accumulation of fluid called *pleural effusion*. A tumour developing at the top of the lung may press on the nerves supplying the arm on that side, causing pain and weakness in the arm.

Lung cancer can spread to other parts of the body, especially the liver, brain, and bones, causing pain and other problems in these areas.

DIAGNOSIS AND TREATMENT

In most cases, the cancer is revealed in a *chest X-ray* or diagnosed from abnormal cells in a sputum sample. A doctor may also perform a *bronchoscopy* to view inside the airways. To confirm the diagnosis, a *biopsy* (tissue sample) is taken and is examined microscopically for the presence of cancerous cells (see *cytology*). Blood tests, and *CT scanning* or *MRI*, may be used in order to determine whether or not the cancer has spread to other areas.

If lung cancer is diagnosed at an early stage, *pneumonectomy* (removal of the whole lung) or *lobectomy* (removal of the diseased lobe of the lung) may be a possibility. Surgery is usually considered only in cases in which the tumour is still relatively small and has not spread beyond the lung. *Anticancer drugs* and *radiotherapy* may be used in order to contain the spread of the tumour and to treat any metastases (cancerous cells that have spread to other areas of the body). Small cell carcinoma is usually treated by means of radiotherapy and chemotherapy.

lung, collapse of

See *atelectasis*; *pneumothorax*.

lung disease, chronic obstructive

See *pulmonary disease, chronic obstructive*.

lung-function tests

See *pulmonary function tests*.

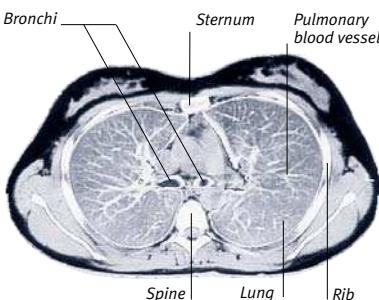

lung imaging

Techniques that are used to provide images of the lungs in order to facilitate the diagnosis of lung disease. Most *lung disorders* can be detected by means of *chest X-ray*. *CT scanning* and *MRI* play an important role in detecting the presence and the spread of *lung tumours*. *Ultrasound scanning* is sometimes used to reveal *pleural effusion* (buildup of fluid around a lung). *Radioisotope scanning* is used to detect evidence of *pulmonary embolism* (in which a clot obstructs a blood vessel in a lung); alternatively, a pulmonary *angiogram* contrast X-ray may be performed.

Chest X-ray

This is the most important lung imaging technique. It provides information about the lungs, their blood vessels and main airways.

CT scanning of the lungs

This scan shows detailed horizontal slices through the lungs. CT scans are useful for showing the extent and spread of lung tumours.

lung lobectomy

See *lobectomy*, *lung*.

lung tumours

Growths in the lungs. These tumours may be either cancerous (see *lung cancer*) or noncancerous.

Noncancerous tumours occur less frequently than cancers. The most common of these tumours is a bronchial *adenoma*, which arises in the lining of a bronchus. Adenomas often cause bronchial obstruction; affected people may also cough up blood. Treatment of adenoma involves surgical removal of the tumour.

Other rare noncancerous tumours include *fibromas* (which consist of fibrous tissue) and *lipomas* (which consist of fatty tissue). No treatment is necessary for these, unless the tumours are causing problems.

lupus erythematosus

An *autoimmune disorder* that causes inflammation of *connective tissue*. The most common type of this disorder is discoid lupus erythematosus (DLE), which affects only exposed areas of skin. The more serious form, *systemic lupus erythematosus* (SLE), affects many of the body systems, including the skin.

SYMPTOMS

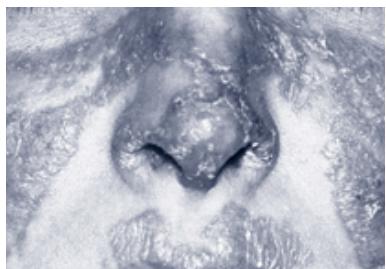

In both varieties of lupus erythematosus, the symptoms periodically subside and recur with varying severity.

In DLE, the rash starts as one or more red, circular, and thickened areas of skin. These areas of skin subsequently become scarred. The patches may occur on the face, behind the ears, and on the scalp.

SLE causes a variety of symptoms. A characteristic red, blotchy, butterfly-shaped rash may appear on the cheeks and the bridge of the nose; other symptoms include fatigue, fever, nausea, loss of appetite, joint pain, and weight loss. There may also be associated problems including *anaemia*, neurological or psychiatric problems, *kidney failure*, *pleurisy* (inflammation of the membrane that lines the lungs), *arthritis*, and *pericarditis* (inflammation of the membrane surrounding the heart).

DIAGNOSIS AND TREATMENT

Diagnosis is made by *blood tests* and sometimes a *skin biopsy*. DLE is usually treated with topical *corticosteroid drugs*. Both DLE and SLE may be treated with the antimalarial drug hydroxychloroquine. Sufferers of mild forms of SLE may have near normal health for many years, and treatment with *corticosteroid drugs* and *immunosuppressant drugs* can improve life expectancy. Other treatments are available to treat specific features of the disease; however, SLE is still a potentially fatal disorder.

Systemic lupus erythematosus on face
The disease can cause a skin eruption across the nose and cheeks. The distinctive pattern this causes is known as a butterfly rash.

lupus pernio

A form of *sarcoidosis* affecting the skin, in which purple swellings resembling chilblains appear on the ears, nose, or cheeks.

lupus vulgaris

A rare form of *tuberculosis* affecting the skin, especially on the head and neck. Painless, clear, red-brown nodules appear and ulcerate; the ulcers eventually heal, leaving deep scars.

Lüscher colour test

Developed in the 1960s by Dr. Max Lüscher, the Lüscher colour test is based on the idea that psychological information about a person can be gained through that person's choices and rejections of eight colours: grey, blue, green, red, yellow, violet, brown, and black. The test is sometimes used in the workplace to test job applicants for suitability. It can also be a useful tool for psychologists when they are trying to determine the current state of mind of an individual.

luteinizing hormone

Also known as LH, a *gonadotrophin hormone* produced by the pituitary gland.

luteinizing hormone-releasing hormone

A naturally occurring *hormone*, also known as LH-RH, that is released by the *hypothalamus* in the brain. This hormone is also prepared synthetically as a drug. Natural LH-RH stimulates the release of *gonadotrophin hormones* from the *pituitary gland*. Gonadotrophin hormones control the production of *oestrogen hormones* and *androgen hormones*. Synthetic LH-RH, also called synthetic *gonadorelin*, is used to treat delayed and precocious puberty and to treat infertility in women by desensitizing the pituitary.

LH-RH may cause headache, nausea, hot flushes, vaginal dryness, and irregular menstrual periods.

Lyell's syndrome

Also known as toxic epidermal necrolysis, a life-threatening drug reaction in which the skin, mucous membranes, and lining of internal organs such as the bladder and intestine blister and slough off. Drugs that are known to have caused this condition include *penicillin*, *carbamazepine*, and *nonsteroidal anti-inflammatory drugs* (NSAIDS). Cases of Lyell's syndrome require treatment in an *intensive care unit*.

Lyme arthritis

Inflammation of the joints as a result of *Lyme disease* (infection transmitted by the bite of a deer tick). *Arthritis* affects up to half of those infected with Lyme disease. It develops within a few weeks to two years of the original infection and causes joint pain and swelling. The knee is most commonly affected.

Lyme disease

A disease caused by the bacterium *BORRELIA BURGDORFFERI*, which is transmitted by ticks that usually live on deer.

SYMPOTMS

At the site of a tick bite, a red dot may appear and gradually expand into a circular area up to 15 cm across. Symptoms including fever, headache, and muscle pain usually develop; they are followed by joint inflammation, which typically affects the knees and other large joints. Symptoms of Lyme disease may vary in severity and occur in cycles lasting for about one to three weeks.

COMPLICATIONS

If Lyme disease is not treated promptly, complications may develop; these include *meningitis* (inflammation of the membranes covering the brain), *facial palsy*, and an abnormal heartbeat (see *arrhythmia*, *cardiac*). The most serious long-term complications of Lyme disease are *Lyme arthritis* and persistent neurological disorders that are similar to *multiple sclerosis*.

TREATMENT

Treatment of Lyme disease is with *antibiotic drugs* and is most effective when given soon after initial infection. *Nonsteroidal anti-inflammatory drugs* are given to relieve joint pain.

In areas that are known to be infested with the ticks, people should take measures to prevent tick bites. Such action

includes wearing clothes that cover the body and fit closely at the wrists and ankles, and taking care not to walk through thick undergrowth.

lymph

A watery or milky body fluid containing *lymphocytes* (a type of white blood cell), proteins, and fats. It plays an important role in the *immune system* and in absorbing fats from the intestine.

Lymph accumulates outside the blood vessels in the intercellular spaces of body tissues, and is collected by the vessels of the *lymphatic system*. This system filters the fluid and eventually returns it to the bloodstream.

lymphadenitis

A medical term for inflammation of the *lymph nodes*, which is a common cause of *lymphadenopathy*.

lymphadenopathy

The medical term for swollen *lymph nodes* (see *glands, swollen*).

lymphangiography

A diagnostic procedure that involves injecting a *contrast medium* into lymph vessels (see *lymphatic system*) in order that the vessels and lymph nodes, and any abnormalities, can be seen on *X-rays*. Lymphangiography has been superseded largely by *CT scanning* and *MRI*.

lymphangioma

A rare, noncancerous tumour consisting of a mass of lymph vessels and often affecting the skin and the deeper tissues. It may be present from birth. Lymphangiomas are sometimes removed with *laser treatment*.

lymphangitis

Inflammation of the lymphatic vessels (see *lymphatic system*) due to the spread of *bacteria* (commonly *streptococci*) from an infected wound. The inflammation causes the appearance of tender red streaks on the skin overlying the lymphatic vessels. These red streaks extend from the infection site towards the nearest *lymph nodes*. The affected nodes become swollen and tender, and the affected individual usually has a fever and a general feeling of illness.

Lymphangitis requires urgent treatment with *antibiotic drugs* to prevent *septicaemia* (a life-threatening disorder resulting from high levels of bacteria, and bacterial toxins, in the blood).

lymphatic system

A system of vessels (lymphatic vessels) that drains *lymph* from tissues all over the body back into the bloodstream. The lymphatic system is part of the *immune system* and has a major function in defending the body against infection and cancer. The lymphatic system also plays a part in the absorption of fats from the intestine.

STRUCTURE AND FUNCTION

All body tissues are bathed in lymph, a watery fluid that is derived from the bloodstream. Much of this fluid is returned to the bloodstream through the walls of the capillaries (see *circulatory system*), but the remainder of the fluid is transported to the heart through the lymphatic system.

Lymph is moved along the lymphatic vessels during physical activity, in which the contraction of muscles compresses the vessels; valves inside the vessels ensure that the lymph always flows in the correct direction.

Situated on the lymphatic vessels are *lymph nodes*, through which the lymph passes. These nodes filter the lymph and trap or destroy infectious microorganisms or other foreign bodies. Also included in the lymphatic system are the *spleen* and the *thymus*, which produce *lymphocytes* (white blood cells that fight infection or harmful cells).

DISORDERS

If infection or inflammation occurs in any part of the body, the lymph nodes in that particular area may become swollen and tender as the white blood cells within them try to combat the organisms or cells causing the problem. If an infection is particularly severe, the lymphatic vessels leading from the nodes may also become inflamed (see *lymphangitis*).

If a lymphatic vessel becomes obstructed (for example, by worms or by cell debris), lymph will collect in the nearby tissues, which will lead to *lymphoedema*.

Cancer commonly spreads to other parts of the body through the lymphatic system. If a primary tumour invades the lymphatic vessels, cells from the tumour may break off and enter the vessels (see *metastasis*). They may then become lodged in lymph nodes situated nearby, where they may then grow into secondary tumours. In *breast cancer*, for example, the cells from a breast tumour may spread to the lymph nodes in the armpit.

lymph gland

A popular name for a *lymph node*. (See also *lymphatic system*.)

lymph node

A small organ lying along the course of a lymphatic vessel (see *lymphatic system*). Lymph nodes are commonly, but incorrectly, called lymph glands. Lymph nodes vary in size; they can be microscopic or can be up to about 2.5 cm in diameter.

STRUCTURE

A lymph node is composed of a thin, fibrous outer capsule and an inner mass of lymphoid tissue. Penetrating the capsule are several small lymphatic vessels, which transport lymph into the node. Each lymph node contains sinuses (spaces) in which the lymph is filtered. A single, larger vessel carries lymph out of the node.

FUNCTION

Lymph nodes act as a barrier to the spread of infection by destroying or filtering out bacteria before they can pass into the bloodstream. As lymph passes through a node, narrow channels in the sinuses slow down its movement; this reduction in the flow of lymph allows macrophages (white blood cells that engulf and destroy foreign and dead material) to filter microorganisms from the lymph. In addition, germinal centres, which are located in the lymph node, release white blood cells known as *lymphocytes*. These cells also help to fight infection.

lymphocyte

Any one of a group of white *blood cells* that are of crucial importance to the *immune system* because they combat infectious organisms and cancer. There are two principal types of lymphocyte: B- and T-lymphocytes.

B-LYMPHOCYTES

B-lymphocytes produce *immunoglobulins* or *antibodies* (proteins that attach themselves to *antigens* (proteins) on the surfaces of bacteria). This action starts a process that leads to the destruction of the bacteria.

T-LYMPHOCYTES

The T-lymphocytes are classified in two main groups, according to the type of antigens found on their surfaces. One group (known as CD8) includes killer (cytotoxic) and suppressor cells; the other group (CD4) includes helper cells. The killer T-lymphocytes attach themselves to abnormal cells (such

as tumour cells, cells that have been invaded by viruses, and those in transplanted tissue) and release chemicals that help to destroy the abnormal cells. Suppressor T-cells act to "damp down" the immune response. Helper T-cells enhance the activities of the killer T-cells and the B-cells, and also orchestrate the immune response.

MEMORY FUNCTION

Some B- and T-lymphocytes do not participate directly in immune responses but serve as a memory bank for antigens that have been encountered. These lymphocytes are created when the immune system cells respond to an infection, and they contain information on how to deal with that infection. Once the immune response is over, the memory cells are then stored in the body in order to aid subsequent immune responses to that infection.

lymphocytosis

An increase in the number of *lymphocytes*, a type of white blood cell that mounts the immune response, either by attacking foreign cells directly or by producing antibodies that cause their destruction. Lymphocytosis, which can be detected by blood test, most commonly occurs in viral infections. Rarely, a massive increase in lymphocytes may be due to *leukaemia*.

lymphoedema

An abnormal accumulation of *lymph* in the tissues, which occurs when the normal drainage of lymph is disrupted (see *lymphatic system*).

CAUSES

There are various possible causes for lymphoedema. Cancer can lead to the condition if the vessels become blocked by deposits of cancer cells. Surgical removal of *lymph nodes* under the arm (as in radical *mastectomy*) or in the groin, or *radiotherapy* to an area containing lymph nodes, may also result in lymphoedema. In the tropical disease *filariasis*, the lymphatic vessels may be blocked by parasitic worms. Rarely, the condition is due to a *congenital* abnormality of the lymphatic vessels known as Milroy's disease. In addition, lymphoedema may occur for no known reason.

SYMPTOMS

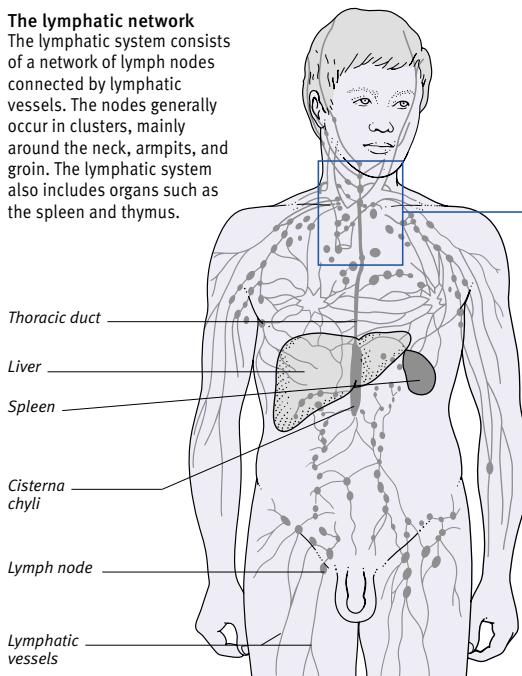

Lymphoedema causes painless swelling in the tissues and thickening of the skin over the affected area. It usually develops in the legs; the swelling may start at the ankle and extend up the leg, and

STRUCTURE AND FUNCTION OF THE LYMPHATIC SYSTEM

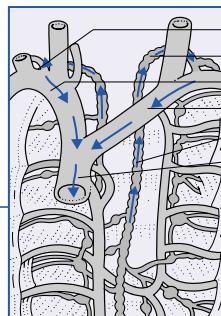

The lymphatic system is a collection of organs, ducts, and tissues that has the dual role of draining tissue fluid (lymph) back into the bloodstream and of fighting infection. Lymph is drained by a system of channels (the lymphatic vessels).

The lymphatic network

The lymphatic system consists of a network of lymph nodes connected by lymphatic vessels. The nodes generally occur in clusters, mainly around the neck, armpits, and groin. The lymphatic system also includes organs such as the spleen and thymus.

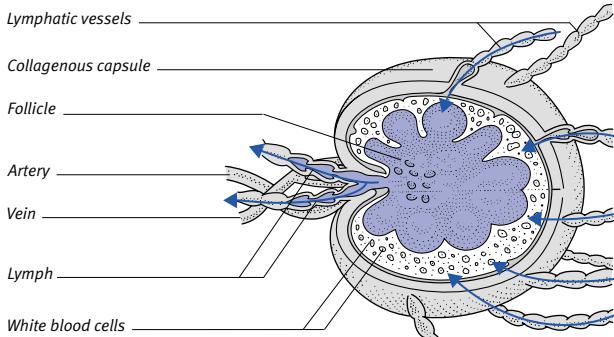

White cells that are produced by the bone marrow, thymus, and spleen are present in lymph nodes, or they circulate through the lymphatic system and the bloodstream, providing defences against infection.

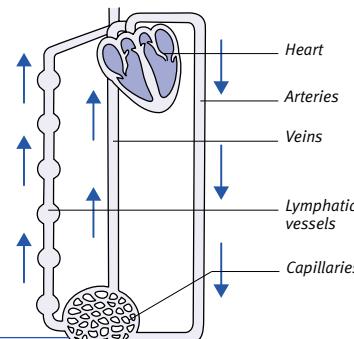

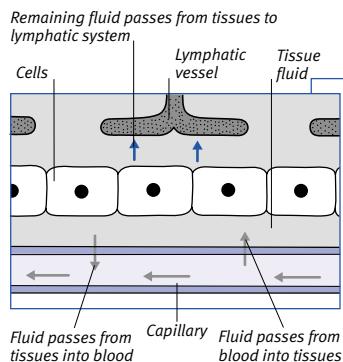

Lymphatic drainage

Just below the neck, the thoracic duct and right lymphatic duct drain into the two subclavian veins. These veins unite to form the superior vena cava, which passes into the heart; in this way, the lymph fluids rejoin the circulation.

MOVEMENTS OF BODY FLUIDS

Lymph is constantly moving around the body, but the lymphatic system has no central pump equivalent to the heart. Lymph is circulated by the movement of the body's muscles; a system of one-way valves in the lymphatic vessels ensures that it moves in the right direction. Exertion also pushes fluid from body tissues into the bloodstream.

Fluid exchange

During a 24-hour period, approximately 24 litres of serumlike fluid pass from the bloodstream to the body's tissues. This fluid bathes the cells and provides them with oxygen and nutrients. During the same period of time, approximately 20 litres of fluid pass back from the tissues to the bloodstream, carrying carbon dioxide and other waste products. The remaining 4 litres pass from the tissues to the lymphatic system and return eventually to the circulation from there.

Structure of a lymph node

Any fluid absorbed into the lymphatic system passes across at least one lymph node before it returns to the circulation. The fluid filters through a mesh of tightly packed white blood cells – some of which are grouped into follicles consisting of similar cells – which attack and destroy harmful organisms. Every lymph node is supplied by its own tiny artery and vein.

Enlarged lymph nodes

This photograph shows a child with an enlarged lymph node in the neck. One cause of such enlargement is infection. Enlarged nodes may also be a result of Hodgkin's disease, a rare cancer of the lymph nodes.

may occur to an incapacitating degree in some individuals. If a limb that is affected by lymphoedema is subsequently injured, infection can easily enter the site of injury and spread rapidly through the body tissues.

TREATMENT

There is no known cure for lymphoedema. Treatment consists of taking *diuretic drugs*, wearing an elastic bandage or compression sleeve, massage, and special exercises; these measures may bring about some improvement.

lymphogranuloma venereum

A sexually transmitted disease caused by a *chlamydial infection*; it is most common in tropical areas.

The first sign of lymphogranuloma venereum may be a small genital blister that heals in a few days. There may also be fever, headache, muscle and joint pains, and a rash. The *lymph nodes*, particularly in the groin, become painfully enlarged and inflamed. *Abscesses* may form, and persistent *ulcers* may develop, on the skin over the affected nodes. Treatment is with *antibiotic drugs*.

lymphoma

Any of a group of cancers in which the cells of lymphoid tissue (found principally in the *lymph nodes* and the *spleen*) multiply unchecked.

Lymphomas fall into two principal categories. If certain characteristic abnormal cells (Reed–Sternberg cells) are present, the condition is called *Hodgkin's disease*. All other forms are known as non-Hodgkin's lymphoma (see *lymphoma, non-Hodgkin's*).

lymphoma, non-Hodgkin's

Any cancer that affects the lymphoid tissue (found mainly in the *lymph nodes* and *spleen*) other than the condition *Hodgkin's disease*.

CAUSES

In most cases, non-Hodgkin's lymphoma has no known cause. Occasionally, however, the disease is associated with suppression of the *immune system*, particularly after an organ transplant. One type of non-Hodgkin's lymphoma, called *Burkitt's lymphoma*, is associated with the *Epstein–Barr virus*.

SYMPOTMS

There is usually painless swelling of *lymph nodes* in the neck or groin. The *liver* and *spleen* may enlarge, and lymphoid tissue in the abdomen may be affected. Many other organs may be-

come involved, leading to diverse symptoms ranging from headache to skin ulceration. In some cases, there may be fever, marked weight loss, and recurrent infections.

DIAGNOSIS

Diagnosis is based on a *biopsy*, usually taken from a lymph node. Further investigations, such as *chest X-ray*, *CT scanning*, *MRI*, *bone marrow biopsy*, and *lymphangiography*, may be needed to assess the extent of the disease.

TREATMENT

In cases where the lymphoma is confined to a single group of lymph nodes, treatment consists of *radiotherapy*. More often, however, the disease is more extensive, and in such cases *anticancer drugs* are given. A *bone marrow transplant*, with drug treatment and/or radiotherapy, may be considered for some people.

lymphopenia

A decrease in the number of *lymphocytes*, a type of white blood cell that mounts the immune response, either by a direct attack on abnormal cells or invading organisms or by producing antibodies that cause their destruction. This condition may occur when the bone marrow fails to produce enough blood cells, as in aplastic anaemia (see *anaemia, aplastic*) or treatment with *radiotherapy* or *anticancer drugs*.

lymphosarcoma

The former name for a condition that is now classified as a type of non-Hodgkin's lymphoma (see *lymphoma, non-Hodgkin's*).

lysergide

see *LSD*.

lysis

A medical term for breaking down or destruction. The term *lysis* is usually applied to the destruction of cells by disintegration of their outer membrane. A common example is *haemolysis*, the breakdown of red blood cells.

Lysis may be caused by chemical action, for example the action of an *enzyme*, or by physical action, for example the action of heat or cold. The term “*lysis*” is also occasionally used to refer to a sudden recovery from a fever.

lysosomal storage disease

One of several different conditions, also known as inborn errors of metabolism (see *metabolism, inborn errors of*) in most

of which an enzyme is missing from the *lysosome* within cells. This absence leads to a buildup of abnormal substances within the cells that causes tissue damage.

lysosome

One of a variety of structures present within every cell that are responsible, when the cell dies, for breaking down the components of the cell for the purposes of recycling.

lysozyme

An *enzyme* found in tears, saliva, sweat, nasal secretions, breast milk, and many tissues. It destroys bacteria by disrupting their cell walls.

M

macro-

A prefix meaning “large”, as in *macrophage* (a large type of cell found in the *immune system*) or *macroglossia* (enlargement of the tongue).

macrobiotics

A dietary system in which foods with a balance of *yin and yang* are eaten. Foods are classed as yin or yang depending on factors such as colour, texture, and taste.

macrocytosis

A condition in which the red *blood cells* are larger than normal. Macrocytosis has many possible causes, the most common of which are megaloblastic anaemia (see *anaemia, megaloblastic*) and the effects of alcohol.

macroglobulinaemia, Waldenström's

A type of *lymphoma* in which *lymphocytes* (a type of white *blood cell*) produce excessive amounts of a protein called immunoglobulin M (IgM), which is normally created to fight disease (see *immunoglobulins*). It tends to occur most commonly in men over 50 years old.

The excess IgM causes the blood to become overly viscous (thick), impairing its flow through the smallest blood vessels. Signs and symptoms include fatigue; headache; dizziness; visual disturbances; easy bruising and bleeding; and numbness and tingling in the hands and feet. The spleen, liver, and *lymph nodes* may become enlarged.

There is no cure, but treatment can relieve the symptoms. Blood viscosity can be lowered by *plasmapheresis*, in which a machine removes excess IgM from the blood plasma. *Anticancer drugs* and *corticosteroids* may also be given.

macroglossia

Abnormal enlargement of the tongue. Macroglossia is a feature of the chromosomal abnormality *Down's syndrome*; *hypothyroidism* (an underactive thyroid gland); and *acromegaly* (a hormonal

disorder causing enlargement of several body parts). It is also caused by some tumours of the tongue, such as a *haemangioma* or a *lymphangioma*.

macrognathia

An abnormally large upper and/or lower *jaw*. Macrognathia can be a feature of the condition *acromegaly*. (See also *prognathism*).

macrolide drugs

A class of *antibiotic drugs* used to treat a wide range of infections including those of the ear, nose, throat, respiratory and gastrointestinal tracts, and skin. Common macrolides include *azithromycin* and *erythromycin*.

macrophage

A cell in the *immune system*. Macrophages are large *phagocytes*, which can engulf and destroy microorganisms and other foreign particles. They are found in most body tissues.

macroscopic

Visible to the naked eye.

macula

The specific area of the *retina* (the light-sensitive layer at the back of the eye) that is responsible for seeing fine detail. The macula surrounds the *fovea*, the part of the retina that contains the highest density of visual cells.

macular degeneration

A progressive, painless deterioration of the *macula*. It is a common disorder in elderly people, and is the most common cause of visual impairment in the UK. The cause is unknown.

There are two forms of macular degeneration: dry and wet. In dry macular degeneration, cells within and just beneath the macula die. In wet macular degeneration, fragile new blood vessels grow beneath the macula; and these vessels may easily leak blood or other fluid, which damages the cells. Both forms of macular degeneration produce a roughly circular area of blindness that increases in size. It does not cause total blindness because the vision is retained around the edges of the visual fields.

Diagnosis is by *ophthalmoscopy* and *vision tests*. If wet macular degeneration is suspected, fluorescein *angiography* (imaging of the blood vessels in the retina) may be performed to detect abnormal blood vessels.

Wet macular degeneration is usually remedied by *laser treatment*. There is no treatment for the dry form of the condition, although the affected individual may benefit from visual aids such as magnifying instruments.

macule

A spot that is level with the skin's surface and discernible only by difference in colour or texture.

maculopathy, diabetic

A complication of *diabetes mellitus* that is characterized by damage to the *macula*, at the back of the retina. Usually, the remainder of the retina is also affected (see *retinopathy*).

madarosis

Loss of the eyelashes or eyebrows.

mad cow disease

The commonly used name for *bovine spongiform encephalopathy* (BSE).

Madelung's disease

The development of multiple, symmetrical, fatty masses resembling *lipomas* under the skin of the head, neck, upper trunk, and upper arms. The disease, also called multiple symmetrical lipomatosis or Lanois–Bensaude syndrome, occurs primarily in adult men.

The cause is unknown, but Madelung's disease has been associated with long-term, excessive alcohol use (see *alcohol-related disorders*).

Madopar

A brand-named drug, containing *levodopa* with *benserazide* (a drug that enhances the effect of levodopa), used in the treatment of Parkinson's disease.

Madura foot

A fungal and/or bacterial infection of the foot that occurs in tropical or subtropical regions such as Central and South America, Africa, India, and Southeast Asia. Madura foot usually affects men aged 20 to 40, often as a result of outdoor work.

The infection enters the foot through broken skin. A nodule or abscess forms, and grows into a mass of diseased tissue with sinuses (abnormal channels) that discharge bloody or pus-filled fluid. The fluid typically contains very small granules, which are fragments of infectious organisms. The infection may progress to involve the foot bones.

Treatment involves removal of diseased tissue (or, if necessary, *amputation*) and the use of *antibiotics* or *antifungal drugs* to destroy the infection.

Maffucci's syndrome

A syndrome characterized by enchondromas (benign tumours of *cartilage*) together with *haemangiomas* (benign tumours of the blood vessels) on the skin or internal organs. The condition develops during childhood, and is more common in males than in females.

Magnapen

A brand-named antibiotic drug containing *ampicillin* with *flucloxacillin*.

magnesium

A mineral that is essential for the formation of bones and teeth, muscle contraction, nerve impulse transmission, and activation of many *enzymes*. Dietary sources include cereals, milk, nuts, soya beans, and fish.

magnesium sulphate

A magnesium compound used as a *laxative drug* and an *anticonvulsant drug*.

M

magnesium trisilicate

A magnesium compound that is used in *antacid drugs*.

magnetic resonance imaging

See *MRI*.

malabsorption

Impaired absorption of nutrients by the lining of the small intestine.

CAUSES

Malabsorption may be caused by many conditions. One possible cause is an inflammatory disorder, such as chronic *pancreatitis* (long-term inflammation of the pancreas) or *Crohn's disease* (an inflammatory bowel condition). Another is infection, such as *giardiasis* (an infection of the small intestine).

Genetic disorders resulting in abnormal intestinal structure or function can also cause malabsorption, as in *lactase deficiency* (lack of an enzyme needed to digest milk sugar), *cystic fibrosis* (a disorder in which an excess of mucus is produced in the intestines), or *coeliac disease* (hypersensitivity to gluten, a substance in certain cereals).

Other causes of malabsorption include *amyloidosis* (a condition in which a starchy substance is deposited in vital organs), *Whipple's disease* (a rare bacter-

ial disorder), and *lymphoma* (cancer of lymph tissue). In addition, the removal of some of the small intestine, and certain operations on the stomach, may also result in malabsorption.

SYMPTOMS

Common symptoms of malabsorption are diarrhoea and weight loss. In severe cases, there may also be malnutrition (see *nutritional disorders*), *vitamin deficiency*, *mineral deficiency*, or *anaemia*.

DIAGNOSIS AND TREATMENT

Diagnosis may be made by tests on faeces, *blood tests*, *barium X-ray examination* and *jejunal biopsy*. In most cases, dietary modifications or supplements are successful in treating the disorder. In severe cases, intravenous infusion of nutrients is needed (see *feeding, artificial*).

maladjustment

Failure to adapt to a change in one's environment, resulting in inability to cope with daily activities. Maladjustment can occur as a reaction to stressful situations such as divorce or moving house.

The person may have feelings of *depression* or *anxiety*; children and adolescents may show disturbed behaviour (see *behavioural problems in children*). Maladjustment often disappears when a person is removed from the stressful situation or if he or she manages to adapt to it.

malaise

A vague feeling of being unwell.

malignment

Positioning of the *teeth* in the *jaw* so that they do not form a smooth arch shape when viewed from above or below (see *malocclusion*).

The term "malignment" may also refer to a *fracture* in which the bone ends are not in a straight line.

malar flush

A high colour over the cheekbones, with a bluish tinge caused by reduced oxygen concentration in the blood. Malar flush is considered to be a sign of *mitral stenosis* (narrowing of one of the heart valves), which often follows *rheumatic fever*. However, malar flush is not always present in mitral stenosis, and many people with this colouring do not have heart disease.

malaria

A serious disease caused by *protozoa* called *plasmodia*. The infection is spread by the bite of *Anopheles* mosquitoes and

is prevalent throughout the tropics. Malaria causes severe fever, and, in some cases, fatal complications affecting the kidneys, liver, brain, and blood.

CAUSES

There are four species of plasmodia that cause malaria: *PLASMODIUM FALCIPARUM*, *PLASMODIUM VIVAX*, *PLASMODIUM OVALE*, and *PLASMODIUM MALARIAE*. When a mosquito carrying the infection bites a human, the plasmodia enter the bloodstream. They invade the liver and red blood cells, where they multiply. The red cells then rupture, releasing the new parasites. Some of them infect new red cells, and the others develop into forms that can infect more mosquitoes. *Falciparum* malaria infects more red cells than the other species and thus causes a more serious infection. Most cases of this form occur in Africa.

SYMPTOMS

Symptoms of malaria include fever, shaking, and chills. There may also be severe headache, general malaise, and vomiting. The fever often develops in cycles, occurring every other day (in *vivax* and *ovale* infections) or every third day (in *malariae* infections).

Falciparum malaria can be fatal within days. Infected red cells become sticky and block blood vessels in vital organs. The *spleen* becomes enlarged and the *brain* may be affected, leading to *coma* and convulsions. Destruction of red blood cells causes haemolytic anaemia (see *anaemia, haemolytic*). Kidney failure and jaundice often occur.

DIAGNOSIS AND TREATMENT

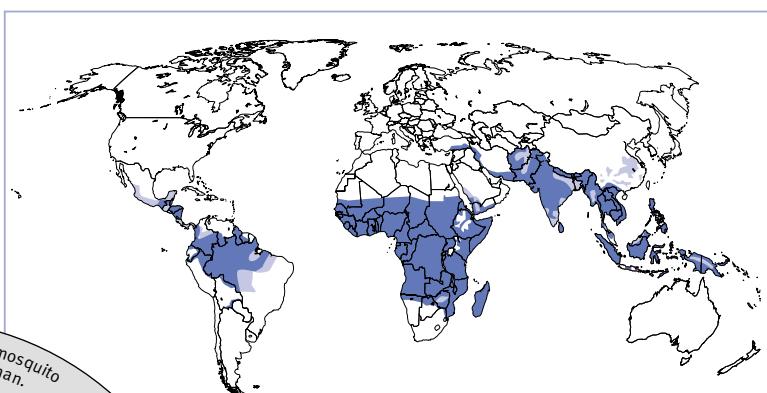

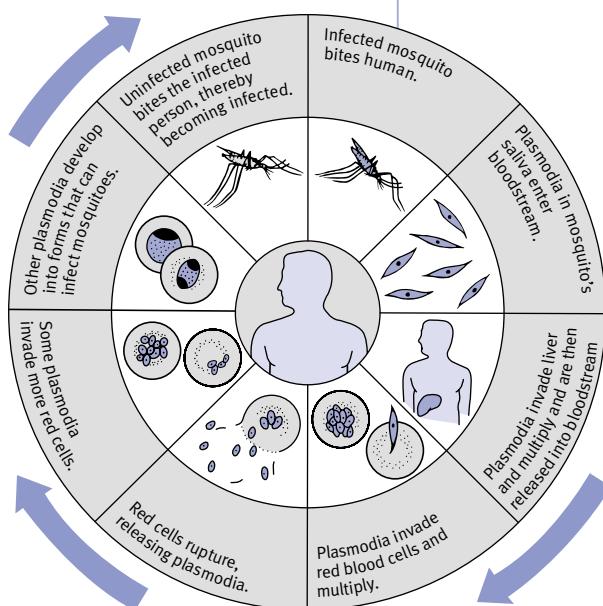

A *blood film* examination is carried out to detect the parasites. *Falciparum* malaria is treated with *quinine* or *mefloquine*, or *proguanil* and *atovaquone*, or *artemether* with *lumefantrine*. *Chloroquine* is the usual treatment for species other than *falciparum*. People with *vivax* or *ovale* malaria must also take the drug *primaquine* to eradicate parasites in the liver. In severe cases, blood transfusions may be necessary.

PREVENTION

People who live in or visit malarial areas should take precautions in order to avoid mosquito bites; such measures include keeping the arms and legs covered and using insect repellents and mosquito nets. In addition, travellers to such areas should take preventive anti-malarial drugs. The course of drugs must be started up to three weeks before the person enters the area, and should be continued for one to four weeks after

THE SPREAD OF MALARIA

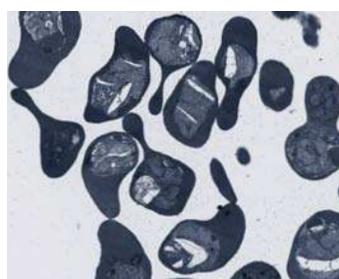

Malaria parasites (plasmodia) are transmitted by the bites of infected *ANOPHELES* mosquitoes. The plasmodia invade the liver and then the red blood cells, where they multiply. When the red blood cells rupture, they release the parasites; some of the plasmodia invade more red cells, while others develop into forms that can infect mosquitoes.

Prevalence of malaria
Malaria, although rare in the UK, is a major problem in the tropics. It affects about 300 million people worldwide, and kills more than one million people a year in Africa alone.

Key

- Areas in which malaria is prevalent
- Areas with limited risk
- Areas with no malaria

Malarial infection of blood cells
Some of the red blood cells on this TEM (transmission electron micrograph) contain the typical "signet ring" forms of one type of malarial parasite.

the visit (exact timings depend on the type of drug). Doctors can provide up-to-date advice on the choice of drugs.

Malarone

A brand-named *antimalarial drug* containing *proguanil* with *atovaquone*.

malathion

An *antiparasitic drug* for skin or hair infestations such as *lice* and *scabies*. The drug kills parasites by interfering with their nervous systems. Malathion is applied as a shampoo or a lotion. If they are used correctly, preparations that contain malathion should not produce adverse effects. They should not be used for more than three weeks at a time, however and should not be applied to broken or infected skin. Some alcohol-based lotions may give off fumes that cause wheezing in people with asthma.

male

The term that is used for a man or a boy. Male sex is determined by the possession of a Y *sex chromosome*, and by the presence of a *penis* and *testes* (see *sexual characteristics, primary*).

male-pattern baldness

The most common type of *alopecia*.

malformation

A deformity, particularly one that results from the faulty development of a baby in the mother's uterus. (See *embryo* and *uterus*).

malignant

A term used to describe a condition that tends to become progressively worse and eventually result in death. The term "malignant" is primarily used with reference to a cancerous *tumour* whose

cells spread from the original site to form secondary tumours in other parts of the body.

malignant hypertension

Severe *hypertension* in which the blood pressure rises suddenly to a very high level, usually for no obvious cause, resulting in damage to arterioles and capillaries (tiny blood vessels). The condition occurs in a small minority of people with existing hypertension, particularly if it is due to kidney disorders; it is more common in young adults.

Most of the symptoms are caused by increased pressure in blood vessels in the head; they include headache, blurred vision, confusion, drowsiness, nausea, and vomiting. There may also be chest pain and shortness of breath. In addition, the pressure may produce changes in internal organs; for example, it causes

papilloedema (swelling of the optic nerve) and enlargement of the heart, and may also cause retinal bleeding and acute kidney failure. If left untreated, it can cause death within six months.

Diagnosis is based on measurement of blood pressure and tests to detect damage to organs such as the kidneys. An affected person will need hospital treatment to lower blood pressure.

malignant hyperthermia

See *hyperthermia, malignant*.

malignant melanoma

See *melanoma, malignant*.

malingering

The deliberate simulation of symptoms for a particular purpose, such as taking time off work or obtaining compensation. Malingering is different from *factitious disorders* and *hypochondriasis*, in which the motivation for illness is not under the individual's voluntary control.

malleolus

The bony protuberance on each side of the *ankle*.

mallet finger

Injury to the tendon or bone in a fingertip that forces the tip into a bent position. A common sports injury, it occurs when a ball strikes a finger.

Treatment is with a splint or by temporary insertion of wire through the bones to hold the finger straight. The injury heals in two to three months.

mallet toe

See *claw-toe*.

malleus

One of the three tiny bones (known collectively as the auditory ossicles) that are situated in the middle ear. The malleus, together with the *incus* and the *stapes*, transmits sound vibrations from the eardrum to the inner ear.

Mallory–Weiss syndrome

A tear at the lower end of the *oesophagus*, causing vomiting of blood. The syndrome is commonly caused by retching and vomiting after drinking excess alcohol, or as a result of food poisoning. Less often, violent coughing, a severe asthma attack, or epileptic convulsions may be the cause.

An *endoscope* is passed down the oesophagus to confirm the diagnosis. The tear generally heals within about

ten days, with no special treatment required; however, a *blood transfusion* may sometimes be necessary.

malnutrition

See *nutritional disorders*.

malocclusion

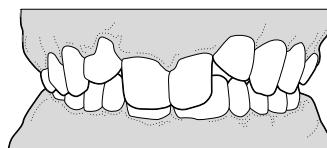

An abnormal relationship between the upper and lower sets of *teeth* when they are closed, affecting the bite or the appearance of the teeth.

CAUSES

Malocclusion usually develops during childhood. In some cases, it may be inherited. Alternatively, it may be due to thumb-sucking or to a mismatch between the teeth and jaws – for

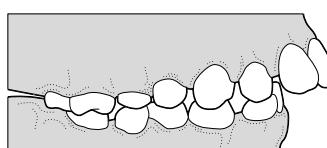

CLASSES OF MALOCCLUSION

Unsatisfactory contact between the upper and lower teeth is known as malocclusion. There are three main classes, as shown below.

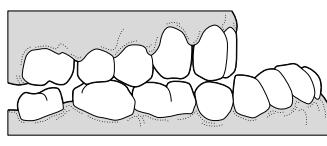

Class 1 malocclusion

In this (the most common) type, the jaw relationship is normal. However, because the teeth are poorly spaced, tilted, or rotated, the upper and lower set do not meet properly.

Class 2 malocclusion

In this type – called retrognathism – the lower jaw is lying too far back; the normally small overbite of the upper incisors is greatly increased, and the molar bite is displaced backwards.

Class 3 malocclusion

In this (the least common) type – called prognathism – the lower jaw is lying too far forward; the lower incisors meet, or lie in front of, the upper ones, and the molar bite is displaced forwards.

example, the combination of large teeth and a small mouth (see *overcrowding, dental*).

TREATMENT

Orthodontic appliances (braces) may be used to reposition the teeth; if there is dental overcrowding, some of the teeth may be extracted. *Orthognathic surgery* is used to treat severe recession or protrusion of the lower jaw. Treatment is best carried out in childhood or adolescence.

malpresentation

A condition in which a baby is not in the usual head-first position for *childbirth*. Malpresentation includes breech presentation (in which the baby's bottom appears first), face presentation, and shoulder presentation (in which the baby is lying across the uterus). Breech presentations are the most common. A breech baby may be born by *breech delivery* or *caesarean section*. A shoulder presentation baby usually has to be delivered by caesarean section.

MALT

The abbreviation for mucosa-associated lymphoid tissue. This tissue is part of the *lymphatic system*, which helps to defend the body against infection. It is found in the digestive tract, particularly in the *tonsils* and in areas called *Peyer's patches* in the small intestine.

maltose

A sugar composed of two *glucose* molecules (see *disaccharide*). Maltose is found in germinating cereal seeds.

mammary dysplasia

Normal variations in *breast* tissue that cause thickening and general lumpiness of the breasts. It may develop just before menstruation and subside afterwards. The condition is common in women between 30 and 50 years of age but is lower in those taking *oral contraceptives*.

The condition is not a disorder and does not lead to breast cancer. In many cases, no treatment is needed; in more severe cases, oral contraceptives may be prescribed. In contrast, any distinct *breast lump* should be assessed by a doctor.

mammary gland

See *breast*.

mammography

An X-ray procedure for examining the *breast*. The breast is flattened between an X-ray plate and a plastic cover so that

as much tissue as possible can be imaged. Two images are taken of each breast. Mammography is used to investigate *breast lumps*, and to screen for *breast cancer*, because it reveals tumours too small to be found in a physical examination. It is offered every three years to all women between the ages of 50 and 65 years.

mammoplasty

An operation that is performed in order to make large breasts smaller, to enlarge small breasts, or to reconstruct a breast following surgery for *breast cancer*. In many cases, mammoplasty is performed for cosmetic reasons. However, the reduction of excessively large breasts may have the physical benefit of reducing back pain.

Reconstruction of a breast

The right breast (left in the image) was removed in an earlier mastectomy operation. The breast has been reconstructed using a silicone implant.

PROCEDURES

In breast reduction, excess tissue and skin is removed and the tissue is raised and reshaped to correct drooping. Breast enlargement or augmentation involves the insertion of a soft, fluid-filled *breast implant* behind the breast tissue or behind the muscles of the chest wall. In women undergoing a *mastectomy* (removal of a breast) for cancer, breast reconstruction may be carried out either at the same time or as a separate procedure. The normal contours of the breast are restored by the insertion of an implant.

RISKS

Breast reduction carries few risks, but enlargement may cause complications. These problems include leakage from the implant, hardening of the surrounding breast tissue, and scarring. Further surgery may be needed.

mandible

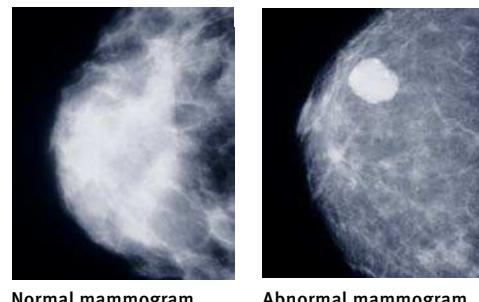

The lower *jaw*. The mandible consists of two fused pieces of bone forming a U shape. The upper surface bears the lower

PROCEDURE FOR MAMMOGRAPHY

Mammography is a simple, safe procedure and causes only slight discomfort. Only low-dose X-rays are used. The breast may be X-rayed from above, the side, or both; and sometimes an oblique (angled) view is taken.

How mammography is done
In the method shown here, the breast is placed on the machine and gently compressed between the X-ray plate below and a plastic cover above. This flattens the breast so that as much tissue as possible can be imaged. Several views may be taken. In another method, the breast hangs freely and is X-rayed from the side.

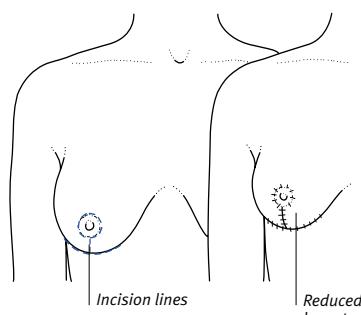

Mammograms
The mammogram on the far left shows a side view of the healthy, relatively dense, breast tissue of a younger woman. In the mammogram on the left, a fibroadenoma (noncancerous tumour made up of fibrous tissue) is present on the upper part of the breast. A biopsy (removal of a tissue sample for analysis) can confirm whether or not a tumour is cancerous.

PROCEDURES FOR MAMMOPLASTY

One of the most common cosmetic operations, mammoplasty is carried out to improve the appearance of the breasts by removal of excess fat and skin or by using an implant to increase their size.

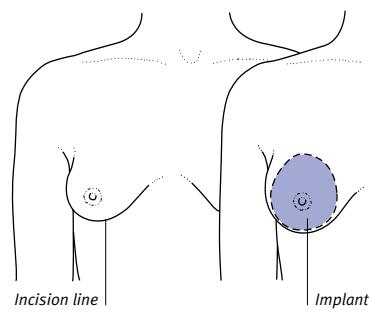

BREAST REDUCTION

Procedure for breast reduction

Incisions are made around the edge of the nipple, in the crease under the breast, and from the nipple to the crease. Excess tissue and skin are removed, and the nipple is repositioned, then the incisions are closed.

BREAST ENLARGEMENT

Procedure for breast enlargement

An incision is made in the armpit or along the crease under the breast, and a pocket is created behind the breast or the chest muscles to receive the implant. After the implant has been inserted, the incision is stitched.

set of teeth. The mandible is joined to the rest of the skull at the *temporomandibular joint*. It is the only skull bone capable of movement; it is moved by the cheek muscles for chewing and speech.

mania

A mental disorder characterized by episodes of overactivity, elation, or irritability. Mania usually occurs as part of a *manic-depressive illness*.

SYMPOTMS

Manic behaviour may include extravagant spending; repeatedly starting new tasks; sleeping less than normal; an increased appetite for food, alcohol, sex, and exercise; outbursts of inappropriate anger or laughter; a sudden increase in socializing; and delusions of grandeur. Milder forms are called hypomania.

TREATMENT

Severe mania is usually treated in hospital with *antipsychotic drugs*. Taking *lithium* or *carbamazepine* may prevent relapses.

manic-depressive illness

A mental disorder that is characterized by a disturbance of mood. The disturbance may be unipolar (consisting of either *depression* or *mania*) or bipolar (swinging between the two). In a severe form sometimes referred to as manic-depressive psychosis, there may also be grandiose ideas or negative delusions.

CAUSES

Some people inherit a tendency to manic-depressive illness. In addition, it is thought that abnormalities in brain biochemistry, or in the structure and/or function of certain nerve pathways in the brain, may underlie the illness.

TREATMENT

Severe illness often needs hospital treatment. *Antidepressant drugs* and/or *ECT* are used to treat depression, and *antipsychotic drugs* are given to control manic symptoms. *Carbamazepine* or *lithium* may be used to prevent relapse.

Group therapy, *family therapy*, and individual *psychotherapy* may be useful in certain circumstances. *Cognitive-behavioural therapy* may also help.

OUTLOOK

With treatment, most affected people improve or remain stable. Even those with severe illness may be restored to near-normal health with lithium therapy.

manipulation

A therapeutic technique involving the use of the hands to move parts of a patient's body in order to treat certain

disorders. Manipulation is important in *orthopaedics*, *physiotherapy*, *osteopathy*, and *chiropractic*. It may be used to treat deformity and stiffness caused by bone and joint disorders, to realign bones in a displaced *fracture*, to reposition a joint after a *dislocation*, or to stretch a *contracture*. Occasionally, manipulation is used to help treat *frozen shoulder*.

mannitol

An osmotic *diuretic drug* used to treat *oedema* (accumulation of fluid) in the brain and to relieve *glaucoma* (a buildup of fluid, and pressure, in the eyeball).

manometry

The measurement of pressure (of either a liquid or a gas) using an instrument called a manometer. Manometry is used to measure the blood pressure by means of an instrument called a *sphygmomanometer*.

Manson's disease

See *schistosomiasis*.

mantoux test

A skin test that is performed to detect tuberculosis (see *tuberculin tests*).

manubrium

The top part of the *sternum* (breastbone).

MAOI

An abbreviation for *monoamine oxidase inhibitor* drugs.

maple syrup urine disease (MSUD)

An inherited defect in body chemistry (see *metabolism*, *inborn errors of*) that interferes with the normal breakdown of amino acids. Abnormal acids accumulate in the blood and urine, giving the urine a characteristic smell of maple syrup, and causing severe *ketoacidosis*, *seizures*, and *coma*.

If left untreated, MSUD leads to learning difficulties and eventually to death during infancy. The condition can, however, be controlled with a low-protein diet.

marasmus

A severe form of protein and calorie malnutrition that usually occurs in famine or semi-starvation conditions. Marasmus is common in young children in developing countries. It causes stunted growth, emaciation, and loose folds of skin on the limbs and buttocks

due to loss of muscle and fat. Other signs include sparse, brittle hair; diarrhoea; and dehydration.

Treatment includes keeping the child warm and giving a high-energy, protein-rich diet. Persistent marasmus can lead to learning difficulties and can also cause impaired growth. (See also *kwashiorkor*.)

marble bone disease

See *osteopetrosis*.

Marburg virus disease

A rare form of *haemorrhagic fever*, also called green monkey disease, that is transmitted by African vervet monkeys.

The onset of the disease is sudden, with fever; severe headache; chest and abdominal pain; vomiting; diarrhoea; and a rash on the trunk. The symptoms become increasingly severe; they may include weight loss, delirium, *jaundice*, massive haemorrhaging (internal bleeding), failure of the liver and other organs, and *shock*.

There is no specific treatment for the disease; affected people must be admitted to hospital, where their blood and fluid levels will be maintained and any further infections treated.

march fracture

A break in one of the *metatarsal bones* (the long bones in the foot) that is caused by running or walking for long distances on a hard surface. The fracture results in pain, tenderness, and swelling; however, it may not show on *X-rays* until callus (new bone) has started to form. Treatment for a march fracture involves rest and, occasionally, immobilization of the foot in a plaster *cast*. (See also *stress fracture*.)

Marfan syndrome

A *genetic disorder* of *connective tissue* (material that holds body structures together) that results in skeletal, heart, and eye abnormalities. It is inherited in an autosomal dominant manner. Marfan syndrome is one of the most common disorders of connective tissue.

The features of Marfan syndrome usually appear after the age of 10. Affected people are very tall and thin. They have long, thin limbs, fingers, and toes, and weak ligaments and tendons. The chest and spine are often deformed and the lens of the eye may be dislocated. The heart is often abnormal and the *aorta* weakened.

Features of Marfan syndrome

One of the characteristic features of Marfan syndrome is long, thin, "spider" fingers (arachnodactyly). The condition is apparent when the hand of a person with Marfan syndrome (left) is compared to that of a normal person.

There is no cure for Marfan syndrome, but children are monitored and any complications are treated as they arise. Many affected children need glasses. Children may also be given *beta-blockers* to help prevent weakening of the aorta, and those with defects of the heart valve or aorta may undergo corrective surgery.

If a family has a member with Marfan syndrome, tests may be used (see *genetic counselling*) to find out whether or not relatives will pass on the gene.

marijuana

The flowering tops and dried leaves of the Indian hemp plant *CANNABIS SATIVA*, containing the active ingredient THC (tetra-hydrocannabinol). The leaves are usually smoked but can also be drunk as tea or eaten in food.

Physical effects of marijuana include dry mouth, mild reddening of the eyes, slight clumsiness, and an increased appetite. The main subjective feelings are usually of calmness and wellbeing, but depression occurs occasionally.

Large doses may cause panic, fear of death, and delusions. In rare cases, *drug psychosis* occurs, with symptoms such as paranoid delusions and confusion, which usually disappear in a few days.

There is increasing evidence that regular use of marijuana can aggravate mental health problems, particularly *depression* and *schizophrenia*, in people with these illnesses. Adolescents are most at risk. In addition, regular smoking of marijuana may cause worse lung damage than that caused by tobacco; the effect of three joints (marijuana cigarettes) is thought to be equivalent to 20 tobacco cigarettes.

Maroteaux–Lamy syndrome

A form of *mucopolysaccharidosis* caused by a deficiency in levels of the enzyme arylsulphatase B. The condition causes

features similar to those of *Hurler's syndrome*, such as coarsening of the facial features, skeletal deformities, cardiac abnormalities, and enlargement of the liver and spleen; however, the affected child's level of intelligence is normal. The condition often appears early in childhood. There is no specific treatment, and death from *heart failure* often occurs between 20 and 30 years of age.

marriage guidance

See *relationship counselling*.

marrow, bone

See *bone marrow*.

marsupialization

A surgical procedure carried out to drain some types of *abscess* or *cyst* and to prevent further abscesses. It is used to treat certain types of cyst affecting the *pancreas* and *liver*, and cysts affecting the *Bartholin's glands* at the entrance to the vagina.

In marsupialization, the cyst is first cut open and drained, then its edges are stitched to the surrounding skin or tissue (to form a pouch) so that it is kept open until it has healed.

Marvelon

A brand-named *oral contraceptive* containing the synthetic female hormones *ethinylestradiol* (an oestrogen drug) and *desogestrel* (a progestogen).

masculinization

See *virilization*.

masking

A technique used in a *hearing test* that involves applying a noise to one ear while testing the hearing of the other.

The term "masking" may also be used in connection with pairs of *genes* in which the effects of an abnormal gene are concealed by its normal equivalent. (See *genetic disorders*; *inheritance*.)

masochism

A desire to be physically, mentally, or emotionally abused. The term "masochism" is primarily used to refer to obtaining sexual excitement through one's own suffering in activities such as bondage, flagellation, and verbal abuse. (See also *sadism*; *sadomasochism*.)

massage

Rubbing and kneading areas of the body, usually with the hands. Massage increases the blood flow and relaxes

muscles; it may be used to relieve muscle spasm, treat muscle injury, and reduce *oedema* (accumulation of fluid in body tissues). Although massage is most effective when carried out by someone else, self-massage can alleviate pain caused by muscle tension.

masseter

The large muscle in the cheek that stretches between the cheekbone and the angle of the lower jaw. The muscle lifts the lower jaw during chewing.

mass hysteria

Intense emotion and irrational behaviour that spreads through a group of people in response to a highly exciting or upsetting event. The term may also be used to describe the occurrence of identical physical or emotional symptoms simultaneously in a particular group of people, such as children in the same class or school.

mastalgia

The medical term for pain in the *breast*.

mast cell

A type of cell that plays an important part in *allergy*. In an allergic response, antibodies (proteins produced by the immune system to neutralize an allergen) attach themselves to mast cells. The cells burst and release a chemical called *histamine*, which produces an inflammatory response in surrounding tissues, thereby causing many of the symptoms of allergic conditions.

mastectomy

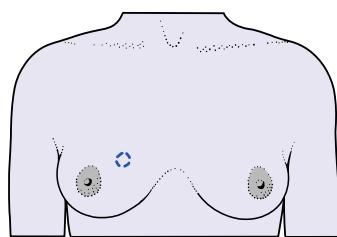

The surgical removal of all of the *breast*, usually performed to treat *breast cancer*. Mastectomy may be used if the cancer cannot be removed by *lumpectomy* (removal of the tumour and a small area of surrounding tissue) or *quadrantectomy* (removal of part of the breast) because of its size or position. Less commonly, a procedure known as subcutaneous mastectomy may be recommended for women who have a very high risk of developing breast cancer because they carry an abnormal gene that causes the disease.

HOW IT IS DONE

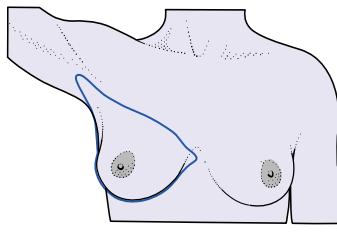

Formerly, a procedure called radical mastectomy was used; this involved removal of the breast together with an extensive area of muscle down to the chest wall. Today, however, the usual procedure is a total mastectomy. This operation involves

TYPES OF MASTECTOMY

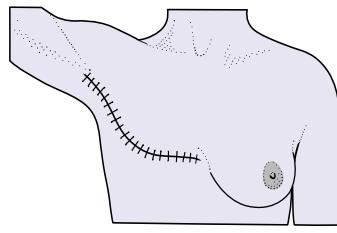

The type of operation depends on many factors, including the size and site of the tumour and the woman's wishes. A small tumour may be treated by lumpectomy; other cases may require more extensive surgery.

LUMPECTOMY**Site of incision for a lumpectomy**

Only the cancerous tissue (shown here by a dotted line) and some of the surrounding normal tissue is removed. Lumpectomy leaves the breast looking relatively normal.

TOTAL MASTECTOMY

1 A large, elliptical incision that encompasses the nipple and sometimes the entire breast, is made. Part of the incision is extended into the armpit. All of the breast tissue, including the skin and some of the fat, is dissected (separated by cutting) down to the chest muscles. The dissection is continued under the skin into the armpit, to free the upper and outer "tail" of breast tissue with its lymph nodes.

2 All of the bleeding vessels are tied off, then a drainage tube is inserted and the skin is closed with stitches or clips. The scar runs diagonally across the chest. The woman may wear a prosthesis or may have an implant inserted later.

removal of all of the breast tissue and usually some or all of the *lymph nodes* in the armpit. Cells from the nodes are examined to determine whether cancerous cells have spread. The operation is performed under a general *anaesthesia* and usually requires a stay in hospital of a few days. *Plastic surgery* to reconstruct the breast may be carried out at the same time as the mastectomy or at a later date (see *mammoplasty*).

RISKS

After the operation, the scar may be tender. If the lymph nodes have been removed, there is a risk of *lymphoedema* developing in the arm.

mastication

The process of chewing food. The canines and incisors (front teeth) shear the food. The tongue then pushes it between the upper and lower premolars and molars (back teeth) to be ground by movements of the lower jaw. *Saliva* is mixed with the food to help break it down for swallowing.

mastitis

Inflammation of *breast* tissue. Mastitis is usually caused by bacterial infection and sometimes by hormonal changes.

CAUSES

Mastitis usually occurs when bacteria enter the nipple during *breast-feeding*. It can also be caused by changes in levels of *sex hormones* in the body – for example, at the onset of *puberty*.

SYMPTOMS

The condition causes pain, tenderness, and swelling in one or both breasts. Bacterial mastitis during breast-feeding also causes redness and *engorgement* and may result in a *breast abscess*.

TREATMENT

Mastitis due to infection is treated with *antibiotic drugs* and *analgesic drugs*, and by *expressing milk* to relieve engorgement. Mastitis caused by hormonal changes usually clears up in a few weeks without treatment.

mastocytosis

An unusual condition in which itchy, irregular, yellow or orange-brown swellings occur on the skin, most commonly on the trunk. Mastocytosis may also affect body organs, including the liver, spleen, and intestine, and may cause symptoms such as diarrhoea, vomiting, and fainting. Very rarely, it leads to *anaphylactic shock* (a severe form of allergic reaction), which can be fatal.

Mastocytosis usually begins in the first year of life and clears up by adolescence. *Antihistamine drugs* may be helpful in relieving the symptoms.

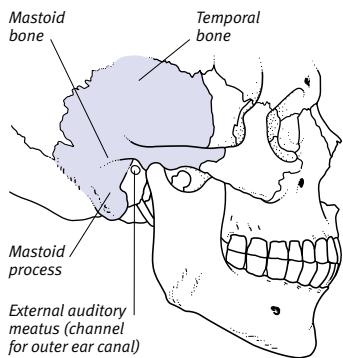

mastoid

The lower part of the temporal bone in the *skull*. The mastoid has a projection, called the mastoid process, which can be felt behind the ear. The bone is honeycombed with cavities called air cells; these spaces are connected to a larger cavity called the mastoid antrum, which leads into the middle ear.

In some cases, infections of the middle ear (see *otitis media*) spread through the mastoid bone to cause acute *mastoiditis*.

LOCATION OF MASTOID

The mastoid is the lower part of the temporal bone. The mastoid process can be felt as a hard prominence just behind the ear.

**mastoiditis**

Inflammation of the *mastoid*, in the skull.

CAUSE

Mastoiditis is due to infection spreading from the middle ear (see *otitis media*) to the air cells in the mastoid through a cavity called the mastoid antrum.

SYMPTOMS

The condition causes earache and severe pain, swelling, and tenderness behind the ear. There is usually also fever, a creamy discharge from the ear, progressive hearing loss, and displacement of the outer ear. If the infection spreads, it may lead to *meningitis*, a *brain abscess*, blood clotting in veins within the brain, or *facial palsy*.

TREATMENT

Treatment is with *antibiotic drugs*. If the infection persists, an operation called a

mastoidectomy may be carried out; in this procedure, the mastoid is opened and the infected air cells removed.

masturbation

Sexual self-stimulation, usually to produce *orgasm*. Massaging the *penis* or the *clitoris* with the hand is the usual method of masturbation.

maternal mortality

The death of a woman during *pregnancy*, or within 42 days of *childbirth*, *miscarriage*, or an *induced abortion*, from any pregnancy-related cause. Maternal mortality rate is the number of such deaths per 100,000 live births as measured over a given year.

Maternal deaths may be a direct result of complications of pregnancy or may be caused indirectly by a medical condition that is worsened by pregnancy. The major direct causes of death include *pulmonary embolism* (blood clots in the lungs), *antepartum haemorrhage*, *postpartum haemorrhage*, *hypertension* (high blood pressure), *eclampsia* (a condition causing seizures in late pregnancy), and *puerperal sepsis* (infection following childbirth). Indirect causes include heart disease, *epilepsy*, and some cancers.

Maternal mortality is lowest for second pregnancies. After the age of 20, it rises with age, being greatest for women over the age of 40.

maturation

The process by which full development is reached. The term "maturation" is used with reference to cells (particularly *ova* and *sperm*) and some microorganisms; it may also be used of physical and emotional development in people.

maxilla

Each of a pair of bones that together form the centre of the face, the upper jaw, and the roof of the mouth. In addition, the top of the maxilla forms the base of the orbit (eye socket). Each bone contains a large, air-filled cavity called the maxillary sinus (see *sinus, facial*), which is connected to the nasal cavity.

McArdle's disease

A rare *genetic disorder* characterized by muscle stiffness and painful cramps that increase during exertion and afterwards. The cause is a deficiency of an *enzyme* in muscle cells that stimulates breakdown of the carbohydrate *glycogen* into the simple sugar glucose. The result is a

buildup of glycogen and low levels of glucose in the muscles. Damage to the muscles occurs, causing myoglobinuria (the presence of pigment from muscle cells in the urine); this condition, in turn, may lead to *kidney failure*.

There is no treatment, but symptoms may be relieved by eating glucose or fructose before exercise.

MDMA

The hallucinogenic substance methylenedioxymethamphetamine, which has the street name *Ecstasy*.

ME

The abbreviation for the condition myalgic encephalomyelitis (see *chronic fatigue syndrome*).

measles

A potentially dangerous viral illness that causes fever and a rash. Measles mainly affects children, but can occur at any age. It is spread primarily by airborne droplets of nasal secretions. It can be transmitted during the *incubation period* (eight to 14 days after infection) and up to seven days after symptoms appear.

SYMPTOMS AND SIGNS

The illness starts with a fever, runny nose, sore eyes, cough, and a general feeling of being unwell. After three to four days, a red rash appears, usually starting on the head and neck and spreading to cover the body. The spots sometimes join to produce large red

blotches, and the *lymph nodes* may be enlarged. After three days, the rash starts to fade and the symptoms subside.

COMPLICATIONS

The most common complications are ear and chest infections, which usually develop two to three days after the rash has appeared. Diarrhoea, vomiting, and abdominal pain may occur. Febrile convulsions (see *convulsion, febrile*) are also common, but are not usually serious.

In a tiny minority of cases, *encephalitis* (inflammation of the brain) occurs, causing headache, drowsiness, and vomiting. Seizures and *coma* may follow, sometimes leading to *brain damage* or even death. In very rare cases, a progressive brain disorder called *subacute sclerosing panencephalitis* develops several years after infection.

If a woman has measles during pregnancy, the infection may be fatal to the fetus; however, there is no evidence that measles causes birth defects.

TREATMENT

There is no specific treatment. Plenty of fluids and *paracetamol* are given for fever. In addition, *antibiotic drugs* may be given to treat bacterial infections that occur as complications.

PREVENTION

To help prevent measles, immunization with the *MMR vaccination* is recommended at between 12 and 15 months of age. This measure produces immunity in about 90 per cent of cases, with a booster shot given before a child enters school or nursery school.

M

meatus

A canal or passageway through part of the body. The term usually refers to the external auditory meatus, the canal in the outer *ear* that leads from the outside of the ear to the eardrum.

mebendazole

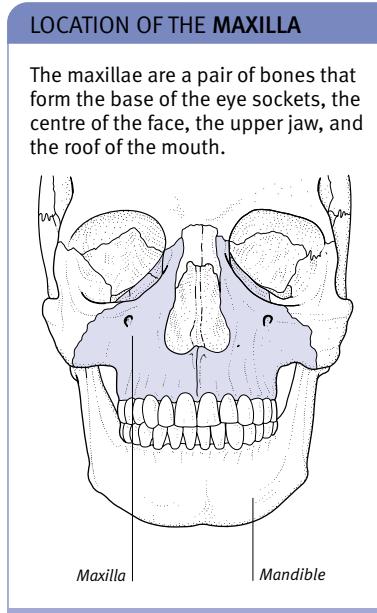

An *anthelmintic drug* that is used to treat various *worm infestations* of the intestine. Possible adverse effects include abdominal pain and diarrhoea.

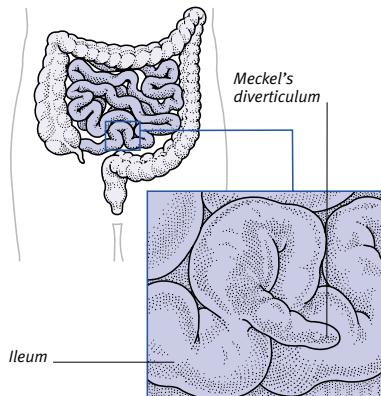

mebeverine

An *antispasmodic drug* used to treat *irritable bowel syndrome*.

Meckel's diverticulum

A common abnormality, present at birth in about 1 in 40 people, in which a small, hollow, wide-mouthed sac protrudes from the *ileum*. Symptoms only occur if the diverticulum becomes

**anatomy of Meckel's diverticulum**

In this common birth defect, an appendix-type sac protrudes from the ileum (the last section of the small intestine).

infected, obstructed, or ulcerated. The most common symptom is painless bleeding from the rectum; this bleeding may be sudden and severe, making immediate *blood transfusion* necessary. Inflammation may cause symptoms very similar to those of *appendicitis*, such as lower abdominal pain. Meckel's diverticulum occasionally causes *intussusception* (telescoping) or *volvulus* (twisting) of the small intestine.

Diagnosis of the abnormality may be made by using technetium *radionuclide scanning*. If any complications develop, they will be treated by surgical removal of the diverticulum.

meconium

The thick, sticky, greenish-black faeces that is passed by infants in the first day or two after birth. Meconium consists of *bile*, mucus, and intestinal cells that have been shed.

Occasionally, the fetus passes meconium into the *amniotic fluid* while still in the uterus. This problem is more common in those babies who experience *fetal distress* during labour or who are over 40 weeks' gestation. Meconium in the amniotic fluid may be inhaled when the baby starts to breathe, sometimes blocking the airways and damaging the lungs. In some babies with *cystic fibrosis*, the meconium is so thick and sticky that it blocks the intestine (see *intestine, obstruction of*).

medial

A medical term that means "situated towards the midline of the body". Less commonly, the term refers to the middle layer of a body structure.

median nerve

One of the main nerves of the arm. The median nerve is a branch of the *brachial plexus* and runs down the arm from the shoulder into the hand. It controls the muscles that carry out bending movements of the wrist, fingers, and thumb, and the muscles that rotate the forearm palm-inwards. The nerve also conveys sensations from the thumb and first three fingers, and from the region of the palm at their base.

DISORDERS

Damage to the nerve may result from injury to the shoulder, a *Colles' fracture* just above the wrist, or pressure on the nerve where it passes through the wrist (*carpal tunnel syndrome*). Symptoms of damage include numbness and weakness in areas controlled by the nerve.

mediastinoscopy

Viewing of the *mediastinum* using an *endoscope* inserted through an incision just above the sternum (breastbone). The procedure is performed under general anaesthesia.

Mediastinoscopy is used mainly to perform a *biopsy* of a *lymph node*, often in diagnosing *lymphoma*. The tissue sample is removed by tiny blades attached to the endoscope.

mediastinum

The membranous partition between the lungs and the other structures within the chest cavity. These other structures include the *heart* and associated blood vessels; the *trachea* (windpipe); the *oesophagus*; the *thymus* gland; *lymph nodes*; lymphatic vessels; and nerves.

MedicAlert bracelet

An item, available from a charitable organization called the MedicAlert foundation, that provides vital information about a person's identity and medical status in case he or she needs urgent medical help. The items are designed to be worn by individuals with a hidden medical condition (such as *epilepsy* or *diabetes mellitus*) or a serious allergy (such as *penicillin allergy*).

MedicAlert bracelets, and necklaces, are engraved with an emblem that is instantly recognizable to medical workers and carries details of important medical conditions affecting the wearer. They also carry a personal identification number and a 24-hour telephone number so that further medical details can be accessed anywhere in the world.

medical ethics

The professional values and guidelines that govern medical decisions, particularly medical practitioners' treatment of patients and their relatives and of colleagues. Ethical requirements also play a part in medical research; for example, when new drugs or other treatments are tested on patients, the trials must be designed so that they will not cause any harm to the patients involved.

medical history

See *history-taking*.

medical tests

See *tests, medical*.

medication

Any substance prescribed to treat disease. (See also *drug; medicine*.)

medicine

The study of human diseases and their causes, frequency, treatment, and prevention. The term "medicine" is also used of a substance that is prescribed to treat an illness. In some circumstances, it is used to refer to treatments that do not involve surgery.

medicolegal

A term used of matters in which medicine and the law overlap. Among the issues on which medicolegal experts advise people are laws concerning damages for injuries that are due to medical negligence or malpractice; evidence concerning the extent of injury in a civil action; the use of paternity tests; the mental competence of people who have drawn up wills; and restrictions placed on mentally ill people.

Medicolegal issues also include an individual's right to die (see *brain death; euthanasia; living will*); the necessity for informed *consent* to any surgical procedure; the legal aspects of *artificial insemination, in vitro fertilization, sterilization, and surrogacy*; and a patient's right to *confidentiality* concerning his or her illness. (For the medical aspects of criminal law, see *forensic medicine*.)

meditation

Concentration on an object, a word, or an idea with the aim of inducing an altered state of consciousness. At its deepest level, meditation can resemble a trance. More commonly, it is a calming therapy and can be a way to reduce stress levels and treat stress-related dis-

LANDMARKS IN MEDICINE: DIAGNOSIS

Date	Development
c.400 BC	Disease concept Introduced by the Greek physician Hippocrates.
1612	Medical thermometer Devised by the Italian physician Sanctorius.
c.1660	Light microscope Single-lens microscope developed by the Dutch naturalist Antonij van Leeuwenhoek, who discovered microorganisms with it. A practicable compound microscope was not developed until the 19th century.
1810	Stethoscope Invented by the French physician René Laennec.
1850–1900	Germ theory of disease Proposed by the French scientist Louis Pasteur and developed by the German bacteriologist Robert Koch.
1851	Ophthalmoscope Invented by the German scientist Herman von Helmholz.
1895	X-rays Discovered by the German physicist Wilhelm Roentgen. He also produced the first X-ray picture of the body.
1906	Electrocardiograph (ECG) Invented by the Dutch physiologist Willem Einthoven.
c.1932	Transmission electron microscope (TEM) Constructed by the German scientists Max Knoll and Ernst Ruska.
1938	Cardiac catheterization First performed by George Peter Robb and Israel Steinberg in New York.
1957	Fibre-optic endoscopy Pioneered by the South African-born doctor Basil Hirschowitz at the University of Michigan.
1972	CT scanner Invented by the British engineer Godfrey Hounsfield of EMI Laboratories, England, and the South African-born physicist Alan Cormack of Tufts University, Massachusetts.
1975	Monoclonal antibodies Large-scale production method for monoclonal antibodies developed by the Argentinian-born scientist César Milstein at the Medical Research Council Laboratories, England.
1976	Chorionic villus sampling Developed by Chinese gynaecologists as an aid to the early diagnosis of genetic disorders.
1981	MRI scanner Developed by scientists at Thorn-EMI Laboratories and Nottingham University, England.
1985	Polymerase chain reaction Rapid copying of DNA sequences developed by Kary Mullis of the Cetus Corporation, California.
1995	Genetics Chromosome sequence of first nonviral organism, <i>Haemophilus influenzae</i> , identified.
2003	Human Genome Completion of the Human Genome Project by the International Human Genome International Consortium, following first draft produced in 2001.

orders. A common form of meditation practised in Europe and North America is transcendental meditation (TM).

Mediterranean diet

A diet based on the traditional foods eaten in Mediterranean countries, where people have a lower risk of cardiovascular disease and *cancer* than people in northern European countries. The bulk of the diet consists of fruit, vegetables, and grain-based foods such as pasta and couscous. The major source of fat is olive oil, a *monounsaturated fat* (see *fats and oils*). The diet also includes fish, but only small amounts of meat, poultry, eggs, and dairy products.

Mediterranean fever

See *brucellosis*.

Mediterranean fever, familial

See *family Meditarranean fever*.

medroxyprogesterone

A *progestogen drug* used to treat *endometriosis* (a condition in which fragments of uterine lining are found in the pelvic cavity), as well as certain types of *breast cancer* and uterine cancer (see *uterus, cancer of*). In addition, it is sometimes used to treat menstrual disorders such as *amenorrhoea* (absence of menstruation). The drug can also be used as a contraceptive, given by injection at three-month intervals (see *contraception, hormonal methods of*). Possible adverse effects include weight gain, swollen ankles, and breast tenderness.

medulla

The innermost part of a body structure; for example, the adrenal medulla is the central area of an *adrenal gland*. In addition, the word "medulla" is sometimes used to refer to the *medulla oblongata*.

medulla oblongata

Also called the *medulla*, the lowest part of the *brainstem*. The medulla oblongata lies at the base of the skull. It connects the brain to the *spinal cord*.

medulloblastoma

A type of cancerous *brain tumour* that occurs mainly in children. A medulloblastoma usually arises from the *cerebellum*, the region of the brain that is concerned with posture, balance, and coordination. The tumour grows rapidly and may spread to other parts of the brain and also to the *spinal cord*. A

LANDMARKS IN MEDICINE: SURGERY	
Date	Development
1545	Basic surgical principles Established by the French surgeon Ambroise Paré.
1842	General anaesthesia First operation using general anaesthesia performed by the American surgeon Crawford Long, who used ether. In 1845, the American dentist Horace Wells used nitrous oxide (laughing gas) as an anaesthetic. In 1847, the British obstetrician James Simpson introduced chloroform anaesthesia.
1870	Antiseptic surgery Pioneered by the British surgeon Joseph Lister, who used a carbolic acid (phenol) spray during surgery to help prevent infection.
1901	Blood groups ABO blood groups discovered by the Austrian pathologist Karl Landsteiner, so establishing the basis for safe transfusions.
1951	Coronary artery bypass graft First attempted by the Canadian surgeon Arthur Vineberg at the Royal Victoria Hospital, Montreal.
1955	Kidney transplant First successful kidney transplant (between identical twins) performed by a team of American surgeons, led by Joseph Murray, of the Harvard Medical School, Massachusetts.
1967	Heart transplant First human heart transplant performed by the South African surgeon Christian Barnard at the Groote Schur Hospital, Cape Town.
1976	Coronary angioplasty Introduced by the Swiss surgeon Andreas Grüntzig at the University Hospital, Zurich.
1987	Minimally invasive surgery The first cholecystectomy (gallbladder removal) using laparoscopic techniques under video control performed by the French doctor P. Mouret, in Lyon.
1998	Robotic surgery First coronary artery bypass surgery using a robot performed by a team under Professor Friedrich-Wilhelm Mohr, at Leipzig Heart Centre, Germany.

M

LANDMARKS IN MEDICINE: OTHER TREATMENTS	
Date	Development
c.1270	Glasses Thought to have been invented in Italy. Contact lenses were invented in 1887 by the Swiss optician Eugen Frick.
1817	Dental plate Introduced by the American dentist Anthony Plantson.
1891	Baby incubator Introduced by the French doctor Alexandre Lion.
1901	Hearing-aid (electric) Developed by the American inventor Miller Reese Hutchinson. The first truly miniature hearing-aid was introduced in 1952 by the Sonotone Corporation.
1945	Kidney dialysis machine Developed by the Dutch surgeon Willem Kolff.
1978	"Test-tube baby" Louise Brown, the first baby resulting from in-vitro fertilization, was born in the UK. The IVF techniques were developed by the British gynaecologist Patrick Steptoe and the embryologist Robert Edwards.
1979	Shock-wave lithotripsy Pioneered by researchers at the University Hospital, Munich, Germany.
1990	Gene therapy First attempted at the US National Institute of Health, by doctors W. French Anderson, Michael Blaese, and Kenneth W. Culver, to treat a four-year-old girl with a form of Severe Combined Immunodeficiency (SCID). Gene therapy has since had some success, but to date it is still at an experimental stage.

morning headache, repeated vomiting, and a clumsy gait develop. There are also frequent falls.

The tumour is diagnosed by *CT scanning* or *MRI* and can often be treated with *radiotherapy*. Surgery and *anticancer drugs* may also be needed.

mefenamic acid

An NSAID (see *nonsteroidal anti-inflammatory drugs*) used to relieve pain and inflammation. Mefenamic acid may be given for conditions such as headache, toothache, and *dysmenorrhoea* (painful menstrual periods), and to reduce *menorrhagia* (excessive menstrual bleeding). It may also be prescribed for long-term relief of joint pain and stiffness in *osteoarthritis* and *rheumatoid arthritis*.

Possible adverse effects are typical for NSAIDs; they include abdominal pain, indigestion, nausea, and vomiting.

mefloquine

A drug used to prevent and treat *malaria* in parts of the world where the parasite that causes it is resistant to *chloroquine*. Mefloquine is one of the preferred treatments for *falciparum malaria*.

Side effects include nausea, vomiting, and diarrhoea. Rarely, there may be *panic attacks*, *hallucinations*, and *psychosis*. Mefloquine is not recommended for people who have a history of disorders such as *depression* or *epilepsy*.

mega-

A prefix meaning "very large", as in *megacolon*, a condition in which the colon is greatly enlarged. The prefix "megal-" has the same meaning.

megacolon

A gross distension (enlargement) of the *colon*, usually accompanied by severe, chronic *constipation*.

CAUSES

In children, the main causes of megacolon are *anal fissures*, *Hirschsprung's disease*, and psychological factors that may have arisen during toilet-training. In elderly people, causes include the long-term use of strong *laxative drugs*. People suffering from chronic *depression* or *schizophrenia* often have megacolon. Other, rarer causes include *hypothyroidism*, *spinal injury*, and the use of drugs such as *morphine* and *codeine*.

SYMPTOMS

Megacolon causes constipation and abdominal bloating. Some affected individuals experience loss of appetite, which

LANDMARKS IN MEDICINE: DRUGS

Date	Development
1666	Quinine The British physician Thomas Sydenham popularized the use of Jesuits' bark (containing quinine) for treating malaria.
1785	Digitalis The use of digitalis to treat heart failure described by the British physician William Withering.
1796	Smallpox vaccination The first vaccination to be performed, by the British physician Edward Jenner. The first true vaccine (consisting of weakened microorganisms), against chicken cholera, was developed in 1880 by the French scientist Louis Pasteur.
1805	Morphine Extracted from opium and used to relieve pain, by the German pharmacist Friedrich Sertürner.
1911	Salvarsan Introduced by the German bacteriologist Paul Ehrlich to treat syphilis.
1928	Penicillin Antibacterial action first recognized by the British bacteriologist Alexander Fleming. Produced as a drug in 1940, by the Australian-born British pathologist Howard Florey and the German-born British biochemist Ernst Chain.
1935	Sulphonamides Antibacterial action discovered by the German pharmacologist Gerhard Domagk.
1951	Oral contraceptive Developed by the American doctors Gregory Pincus and John Rock, and the Austrian-born American chemist Carl Djerassi.
1959	Librium (chlordiazepoxide) The first benzodiazepine minor tranquillizer, introduced by the Swiss pharmaceutical company Hoffmann-LaRoche.
1962	Nethalide (pronethalol) The first beta-blocker heart drug, developed by scientists at Imperial Chemical Industries, England.
1984	Genetically engineered human insulin Developed by scientists at Genentech, California.
1986	Zidovudine (originally called AZT) Introduced to treat AIDS after development by scientists at Burroughs Wellcome Research Laboratories, North Carolina.
1998	Viagra (sildenafil) Introduced as a treatment for erectile dysfunction after development by the Pfizer Corporation, US.

may lead to weight loss. Diarrhoea may occur if semi-liquid faeces leak around the obstructing hard faeces.

DIAGNOSIS AND TREATMENT

The diagnosis is made by *proctoscopy* (viewing of the rectum with an endoscope), *barium X-ray examination*, and tests to assess the functioning of the intestinal muscles. If Hirschsprung's disease is suspected, *biopsy* of the large intestine may be performed.

Impacted faeces are often removed using *enemas*. In severe cases, the faeces must be removed manually.

megaloblastic anaemia

See *anaemia, megaloblastic*.

megalomania

An exaggerated sense of one's importance or ability that often occurs in *mania*. Megalomania may take the form of a *delusion* of grandeur, or may manifest itself as a desire to organize large-scale activities that are expensive and involve many people.

-megaly

A suffix meaning "enlargement", as in *acromegaly*, a disorder in which the jaw, skull, hands, and feet are enlarged.

megaureter

Gross distension (widening) of a *ureter*, the tube that carries urine from each kidney to the bladder. One possible

cause of megaureter is a long-standing blockage in the ureter that stops the flow of urine. Another is backward flow of urine from the bladder into the ureters while the bladder is being emptied (see *vesicoureteric reflux*). In some cases, the condition is congenital (present at birth) and has no known cause.

Megaureter is treated by surgery to remove blockages or to relieve reflux.

megestrol

A *progestogen drug* that is used to treat uterine cancer (see *uterus, cancer of*) and certain types of *breast cancer*. Megestrol may be prescribed when a tumour is inoperable, if a tumour has recurred after surgery, or when other *anticancer drugs* or *radiotherapy* prove ineffective.

Possible adverse effects of the drug include swollen ankles, weight gain, nausea, dizziness, headache, rash, and, rarely, raised blood calcium levels.

meibomian cyst

See *chalazion*.

meibomian gland

A small sebaceous (oil-secreting) gland situated under the *conjunctiva* (membranous lining) of each eyelid. If one of the glands becomes blocked, it enlarges to create a swelling within the lid, which is known as a *chalazion*.

meibomianitis

Inflammation of the *meibomian glands*, the sebaceous (oil-secreting) glands within the eyelids. The condition is caused by excessive or unusually thick glandular secretions, which result in an overgrowth of bacteria on the eyelids. Conditions that can increase the secretions include skin disorders affecting the face (such as *acne* or *rosacea*), allergic reactions, and the hormonal changes that occur in adolescence.

Symptoms of meibomianitis include swelling of the eyelid edges, brief blurring of the vision due to oily tears, and frequent *styes*. Careful cleansing of the eyelids may relieve the symptoms. Antibiotic eye ointment may be prescribed to clear up infection.

Meig's syndrome

A rare condition in which a tumour of an *ovary* is accompanied by *ascites* (an accumulation of fluid in the abdomen) and a *pleural effusion* (fluid around one of the lungs). The fluid usually disappears when the tumour is removed.

meiosis

A type of cell division that occurs in the *ovaries* and *testes* during the production of egg and sperm cells. During meiosis in humans, a cell containing 23 pairs of chromosomes (46 in total) divides to form four sperm or egg cells, each with 23 single chromosomes.

First, each chromosome is duplicated (making a total of 92); the doubled chromosomes are joined at a point called the centromere. Matching pairs of doubled chromosomes line up and exchange genetic material. The cell then divides twice to form four daughter cells, with each taking one copy of each chromosome.

Egg and sperm cells therefore have 23 single chromosomes, which is only half the usual chromosome content of a body cell, so each parent contributes half of the offspring's genetic material. The exchange between chromosomes means that each daughter cell has a unique genetic make-up. (See also *mitosis*).

melaena

Black, tarry *faeces* caused by bleeding, usually in the upper gastrointestinal tract. The blood is blackened by the action of secretions during digestion. Melaena is usually caused by a *peptic ulcer* but may indicate cancer.

M**melancholia**

Former term for *depression*.

melanin

The brown or black pigment that gives skin, hair, and the iris of the eyes their colouring. Melanin is produced by cells called *melanocytes*.

Exposure to sunlight increases the production of melanin, which protects the skin from the harmful effects of ultraviolet rays and causes the skin to darken. Localized overproduction of melanin in the skin can result in a pigmented spot, most commonly a *freckle* or mole (see *naevus*).

melanocyte

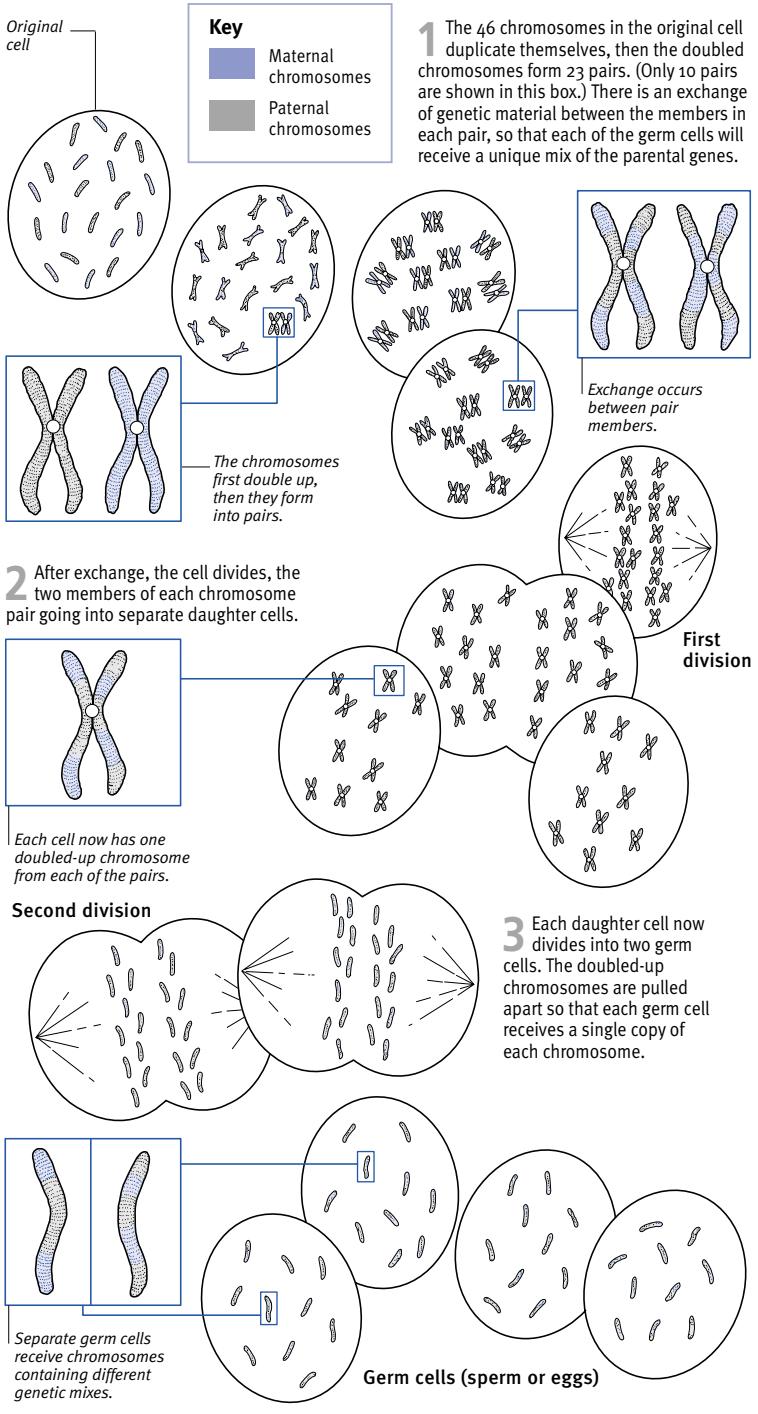

A specialized skin cell that produces the pigment *melanin*. The cells can be damaged by overexposure to the sun; this damage may result in skin cancer (see *melanoma, malignant*).

melanoma, juvenile

A raised, reddish-brown skin blemish, also called a Spitz naevus, which sometimes appears on the face or legs in

MECHANISM OF MEIOSIS

In meiosis, a cell in the *testis* or *ovary* containing 46 chromosomes divides to form four germ cells (sperm or eggs), each with 23 chromosomes. Germ cells have only half the usual chromosome content because a child can receive only half the genes of each parent.

early childhood (see *naevus*). Despite the name, it is noncancerous. Although it is harmless, an unsightly growth, or one that is suspected of being skin cancer, may be removed surgically.

melanoma, malignant

The most serious of the three types of skin cancer. (The other two forms of the disorder are *basal cell carcinoma* and *squamous cell carcinoma*.) If left untreated, the cancer may be fatal.

CAUSE AND INCIDENCE

Malignant melanoma is a tumour of melanocytes, the cells that produce the pigment *melanin*, and is due to long-term exposure to strong sunlight. It is most common in middle-aged and elderly people with pale skin and fair hair who have spent many years in sunny climates. Severe sunburn during childhood doubles the risk of developing melanoma in later life.

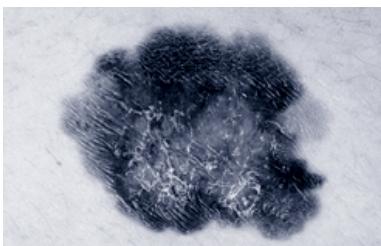

There is an increasing number of new cases and deaths in the UK each year from this skin cancer, probably due to people sunbathing and taking holidays in sunny countries.

SYMPOTMS

Tumours usually develop on areas of exposed skin but may occur anywhere on the body, including in the eye. A melanoma usually grows from an existing mole. An affected mole may change colour, increase in size, or develop an irregular edge. Other signs include a mole becoming lumpy, bleeding or crusting, forming a scab, or becoming itchy or inflamed. Such changes should be reported to a doctor. Occasionally, a melanoma develops in normal skin. If left untreated, the cancer can grow down through the layers of skin and rapidly spread to other parts of the body.

DIAGNOSIS AND TREATMENT

Early diagnosis is vital to help prevent life-threatening spread of the cancer.

Development of malignant melanoma
Only one mole in a million becomes malignant. However, change of shape, darkening, tenderness, pain, itching, or ulceration are warning signs of a malignant melanoma.

Diagnosis is by a *skin biopsy*, in which tissue from the growth, together with some of the surrounding skin, is removed for microscopic examination. Samples from nearby *lymph nodes* may also be examined; the presence of any cancerous cells in these samples would indicate that the cancer has spread.

The melanoma will be removed surgically. If the cancer has spread from the primary site, *radiotherapy* or *anticancer drugs* may also be necessary. *Immunotherapy* may be used to help the body fight the cancer; this treatment involves the use of substances such as interferon or interleukin-2.

melanonychia

Black or dark coloration of a fingernail or toenail, due to an excess of the pigment *melanin*. The colour often forms a vertical streak down the nail.

Melanonychia is a normal occurrence in some black and Asian people. In white people, it may be due to a *naevus* (pigmented blemish) beneath the nail; melanoma (see *melanoma, malignant*); a reaction to a drug; or *HIV* infection.

melanosis coli

Black or brown discolouration of the colon lining. Melanosis coli is associated with chronic *constipation* and prolonged use of certain *laxative drugs*, such as senna, rhubarb, and cascara.

The discolouration is most common in elderly people and is usually symptomless. It clears up when the laxatives are no longer used. Rarely, it is associated with colon cancer (see *colon, cancer of*).

melasma

See *chloasma*.

melatonin

A hormone secreted by the *pineal gland* in the brain that is thought to play a part in controlling daily body rhythms and regulating the sleep-wake cycle. Levels of melatonin rise in response to decreasing light, preparing the body for sleep. Some people believe that taking supplements of melatonin can help to minimize the effects of *jet-lag*, but this has not been proved.

Melleril

A brand name for the antipsychotic drug *thioridazine*.

melphalan

An *anticancer drug* used to treat *multiple myeloma* as well as certain types of *breast cancer* and ovarian cancer (see

ovary, cancer of). Possible adverse effects include nausea, vomiting, sore throat, loss of appetite, reduced numbers of red and other blood cells (see *anaemia, aplastic*), abnormal bleeding, and increased susceptibility to infection.

membrane

A layer of tissue that covers or lines a body surface or forms a barrier.

memory

The ability to remember. Memory is usually regarded as comprising three stages: registration, retention, and recall. In registration, information is perceived, is understood, and is then held in the short-term memory. In retention, more important information is transferred into the long-term memory and stored. Recall involves bringing information into the conscious mind at will. There are a number of factors that determine how well information is remembered, including its familiarity and how much attention has been paid to it.

Where in the brain the memory process takes place is not known. However, the temporal lobe and *limbic system* may be involved. The mechanisms for storing memory are also unknown.

THE STAGES OF MEMORY

Stage 1: Registration

Information is perceived and understood, then held in a short-term memory system. This system seems to be very limited in the amount of material that it can store at one time. Unless refreshed by constant repetition, the contents of short-term memory are lost within minutes, to be replaced by other material.

Stage 2: Retention

If information is sufficiently important, it is transferred into long-term memory for storage. The process of storage involves association of the information with certain words or meanings, with visual imagery evoked by it, or with other experiences, such as smell or sound.

Stage 3: Recall

Information that has been stored at an unconscious level, in long-term memory, is brought into the conscious mind by an act of will. The reliability of the recall process depends on how well the information was encoded in stage 2.

DISORDERS

Most memory disturbances are due to failure at the retention or recall stage (see *amnesia*). In some cases, the problem occurs at the registration stage. Some people with *temporal lobe epilepsy* have uncontrollable flashbacks of distant past events. The most common memory disorder is the normal difficulty in recall that develops with age. More severe loss of memory may be an early symptom of *dementia*.

memory B-cell

A type of white blood cell, also known as a memory B-lymphocyte (see *lymphocyte*), that is involved in the *immune system* response to invading *bacteria*. Memory B-cells recognize bacteria that the body has previously encountered. They promptly produce huge quantities of *antibodies* that inactivate the bacteria, thus preventing or shortening the organisms' effects. (See also *memory T-cell*.)

memory, loss of

See *amnesia*.

M**memory T-cell**

A type of white blood cell, also known as a memory T-lymphocyte (see *lymphocyte*), that is involved in the *immune system* response to viruses, parasites, and cancer cells. Memory T-cells recognize viruses, parasites, or cancer cells that the body has previously encountered. Some belong to the class of *killer T-cells*, which attach themselves to infected cells and then release toxic proteins to destroy the cells. (See also *memory B-cell*.)

menarche

The onset of *menstruation*. Menarche usually occurs around the age of 12 or 13, two years after *puberty* starts.

Mendelian inheritance

A form of *inheritance* first described by the Austrian monk Gregor Mendel. He discovered that certain distinct, unchanging physical characteristics are controlled by factors that are now called *genes*, which are transmitted through many generations. He also revealed the existence of *dominant* and *recessive* genetic characteristics.

Mendel formulated two laws concerning inheritance. Mendel's first law, or the law of segregation, states that the characteristics of an organism are determined by pairs of genes, and that

during reproduction the genes in each pair separate, with only one *allele* (gene from a pair) being carried in a *gamete* (egg or sperm cell) and passed on to an offspring (see *meiosis*). Mendel's second law, or the law of independent assortment, states that each gene in a pair can be combined with either of the genes from any other pair, so that gametes can show all possible combinations of non-paired genes.

Mendelson's syndrome

Inhalation of regurgitated stomach contents by someone who is under general *anaesthesia*; also called pulmonary acid aspiration syndrome. Stomach acid can damage the mucous membranes lining the airways; it can also cause bronchospasm (sudden constriction of the airways leading to each lung), and pulmonary oedema (a buildup of fluid in the lungs). Breathing may be severely impaired and the person may die.

The problem is particularly associated with general anaesthesia for emergency obstetric procedures during labour. It can be prevented by giving drugs to inhibit stomach acid secretion before operating.

Ménière's disease

An inner ear disorder characterized by recurrent *vertigo* (a spinning sensation), *deafness*, and *tinnitus* (ringing in the ears). It is uncommon before the age of 40.

CAUSE

The cause of the disorder is an accumulation of fluid in the *labyrinth*. The buildup may damage the labyrinth and sometimes the adjacent *cochlea*.

SYMPTOMS

There is a sudden attack of vertigo, lasting from a few minutes to several hours. This is usually accompanied by nausea, vomiting, *nystagmus* (abnormal jerky eye movements), and deafness, tinnitus, and a feeling of pressure or pain in the affected ear.

DIAGNOSIS AND TREATMENT

Diagnosis is usually made with audiology (see *hearing tests*) or other hearing tests, and a *caloric test*.

Treatment with certain *antihistamine drugs*, such as *cinnarizine*, or with *beta-histine* usually relieves the symptoms. *Prochlorperazine* may be given, either rectally or by injection, for severe attacks. Ménière's disease can also be treated by surgery to the inner ear if symptoms are not controlled by drugs. If deafness eventually becomes total, the other symptoms usually disappear.

meninges

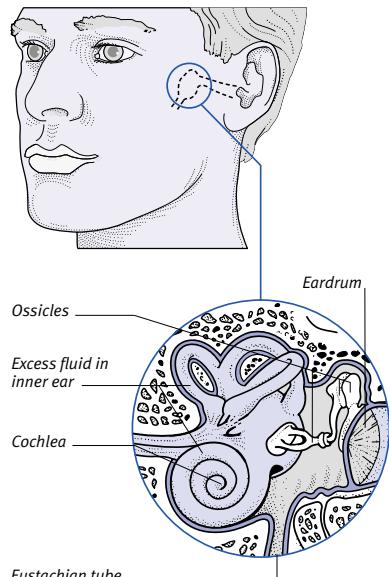

The three membranes that cover and protect the *brain* and the *spinal cord*. The outermost membrane, the *dura mater*, is tough and fibrous; it lines the inside of the skull and forms a loose sheath around the spinal cord. The middle membrane, the *arachnoid mater*, is elastic and weblike. The innermost membrane, the *pia mater*, lies next to the surface of the brain.

The *pia mater* is separated from the *arachnoid mater* by the *subarachnoid space*, which contains *cerebrospinal fluid*. Another space, called the *subdural space*, separates the *arachnoid mater* from the *dura mater*.

meningioma

A rare, noncancerous tumour of the *meninges* (the membranes surrounding the brain). A meningioma arises from the *arachnoid mater* (the middle membrane) and, in most cases, it then becomes attached to the *dura mater* (the outer membrane).

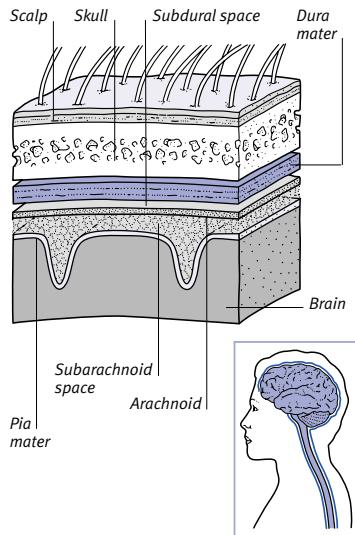

The meningioma slowly expands and may become very large before any symptoms appear. The symptoms may include headache, vomiting, and impaired mental function. There may also be speech loss or visual disturbance. If the tumour invades the overlying skull bone, there may be thickening and bulging of the skull.

**The cause of Ménière's disease**

This condition is caused by excessive fluid in the *labyrinth* and *cochlea*, in the inner ear. These structures may become damaged as a result.

ANATOMY OF THE MENINGES

The pia mater lies on the brain. It is separated from the arachnoid mater by the subarachnoid space. The outermost membrane, the dura mater, lines the inside of the skull.

Meningiomas can be detected by *X-ray* or *CT scanning*, or by *MRI*. The tumours can often be completely removed by surgery. Otherwise, treatment is by *radiotherapy*.

meningitis

Inflammation of the *meninges* (membranes covering the *brain* and *spinal cord*), usually due to infection.

CAUSES

Viral meningitis tends to occur in epidemics in winter; it is usually relatively mild. Bacterial meningitis, however, is life-threatening. It is mainly caused by *HAEMOPHILUS INFLUENZAE*, *STREPTOCOCCUS PNEUMONIAE*, or *MENINGOCOCCUS* types B and C.

The infection usually reaches the meninges via the bloodstream from an infection elsewhere in the body, often in the nose or throat. Less commonly, it passes through skull cavities from an infected ear or *sinus*, or from the air following a *skull fracture*.

SYMPTOMS

The main symptoms are fever, severe headache, nausea and vomiting, dislike of light, and a stiff neck. In viral meningitis, the symptoms are mild and may resemble influenza. In bacterial meningitis, the main symptoms may develop over only a few hours, followed by drowsiness and, occasionally, loss of

consciousness. In about half the cases of meningococcal meningitis, there is also *meningococcaemia* (a potentially life-threatening condition in which bacteria multiply rapidly in the blood). This condition causes a reddish-purple rash under the skin, which does not fade with pressure (see *glass test*). The rash starts as pin-prick spots that can expand to give a bruise-like appearance.

DIAGNOSIS AND TREATMENT

To make a diagnosis, a *lumbar puncture* is performed to remove a small sample of cerebrospinal fluid.

Viral meningitis needs no treatment and usually clears up in a week or two with no after-effects. Bacterial meningitis is a medical emergency. It is treated with intravenous *antibiotic drugs*. With prompt treatment, a full recovery is usually made; the earlier treatment is given, the better the outlook. In some cases, however, *deafness* or *brain damage* may occur, or the person may lose an area of skin, or fingers or toes, as a result of the rash.

PREVENTION

Vaccines are now given to protect children and teenagers against two of the major types of bacterial meningitis: those caused by *HAEMOPHILUS INFLUENZAE* and by *MENINGOCOCCUS* type C (see *immunization*). Antibiotic drugs may be given as a protective measure to people who have come into contact with these infections.

Immunization against some forms of meningitis is recommended for Muslims travelling to Saudi Arabia for the Hajj and Umrah pilgrimages, and for people travelling to Nepal and some parts of sub-Saharan Africa.

meningocele

A protrusion of the spinal cord's *meninges* (protective coverings) under the skin. It is caused by a congenital defect in the spine (see *spina bifida*).

meningococcaemia

An acute, life-threatening infection of the bloodstream caused by *MENINGOCOCCUS* bacteria; also called meningococcal septicaemia. It may occur with uncontrolled *meningococcal meningitis* and produces the characteristic, reddish-purple rash often seen in this condition.

Meningococcaemia can cause *shock*; *kidney failure*; and the loss of areas of skin, or fingers and toes, due to blood vessel damage. It can be fatal. Affected people need to be admitted to hospital immediately. Treatment is with *antibiotic drugs* followed by *intensive care*.

meningococcal meningitis

One of the most common forms of bacterial *meningitis*. Most cases occur in children or young adults. The disease is transmitted by exhaled droplets; it can spread rapidly through groups of people who are in close contact with each other, such as children in boarding schools. If not treated promptly, it may progress to the life-threatening disorder *meningococcaemia*.

meningococcal rash

A rash that occurs in about half of all cases of *meningococcal meningitis* and *meningococcal septicaemia*. The rash arises as pin-prick spots beneath the skin that join together to give the appearance of a bruise (see *purpura*). The rash associated with meningococcal infection does not fade when pressure is applied (see *glass test*).

meningoencephalitis

Inflammation of the *brain* and the *meninges* (the membranes surrounding the brain), usually as a result of a viral infection. See *encephalitis*.

meningomyelocele

Another name for *myelomeningocele*.

meniscectomy

A surgical procedure in which all or part of a damaged *meniscus* (cartilage disc) is removed from a joint, almost always from the knee.

WHY IT IS DONE

Meniscectomy may be performed when damage to the meniscus causes the knee to lock or to give way repeatedly. It cures these symptoms and reduces the risk of premature *osteoarthritis* in the joint.

HOW IT IS DONE

Arthroscopy (in which a viewing instrument is inserted into the joint through a small incision) may be carried out to confirm and locate the damage. The damaged area may then be removed by instruments passed through the arthroscope. Alternatively, the meniscus may be removed through an incision at the side of the *patella* (kneecap).

OUTLOOK

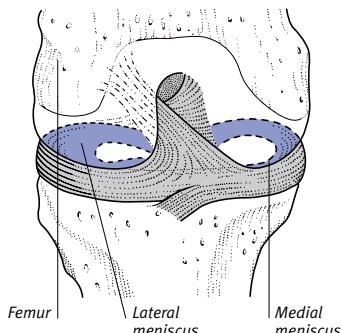

In either case, there may be an increased risk of *osteoarthritis* in later life, but this is less than if the damaged meniscus had been left in place.

meniscus

A crescent-shaped disc of cartilaginous tissue found in several joints. The *knee* joint has two menisci, and the *wrist*

MENISCI

The diagram (right) shows the sites of the menisci. The menisci of the knee are shown in detail below.

joints, and the *temporomandibular joints* of the jaw, have one meniscus each. The menisci are held in position by *ligaments* and help to reduce friction during joint movement.

menopause

The cessation of *ovulation* (egg production) and of *menstruation* (discharge of blood and tissue from the uterus). This process usually occurs between the ages of 45 and 55, the average age being 52 years. The term "menopause" usually refers to a period of physical and psychological changes that occur as a result of reduced *oestrogen* production.

The menopause usually occurs gradually; it is signalled by a change in menstrual patterns (see *perimenopause*) followed by *amenorrhoea* (the cessation of menstrual periods). It can also be brought on by medical procedures that halt the activity of the ovaries, such as *oophorectomy* (surgical removal of the ovaries), *radiotherapy*, or *chemotherapy*. In a few women, the menopause may occur abnormally early, usually before age 40 (see *premature menopause*).

SYMPOTMS

Some women have few difficulties with the menopause. Other women may have symptoms including *hot flushes* and night sweats; vaginal dryness caused by thinning of the vaginal lining; and a decrease in vaginal secretions. The tissues in the neck of the bladder and the

urethra also become thinner, which can cause a feeling of needing to urinate frequently. In addition, the breasts tend to decrease in size. Some women experience psychological symptoms, such as poor concentration, tearfulness, loss of interest in sex, and *depression*.

Changes in *metabolism* occur during the menopause but they may not cause symptoms until later. In all women, the bones become thinner; this process happens most rapidly in the years immediately after the menopause. The loss of bone density may result in *osteoporosis*. The risk of heart disease also increases, gradually approaching that for men of a similar age, due to the drastic reduction in oestrogen hormones (which protect premenopausal women against heart disease).

TREATMENT

Women going through the menopause can protect themselves from losing bone density by regularly taking weight-bearing exercise, such as walking, and by eating foods that are rich in *calcium*, such as dairy products and green, leafy vegetables. Measures such as avoiding fatty foods, stopping smoking, and limiting alcohol intake can help to protect women against heart disease.

Hormone replacement therapy (HRT) may relieve menopausal symptoms and reduce the risk of fractures associated with osteoporosis. However, it is not usually recommended as the first line of treatment because it may increase the risk of abnormal blood clotting and is associated with an increased risk of *breast cancer*.

menorrhagia

Excessive loss of blood during *menstruation*. Menorrhagia may be caused by an imbalance of *oestrogen hormones* and *progesterone hormone*, which control menstruation. The imbalance leads to an excessive buildup of *endometrium* (the uterine lining). Disorders affecting the uterus, such as *fibroids*, *polyps*, or a *pelvic infection*, can also cause menorrhagia.

Treatment may include *nonsteroidal anti-inflammatory drugs*, drugs that affect blood clotting, hormones, or the fitting of an *IUD* (intrauterine device) that releases small amounts of *progestogen*. Menorrhagia may also be treated by *endometrial ablation*.

menotrophin

A *gonadotrophin hormone* given as a drug to stimulate cell activity in the *ovaries* and *testes*. It is used as a treatment for

certain types of male and female *infertility*, as it prepares the ovary for ovulation and may help stimulate sperm production. It is used along with human chorionic gonadotrophin (see *gonadotrophin, human chorionic*).

In women, menotrophin may cause multiple pregnancy, abdominal pain, bloating, and weight gain. In men, it may cause enlargement of the breasts.

menses

Another name for a menstrual period. The word "menses" may also mean the blood, tissue, and fluid that is discharged from the uterus during a menstrual period (see *menstruation*).

menstruation

The periodic shedding of *endometrium* (the lining of the uterus), accompanied by bleeding, that takes place in women who are not pregnant. Menstruation usually begins at *puberty* and continues until the *menopause*.

The loss of the endometrium occurs at the end of the menstrual cycle, which usually lasts for 28 days (with the normal range being between 21 and 35 days). At the beginning of the cycle, a hormone from the *pituitary gland*, known as *follicle-stimulating hormone (FSH)*, prompts several follicles (collections of cells containing eggs) within the *ovaries* to mature. The egg follicles secrete *oestrogen hormones*, which cause the endometrium to thicken.

Ovulation (the release of a mature egg from a follicle) usually occurs in the middle of the cycle. The empty follicle (called the *corpus luteum*) produces *progesterone hormone*. This hormone causes the endometrium to retain fluid and grow thicker, so that a fertilized egg can implant in the tissue. If pregnancy does not occur, production of oestrogens and progesterone diminishes. The endometrium is shed about 14 days after ovulation. Uterine contractions force the tissue, together with fluid and blood, to be expelled via the vagina; this process lasts for one to eight days.

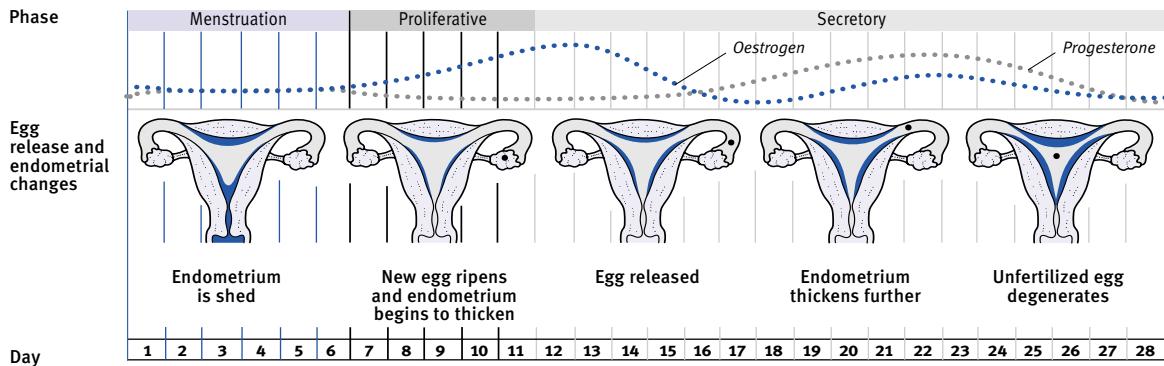

menstruation, anovular

The occurrence of a menstrual period when *ovulation* (the release of an egg from an ovary) has not occurred (see *menstruation*). Anovular menstruation is common in girls who have just started to menstruate, and in women who are approaching the menopause. It may produce irregular menstrual cycles.

THE MENSTRUAL CYCLE

During menstruation, the endometrium (the lining of the uterus) is shed. Following menstruation, a pituitary hormone called follicle-stimulating hormone (FSH) triggers the growth of follicles containing eggs. The follicles secrete oestrogen. Another hormone, luteinizing hormone (LH), causes one of

them to release a mature egg. The empty follicle produces progesterone, which, along with oestrogen, prepares the endometrium to receive the egg. If the egg is unfertilized, then levels of oestrogen and progesterone fall and a new menstrual cycle begins.

menstruation, disorders of

Abnormalities in menstrual bleeding. Menstrual disorders may indicate a problem in the pelvic area, such as *fibroids*, *endometriosis*, or *pelvic inflammatory disease*, but the cause is often unknown.

Dysmenorrhoea (painful periods) is the most common type of menstrual disorder. Other types are *amenorrhoea* (absence of menstruation), *polymenorrhoea* (overly frequent menstruation), *oligomenorrhoea* (infrequent periods or scanty blood loss), and *menorrhagia* (excessive bleeding).

Some women have extreme variations in the length of menstrual cycles or periods, or in the amount of blood lost (see *menstruation, irregular*).

menstruation, irregular

A variation in the normal pattern of *menstruation*. Irregular menstruation includes variations in the interval between periods, the duration of bleeding, or the amount of blood that is lost.

The most common cause is a disturbance in the balance between *oestrogen hormones* and *progesterone hormone*. Other causes include *stress*, travel, a change in *contraception*, unsuspected pregnancy, or early *miscarriage*. Menstruation is often irregular for the first few years, and for several years before the *menopause*.

menstruation, retrograde

The backward flow of tiny amounts of menstrual discharge (see *menstruation*) from the *uterus* through the *fallopian*

tubes instead of the *vagina*. Retrograde menstruation is thought to be a possible cause of *endometriosis*.

menstruation, suppressed

The failure of menstrual (monthly) bleeding (see *menstruation*) to occur. (See also *amenorrhoea*).

mental

A word meaning "relating to the mind".

mental age

A measurement of the intellectual development of a person, with regard to the normal age at which that level of achievement is attained. For example, a 13 year-old child with *learning difficulties* may have a mental age of five years.

mental handicap

Impaired intellectual development. This condition is also known as general *learning difficulties* or disability.

Mental Health Act

The Mental Health Act (1983) details the rights of people with *mental illness* and the grounds for admitting people to psychiatric hospitals against their will. It also outlines forms of legal guardianship for such patients. The Act applies in England and Wales.

The Act is divided into several sections for different situations. (These divisions have given rise to the term "being sectioned" to describe compulsory admission to a mental hospital.)

When individuals are endangering their own or other people's health or safety (for example, threatening harm or suicide) because of a recognized mental illness, they may be compulsorily taken into hospital to be given treatment. If people break the law because of a mental disorder, the courts may remand them to hospital.

mental hospital

A type of hospital, formerly known as an asylum, that specializes in the treatment of psychiatric illness.

Patients who have psychiatric illnesses are increasingly being integrated into mainstream hospitals for their care. Admission to a mental hospital occurs when a patient is sectioned under the *Mental Health Act*.

mental illness

A general term that describes any form of disorder affecting mental functions such as thought, emotion, perception, or memory. Such illnesses are distinct from *learning difficulties*.

Mental illnesses include forms of *psychosis*, in which a person loses contact with reality, and disorders such as *anxiety*, *obsessive-compulsive disorder*, and *post-traumatic stress disorder*, in which mental processes are abnormal but the affected person is fully aware of his or her condition.

mental retardation

See *learning difficulties*.

menthol

An alcohol prepared from mint oils. Menthol is an ingredient of several over-the-counter inhalation preparations used to treat a blocked or stuffy nose.

mentum

The medical term for the *chin*.

meprobamate

An *antianxiety drug* occasionally used in the treatment of *anxiety* and *stress*. It also acts as a muscle relaxant. Meprobamate can, however, induce dependence (see *drug dependence*).

meptazinol

An opioid *analgesic drug* used for the short-term relief of moderate to severe pain, such as after surgery and during childbirth. Possible side effects include nausea, vomiting, and dizziness.

meralgia paraesthetica

Abnormal sensations such as burning pain, numbness, and tingling, in the outer surface of the thigh. The condition occurs in the area supplied by the lateral femoral cutaneous nerve, and is due to the nerve being trapped at the point where it passes under the inguinal ligament, in the groin. (See also *lateral cutaneous nerve entrapment*).

mercaptopurine

An *anticancer drug* used to treat certain types of *leukaemia*. Adverse effects include nausea, mouth ulcers, and loss of appetite. Rarely, it may cause liver damage, *anaemia*, and abnormal bleeding.

Mercilon

A brand-named *oral contraceptive* containing the synthetic female hormones ethinylestradiol (an *oestrogen drug*) and desogestrel (a *progestogen*).

mercury

The only metal that is liquid at room temperature. Mercury is used in certain instruments, such as *thermometers* and *sphygmomanometers* (instruments for measuring blood pressure). It is also included in compounds used as fillings for teeth (see *amalgam*, *dental*).

mercury poisoning

Toxic effects of mercury on the body.

CAUSES

The most common cause of mercury poisoning is breathing in vapour given off by liquid mercury, usually as a result

of industrial exposure. Also, mercury compounds may be absorbed through the intestines (producing symptoms such as nausea, vomiting, diarrhoea, and abdominal pain) or through the skin (causing severe inflammation).

SYMPOTMS

After entering the body, mercury accumulates in organs, principally the brain and kidneys. Mercury deposits in the brain cause tiredness, incoordination, excitability, tremors, and numbness in the limbs. In severe cases, there may be impaired vision and *dementia*. Deposits of mercury in the kidneys may lead to *kidney failure*.

TREATMENT

Treatment of mercury poisoning may involve the use of *chelating agents*, which help the body to excrete the mercury quickly; haemodialysis (see *dialysis*); and induced vomiting or pumping out the stomach, if mercury has been swallowed within the previous few hours.

Merkel cell tumour

A rare form of cancerous skin tumour that occurs in people over 60 years old, on areas of skin that have been exposed to the sun. The tumour arises from Merkel cells, which are found deep in the skin, close to nerve endings; these cells are thought to be part of the neuroendocrine system, which produces hormones that trigger nerve signals.

The cancer is initially treated by surgery, but metastasis (migration of cancer cells to other parts of the body) may occur. In this case, *radiotherapy* or *chemotherapy* may be given, but these treatments rarely produce a cure.

mesalazine

A drug that is used to reduce intestinal inflammation in *ulcerative colitis*. It may be prescribed to relieve symptoms in acute attacks or given as a preventive measure. Adverse effects of mesalazine include nausea, diarrhoea, abdominal pain, and headache.

mescaline

A *hallucinogenic drug* obtained from the crowns of the Mexican peyote cactus (*LOPHOPHORA WILLIAMSII*).

mesenteric lymphadenitis

An acute abdominal disorder, mainly affecting children, in which *lymph nodes* in the *mesentery* (a membrane that anchors organs to the abdominal wall) become inflamed.

The main symptoms are pain and tenderness in the abdomen, which may mimic appendicitis. There may also be mild fever. Mesenteric lymphadenitis usually clears up rapidly, needing only *analgesic drugs* to reduce pain and fever.

mesentery

A membrane that attaches organs to the abdominal wall. The term particularly refers to the membranous fold that encloses the small intestine, attaching it to the back of the abdominal wall. The mesentery contains the blood vessels, nerves, and lymphatic vessels for the intestines.

mesial

A word meaning the same as "medial" (relating to, or situated at, the centre of an organ, tissue, or the body). The term "mesial" is often used in dentistry, to refer to a tooth surface or position.

mesomorph

A term used for an individual whose body is characterized by a square head; a large heart; broad and muscular chest and shoulders; powerful arms and legs; and little body fat. The term has no clinical significance, however. (See also *ectomorph*; *endomorph*.)

mesothelioma

A cancerous tumour of the *pleura* (the membrane that lines the chest cavity and covers the lungs). Exposure to asbestos dust is a risk factor (see *asbestos-related diseases*). Symptoms do not always occur. Those that do include cough, chest pain, and breathing difficulty, especially if a *pleural effusion* (a collection of fluid around the lung) develops.

Diagnosis is made with a *chest X-ray* followed by pleural *biopsy* or examination of a sample of fluid from any effusion. If the tumour is small, surgery is often successful. There is no effective treatment for large tumours, although *radiotherapy* may alleviate symptoms.

mesothelium

A type of *epithelium* (surface cell layer) covering the *peritoneum* (the membrane lining the abdominal cavity), the *pleura* (the membrane lining the chest cavity and surrounding the lungs), and the *pericardium* (the covering of the heart).

messenger RNA

An RNA chain (see *nucleic acids*), also called mRNA, involved in *protein synthesis* within cells. The mRNA is made

from free nucleotide bases (of which three types are the same as those of DNA, and one is unique to mRNA); these attach themselves to corresponding bases on a single strand of DNA. By following the sequence of bases in a length of DNA, the mRNA copies instructions for making a protein. It then passes from the cell's nucleus to its cytoplasm, where the sequence of bases is decoded to form the protein.

mesterolone

An *androgen hormone* (male sex hormone) used as replacement therapy in *hypogonadism*. Adverse effects of mesterolone can include prostate problems, headache, and *depression*.

mestranol

An *oestrogen drug* that is used in some *oral contraceptives*.

metabolic acidosis

Increased acidity of the blood and tissues due to chemical processes in the body. It may result from uncontrolled or abnormal processes, as in *diabetic ketoacidosis* and *lactic acidosis*, or from a failure to remove waste from normal processes, as in kidney disease (see *renal tubular acidosis*). Alternatively, it may be due to loss of alkali in conditions such as diarrhoea. Acidosis may also be due to poisoning with antifreeze (ethylene glycol) or aspirin. If untreated, it can be fatal. Treatment involves giving sodium bicarbonate to correct the acidosis, and measures to relieve the underlying cause. (See also *acidosis*; *acid-base balance*.)

metabolic alkalosis

Increased alkalinity of the blood and body tissues, due to chemical processes in the body. One possible cause is loss of stomach acids through prolonged vomiting. Metabolic alkalosis can also result from excessive consumption of alkaline substances, such as sodium bicarbonate in *antacid drugs*.

Treatment is for the underlying cause. (See also *alkalosis*; *acid-base balance*.)

metabolic disorders

A group of disorders in which some aspect of body chemistry is disturbed. Some metabolic disorders result from an inherited malfunction or deficiency of an *enzyme* involved in a particular chemical reaction (see *metabolism*, *inborn errors of*). Others result from under-

overproduction of a hormone that controls metabolic activity, as occurs in *diabetes mellitus* and *hypothyroidism*.

metabolism

A collective term for all of the chemical processes that take place in the body. It is divided into catabolism (in which complex substances are broken down into simpler ones) and anabolism (in which complex substances are built up from simpler ones). Usually, catabolism releases energy, while anabolism uses it. These chemical processes are regulated by proteins called *enzymes*.

metabolic rate

The energy needed to keep the body functioning at rest is called the basal metabolic rate (BMR). It is measured in kilojoules (or kilocalories) per square metre of body surface per hour. The BMR increases in response to factors such as stress, fear, exertion, and illness. It is chiefly controlled by hormones such as *thyroxine*, *adrenaline* (*epinephrine*), and *insulin*. (See also *metabolism*, *inborn errors of*; *metabolic disorders*.)

metabolism, inborn errors of

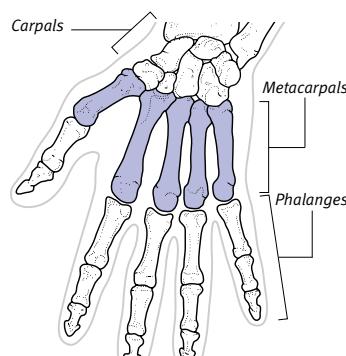

Inherited defects of body chemistry.

CAUSE AND TYPES

Inborn errors of metabolism are caused by single *gene* defects, which lead to the abnormal functioning of an *enzyme*. Some defects are harmless, but others are severe enough to cause death or physical or mental disability. Examples are *Tay-Sachs disease*, *phenylketonuria*, *Hurler's syndrome*, and *Lesch-Nyhan syndrome*.

LOCATION OF THE METACARPAL BONES

The five metacarpals lie between the carpal (wrist) bones and the phalanges of the fingers.

SYMPTOMS

Symptoms of these disorders are usually present at or soon after birth. They may include unexplained illness or failure to thrive, developmental delay, floppiness, persistent vomiting, or *seizures*.

DIAGNOSIS AND TREATMENT

Routine tests are performed on newborn babies for some genetic disorders, such as *phenylketonuria*.

For some inborn errors of metabolism, no treatment is needed. For others, avoidance of a specific environmental factor, such as certain foods, may be sufficient. In some cases, the missing enzyme or the protein that it produces can be manufactured with the use of *genetic engineering* techniques, or a vitamin supplement can help to compensate for the defective enzyme. If the enzyme is made in blood cells, a *bone marrow transplant* may provide a cure.

PREVENTION

People with a child or a close relative who is affected may wish to consider having *genetic counselling* before planning a new pregnancy.

metabolite

Any substance involved in a metabolic reaction (a chemical reaction in the body). The term "metabolite" is sometimes used only for the products of such a reaction. (See also *metabolism*.)

metacarpal bone

One of five long, cylindrical bones in the hand. The bones run from the wrist to the base of each digit, with the heads of the bones forming the knuckles.

metaphysis

The part of a long *bone* that forms new tissue to lengthen the bone during normal childhood growth. The metaphysis is situated between the *diaphysis* (bone shaft) and *epiphysis* (bone end). In children the area consists of spongy bone, but in adults it has become hard and fused with the epiphysis.

metaplasia

A change in tissue that results from the transformation of one type of cell into another. Metaplasia is usually harmless but is occasionally precancerous. It can affect the lining of various organs, such as the bronchi (airways) and the bladder. Metaplasia of the cervix (the neck of the uterus), which occurs in *cervical erosion*, can be detected by means of a *cervical smear test*.

metastasis

A secondary cancerous tumour (one formed from cells that have spread from a primary *cancer* to another part of the body). The term metastasis also applies to the process by which such migration occurs. Metastases can spread through the *lymphatic system*, in the bloodstream, or across a body cavity.

metastatic abscess

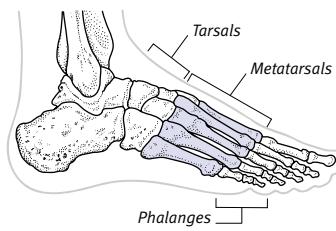

An *abscess* (localized collection of pus) formed by bacteria that have spread from another site via the blood or *lymph*. The bacteria may come from an existing (primary) abscess or from an infected wound. One example of this process is the spread of bacteria from the heart valves (see *endocarditis*) to form an abscess in the brain.

metatarsal bone

One of five long, cylindrical bones in the foot. The metatarsal bones make up the central skeleton of the foot, connecting the *phalanges* (the bones of each toe) to the *tarsal bones* (which form the ankle). The bones are held together in an arch by the *ligaments* that surround them.

LOCATION OF THE METATARSAL BONES

The five metatarsals lie between the tarsal bones (which form the ankle and the back of the foot) and the phalanges of the toes.

**metatarsalgia**

Pain in the foot. Causes include fracture of a *metatarsal bone*, *flat-feet*, or *neuroma* of a nerve in the foot.

metatarsophalangeal joint

The joint between each *metatarsal bone* and its adjoining toe bone (see *phalanges*). The metatarsophalangeal joint at the base of the big toe is commonly affected by *gout* and by *hallux rigidus* (immobility due to osteoarthritis).

metformin

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) that lowers blood glucose levels and is used to treat type 2 *diabetes mellitus*. Possible adverse effects include loss of appetite, a metallic taste in the mouth, nausea, vomiting, and diarrhoea.

methadone

A synthetic opioid *analgesic drug* that resembles *morphine*. Methadone is administered, under supervision, in gradually decreasing doses, to people who are undergoing a *heroin* or morphine withdrawal programme. It may also be used to treat severe pain in people who cannot tolerate morphine. Side effects may include nausea, vomiting, constipation, dizziness, and dry mouth.

methaemoglobin

An abnormal substance formed by oxidation of the iron in *haemoglobin* (the pigment in red blood cells). Unlike *oxyhaemoglobin*, this compound cannot take up and transport oxygen.

Normal blood usually carries a small amount of methaemoglobin. Excessive blood levels (methaemoglobinaemia) may result from poisoning with substances such as nitrates and chlorates. In some cases, the excess is due to a *congenital* defect in haemoglobin. The resulting symptoms include *cyanosis* (blue-grey colouring of the extremities and lips), headache; drowsiness; and shortness of breath. Very high levels of methaemoglobin lead to coma and death. Treatment is with a substance called methylene blue.

methane

A colourless, odourless, highly inflammable gas that occurs naturally in oil wells and coal mines. Methane is also produced by the decomposition of organic matter; it is one of the gases present in intestinal gas (see *flatus*).

methanol

A poisonous type of *alcohol* that is used as a solvent or paint remover and in some types of antifreeze. Methanol poisoning usually occurs as a result of drinking it as a substitute for ordinary alcohol. Symptoms of poisoning include headache, dizziness, nausea, vomiting, and unconsciousness. Damage may also occur to the *retina* and the *optic nerve*, causing blurred vision. Repeated or large doses of methanol may result in permanent blindness.

methicillin-resistant *staphylococcus aureus*

See *MRSA*.

methotrexate

An *anticancer drug* used to treat *lymphoma* (cancer of the lymph nodes) and some forms of *leukaemia*. Methotrexate is also used for cancers of the uterus, breast, ovary, lung, bladder, and testis, and severe *psoriasis* when other treatments are ineffective. It may cause nausea, vomiting, diarrhoea, mouth ulcers, *anaemia*, increased susceptibility to infection, and abnormal bleeding.

methyl alcohol

An alternative name for *methanol*.

methylcellulose

A bulk-forming *laxative drug* that is used in the treatment of *constipation*, *irritable bowel syndrome (IBS)*, and *diverticular disease*. It increases the firmness of faeces in chronic watery *diarrhoea* and regulates their consistency in people who have a *colostomy* or *ileostomy*.

The drug causes a feeling of fullness, so it is sometimes used to help treat *obesity*.

methyldopa

An *antihypertensive drug* that controls high blood pressure by acting on the part of the brain that regulates the diameter of blood vessels.

Methyldopa does not affect unborn babies, so may be prescribed for women who have high blood pressure during pregnancy. It may also be used for people with kidney disorders, because it does not impair the blood flow to the kidneys. Side effects include drowsiness, depression, and nasal congestion. The drug may also cause premature destruction of red blood cells (see *anaemia, haemolytic*).

methylene dioxy-methamphetamine

See *Ecstasy*.

methylphenidate

A central nervous system *stimulant drug* used, under specialist supervision, to treat *attention deficit hyperactivity disorder (ADHD)* in children. Possible adverse effects include loss of appetite, tremors, sleeplessness, and rashes.

methylprednisolone

A *corticosteroid drug* used to treat severe *asthma*, skin inflammation, *inflammatory bowel disease*, and certain types of *arthri-*

tis. Adverse effects are the same as for other *corticosteroid drugs*; they are more likely to occur if the drug is taken over long periods of time.

methysergide

A drug that is used to prevent *migraine* and *cluster headaches*. Methysergide is usually administered only under hospital supervision, when other treatments have been ineffective.

Adverse effects of the drug can include dizziness, drowsiness, and nausea. Long-term treatment may cause chest pain, *kidney failure*, or leg cramps.

metoclopramide

An *antiemetic drug* that is used to prevent and treat nausea and vomiting, including that which is associated with *migraine* or caused by *anticancer drugs*, *radiotherapy*, or *anaesthetic drugs*. Metoclopramide may be given with a premedication to reduce the risk of a person inhaling vomit when he or she is under general anaesthesia (see *anaesthesia, general*).

Adverse effects of the drug include dry mouth, sedation, or diarrhoea. Large doses may cause uncontrollable movements of the face, mouth, and tongue.

metolazone

A *diuretic drug* used to treat *hypertension* (high blood pressure). Metolazone is also given to reduce *oedema* in people who have *heart failure*, *kidney disorders*, or *cirrhosis*. In addition, it is used to treat certain types of kidney stone (see *calculus, urinary tract*). Adverse effects can include weakness, lethargy, and dizziness.

metoprolol

A cardioselective *beta-blocker drug* that acts mainly on nerve endings in the heart and blood vessels. It is used to prevent the heart from beating too fast, in *angina pectoris* (chest pain due to insufficient blood supply to the heart), and for *hypertension* (high blood pressure). It is also given after a *myocardial infarction* (heart attack) to reduce the risk of further damage to the heart. In addition, metoprolol is used to relieve symptoms of *hyperthyroidism* (overactivity of the thyroid gland). Adverse effects include lethargy, cold hands and feet, nightmares, and rash.

metronidazole

An *antibiotic drug* used to treat infections caused by *anaerobic bacteria*, such as dental *abscess* and *peritonitis*. Metron-

idazole is also used to treat protozoan infections such as *trichomoniasis* and *amoebiasis*. In addition, it may be applied topically as a gel to treat skin conditions such as *acne* and *rosacea*, and it is used to treat gum disease.

Adverse effects include nausea and vomiting, loss of appetite, abdominal pain, and dark-coloured urine. Alcohol should be avoided during treatment, because it frequently interacts with the drug to cause vomiting.

metropathia haemorrhagica

Abnormal, excessive, sometimes continuous menstrual bleeding (see *menstrual cycle*) due to excessive production of *oestrogen hormones*. The high oestrogen levels cause hyperplasia (overgrowth) of the endometrium (uterus lining).

mexiletine

An *antiarrhythmic drug* that is used to treat certain heart-rhythm disorders, usually after a *myocardial infarction* (heart attack). Possible adverse effects include nausea, vomiting, dizziness, and tremor.

mianserin

An *antidepressant drug* that is used to treat severe *depression*, especially if the illness is accompanied by *anxiety* or *insomnia*. Mianserin usually takes several weeks to become fully effective. Possible adverse effects include dry mouth, blurred vision, constipation, dizziness, and drowsiness. Rarely, the drug may cause reduced blood cell production; regular *blood counts* are therefore carried out during treatment.

miconazole

An *antifungal drug* that is used topically (applied directly to the skin), in the form of creams, ointments, or powder, to treat *tinea* skin infections such as *athlete's foot*, or as vaginal suppositories for vaginal *candidiasis* (thrush). Miconazole in the form of a cream or vaginal suppository may, in rare cases, cause a burning sensation or a rash. Preparations used in the vagina may damage *diaphragms* or *latex condoms*.

micro-

A prefix meaning "small", as in *microorganisms* (tiny organisms).

microalbuminuria

A slight increase in the level of the protein *albumin* in the urine, usually due to early kidney damage. Microalbuminuria

is a very early sign of kidney disease in people with *diabetes mellitus*. (See also *albuminuria*.) If left untreated, it may lead to diabetic kidney disease (see *diabetic nephropathy*) in people with type 1 diabetes, or may increase the risk of cardiovascular disorders in those who have type 2 diabetes.

The increase is too small to be measured by routine dipstick tests on urine, but can be confirmed by testing urine over 24 hours or with a special kit. Treatment with *ACE inhibitor drugs* is usually advised, even if the affected person's blood pressure is normal.

microaneurysm

A tiny, localized swelling in a *capillary* (the smallest form of blood vessel). Microaneurysms in the vessels of the *retina* are a characteristic sign of *diabetic retinopathy* in *diabetes mellitus*; they may also be due to blockage of a retinal vessel. The swellings can be seen as small red dots when the retina is examined with an *ophthalmoscope*.

microangiopathy

Any disease or disorder of the smallest blood vessels. It may be a feature of conditions such as *diabetes mellitus*, *septicaemia*, *eclampsia*, *glomerulonephritis*, and advanced *cancer*. When microangiopathy occurs with these conditions, the small blood vessels become distorted and the red *blood cells* are damaged, leading to microangiopathic haemolytic anaemia (see *anaemia, haemolytic*).

microbe

A popular term for a microorganism, particularly a type that causes disease.

microbiology

The study of microorganisms, particularly of pathogenic types (organisms that cause disease).

microcephaly

An abnormally small head. Microcephaly is associated with *learning difficulties*. It may be the result of certain *chromosomal abnormalities*; in addition, it may occur if the brain is damaged before or during birth, or if it is injured or diseased in early infancy.

microcytic anaemia

Any form of *anaemia* in which there is a defect in the production of *haemoglobin* (the oxygen-carrying pigment in the blood), causing a reduction in size of

the *red blood cells*. An example of microcytic anaemia is *iron-deficiency anaemia*. (See also *normocytic anaemia*.)

microdiscectomy

Surgery to relieve pressure on the spinal cord, or on a nerve root emerging from it, due to protrusion of the core of an intervertebral disc (see *disc prolapse*). The procedure is performed under general *anaesthesia* and involves removing the protruding tissue via a small incision in the outer coat of the disc.

microfilaria

The immature forms of certain types of worm. Microfilaria are produced by adult worms that have infected a human being or an animal (see *filariasis*), and circulate in the blood or *lymph*. They complete their life cycle when they are ingested by mosquitoes or other insects that bite infected people or animals; they turn into larvae within the insect, and are then passed on when it bites another victim.

The presence of microfilaria in the body can be determined by microscopic examination of blood samples.

microglioma

An obsolete term for a *primary central nervous system lymphoma* (PCNSL).

microglossia

An abnormally small tongue. The condition is often due to a *genetic disorder* and associated with *micrognathia* (an abnormally small jaw).

micrognathia

An abnormally small jaw (usually the lower jaw). Micrognathia is *congenital* (present at birth), and may stop a baby from feeding properly. It is a feature of various *chromosomal abnormalities*. In many cases, the problem disappears as the child's skull grows.

micrograph

A photographic image of a tiny object seen through a *microscope*.

Micrygonon 30

A brand-named *oral contraceptive* that contains the female hormones *ethinyl estradiol* (an *oestrogen drug*) and *levonorgestrel* (a *progestogen*).

microinvasion

The spread of cancerous cells into normal tissue adjacent to the tumour. It is detectable only by microscopic exami-

nation of a tissue sample. This is a transitional stage between *carcinoma in situ* and invasion (see *staging*).

Micronor

A brand-named *oral contraceptive* that contains the female hormone *norethisterone* (a *progestogen*).

microorganism

A single-celled living organism. Most microorganisms are too small to be seen by the naked eye. The main groups of disease-causing microorganisms are *bacteria*, *viruses*, *protozoa*, and *fungi*.

microphthalmos

A rare congenital eye disorder. Affected children are born with an abnormally small eye on one or both sides.

microscope

An instrument for producing a magnified image of a very small object. Microscopes are used to examine the structure and chemical composition of cells and tissues, and to investigate microorganisms and diseased tissues. In the operating theatre, microscopes are used in *microsurgery*.

LIGHT MICROSCOPES

Compound microscopes are the most widely used type. They have two lens systems (the objective and the eyepiece), mounted at opposite ends of a tube called the body tube. There is a stage to hold the specimen, a light source, and an optical condenser which concentrates the light. The maximum magnification is about 1,500 times.

Phase-contrast and interference microscopes are modified light microscopes that allow unstained transparent specimens to be seen. They are used for examining living cells and tissues.

Fluorescence microscopes use ultraviolet light to study specimens stained with fluorescent dyes.

ELECTRON MICROSCOPES

Electron microscopes give much higher magnifications than light microscopes by using a beam of electrons instead of light. There are two types: transmission electron microscopes (TEMs) and scanning electron microscopes (SEM). TEMs can magnify objects up to about 5,000,000 times, enabling tiny viruses and molecules to be seen. SEMs have a lower maximum magnification (100,000 times), but produce three-dimensional images, so are useful for studying surface structures of cells and tissues.

microsurgery

Surgery on minute, delicate, or not easily accessible tissues in the body. In procedures involving microsurgery, the surgeon views the operation site using a special binocular microscope with pedal-operated magnification, focusing, and movement. He or she carries out the procedure using tiny, specially adapted surgical instruments, such as forceps, clamps, and very fine suturing needles and thread.

The technique of microsurgery is applied to a variety of procedures. It is used for eye operations such as repairing a detached *retina* or replacing a diseased *lens*. Microsurgery may be carried out to fit a prosthesis to replace a diseased bone in the inner ear (see *stapedectomy*). After serious injuries, it may be performed to rejoin the severed ends of blood vessels or nerves. Microsurgery may also be used to reverse female or male sterilization (see *sterilization, female*; *vasectomy*), by rejoining structures that have been surgically severed.

microvillus

One of the many microscopically small, hairlike structures covering the surface of a *villus* (a tiny projection from the wall of the small intestine).

microwave therapy

A form of *diathermy* that uses microwaves (electromagnetic waves of very short wavelength). One form of microwave therapy in which the waves are directed through probes into tumours, to kill or shrink the abnormal tissue, is currently being investigated as a possible treatment for *breast cancer* and *prostate cancer*. Microwave therapy is also used to treat *benign prostatic hyper trophy*, although it is less effective than other treatments.

micturition

A medical term for passing *urine*.

micturition syncope

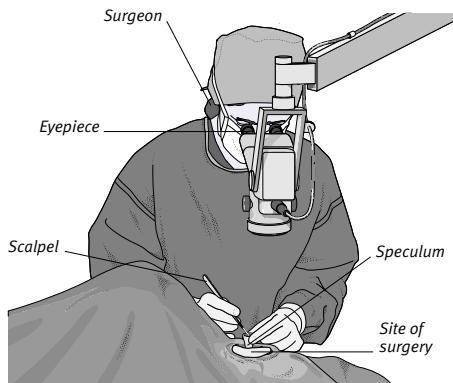

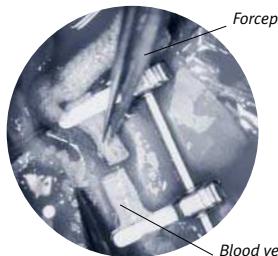

A brief loss of consciousness (see *syncope*) that occurs during or just after *micturition* (passing urine), usually when a person has got out of bed to urinate at night. The condition is more common in older men. It is thought to result from a drop in blood pressure as the person gets up (see *orthostatic hypotension*), combined with changes in blood flow as the bladder empties.

TECHNIQUES OF MICROSURGERY

Microsurgery started with ophthalmic surgeons, whose demands for more delicate operating instruments led to the adoption of the operating microscope. The results were so favourable that surgeons working in other specialties began to use the technique for intricate operations.

The operating microscope

This surgeon is performing microsurgery with the aid of an operating microscope. The photograph below shows a blood vessel as seen through the microscope.

Replantation microsurgery

A major application of microsurgery is the replantation of severed fingers, toes, hands, feet, or even entire limbs. This is successful only if the severed blood vessels and nerves are accurately rejoined so that regeneration occurs.

midazolam

A benzodiazepine drug that is used as *pre-medication*. Adverse effects of midazolam include confusion, drowsiness, and dizziness. If benzodiazepines are taken for a long time, *dependence* may result.

midbrain

The top part of the *brainstem*, situated above the pons. The midbrain is also called the mesencephalon.

middle ear

See *ear*.

middle-ear effusion, persistent

See *glue ear*.

middle-ear infection

See *otitis media*.

mid-life crisis

A popular term for the feelings of distress that affect some people in early middle age when they realize that they are no longer young. Counselling and support are usually effective in helping people to come to terms with aging.

midwifery

The profession concerned with assisting women in pregnancy and childbirth, and in the weeks just after a birth.

mifepristone

A sex hormone drug that is used to induce medical termination of a very early pregnancy (see *abortion, induced*).

Possible adverse effects include malaise, faintness, nausea, rash, and, rarely, uterine bleeding. Women over 35 who smoke should not be given the drug.

migraine

A severe headache, typically lasting from four to 72 hours, accompanied by light and noise sensitivity and/or nausea and vomiting. Migraine attacks are due to spasm, followed by excessive dilation, of blood vessels in the brain.

CAUSES

There is no single cause of migraine, although it tends to run in families. Stress-related, food-related, or sensory-related factors (such as eating cheese or chocolate, or drinking red wine) may trigger attacks. In women, *menstruation*, *oral contraceptives*, and *HRT* may also be triggers.

TYPES AND SYMPTOMS

There are two types: migraine with aura (an impression of flashing lights and/or other neurological symptoms such as numbness and tingling) and migraine without aura. In migraine without aura, there is a slowly worsening headache, often on one side of the head, with nausea and sometimes vomiting and/or light and noise sensitivity.

In migraine with aura, there may be visual disturbances for up to an hour, followed by a severe, one-sided headache, nausea, vomiting, and sensitivity to light and noise. Other temporary neurological symptoms, such as weakness in one half of the body, may occur.

DIAGNOSIS AND TREATMENT

Diagnosis is usually made from the history and a normal outcome from any physical examinations between attacks. Treatment for an attack is an *analgesic drug* such as *aspirin*, *paracetamol*, or a *nonsteroidal anti-inflammatory drug*, with an *antiemetic drug*, if needed. If this is not effective, drugs called *5HT₁* agonists (see *serotonin agonists*), such as *sumatriptan*, may be prescribed. These drugs are taken as early as possible at the start of an attack, and may prevent the development of a full-blown attack. Sleeping in a darkened room may hasten recovery.

For frequent attacks, preventive treatment may be required. Keeping a diary can help people to identify trigger factors, and prophylactic drugs may be prescribed. Drugs that contain *ergotamine* may prevent an attack if taken before the headache begins, but are now rarely used; they have largely been replaced by *serotonin antagonists* such as *pizotifen*. *Beta-blocker drugs*, or low doses of tricyclic *antidepressant drugs*, may also be used to prevent attacks. (See also *cluster headaches*.)

migrainous neuralgia

See *cluster headaches*.

Migraleve

A brand-named drug for migraine relief that contains the *analgesic drugs* (pain-killers) *paracetamol* and *codeine* and the *antiemetic drug* *buclizine*.

Migril

A brand-named drug for migraine relief containing *caffeine*, *ergotamine* (to relieve migraine symptoms), and the *antihistamine drug* cyclizine (to relieve nausea).

milia

Tiny, harmless, hard, white spots that usually occur in clusters around the nose and on the upper cheeks in newborn babies and also in young adults.

miliary tuberculosis

A potentially life-threatening form of *tuberculosis* in which bacteria from the original site of infection enter the bloodstream and spread throughout the body to form millions of tiny tubercles (nodular masses) in other organs and tissues. The condition occurs in only a small minority of people with tuberculosis; it is most common in *immuno-compromised* people such as those with *AIDS* or those taking *corticosteroid drugs*.

milk

A *nutrient* fluid produced by the mammary glands of female mammals. Milk contains fat, carbohydrate, protein, vita-

mins, and minerals. The composition of milk varies between species; for example, human breast milk contains more sugar (lactose) and less protein than cows' milk.

milk–alkali syndrome

A rare type of *hypercalcaemia* (abnormally high level of calcium in the blood) together with *alkalosis* (reduced acidity of the blood) and *kidney failure*. The syndrome is caused by excessive, long-term intake of *antacid drugs* containing calcium and of milk. It is most common in people with a *peptic ulcer*. Symptoms include weakness, muscle pains, irritability, and apathy. Treatment is to reduce the intake of milk and antacids.

Milk of Magnesia

A magnesium preparation used as an *antacid* and *laxative drug*.

milk teeth

See *primary teeth*.

Milroy's disease

An inherited form of *lymphoedema* (the accumulation of *lymph* in the tissues) that is caused by a malformation of the

lymphatic vessels that prevents the free flow of lymph. The disease is a *genetic disorder* inherited in an autosomal dominant manner and is *congenital* (present from birth). The condition usually affects the legs.

Minamata disease

The name given to a severe form of *mercury poisoning* that occurred in the mid-1950s, in people who had eaten polluted fish taken from Minamata Bay, Japan. Many affected people suffered severe nerve damage, and some died.

mineral

A chemical element that is defined in *nutrition* as being essential in the diet for the maintenance of health. At least 20 minerals, including calcium, iron, potassium, and sodium, are vital for health. Some, such as zinc, are needed in only tiny amounts (see *trace elements*). A well-balanced diet that has sufficient amounts of nutrients should provide all the minerals that the body needs. (See also *Minerals and main food sources* table, opposite; *Reference nutrient intake (RNI)* table, below.)

M

REFERENCE NUTRIENT INTAKE (RNI) FOR SELECTED MINERALS

The table below gives the reference nutrient intake (RNI) of the minerals for which amounts have been established; when different, the RNI for males and females is denoted by the letters M and F. Iron requirements during pregnancy and										breast-feeding are approximately the same as those for nonpregnant women, but additional iron may be recommended for two to three months after the birth to replenish iron stores depleted by pregnancy.	
	0–6 months	6 months–1 year	1–3 years	4–6 years	7–10 years	11–14 years	15–18 years	19–50 years	51+ years	Extra needed: Pregnancy	Breast-feeding
Calcium (mg/day)	525	525	350	450	550	M 1000 F 800	M 1000 F 800	M 700 F 700	M 700 F 700	0	+550
Iodine (mcg/day)	50	60	70	100	110	130	140	140	140	0	0
Iron (mg/day)	4.3	7.8	6.9	6.1	8.7	M 11.3 F 14.8*	M 11.3 F 14.8*	M 8.7 F 14.8*	8.7	0	0
Magnesium (mg/day)	60	80	85	120	200	M 280 F 280	M 300 F 300	M 300 F 270	M 300 F 270	0	+50
Phosphorus (mg/day)	400	400	270	350	450	M 775 F 625	M 775 F 625	M 550 F 550	550	0	+440
Selenium (mcg/day)	13	10	15	20	30	45	M 70 F 60	M 75 F 60	M 75 F 60	0	+15
Sodium (mg/day)	280	350	500	700	1200	1600	1600	1600	1600	0	0
Zinc (mg/day)	4	5	5	6.5	7	9	M 9.5 F 7	M 9.5 F 7	M 9.5 F 7	0	+6
* Insufficient for women with heavy menstrual periods, who should take iron supplements.										Units: mg = milligrams (thousandths of a gram) mcg = micrograms (millionths of a gram)	

mineralization, dental

The deposition of calcium crystals and other mineral salts in developing teeth. (See *calcification, dental*.)

mineralocorticoid

The term used for a *corticosteroid hormone* that controls the amount of salts that are excreted in urine.

mineral supplements

Dietary supplements containing one or more *minerals* in tablet or liquid form. Most people obtain sufficient amounts from their diet; supplements are only necessary for those with a recognized deficiency. Some mineral supplements may even be harmful if taken in excess. (See also entries for individual minerals.)

Iron, the most commonly taken mineral supplement, is used to treat people with *iron-deficiency anaemia*, which may

occur in women who have heavy menstrual periods or are pregnant or breast-feeding, vegans (people who eat no meat, eggs, or dairy products), and people with persistent internal bleeding (for example, from a *peptic ulcer*).

miner's lung

See *pneumoconiosis*.

minilaparotomy

A procedure for female sterilization (see *sterilization, female*).

minimal access surgery

See *minimally invasive surgery*.

minimal brain dysfunction

A hypothetical condition that is thought to account for behavioural and other problems in children for which no physical cause is found. It may be a pos-

sible cause of some *learning difficulties*, difficulty in concentrating, impulsiveness, and *hyperactivity*.

minimally invasive surgery

Surgery using a rigid *endoscope* passed into the body through a small incision. Further small openings are made for instruments so that the operation can be performed without a long incision.

Minimally invasive surgery may be used for a range of operations on the abdomen (see *laparoscopy*), including *appendicectomy*, *cholecystectomy*, *hernia repair*, and many *gynaecological* procedures. Operations on the knee (see *arthroscopy*) are also often performed by minimally invasive surgery.

minipill

Also known as the progestogen-only pill (POP), an *oral contraceptive* that contains only a *progestogen drug*. The mini-pill makes the mucus that lines the cervix so thick that sperm cannot pass and has other effects that impede conception. Possible adverse effects include menstrual irregularities, bleeding between periods, and *ovarian cysts*.

minocycline

A tetracycline *antibiotic drug* used to treat *acne*, respiratory-tract infections such as *pneumonia*, and some genitourinary infections, such as *gonorrhoea* and *nongonococcal urethritis*. It is also used to prevent *meningococcal meningitis*.

The most common side effects are nausea, dizziness, and diarrhoea. The drug may also interfere with the balance mechanism within the inner ear, causing dizziness or *vertigo*, but these problems usually disappear once the drug is no longer being used.

minoxidil

A *vasodilator drug* used to treat severe *hypertension* (high blood pressure) when other drugs have been ineffective.

Prolonged use can stimulate hair growth, especially on the face. This effect may be a problem for people using the drug to control high blood pressure. It can, however, be beneficial for male-pattern baldness (see *alopecia*); preparations containing minoxidil are applied topically to stimulate hair regrowth.

miosis

Constriction of the pupil of the *eye*. Miosis may be caused by drugs such as *pilocarpine* or *opium*, by a disease

MINERALS AND MAIN FOOD SOURCES

Mineral	Sources
Calcium	Milk, cheese, calcium-fortified bread, butter and margarine, green vegetables, pulses, nuts, soya bean products, hard water
Chromium	Red meat, cheese, butter and margarine, whole-grain cereals and breads, green vegetables
Copper	Red meat, poultry, liver, fish, seafood, whole-grain cereals and breads, green vegetables, pulses, nuts, raisins, mushrooms
Fluorine	Fish, fluoridated water, tea
Iodine	Milk, cheese, butter and margarine, fish, whole-grain cereals and breads, iodized table salt
Iron	Red meat, poultry, liver, eggs, fish, whole-grain cereals and breads, dried fruit
Magnesium	Milk, fish, whole-grain cereals and breads, green vegetables, pulses, nuts, hard water
Phosphorus	Red meat, poultry, liver, milk, cheese, butter and margarine, eggs, fish, whole-grain cereals and breads, green vegetables, root vegetables, pulses, nuts, fruit
Potassium	Whole-grain cereals and breads, green vegetables, pulses, fruit
Selenium	Red meat, liver, milk, fish, seafood, whole-grain cereals and breads
Sodium	Red meat, poultry, liver, milk, cheese, butter and margarine, eggs, fish, whole-grain cereals and breads, green vegetables, root vegetables, pulses, nuts, fruit, table salt, processed foods
Zinc	Red meat, fish, seafood, eggs, milk, whole-grain cereals and breads, pulses

affecting the *autonomic nervous system*, or by bright light. A degree of miosis is normal in older people.

miotic drugs

Drugs used in the treatment of *glaucoma* to reduce pressure in the eye. When applied to the eye, miotic drugs cause the pupil to contract, which opens up the drainage channels and drains fluid from the front of the eye. Side effects include headache, particularly over the eye, and blurred vision. Common miotics include carbachol and *pilocarpine*. (See also *mydriatic drugs*.)

Mirena

A brand-named intrauterine contraceptive device (see *IUD*) containing the female hormone *levonorgestrel* (a progestogen). The Mirena device is fitted inside the uterus, then releases a low dose of the drug continually. It will need to be replaced after five years.

The device may cause irregular bleeding or slightly heavier menstrual periods (see *menstrual cycle*) just after being fitted, but the periods usually become much lighter after about three months. Some women cease to have periods at all, although most continue to ovulate. The device is particularly useful for those women who need to use an IUD but have heavy periods.

miscarriage

Loss of the fetus before the 24th week of pregnancy or viability (the ability to survive outside the uterus without artificial support). The medical term is "spontaneous abortion". The majority of miscarriages occur in the first 12 weeks of pregnancy, and may be mistaken for a late menstrual period.

CAUSES

Miscarriages may occur because of *chromosomal abnormalities* or developmental defects in the fetus, or because of severe illness, exposure to toxins, or an *autoimmune disorder* in the mother. Miscarriages that occur later in pregnancy may be due to *genetic disorders*, *cervical incompetence*, a defect in the uterus, or large uterine *fibroids* (non-cancerous growths).

SYMPOTMS

The symptoms are heavy vaginal bleeding with cramping. Slight blood loss accompanied by severe pain can be a symptom of either a threatened miscarriage or *ectopic pregnancy* (development of the embryo outside the uterus).

TYPES

Miscarriages are classified medically as different types of abortion. In a threatened abortion, the fetus remains alive in the uterus. In an inevitable abortion, the fetus dies and is expelled from the uterus. In a missed abortion, the fetus dies but remains in the uterus.

INVESTIGATION AND TREATMENT

A *pelvic examination* and *ultrasound scanning* may be performed in order to assess the pregnancy. If all of the contents of the uterus are expelled, no further treatment may be necessary. Otherwise, a *D and C* may be performed. Missed abortion requires a *D and C* or *induction of labour* depending on the duration of the pregnancy. Rh-negative women are given anti-D (*Rho*) immunoglobulin to prevent complications related to *Rhesus incompatibility* from occurring in any future pregnancies. (See also *abortion*.)

misoprostol

A synthetic *prostaglandin drug* that inhibits the secretion of stomach acid. Misoprostol may be used alone to treat *peptic ulcers*, or it may be combined with a *nonsteroidal anti-inflammatory drug* (NSAID), such as diclofenac, to prevent the development of peptic ulcers that may be associated with the use of these drugs. The most likely side effects of misoprostol are diarrhoea and indigestion. If severe, or if problems such as vomiting, abnormal vaginal bleeding, abdominal pain, or rash occur, a doctor should be consulted promptly.

mites and disease

Mites are very small animals, usually less than about 1 mm long, with eight legs. Many species of mites have piercing and blood-sucking mouthparts.

Species that may cause disorders include the *scabies* mite, which burrows in human skin causing intense itching; the house-dust mite, which can cause *asthma* when inhaled; and chiggers (American harvest mites), which are found in grass and cause an itchy rash when they bite. Mites in grain or fruit may cause skin irritation – sometimes called grocers' or bakers' itch. Certain mites transmit diseases, particularly scrub *typhus* and *rickettsial pox*.

mitochondria

Small *organelles* found inside *cells* in which cell *respiration* occurs. The mitochondrial wall has two membranes. The

inner one is highly folded to provide a surface for respiration reactions. Cells that use a lot of energy, such as muscle cells, contain many mitochondria.

mitochondrial DNA

A particular form of *DNA* existing in *mitochondria*. In human mitochondria, the DNA is a double-helical circle that codes for 13 proteins. Mitochondria have a distinctive genetic code, and their genomes are not changed by *meiosis* during reproduction; these features make the DNA useful in genetic studies.

The significance of mitochondria having their own DNA is that diseases can be inherited via abnormalities of mitochondrial DNA, and inheritance of the DNA is maternal, directly from the egg.

mitosis

A type of cell division in which the *chromosomes* in a cell nucleus are duplicated into each of two daughter cells.

Before cell division, the chromosomes duplicate themselves and coil up with the two copies joined together. The doubled chromosomes line up in the centre of the cell and are pulled apart to opposite ends of the cell, which then divides. Each daughter cell therefore has the same chromosome content as the original cell. (Egg and sperm cells, in contrast, divide by means of a process called *meiosis*.)

mitral incompetence

Failure of the *mitral valve* of the *heart* to close properly, allowing blood to leak back into the left atrium (upper chamber) when it has been pumped out of the left ventricle (lower chamber). The disorder, also known as mitral regurgitation, may occur in conjunction with *mitral stenosis* (narrowing of the valve).

SYMPTOMS

Symptoms include increasing breathlessness and fatigue, sometimes with *palpitations*. Later, as *heart failure* develops, the ankles may swell.

DIAGNOSIS AND TREATMENT

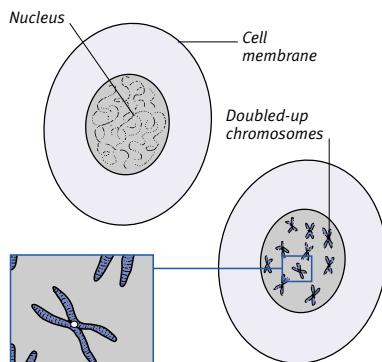

Diagnosis may be made by hearing a characteristic heart *murmur*; from *X-rays*; *ECG*; and *echocardiography*. The heart's interior may also be investigated with a catheter (see *catheterization, cardiac*).

Treatment may include *diuretic drugs*, *ACE inhibitor drugs*, and *anticoagulant drugs*. If symptoms are disabling, *heart valve surgery* may be considered.

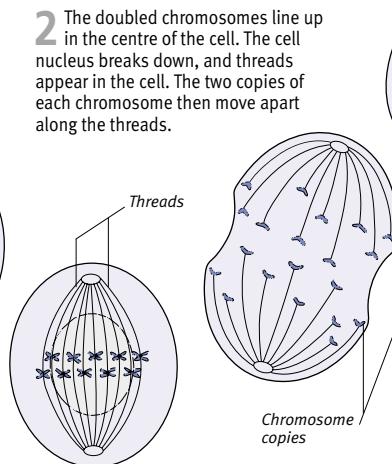

Before dental or other surgery, people with mitral incompetence are given *antibiotic drugs* to prevent *endocarditis*.

THE MECHANISM OF MITOSIS

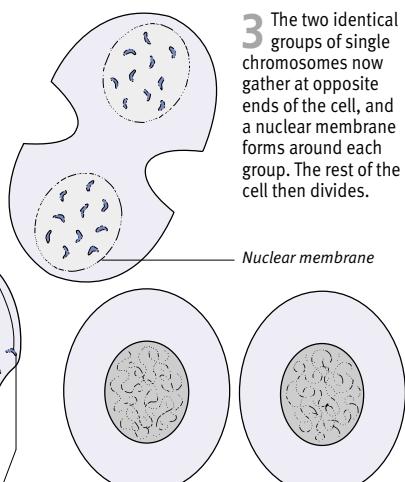

Mitosis is the simplest type of cell division. It provides new body cells to replace those that have died. Each of the new cells receives an identical copy of the chromosomes from the original cell.

1 Chromosomes in a cell nucleus are invisible, long threads. Before cell division, the threads replicate, coil up, and shorten, appearing as dark rods. The two copies of each chromosome are joined at a point called the centromere, so they appear X-shaped.

2 The doubled chromosomes line up in the centre of the cell. The cell nucleus breaks down, and threads appear in the cell. The two copies of each chromosome then move apart along the threads.

3 The two identical groups of single chromosomes now gather at opposite ends of the cell, and a nuclear membrane forms around each group. The rest of the cell then divides.

4 When division has finished and new nuclei have fully formed in the two daughter cells, the chromosomes uncoil to resume their invisible, threadlike form. Mitosis is now complete.

mitral stenosis

Narrowing of the opening of the *mitral valve* in the *heart*. The left atrium (upper chamber) has to work harder to force blood through the narrowed valve. Mitral stenosis is more common in women and may be accompanied by *mitral incompetence* (failure of the valve to close properly). It is usually due to damage caused by *rheumatic fever*.

SYMPOTMS

The main symptom is breathlessness on exertion. As mitral stenosis worsens, breathing difficulty eventually occurs when the person is at rest. Other signs include *palpitations*, *atrial fibrillation* (a rapid, uncoordinated, irregular heartbeat), and flushed cheeks. The person may also cough up blood and feel fatigued. Possible complications are as for mitral incompetence.

DIAGNOSIS AND TREATMENT

A diagnosis is made from the patient's history, listening to heart sounds, and by various investigations such as an *ECG*, *chest X-rays*, *echocardiography*, and *cardiac catheterization*. Drug treatment is broadly the same as for mitral incompetence.

If symptoms persist, balloon *valvuloplasty* may be carried out in order to stretch the valve. Alternatively, *heart-valve surgery* may be performed to replace the valve.

mitral valve

A valve in the left side of the *heart*. The mitral (or bicuspid) valve is made up of two flaps, allowing one-way blood flow from the left *atrium* (upper chamber) into the left *ventricle* (lower chamber).

mitral valve prolapse

A common, slight deformity of the *mitral valve*, in the left side of the *heart*, that can produce a degree of *mitral incompetence* (failure of the valve to close properly). The prolapse is most common in women and causes a heart *murmur*. It may be inherited, but the cause is often unknown.

Usually, there are no symptoms. Occasionally, however, the condition may produce chest pain, *arrhythmia* (irregular heartbeat), or, rarely, *heart failure*.

Often, no treatment is required for mitral valve prolapse, but some people may be treated with *beta-blocker drugs*, *diuretic drugs*, *antiarrhythmic drugs*, or, rarely, *heart-valve surgery*.

mittelschmerz

Lower abdominal pain experienced by some women at the time of *ovulation*. The pain usually occurs on one side of the abdomen and lasts for only a few hours. It may be accompanied by slight vaginal blood loss. In cases of severe mittelschmerz, *oral contraceptives* may be prescribed to suppress ovulation.

mixed connective tissue disorder

An *autoimmune disease* that affects the *connective tissue* (which supports body structures) throughout the body. It combines features of *systemic sclerosis*, *systemic lupus erythematosus*, *polymyositis*, and *rheumatoid arthritis*.

Mixed connective tissue disorder is diagnosed by blood tests that reveal antibodies to a cellular protein called ribonucleic protein (RNP). Treatment is similar to that for *systemic lupus erythematosus*, with *corticosteroid drugs* and *immunosuppressant drugs*.

MMR vaccination

Administration of a combined *vaccine* that gives protection against *measles*, *mumps*, and *rubella*. The vaccination is offered to all children between 12 and 15 months of age, with a booster shot at three to five years. Vaccination is postponed if a child is feverish, and it is not given to children with untreated *cancer* or *allergies* to aminoglycoside *antibiotic drugs* such as *neomycin*.

Mild fever, rash, and malaise may occur after vaccination. In a minority of cases, mild, noninfectious swelling of the *parotid glands* develops three to four weeks after vaccination. There is no evidence for a link between MMR and *Crohn's disease* or *autism*.

mobilization

The process of making a part of the body capable of movement. Mobilization is treatment that is designed to increase mobility in a part of the body that is recovering from injury or affected by disease.

Surgeons use the term to refer to the freeing of an organ or structure from surrounding *connective tissue* or fibrous adhesions (bands of tissue joining normally unconnected parts of the body).

Möbius' syndrome

A rare *genetic disorder* characterized by *paralysis* of both sides of the face, due to absence or underdevelopment of the sixth and seventh *cranial nerves*. The condition is *congenital* (present from birth). An affected child has a mask-like facial expression and cannot move the eyes fully from side to side. Newborn babies are unable to feed properly. In some cases, the syndrome is associated with abnormalities of the limbs or with *learning difficulties*. There is no specific treatment, but surgery may restore some facial expression.

moclobemide

An *antidepressant drug* that is used to treat severe resistant depression and social phobia. Moclobemide is a reversible *monoamine oxidase inhibitor* and is less likely than other MAOIs to cause high blood pressure. As with all MAOIs, however, interactions occur with some foods, and dietary restrictions still apply: people taking the drug should not consume foods such as cheese, meat, or yeast extracts, or drink red wine or beer.

Mogadon

A brand name for the benzodiazepine drug *nitrazepam*.

molar

See *teeth*.

molar pregnancy

A pregnancy in which a tumour develops from the placental tissue and the embryo does not develop normally. A molar pregnancy may be noncancerous (a *hydatidiform mole*) or may invade the wall of the uterus (an invasive mole). A molar pregnancy that becomes cancerous is called a *choriocarcinoma*.

If the dead embryo and placenta are not expelled from the uterus after a *miscarriage*, the dead tissue forms a mass called a *carneous mole*.

mole

A type of pigmented *naevus*. (See also *molar pregnancy*.)

molecule

The smallest complete unit of a substance that can exist independently and still retain the characteristic properties of that substance. Almost all molecules consist of two or more atoms bonded together. Those that consist of only one atom are called monatomic molecules.

molluscum contagiosum

A harmless viral infection characterized by shiny, pearly white papules (tiny lumps) on the skin surface. Each papule has a central depression, and releases a cheesy fluid when it is squeezed. A crust forms before healing occurs.

The papules often appear on the genitals, the insides of the thighs, or the face. Children are more commonly affected than adults. The infection is transmitted by direct skin contact or during sexual intercourse; it usually clears up within a few months, but may last for up to 18 months.

Mongolian blue spot

Blue-black pigmented spots found on the lower back and buttocks at birth. The spots are a type of *naevus*, caused by a concentration of melanocytes (cells that produce pigment). Mongolian blue spots are commonly found in black or Asian children. They usually disappear by the age of three to four years.

Mongolism

An outdated name for *Down's syndrome*.

moniliaisis

See *candidiasis*.

monitor

To maintain a constant watch on the condition of a patient. The word "monitor" is also used to refer to any device used to carry out monitoring.

monoamine oxidase inhibitors

Also known as MAOIs, one of the three main types of *antidepressant drug*. They work by preventing the breakdown of certain *neurotransmitters* by the *enzyme* monoamine oxidase. The increased levels of neurotransmitters that result are associated with improved mood.

Common drugs include *phenelzine* and isocarboxazid. All MAOIs interact with certain other drugs and foods such

as cheese and red wine. *Moclobemide*, however, is a type called a reversible MAOI, or RIMA, which makes the adverse reactions less likely to occur.

monoarthritis

Inflammation that affects a single joint, causing pain and stiffness. Common causes of monoarthritis include *osteoarthritis*, *gout*, and *infection*.

monoclonal antibody

See *antibody*, *monoclonal*.

monocyte

One of the main types of white blood cell. Monocytes are *phagocytes* (cells that surround and engulf invading microorganisms) and play an important role in the *immune system*.

mononucleosis, infectious

An acute viral infection, commonly called glandular fever, that is characterized by a high temperature, sore throat, and swollen *lymph nodes*.

CAUSE

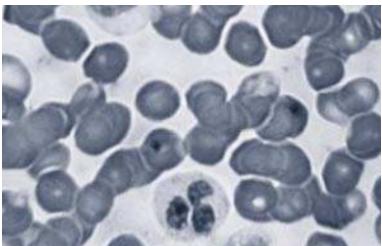

The infection is caused by the *Epstein-Barr virus*. It is transmitted via saliva, through close personal contact (including kissing), or possibly on cups or cutlery.

SYMPTOMS

In the body, the virus multiplies in the *lymphocytes* (also called mononuclear cells). If the infection occurs in early childhood, it may cause no symptoms. However, symptoms are common in adolescence or early adulthood; and the first to appear are a fever and headache, followed by swollen lymph nodes (particularly in the neck) and a severe sore throat. In rare cases, enlargement of the tonsils may obstruct breathing. The spleen may become enlarged. In addition, the liver may become inflamed, sometimes causing *jaundice*.

DIAGNOSIS AND TREATMENT

Diagnosis of the condition is often made from the symptoms and from a blood test (see *monospot test*); affected lymphocytes have an atypical appearance. Recovery usually takes four to six weeks, with rest the only treatment needed. In rare cases, *corticosteroid drugs* are given to reduce severe inflammation of the tonsils, particularly if the breathing is obstructed. Contact sports should be avoided until the spleen has returned to its normal size. For two to three months after recovery, people often feel depressed, lacking in energy, and sleepy during the day.

**Blood smear in mononucleosis**

The large cell with a three-lobed nucleus, surrounded by many red blood cells, is an atypical lymphocyte (it is bigger than normal). Such cells are a feature of mononucleosis.

monorchism

The presence of only one *testis*. The most probable causes of monorchism are surgery (see *orchidectomy*) and *congenital* absence of the testis.

monosaccharide

An alternative term for a simple sugar (see *carbohydrates*).

monosodium glutamate

A *food additive* that is used as a flavour enhancer and seasoning in food. Monosodium glutamate (MSG) is the sodium salt of an *amino acid*.

Some individuals who eat foods that contain MSG develop a short-lived illness, which involves pain in the neck and chest, *palpitations*, feeling hot, and a headache.

monospot test

A blood test that is used in the diagnosis of infectious mononucleosis (see *mononucleosis, infectious*). It is designed to detect certain antibodies (proteins produced by the immune system to fight infection) that are associated with this disorder.

monounsaturated

A term that is used to describe a form of unsaturated fatty acid that is found in certain oils that are used for food, such as olive oil and groundnut oil. (See *fats and oils*.)

monozygotic twins

The medical term for identical twins. (See *twins*.)

mons pubis

The rounded area over the front of the *pubic bone*. The mons pubis is formed by a pad of fatty tissue underneath the skin. It becomes covered with pubic hair at *puberty*.

Monteggia's fracture

Fracture of the *ulna* (the bone on the inner side of the forearm) just below the elbow, together with dislocation of the *radius* (the outer forearm bone) from the elbow joint.

montelukast

A specific *leukotriene receptor antagonist drug* used in the management of asthma. It is not, however, used to treat acute attacks.

Montgomery's tubercles

Raised sebaceous glands on the *areola* (the pigmented area around the nipple). The glands tend to become more obvious during pregnancy.

mood

See *affect; affective disorders*.

mood swings

Rapid changes in mood. Milder forms of mood swings, such as changes from a calm state to a state of anxiety, irritability, or tearfulness, may occur in women suffering from *premenstrual syndrome* or those who are going through the *menopause*. Extreme mood swings, from *mania* (abnormal overactivity and elation) to *depression*, are associated with bipolar affective disorder (see *manic-depressive illness*).

moon face

Rounding of the face that is due to abnormally high levels of natural corticosteroid hormones in the body, as in *Cushing's syndrome*, or to prolonged courses of *corticosteroid drugs*.

Moraxella

A group of bacteria that exist in a variety of mammals, including humans. The bacteria can cause a wide range of disorders; for example, the bacterium *MORAXELLA LACUNATA* may cause *conjunctivitis* and infections of the *cornea* (the transparent covering over the front of the eye), and *M. CATARRHALIS* occasionally causes *otitis media* (infection of the middle ear) and certain infections of the upper respiratory tract, such as *sinusitis* and *bronchitis*.

morbid anatomy

Also called pathological anatomy, the study of the structural changes that occur in body tissues as a result of disease, especially the changes that are visible to the naked eye.

morbidity

The state of being diseased. In medical statistics, the morbidity ratio is the proportion of diseased people to healthy people in a particular community.

morbilli

Another name for *measles*.

morning-after pill

See *contraception, emergency*.

morning sickness

See *vomiting in pregnancy*.

Moro reflex

An automatic movement in infants (see *reflex, primitive*) in which the arms are flung outwards before coming together in an embracing movement, the head jerks backwards, and the legs extend. The Moro reflex occurs in response to a stimulus such as the head being allowed to fall back momentarily.

morphine

An opioid *analgesic drug* derived from the opium poppy. Morphine is given to relieve severe pain caused by *myocardial infarction* (heart attack), major surgery, serious injury, and *cancer*. It blocks the transmission of pain signals at sites called opiate receptors in the *brain* and *spinal cord*. The drug also induces a sense of wellbeing or euphoria.

Side effects include drowsiness, dizziness, constipation, nausea, vomiting, and confusion. Long-term use of morphine may lead to *drug dependence*, with severe flu-like symptoms when the drug is withdrawn (see *withdrawal syndrome*).

morphea

A condition in which one or more hard, flat patches develop on the skin. It is a type of *scleroderma* but is confined to the skin. Although harmless, the condition can be disfiguring.

mortality

The death rate – the number of deaths per 100,000 (or 10,000 or 1,000) of the population per year. Mortality is often calculated for specific groups. For example, *infant mortality* measures the deaths of live-born infants during the first year of life.

Standardized mortality is a measure that allows comparison of the death rate in, for example, a particular occupational or socioeconomic group with that for the entire population. (See also *life expectancy; maternal mortality*.)

morula

A stage in the development of an *embryo* following *fertilization*. The fertilized egg divides repeatedly as it travels down the *fallopian tube* towards the *uterus*. Once it has developed into a ball of cells, it is called a morula.

mosaicism

The presence of two or more groups of cells containing different genetic material within one person.

Some people who have syndromes that are caused by *chromosomal abnormalities* (such as *Down's syndrome* and *Turner's syndrome*) also have mosaicism. Depending on the proportion of the abnormal cells and the type of abnormality, they range from appearing physically normal to having features typical of the syndrome.

mosquito bites

Mosquitoes are flying insects found throughout the world. The females bite humans or animals to obtain blood, which they need to produce eggs. The males do not bite. A doctor should be consulted if there is a severe skin reaction to a mosquito bite.

DISEASE TRANSMISSION

In addition to causing skin irritation, mosquito bites are also capable of transmitting diseases. The main types of disease-transmitting mosquitoes belong to three different groups: *ANOPHELES* (which transmits *malaria*), *AEDES* (which carries *yellow fever*), and *CULEX* (which transmits *filariasis*).

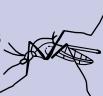

PREVENTION

Preventive measures should be taken in any area where mosquitoes are rampant. The most effective measures are wearing long-sleeved shirts and socks, fitting mosquito screens over windows, and using insect-repellent sprays or slow-burning impregnated coils that release insecticidal smoke. In addition, mosquito nets should be placed over beds. (See also *insect bites*; *insects and disease*.)

motility stimulant drugs

Drugs that stimulate movement through the gastrointestinal tract. There are two main types of motility stimulant: those that work as *antiemetic drugs* and affect the upper gastrointestinal tract (*metoclopramide* and *domperidone*, for example); and intestinal stimulant *laxative drugs*, such as *dantron* and *senna*, which are used to treat constipation.

DANGEROUS MOSQUITOES

Mosquito	Appearance	Habits	Diseases transmitted
<i>ANOPHELES</i> species	 Head and body in straight line and at an angle to surface.	Mainly rural; bite at night.	Malaria; filariasis.
<i>CULEX</i> species	 Body parallel to surface; head bent down; whining sound in flight; brown colour.	Urban or rural; bite in evening or at night.	Viral encephalitis; filariasis.
<i>AEDES</i> species	 Body shape as for <i>CULEX</i> , but tropical species are black and white.	Urban or rural; bite during day.	Dengue; yellow fever; viral encephalitis.

motion sickness

A problem that some people experience during road, sea, or air travel. Symptoms range from uneasiness and headache to distress, excessive sweating and salivation, pallor, nausea, and vomiting.

Motion sickness is caused by the effect of repetitive movement on the organ of balance in the *inner ear*. Factors such as anxiety, a fume-laden atmosphere, or the sight of food may make the condition worse. So, too, can focusing on nearby objects; sufferers should look at a point on the horizon. The sickness may be prevented or controlled by *antiemetic drugs* or by wearing acupressure bands on the wrist.

motor

A term used to describe any body structure that brings about movement, such as a *muscle* or a *nerve*.

motor nerve

A bundle of *nerve* fibres that carry electrical impulses from the *central nervous system* (the brain and spinal cord) to a muscle to bring about activity. (See also *sensory nerve*.) A group of muscle fibres that are activated by a single motor nerve fibre is called a motor unit.

motor neuron disease

A group of disorders in which there is degeneration of the *nerves* in the *central nervous system* that control muscular activity. This nerve degeneration causes weakness and wasting of the muscles. The cause is unknown.

TYPES AND SYMPTOMS

The most common type of the disease is amyotrophic lateral sclerosis (also

called ALS, or Lou Gehrig's disease). It usually affects people over the age of 50 and is more common in men. Some cases run in families. Usually, symptoms start with weakness in the hands and arms or legs, and muscle wasting. There may be irregular muscle contractions, and muscle cramps or stiffness. Soon, all four extremities are affected.

Progressive muscular atrophy and progressive bulbar palsy are conditions that both start with patterns of muscle weakness different from ALS but usually develop into ALS.

There are two types of motor neuron disease that first appear in childhood or adolescence. In most cases, these disorders are inherited. *Werdnig-Hoffman disease* affects infants at birth or soon afterwards. In almost all cases, progressive muscle weakness leads to death within only a few years. Chronic spinal muscular atrophy begins in childhood or adolescence, causing progressive weakness but not always serious disability.

DIAGNOSIS

There are no specific tests for motor neuron disease. Diagnosis is based on careful clinical examination by a neurologist. Tests including *EMG*, *muscle biopsy*, *blood tests*, *myelography*, *CT scanning*, or *MRI* may be performed.

TREATMENT AND OUTLOOK

The disease typically progresses to affect the muscles involved in breathing and swallowing, leading to death within two to four years.

The nerve degeneration cannot be slowed down, but *physiotherapy* and the use of various aids may help to reduce disability. The drug riluzole is used to

extend life (or the time until mechanical ventilation is required) in people who have ALS.

mould

Any of a large group of *fungi* that exist as many-celled, filamentous colonies. Some moulds are the source of *antibiotic drugs*. Others, however, can cause diseases such as *aspergillosis*.

mountain sickness

An illness that can affect people who have ascended rapidly to heights above 2,400–3,000 m. Mountain sickness, also called altitude sickness, is caused by the reduced atmospheric pressure and oxygen levels that exist at high altitude.

SYMPOTMS AND SIGNS

Affected people breathe abnormally fast and deeply (see *hyperventilation*) to compensate for the lack of oxygen; as a result, the level of carbon dioxide in the blood falls abnormally low. Other symptoms include nausea, headache, anxiety, and exhaustion. In severe cases, *pulmonary oedema* (the accumulation of fluid in the lungs) may occur, leading to acute shortness of breath (see *respiratory distress syndrome*). Fluid may also accumulate in the brain (see *cerebral oedema*), causing confusion, loss of consciousness, or *coma*.

TREATMENT

An affected person should be returned to a lower altitude as rapidly and safely as possible. He or she may need extra oxygen. Pulmonary or cerebral oedema will need treatment in hospital.

PREVENTION

Mountain sickness can be prevented or minimized if the affected person ascends gradually, stopping for one or two days of rest for every 600 m above 2,400 m. He or she should drink plenty of fluids, have regular high-carbohydrate meals, and avoid drinking alcohol. Those with existing heart or lung disorders should avoid ascending to high altitudes.

mouth

The oral cavity. The mouth breaks down food for swallowing (see *mastication*) and is used in breathing. In addition, it helps to convert sound vibrations from the *larynx* into speech.

mouth breathing

Breathing through the open mouth, rather than through the nose. It may be due to obstruction of the nasal passages by thick secretions (as in a heavy *cold* or

sinusitis) or by enlarged *tonsils* or *adenoids*. Noisy mouth breathing that occurs during sleep is called *snoring*.

mouth cancer

Forms of cancerous tumour that develop in the lips, tongue, and oral cavity. Lip cancer and tongue cancer are the most common types.

CAUSES AND INCIDENCE

Predisposing causes of mouth cancer are *smoking*, poor *oral hygiene*, drinking alcoholic spirits, chewing tobacco, and inhaling snuff. Irritation from ill-fitting dentures or jagged teeth are other risk factors. Men are affected twice as commonly as women; most cases occur in men over the age of 40.

SYMPTOMS

In the majority of cases, the cancer begins with a whitish patch, called *leukoplakia*, or a small lump. These lesions may cause a burning sensation, but are usually painless. As a tumour grows, it may develop into an *ulcer* or a deep fissure, which may bleed and erode surrounding tissue.

DIAGNOSIS AND TREATMENT

Diagnosis is based on a *biopsy*. Treatment consists of surgery, *radiotherapy*, or both. Surgical treatment may cause facial disfigurement and problems with eating and speaking, which may then necessitate *plastic surgery* to restore appearance and function. Radiotherapy may be given either externally or with

implants in the area (brachytherapy); however, it sometimes damages the salivary glands (see *mouth, dry*).

When mouth cancer is detected and treated early, the outlook is good. Any nonhealing ulcer or lump in the mouth should be assessed by a doctor or dentist within two weeks, to maximize the chance of effective treatment.

mouth, dry

A condition caused by inadequate production of saliva. Dry mouth is usually a temporary problem resulting from fear, infection of a *salivary gland*, or the action of *anticholinergic drugs*.

Rarely, permanent dry mouth may result from *Sjögren's syndrome* or *radiotherapy* for mouth cancer. The dryness causes swallowing and speaking difficulty, impaired taste, and tooth decay (see *caries, dental*). Spraying the inside of the mouth with artificial saliva or taking *pilocarpine* tablets may help.

mouth-to-mouth resuscitation

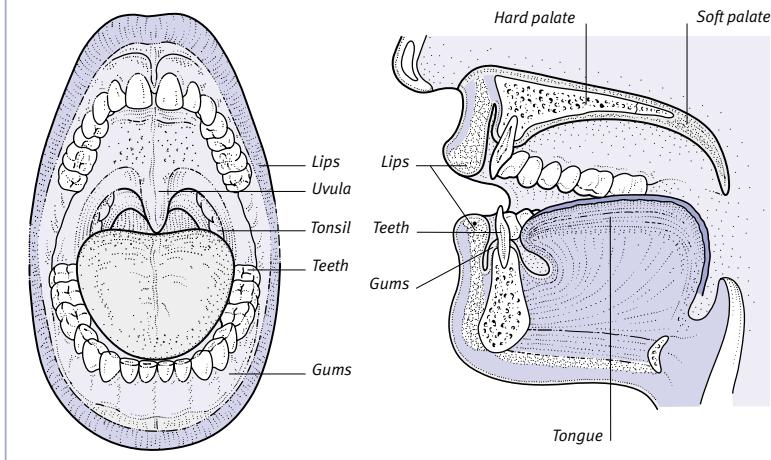

See *artificial respiration*.

mouth ulcer

An open sore that is caused by a break in the *mucous membrane* that lines the mouth. Mouth ulcers are white, grey, or yellow spots with an inflamed border. The most common types are aphthous ulcers (see *ulcer, aphthous*) and ulcers caused by the *herpes simplex virus*.

ANATOMY OF THE MOUTH

The mouth has a complex structure, which reflects its various functions. For example, the tongue, lips, teeth, and palate play an essential role in speech production. The same parts of the mouth, with the salivary glands, also begin the process of digestion by taking in and swallowing food and drink.

MOUTHWASH

A mouth ulcer may be an early stage of *mouth cancer*. Those that fail to heal within a month may need to be investigated with a *biopsy*.

mouthwash

A solution for rinsing the mouth. Many only leave the mouth feeling fresh and remove loose food debris from the teeth. Some, such as those containing *hydrogen peroxide*, can help to clean the teeth if the gums are too tender for proper toothbrushing, as in some types of *gingivitis*. Those containing *chlorhexidine* are effective against plaque when routine dental hygiene is impossible.

Fluoride mouthwashes help to prevent tooth decay (see *caries, dental*), and a mouthwash of warm salt water can help to ease painful inflammation caused by tooth disorders. Antiseptic mouthwashes intended to combat *halitosis* are usually ineffective because they do not treat the cause of the problem.

movement

Any motion of limbs or other areas of the body, or any motion within soft tissues and body organs. All movements are caused by the actions of muscles. They may be either voluntary (willed) or involuntary (automatic). Certain movements occur as *reflex* actions.

SKELETAL MOVEMENTS

These movements involve the bones, the joints, and the skeletal muscles. Most of them are voluntary. They are initiated in a part of the cerebrum (the main mass of the *brain*) called the motor cortex. Signals are sent down the *spinal cord* along some nerve fibres, and, from there, along separate nerve fibres to the appropriate muscles. Control relies on information supplied by sensory nerve *receptors*, in the muscles and elsewhere, that record the position of different body parts and the degree of contraction in each muscle. This information is integrated in specific regions of the brain (including the *cerebellum* and *basal ganglia*) that control the coordination, initiation, and cessation of movement.

Skeletal movements can also occur as simple reflexes in response to certain sensory warning signals. These movements are automatic and less controlled, involving far fewer nerve connections.

OTHER MOVEMENTS

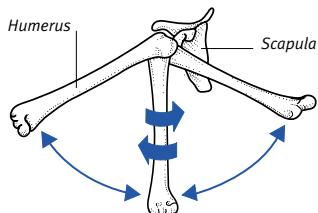

Some body movements do not involve the skeleton. For example, eye and tongue movements result from the con-

MOVEMENT

Various movements occur constantly throughout the body. All movement is either voluntary (willed) or involuntary (automatic). Visible movements are caused by the contraction of skeletal muscles or eye muscles, usually for only brief periods at a time.

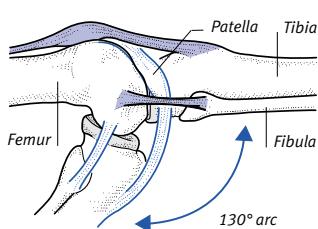

SKELETAL MOVEMENT

This action involves the movement of bones relative to one another, often at the joints. Many muscles are involved. Some act to brace certain bones, while others move adjacent bones.

Arm movements

A ball-and-socket joint, the shoulder allows combined rotation and displacement movements in all directions.

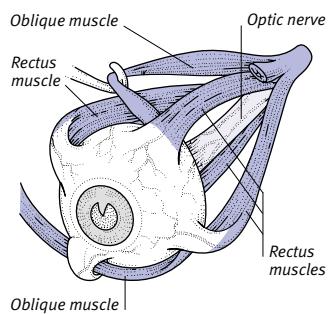

Knee movement

A hinge joint, the knee allows movement (through an arc of about 130°) in only one plane: forwards or backwards.

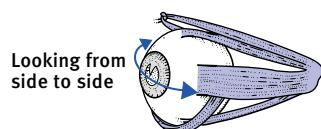

EYE MOVEMENT

A group of six muscles act together on each eyeball to give a range of smooth, precise movements. The eyeball can move through an arc of about 100° horizontally and about 80° vertically.

Eye muscles

The four rectus eye muscles run directly from the eyeball to a tendon at the back of the eye socket. The oblique muscles are attached to the eyeball at an angle.

Looking up and down

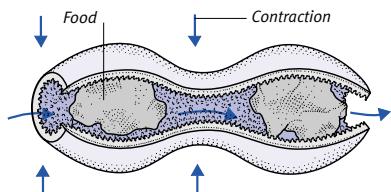

Actions of the eye muscles

Two rectus muscles control side-to-side movements. The other rectus muscles, with the oblique muscles, control up-and-down and rotational movements.

INVOLUNTARY MOVEMENT

Many movements in the body are involuntary (automatic), and are regulated by the autonomic nervous system. One example of involuntary movement is the beating of the heart, which automatically speeds up in response to increased demands for oxygenated blood by body tissues and slows down again when these demands decrease. Another example is peristalsis (see right).

Peristalsis

This is an example of movement caused by involuntary muscle action. Waves of contraction pass along muscles in the intestinal wall, forcing the contents forwards and preventing obstruction.

tractions of muscles attached to other soft tissues. These movements may be voluntary or reflex.

The movements of the internal organs are involuntary; they include the *heartbeat* and *peristalsis*.

movement, loss of

See *akinesia*.

moxibustion

A form of treatment, often used with *acupuncture*, in which a cone of wormwood leaves (moxa) or certain other plant materials is burned just above the skin to relieve internal pain.

moxislyte

A *vasodilator drug* used to treat *Raynaud's disease*. Side effects include nausea, diarrhoea, hot flushes, headache, and dizziness.

MRI

The abbreviation for magnetic resonance imaging. MRI is a diagnostic technique that produces cross-sectional or three-dimensional images of organs and other body structures.

HOW IT IS DONE

The patient lies inside a scanner surrounded by a large, powerful magnet. A receiving magnet is placed around the part of the body to be investigated. If large areas, such as the abdomen, are to be imaged, the receiving magnet is fitted inside the scanner; for a smaller area, such as a joint, a magnet may be placed around the part to be scanned.

The scanner generates a strong magnetic field, which causes the atoms in the body to line up parallel to each other. Short pulses of radio waves from a radiofrequency source briefly knock the atoms out of alignment. As the atoms realign they emit tiny signals, which are detected by the receiving magnet. Information about these signals is passed to a computer, which builds up an image based on the signals' strength and location.

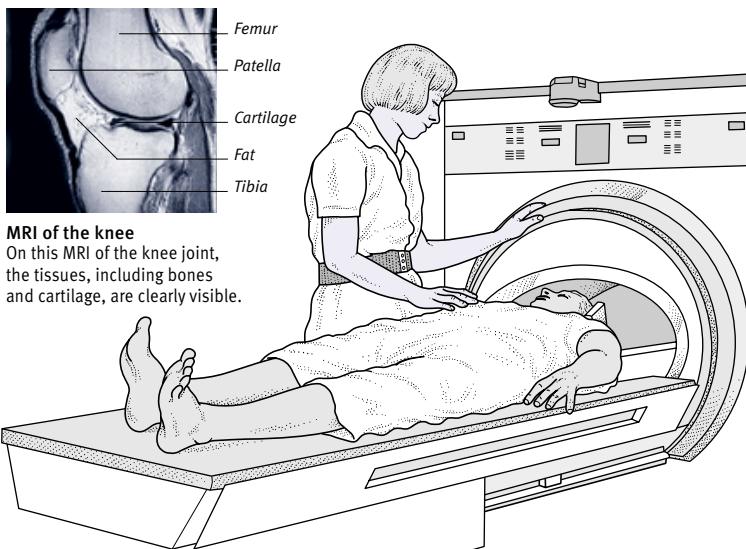

MR images can be enhanced by use of a *contrast medium* to highlight particular body structures, such as tumours and blood vessels.

WHY IT IS DONE

Images from MRI are similar to those produced by *CT scanning*, but they give greater contrast between normal and abnormal tissues. MRI is useful for studying the brain and spinal cord, the internal structure of the eye and ear, the internal organs, and blood flow.

MAGNETIC RESONANCE IMAGING (MRI)

A valuable diagnostic technique, MRI has been in use since the early 1980s. The patient lies down and is surrounded by a massive electromagnet and is exposed to short bursts of powerful magnetic fields and radio-waves. The bursts stimulate protons (hydrogen nuclei) in the patient's tissues to emit radio signals, which are detected and analysed by computer to create an image of a "slice" of the patient's body.

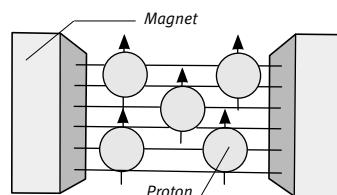

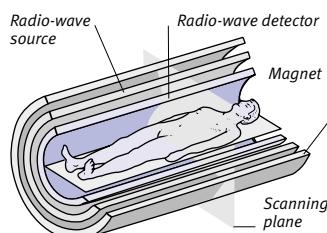

MRI of the knee

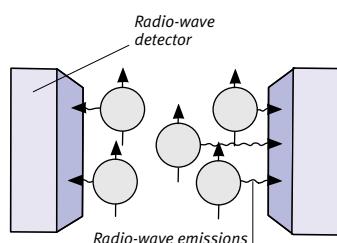

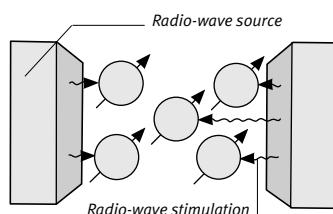

On this MRI of the knee joint, the tissues, including bones and cartilage, are clearly visible.

THE SCANNING PROCESS

An MRI scanner consists of a powerful electromagnet, a radio-wave emitter, and a radio-wave detector. A plane of the body is selected for imaging and the electromagnet is turned on.

1 Normally, the protons (nuclei) of the body's hydrogen atoms point randomly in different directions, but under the influence of the scanner's powerful magnetic field they align themselves in the same direction.

2 Next, the radio-wave source emits a powerful pulse of radio-waves, which knocks the protons out of alignment.

3 However, milliseconds later, the protons realign themselves. As they do so, they emit faint radio signals, which are picked up by the scanner's radio-wave detector.

RISKS

There are no known risks or side effects. The scans do not use ionizing radiation and can be performed repeatedly. The scanner may, however, interfere with the functioning of pacemakers, hearing aids, and other electrical devices.

MRSA

The abbreviation for methicillin-resistant *STAPHYLOCOCCUS AUREUS*, a bacterium that is resistant to methicillin and many other *antibiotic drugs*. It is responsible for the emergence of difficult-to-treat infections in hospitals and can sometimes be fatal.

MS

The abbreviation for *multiple sclerosis*.

MSG

The abbreviation for the food additive *monosodium glutamate*.

MST Continus

A brand name for a modified-release preparation of the opioid analgesic (painkilling) drug *morphine*.

MSU

The abbreviation for midstream specimen of urine: a sample to be examined for microorganisms in the urinary tract. Allowing the first part of the stream to flow into the toilet helps clear contaminants from the skin or urethral lining.

Muckle–Wells syndrome

An autosomal dominant *genetic disorder* that leads to *amyloidosis* (the formation of protein deposits) in the kidneys. It causes *nephritis* (inflammation of the kidneys), *deafness*, pain in the extremities, and recurrent *urticaria* with fever.

mucocele

A sac or cavity in the body that is filled with *mucus* secreted by its inner lining.

mucolipidoses

A group of rare metabolic disorders (see *metabolism, inborn errors of*) in which a particular *enzyme* deficiency causes an abnormal accumulation of *lipids* and substances called mucopolysaccharides in cells. The disorders appear in childhood; they may cause *learning difficulties* and a variety of physical abnormalities.

mucolytic drugs

Drugs that make sputum (phlegm) less sticky and easier to cough up. An example is *acetylcysteine*.

mucopolysaccharidosis

A group of rare inherited metabolic disorders (see *metabolism, inborn errors of*) of which *Hurler's syndrome* is the most well known. Mucopolysaccharidoses are *genetic disorders* in which there is an abnormality of a specific *enzyme*, causing the accumulation of substances called mucopolysaccharides in body cells.

SYMPOTMS

Features may include abnormalities of the skeleton and/or the central nervous system, with *learning difficulties* and, in some cases, a characteristic facial appearance. There may also be clouding of the *cornea*, enlargement of the liver, and stiffness in the joints.

TREATMENT AND OUTLOOK

No specific treatment is available; however, a *bone marrow transplant* may be used to treat Hurler's syndrome.

Mild forms of mucopolysaccharidoses allow a child to have a relatively normal life. More severe types usually cause death in childhood or adolescence.

mucosa

A term for *mucous membrane*.

mucous membrane

The soft, pink, skinlike layer that lines many of the cavities and tubes in the body, including the *respiratory tract* and the *digestive tract*. Mucous membranes contain cells called goblet cells, which secrete a fluid containing *mucus*.

mucoviscidosis

See *cystic fibrosis*.

mucus

The thick, slimy fluid that is secreted by *mucous membranes*. Mucus moistens, lubricates, and protects parts of the body lined by mucous membranes, such as the digestive and respiratory tracts.

mucus method of contraception

See *contraception, natural methods of*.

MUGA scan

A method of investigating how much blood the *heart* can pump with each heartbeat and whether different parts of the heart wall are contracting properly. The patient's *red blood cells* are injected with a radioactive *isotope* to enable an image to be formed of the blood pool within the heart at different times during the heart cycle. A MUGA scan, or multiple-gated acquisition scan, uses *ECG*, a *gamma camera*, and a computer.

multi-infarct dementia

A deterioration in brain function (see *dementia*) resulting from the death of small areas of brain tissue. It is the second most common cause of dementia after *Alzheimer's disease*. The disorder occurs when clots block small blood vessels within the brain, preventing the flow of blood to particular areas and thereby starving the tissue of oxygen. The risk of developing multi-infarct dementia is increased in people with *hypertension* (high blood pressure) and *atherosclerosis* (narrowing of the arteries by fatty deposits on the artery walls).

Symptoms vary depending on the part of the brain that is affected, but they become progressively worse, in distinct steps, after each attack. Symptoms include disruption of memory, so that the person cannot recall recent events or gets lost in familiar surroundings; difficulty in making decisions or carrying out simple tasks; and changes in mood, such as depression or agitation. Affected people often experience repeated *transient ischaemic attacks* or *strokes*.

Diagnosis is based on the symptoms and, if necessary, confirmed by *MRI* or *CT scanning* of the brain. *Antihypertensive drugs* may be prescribed to control blood pressure, and *aspirin* is often prescribed to reduce the risk of the condition progressing. People can also help to protect themselves from any further infarcts by following a low-fat diet and exercising regularly.

multiparous

A term for a woman who has had two or more pregnancies resulting in birth (whether or not the fetuses were alive at the time of birth).

multiple endocrine neoplasia (MEN)

The name for a group of rare, autosomal dominant *genetic disorders* that cause tumours to develop in several of the *endocrine glands*. Each disorder is caused by a different abnormal gene. One form of MEN causes tumours in the *pancreas, parathyroid glands, and pituitary gland*, and sometimes also in the *adrenal gland* and the *thyroid gland*. Another, less common form produces tumours in the adrenal, thyroid, and parathyroid glands. Tumours may arise simultaneously or at different times over several years. The affected glands may produce excess hormones. One type of thyroid tumour, which secretes

the hormone calcitonin, is usually cancerous, but most tumours in other endocrine glands are not.

Tumours are usually removed by surgery, and the person will be monitored afterwards so that any further endocrine abnormalities can be detected. The person's relatives may be offered screening for the abnormal gene or the effects of the disorder (see *family screening*).

multiple-gated acquisition scan

See *MUGA scan*.

multiple myeloma

A rare, cancerous disorder, also called myelomatosis, in which plasma cells in the *bone marrow* proliferate uncontrollably and function incorrectly. It is more common in elderly people.

CAUSE

Plasma cells are a type of *B-lymphocyte* that produce *immunoglobulins*, which help protect against infection. In multiple myeloma, the proliferating plasma cells produce excessive amounts of one type of immunoglobulin while the production of other types is impaired. This makes infection more likely.

SYMPOTMS

Proliferation of the abnormal cells in the bone marrow causes pain and destroys the bone tissue. Affected *vertebrae* may collapse and compress the *spinal cord* or *spinal nerves*, causing numbness or *paralysis*. As bone is destroyed, levels of calcium in the blood increase, as may the levels of one or more immunoglobulins. These changes in the blood may lead to damage of the kidneys, resulting in *kidney failure*. There may also be *anaemia* and a tendency for abnormal bleeding.

DIAGNOSIS AND TREATMENT

The disease is diagnosed by a *bone marrow biopsy*, *blood tests* or *urinalysis*, and *X-rays*. Treatment includes *radiotherapy* for localized bone deposits, to relieve pain and reduce the risk of fractures; *anticancer drugs* to slow the course of the disease; correction of associated problems, such as kidney failure; and supportive measures, including *blood transfusions*, *antibiotic drugs*, and *analgesic drugs* (painkillers). No treatment provides a cure, however.

The outlook for multiple myeloma varies depending on the severity of the illness. Some people remain well for months or years, and then the progression of the disease accelerates.

multiple organ failure

Loss of function in several organs at once. This life-threatening condition affects the lungs (see *respiratory distress syndrome*), kidneys and other organs, and the circulation. It is most often triggered by overwhelming infection, but may also be due to *shock* following severe injury.

multiple personality disorder

A rare disorder in which a person has two or more distinct personalities, each of which dominates at different times. Each personality may be unaware that the others exist. The transition from one personality to another is often sudden, and may be triggered by *stress*. The condition is thought to result from severe emotional trauma, such as violent *sexual abuse*, during childhood.

multiple pregnancy

See *pregnancy, multiple*.

multiple sclerosis

A progressive disease of the central *nervous system*, in which patches of *myelin* (the protective covering of nerve fibres) in the brain and the spinal cord are disrupted. The damaged patches are called plaques. The nerves cannot conduct electrical impulses, so functions such as movement and sensation may be lost. Any part of the central nervous system may be affected.

CAUSES AND INCIDENCE

There may be a genetic predisposition, because MS sometimes runs in families. There may also be an environmental cause. It is more common in temperate zones than in the tropics.

SYMPOTMS

MS usually develops between the ages of 20 and 45, and is more common in women. Symptoms depend on the area of the brain or spinal cord that is involved in an attack. Spinal cord damage may cause tingling, numbness, weakness in the extremities, *spasticity*, *paralysis*, and *incontinence*. Damage to white matter (myelinated nerves) in the brain may cause fatigue, *vertigo*, clumsiness, muscle weakness, slurred speech, blurred vision, facial numbness, or facial pain. For further information see *Features of multiple sclerosis* box, overleaf.

An attack may last for several weeks or months. It is followed by a variable period of remission, in which dramatic improvements may be made. After a remission period, a further attack or a

relapse occurs. Most people have mild relapses and long periods of remission (relapsing-remitting MS), with few permanent effects. Others have a form called chronic-progressive MS, becoming gradually more disabled from the first attack. A few have a form called fulminant MS, which progresses rapidly in the first year of illness.

DIAGNOSIS

There is no single diagnostic test, but *MRI* may show damage to white matter in the brain, and a *lumbar puncture* may show abnormal proteins in the fluid around the spinal cord. *Evoked response* tests on the eyes may reveal disruption of the nerve pathways from the optic nerves.

TREATMENT

There is no specific treatment. A short course of *corticosteroid drugs* may reduce the severity of relapses, while beta *interferon* can lengthen the time between attacks; however, these drugs do not improve the outlook. The use of *rehabilitation*, *physiotherapy*, and *occupational therapy* is essential so that people can carry out daily activities more easily.

Some people try remedies such as taking sunflower seed oil, following a gluten-free diet, *hyperbaric oxygen therapy*, or having various vaccines. To date, however, there is no evidence that any of these measures are beneficial.

multivitamins

Over-the-counter preparations, containing a combination of vitamins, that are used as a dietary supplement. (See *vitamin supplements*.)

mumps

An acute viral illness usually occurring in childhood. The main symptom is inflammation and swelling of one or both

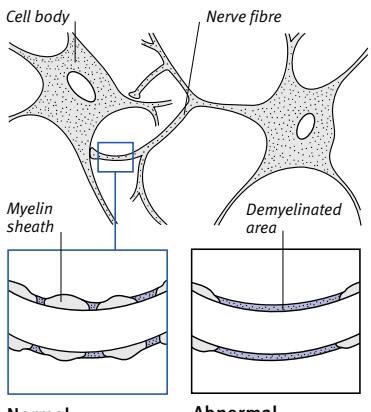

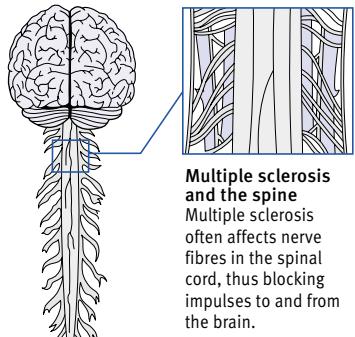

Appearance of mumps

The swelling may be present on either or both sides and can give the affected child's face a bloated appearance.

FEATURES OF MULTIPLE SCLEROSIS

The disease can affect any area of the white matter of the brain and spinal cord. The plaques of demyelination are areas in which the fatty myelin sheaths of the nerve fibres have been

destroyed. The affected fibres cannot conduct nerve impulses, so functions such as movement and sensation may be lost. The patchy distribution of plaques causes very varied effects.

Effects of multiple sclerosis

The fibre of the nerve tract is not usually destroyed, but the loss of insulating myelin alters normal ion movements, so that the fibre can no longer conduct impulses.

AFFECTED AREAS

The brain and spinal cord control all parts of the body, so damage to these parts by multiple sclerosis may affect any function or any organ.

Coordination

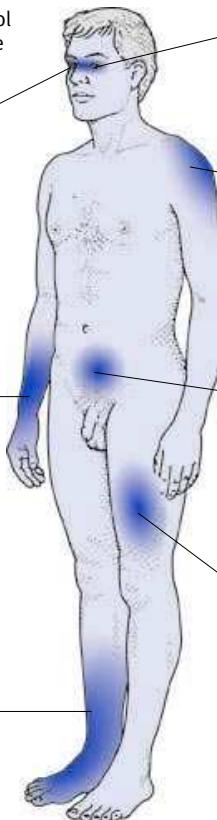

When the nerve fibres in the brainstem are involved, there may be incoordination, loss of balance, and double vision.

Sensation

The nerve tracts that carry impulses for sensation are often involved. This causes areas of numbness, or a feeling of pins-and-needles in the skin.

Balance

Damage to nerves in the brain stem may affect balance.

Vision

The optic nerves may be involved, causing severe (but usually temporary) loss of the centre of the visual field.

Strength

Damage to the nerve fibres in the spinal cord can cause weakness and heaviness in the arms.

Bladder

In people severely affected by multiple sclerosis, spinal cord damage often leads to incontinence due to loss of sphincter control in the bladder.

Movement

Plaques on the long motor nerve tracts in the brain or spinal cord may affect walking, sometimes causing dragging of one leg or a feeling of weakness.

parotid glands, which are situated inside the angle of the jaw. One attack of mumps confers lifelong immunity. Since routine **MMR vaccination**, epidemics of mumps no longer occur.

CAUSE

The mumps virus is spread in airborne droplets. The **incubation period** is two to three weeks; an affected person is infectious for about a week before and up to two weeks after symptoms appear.

SYMPTOMS

Infected children often have no symptoms, or they may feel slightly unwell and have some discomfort around the parotid glands. In more serious cases, there is pain around the glands and chewing becomes difficult; one or both

glands then become swollen and tender. A fever and headache may develop. The swelling subsides within a week to ten days. When only one gland is affected, the second gland often swells as the swelling in the first subsides.

COMPLICATIONS

Mumps may lead to a number of other conditions including viral **meningitis** (inflammation of the membranes covering the brain and spinal cord), **pancreatitis** (inflammation of the pancreas), or, in adolescent or adult males, **epididymo-orchitis** (inflammation of the testes).

DIAGNOSIS AND TREATMENT

Diagnosis is usually made from the symptoms. There is usually no treatment; rest and painkillers may ease symptoms.

Munchausen's syndrome

A chronic **factitious disorder** in which a person complains of physical symptoms that are pretended or self-induced in order to play the role of patient.

The usual complaints are abdominal pain, bleeding, neurological symptoms, rashes, and fever. People typically invent dramatic histories. Most sufferers are repeatedly admitted to hospital, and many have detailed medical knowledge and scars from self-injury or previous treatment. In Munchausen's syndrome by proxy, parents simulate disorders in children.

Treatment consists of protecting the sufferers from unnecessary operations and drug treatments.

mupirocin

An *antibacterial* cream or ointment used to treat skin infections such as *impetigo*.

mural aneurysm

A dilated, weakened area in the wall of the left *ventricle* in the heart; also called a *ventricular aneurysm*.

mural thrombus

A *thrombus* (blood clot) on the inner wall of a heart chamber, usually a ventricle (lower chamber). The clot develops on an area of tissue that has been damaged by a *myocardial infarction* (heart attack).

murmur

A sound caused by turbulent blood flow through the *heart*, as heard through a *stethoscope*. Heart murmurs are regarded as an indication of possible abnormalities in the blood flow. Apart from *innocent murmurs*, the most common cause of extra blood turbulence is a disorder of the *heart valves*. Murmurs can also be caused by some types of congenital heart disease (see *heart disease, congenital*) or by rarer conditions such as a *myxoma* in a heart chamber. (See also *systolic murmur*.)

muscle

A structure composed of bundles of specialized cells, which are capable of contraction and relaxation to create movement. There are three types of muscle: skeletal, smooth, and cardiac.

SKELETAL MUSCLE

The skeletal muscles are the most prominent muscle group in the body (see

muscular system). They are called voluntary muscles because they are under conscious control (see *The body's muscles* box, overleaf).

Skeletal muscles comprise groups of muscle fibres arranged in bundles called fascicles. A fibre is made up of longitudinal units called myofibrils, the working units of which are filaments of actin and myosin (two proteins that control contraction). Impulses from the brain cause the myosin filaments to slide over the actin, making the muscle fibres contract and move the body. Conversely, nerve fibres in the muscle register the force of contraction (while nerves in the tendon register how much it has stretched) and transmit this information back to the brain, which limits the strength of the contraction. The muscle activity is affected by changes in the chemical composition of the fluid that surrounds the muscle cells. A fall in the level of potassium ions causes muscle weakness; a decrease in calcium ions causes muscle spasm.

A state of partial contraction is constantly maintained, even when the muscles are not moving; this is called muscle tone (see *tone, muscle*). Some disorders may cause abnormalities in muscle tone, such as excessive rigidity (*spasticity*) or floppiness (*hypotonia*).

SMOOTH MUSCLE

This type of muscle exists in the walls of internal organs. It produces movements such as *peristalsis* in the intestine and contractions of the uterus in childbirth. Smooth muscle also forms part of the lining of hollow structures such as the

blood vessels, airways, and bladder. It is also called involuntary muscle, because it is not under conscious control.

The muscle is made of long, spindle-shaped cells, and contracts by the same action of actin and myosin as skeletal muscle. It is stimulated by the *autonomic nervous system*; it also responds to *hormones* and to levels of chemicals in the fluid around the muscle.

CARDIAC MUSCLE

Cardiac muscle (also called myocardium) is found only in the *heart*. It is able to contract continually and rhythmically, about 100,000 times a day. Contraction is stimulated by the autonomic nervous system, by hormones, and by the stretching of muscle fibres. The initial electrical stimulus comes from the *sinoatrial node*; it spreads through specialized conduction cells that form a network throughout the muscle fibres. The fibres are joined end to end by areas of extensive folds that enable contractions to be transmitted rapidly from one fibre to another.

DISORDERS

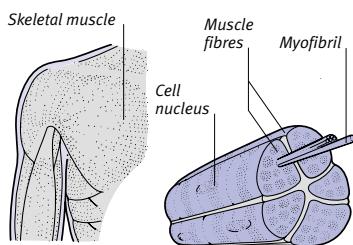

The most common disorders are injury and lack of blood supply to a muscle. (See also *Disorders of muscle*, overleaf.)

muscle enzymes

Proteins that regulate the rate of chemical reactions in muscle cells. Measuring the blood levels of muscle enzymes (see *blood tests*) can help doctors to diagnose certain disorders. One such disorder is *myocardial infarction* (heart attack), in which damaged heart muscle leaks higher than normal levels of enzymes into the blood. Another is *muscular dystrophy*,

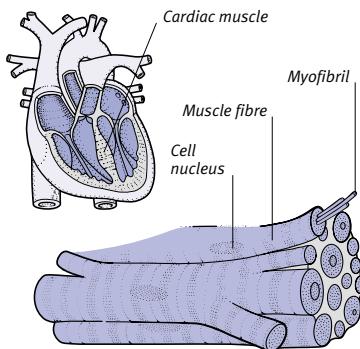

MUSCLE TYPES

In each main muscle type, the fibres form a distinctive structure that enables the muscle to fulfil a specific function.

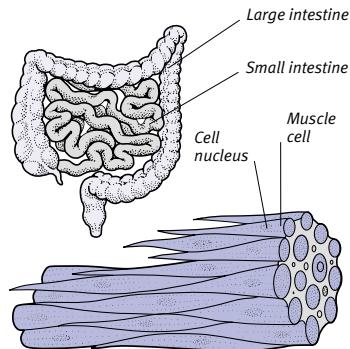

Skeletal muscle

Long bundles of muscle fibres, each containing myofibrils (contractile elements), allow skeletal muscle to contract briefly but powerfully.

Cardiac muscle

This muscle comprises short, branching cells that interconnect, so that nerve signals can spread instantly throughout the heart.

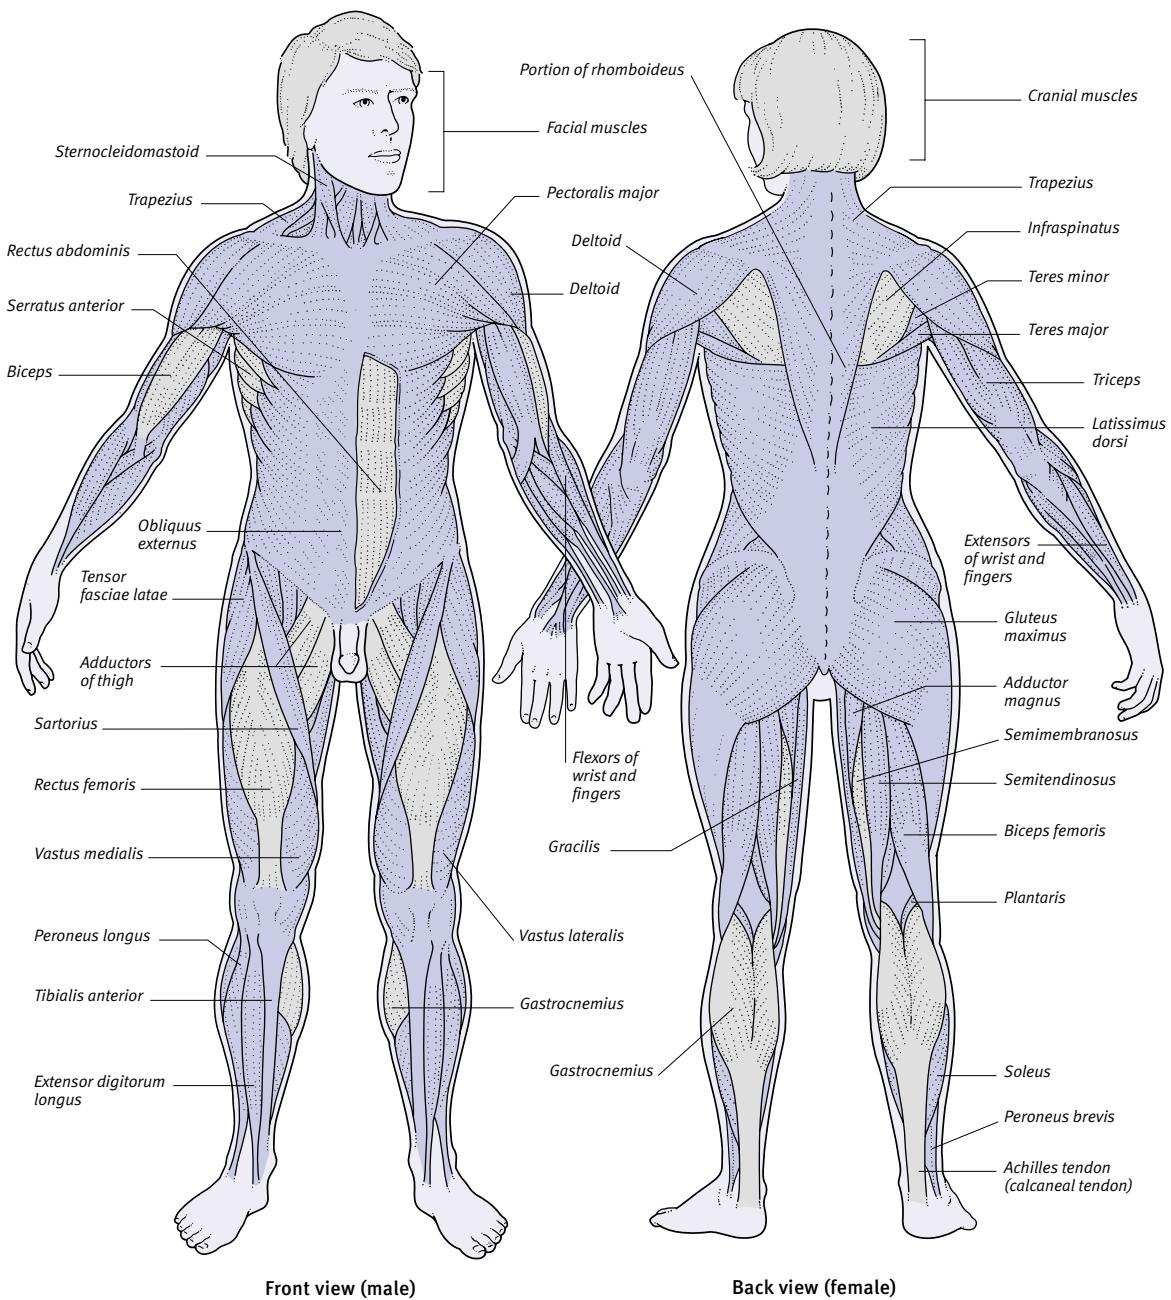

Smooth muscle

In smooth muscle, loosely woven, tapering cells form flat sheets of tissue. Contraction is slower than in other muscle types.

THE BODY'S MUSCLES

The most prominent muscles in the body are the skeletal muscles, which account for 40 to 45 per cent of body weight. These muscles are defined as voluntary because they are under conscious control; some important voluntary muscles

are indicated on the illustration below. In contrast, many of the internal organs, such as the heart and the intestines, consist partly or entirely of involuntary muscle, which is not under conscious control.

in which the raised levels of muscle enzyme are due to the death of muscle cells. Enzymes leaked from the heart muscle differ from those from skeletal muscle; this distinction helps doctors to identify the site of the muscle damage.

muscle-relaxant drugs

A group of drugs that are used to relieve muscle spasm and *spasticity*. Muscle-relaxant drugs are used mainly in the treatment of nervous-system disorders

such as *multiple sclerosis* and painful muscular conditions such as *torticollis*. They are occasionally used to relieve muscle rigidity due to injury. Some types of muscle-relaxant drugs are used to cause temporary paralysis during surgery under general *anaesthesia*.

Most muscle-relaxant drugs partially block nerve signals that stimulate muscle contraction. *Dantrolene*, in contrast, interferes with the chemical activity in muscle cells needed for contraction.

The drugs may cause muscle weakness and drowsiness. In rare cases, dantrolene causes liver damage.

muscle spasm

Sudden and involuntary contraction of a muscle. Spasm is a reaction to pain and inflammation around a joint. Common causes are *strain*, *disc prolapse* (slipped disc), and stress. Usually, the underlying cause is treated. *Muscle-relaxant drugs* may also be needed. (See also *spasticity*.)

DISORDERS OF MUSCLE

The most common muscle disorder is *injury*, followed by symptoms caused by a lack of blood supply to a muscle (including the heart muscle). There are also various other, rare disorders that can affect the muscles.

Injury

Muscle injuries, such as tears and *strains*, are very common. They cause bleeding into the muscle tissue. Healing may lead to the formation of a scar in the muscle, which shortens its natural length. Blunt injury may result in the formation of a *haematoma* (a localized collection of blood) from bleeding into the muscle. Rarely, bone may form in a blood clot, causing *myositis ossificans*.

Impaired blood supply

Muscles depend on a good blood supply in order to function normally. A temporary lack of blood flow, which is sometimes associated with severe exertion, may cause *cramp*. *Peripheral vascular disease*, in which blood vessels in the legs (and sometimes the arms) are narrowed, restricts the blood supply, causing *claudication* (muscle pain on exercise). *Angina pectoris* (chest pain caused by lack of blood supply to heart muscle) may occur in people with *coronary artery disease*.

The *compartment syndrome* is pain in muscles as a result of pressure that limits their blood supply. It may be brought on by injury or exercise, and occurs most often in athletes who have well-developed muscles.

Infection

The most serious infection of muscle is *gangrene*, which may complicate deep wounds (especially those contaminated by soil). *Tetanus* is acquired in a similar

way; it causes widespread muscle spasm through the release of a powerful toxin.

Viruses (especially influenza B) may also infect muscles (causing *myalgia*), as may the organism causing *toxoplasmosis*. Lastly, a parasitic disease called *trichinosis* can occur in muscle tissue. This disease results from infestation with the worm *TRICHINELLA SPIRALIS*, which is acquired by eating undercooked meat (usually pork).

Tumours

Various forms of tumour may originate in the muscles. Such tumours, called primary muscle tumours, may or may not be cancerous. Noncancerous tumours are called *myomas*; those affecting smooth muscle are called *leiomyomas*, and those developing in skeletal muscle are called *rhabdomyomas*. Myomas of the uterus (see *fibroids*) are among the most common of all tumours. Cancerous tumours, called *myosarcomas*, are very rare; they include *rhabdomyosarcomas*, which are cancers of the skeletal muscle.

Secondary tumours, which spread from a primary site of cancer elsewhere in the body, very rarely involve muscle.

Hormonal and metabolic disorders

Muscle contraction depends on the maintenance of proper levels of sodium, potassium, and calcium in and around muscle cells. Any alteration in the concentration of these substances affects muscle function. For example, a severe drop in the level of potassium (*hypokalaemia*) causes profound muscle weakness and may stop the heart. A drop in blood calcium (*hypocalcaemia*) causes increased excitability of muscles and, occasionally, *muscle spasms*.

Thyroid disease is often associated with muscle disorders, the most common of which is swelling of the small muscles

that move the eyes, causing a bulging eyeball (see *exophthalmos*). Adrenal failure (see *Addison's disease*) causes general muscle weakness.

Poisons and drugs

Several toxic substances can damage muscle tissue. Alcohol can cause damage following a prolonged drinking bout. Other substances that may cause muscle damage include the drugs *chloroquine* and *vincristine*.

Genetic disorders

These disorders include the various forms of *muscular dystrophy*, which cause progressive weakness and disability. Some types appear at birth, some in infancy, and some develop as late as the fifth or sixth decade. *Cardiomyopathy* (disease of the heart muscle) is also inherited in some cases.

Autoimmune disorders

Myasthenia gravis is a disorder involving the transmission of nerve impulses to muscles; it usually begins with drooping of the eyelids and double vision. Other autoimmune diseases that may affect the muscles are *lupus erythematosus*, *rheumatoid arthritis*, *systemic sclerosis*, *sarcoidosis*, and *dermatomyositis*.

INVESTIGATION

Muscle disorders are investigated by EMG (electromyography), which measures the response of muscles to electrical impulses, and by biopsy (removal of a sample of tissue for analysis). In addition, blood tests may be used to detect abnormal levels of muscle enzymes.

muscle wastingSee *muscular atrophy*.**muscular atrophy**

Weakness and shrinking of muscle tissue. Muscular atrophy may have many possible causes, including injury, starvation, loss of function in a body part, degeneration of muscle cells, and disorders of the nerves supplying muscles.

Muscles can atrophy rapidly if a body part is not used and if no measures are taken to prevent the problem. In a broken leg, for example, muscle loss may be visible after only a week. The muscle fibres are not lost, however; they can return to normal if the muscle is stimulated and used.

muscular dystrophy

A group of rare inherited muscle disorders that cause slow, progressive wasting of muscle fibres. This degeneration may lead to disability and death.

TYPES AND SYMPTOMS

The most common and severe form of muscular dystrophy is Duchenne muscular dystrophy. This is caused by a recessive gene carried on the X chromosome (see *sex-linked inheritance*). Boys only have one X chromosome, so if they inherit a copy of the defective gene from their mother they develop the disorder. Girls (with two X chromosomes) are not affected but become carriers of the defective gene.

Affected boys walk with a waddle, find climbing difficult, and may have curvature of the spine. The disorder progresses rapidly: the ability to walk is lost by the age of 12, and few boys survive beyond the teenage years.

Becker's muscular dystrophy starts later in childhood and progresses at a slower rate. Myotonic dystrophy affects the muscles of the hands, face, neck, and feet, and causes *learning difficulties*. Limb-girdle muscular dystrophy mainly affects muscles in the hips and shoulders, and facioscapulohumeral muscular dystrophy affects muscles in the upper arms, shoulder girdle, and face. In this last form, severe disability is rare.

DIAGNOSIS

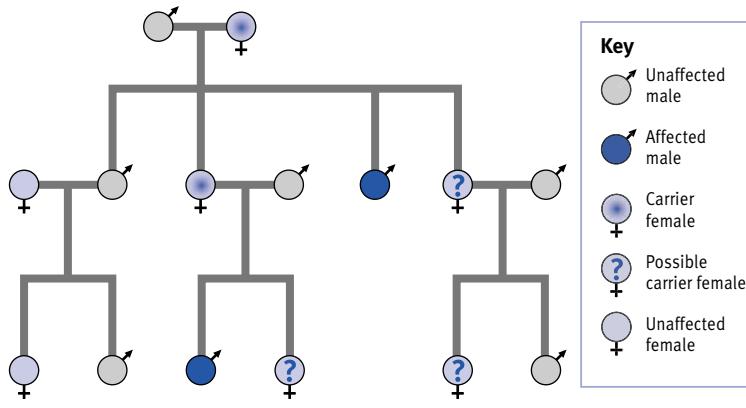

A diagnosis for Duchenne muscular dystrophy can be made with gene testing before symptoms develop. Once muscle weakness has developed, other tests may be used, including measurement of muscle *enzymes* and an *EMG*.

TREATMENT

There is no cure, and *physiotherapy* is the main treatment. Remaining as active

DUCHENNE MUSCULAR DYSTROPHY: A TYPICAL FAMILY TREE

Affected males always inherit the gene for the disorder from their mothers, who are carriers of the gene but are themselves unaffected. About half the sons of carriers are affected; the other sons are neither affected nor carriers. The daughters of carriers have a 50 per cent chance of being carriers themselves. Complex blood tests provide the only means of knowing whether or not a certain daughter (or granddaughter) is a muscular dystrophy carrier.

**TYPES OF MUSCULAR DYSTROPHY****Duchenne muscular dystrophy**

In this type, the child is slow in learning to sit up and walk, and does so much later than normal. The condition is rarely diagnosed before the age of three, but progresses rapidly. Affected children tend to walk with a waddle and have difficulty climbing stairs. In getting up from the floor, the child "climbs up his legs", pushing his hands against his ankles, knees, and thighs.

Sometimes there is curvature of the spine. Despite their weakness, the muscles (especially those in the calves) appear bulky; this is because wasted muscle is replaced by fat. By about the age of 12, affected children are no longer able to walk, few survive beyond their teenage years, usually dying from a chest infection or heart failure. Affected boys often have below-average intelligence.

Becker's muscular dystrophy

This type produces the same symptoms as the Duchenne type, but starts later in childhood and progresses much

more slowly. Patients often reach the age of 50. Both types of dystrophy have sex-linked inheritance.

Myotonic dystrophy

This form affects muscles of the face, hands, and feet. Infants are floppy and slow to develop. The main feature is that the muscles contract strongly but do not relax easily. Myotonic

dystrophy is associated with cataracts in middle age, baldness, mental retardation, and endocrine problems. The condition has an autosomal dominant pattern of inheritance.

Limb-girdle muscular dystrophy

This type takes different forms. It starts in late childhood or early adult life, and progression is slow. The muscles of the hips and shoulders are mainly

affected. Other nerve and muscle conditions must be eliminated before this form of dystrophy can be diagnosed confidently.

Facioscapulohumeral muscular dystrophy

This form usually appears first between the ages of 10 and 40; it affects only the muscle so the upper arms, shoulder girdle, and face. It is inherited in an

autosomal dominant pattern. In this form of muscular dystrophy, progression of the weakness is slow, and severe disability is rare.

as possible keeps healthy muscles in good condition. Surgery to the heel *tendons* may aid walking in some cases.

OUTLOOK

The long-term outlook depends on the particular form. Families in which a child or adult has developed any form of muscular dystrophy may wish to consider *genetic counselling*.

muscular system

The muscles of the body that are attached to the *skeleton*. These muscles are responsible for voluntary movement, and also support and stabilize the skeleton. In most cases, a muscle attaches to a bone (usually by means of a *tendon*) and crosses over a *joint* to attach to another bone.

FUNCTION

Muscles produce movement by contracting and shortening to pull on the bone to which they are attached. They can only pull, not push, and are therefore arranged so that the pull of one muscle or group of muscles is opposed to another, enabling a movement to be reversed. Although most actions of the skeletal muscles are under conscious control, *reflex* movements can occur in response to certain stimuli.

TYPES OF MUSCLE

There are more than 600 muscles in the body, classified according to the type of movement they produce. An extensor opens out a joint, a flexor closes it; an adductor draws a part of the body inwards, an abductor moves it outwards; a levator raises it, a depressor lowers it; and constrictor or sphincter muscles surround and close orifices.

musculoskeletal

Relating to muscle and/or bone. The musculoskeletal system is the skeleton and the muscles attached to it.

musculoskeletal pain

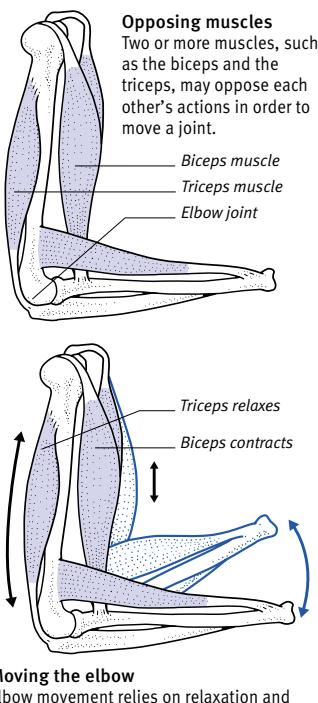

Pain in the bones, joints, muscles, or other parts of the musculoskeletal system. Such pain may have a wide variety of causes, from fever and temporary injuries to soft tissues (such as muscle or tendon *strains* and ligament *sprains*) to severe diseases such as *arthritis*.

mushroom poisoning

There are numerous species of poisonous mushrooms and toadstools in the UK, but many have an unpleasant taste and are therefore unlikely to be eaten in sufficient amounts to cause problems.

MUSCLE MOVEMENT

To move a particular part of the body, a skeletal muscle contracts. It shortens and draws together the bones to which it is attached.

DEATH CAP

Most fatal cases of mushroom poisoning in the UK are caused by *AMANITA PHALLOIDES* (death cap). This mushroom can be confused with the edible field mushroom, although it has white gills instead of pinkish-brown ones.

The death cap and some related species, such as *AMANITA VIROSA* (destroying angel), contain poisons called amatoxins, which attack cells in the liver, kidneys, and small intestine. Symptoms such as severe abdominal pain, vomiting, and diarrhoea usually develop 8 to 14 hours after eating the mushrooms. Later, there may be liver enlargement and *jaundice*, which may lead to death from *liver failure*. There is no antidote; treatment consists of supportive measures only. For people who survive, recovery usually occurs after about a week.

FLY AGARIC

AMANITA MUSCARIA (fly agaric) has a red cap flecked with white. Symptoms of

poisoning appear within 20 minutes to two hours and may include drowsiness, visual disturbances, *delirium*, muscle tremors, nausea, and vomiting. This type of poisoning (and other types that have rapidly developing symptoms) is treated with gastric lavage (see *lavage, gastric*) and activated charcoal. Recovery usually occurs within 24 hours.

MAGIC MUSHROOMS

“Magic” mushrooms contain the hallucinogen *psilocybin*. They may also cause high fever in children. The effects usually last for four to six hours.

mutagen

Any agent that increases the rate of *mutation* (genetic changes) in cells. The main mutagens are ionizing *radiation* (see *radiation hazards*), some chemicals, and certain illnesses.

mutation

A change in a cell's *DNA*. Many mutations are harmless; however, some are harmful, giving rise to *cancers*, *birth defects*, and hereditary diseases. Very rarely, a mutation may be beneficial.

CAUSES

A mutation results from a fault in the replication of DNA when a cell divides. A daughter cell inherits some faulty DNA, and the fault is copied each time the new cell divides, creating a cell population containing the altered DNA.

Some mutations occur by chance. Any agent that makes mutations more likely is called a *mutagen*.

TYPES

There are several types of mutation. Point mutations affect only one *gene* and may lead to the production of defective *enzymes* or other proteins. In other mutations, *chromosomes* (or parts of them) are deleted, added, or rearranged. This type may produce greater disruptive effects than point mutations.

EFFECTS

If a mutated cell is a somatic (body) cell, it can, at worst, multiply to form a group of abnormal cells. These cells often die out, are destroyed by the body's *immune system*, or have only a minor effect. Sometimes, however, they may become a *tumour*.

A mutation in a *germ cell* (immature egg or sperm) may be passed on to a child, who then has the mutation in all of his or her cells. This may cause an obvious birth defect or an abnormality in body chemistry. The mutation may also be passed down to the child's

descendants. *Genetic disorders* (such as *haemophilia* and *achondroplasia*) stem from point mutations that occurred in the germ cell of a parent, grandparent, or more distant ancestor. *Chromosomal abnormalities* (such as *Down's syndrome*) are generally due to mutations in the formation of parental eggs or sperm.

mutism

Refusal or inability to speak. Mutism may be a symptom of profound congenital *deafness*, severe *manic-depressive illness*, catatonic *schizophrenia*, or a rare form of *conversion disorder*. The term "mutism" may also be used of a religious vow of silence.

Elective mutism is a rare childhood disorder (usually starting before age five) in which a child can speak properly but refuses to do so most of the time.

Akinetic mutism is a state of passivity caused by some brain tumours or by *hydrocephalus* (fluid surrounding the brain). Affected people are incontinent, require feeding, and respond at most with a whispered "yes" or "no".

myalgia

Medical term for *muscle* pain.

myalgic encephalomyelitis

Also known as ME, an alternative name for *chronic fatigue syndrome*.

myasthenia gravis

A rare disorder in which the muscles become weak and tire easily. The muscles of the eyes, face, throat, and limbs are most commonly affected.

CAUSE

Myasthenia gravis is an *autoimmune disorder*. In many cases, abnormalities in the thymus gland are present, and in some cases a *thymoma* (tumour of the thymus gland) is found. Women are affected more often than men.

SYMPOTMS

The disease is extremely variable in its effects. In most cases, it causes drooping eyelids, double vision, a blank facial expression, and a weak, hoarse, nasal voice that is hesitant and becomes slurred during extended conversation. The arm and leg muscles may also be affected. In severe cases, the respiratory muscles may become weakened, causing breathing difficulty.

DIAGNOSIS

One common test is injection of the drug edrophonium into a vein, which temporarily restores power to the weak muscles.

Blood tests and *EMG* are also sometimes used. In some cases, *CT scanning* or *MRI* may be performed to detect a thymoma.

TREATMENT AND OUTLOOK

Drugs that facilitate the transmission of nerve impulses can often restore a person's condition to near normal. In some people, the condition may improve, and is sometimes cured, with thymectomy (removal of the thymus gland). In more severe cases, regular *plasmapheresis* may be carried out. *Corticosteroid drugs* may also be given to suppress immune system activity. In a few people, however, *paralysis* of the throat and respiratory muscles may lead to death.

mycetoma

An uncommon tropical infection affecting skin and bone. Mycetoma is caused by *fungi* or by bacteria called actinomycetes. It usually occurs on one limb, causing a hard swelling and a discharge of pus. Infections caused by actinomycetes are treated with *antibiotic drugs*. Surgical removal of diseased tissue may be necessary for a fungal infection.

mycobacterial infections

Diseases caused by bacteria from the *MYCOBACTERIUM* group (see *tuberculosis*; *Hansen's disease*). An increasing range of mycobacterial infections is recognized in *immunocompromised* people, such as those with *AIDS*.

mycology

The study of *fungi*.

mycophenolate mofetil

An *immunosuppressant drug* used after organ transplants to reduce the risk of the body rejecting the organ.

mycoplasma

Any of a group of *bacteria* that are the smallest type capable of free existence. Mycoplasmas are about the same size as *viruses* but, unlike viruses, are capable of reproducing outside living cells. One species, *MYCOPLASMA PNEUMONIAE*, causes primary atypical *pneumonia*.

mycosis

Any disease caused by a fungus. (See *fungal infection*; *fungi*.)

mycosis fungoïdes

A rare type of *lymphoma* that primarily affects the skin of the buttocks, back, or shoulders. The cause is unknown. In its mildest form, mycosis fungoïdes

produces a non-itchy, red, scaly rash, which may spread slowly or remain unaltered for many years. In more severe forms, thickened patches of skin, *ulcers*, and enlarged *lymph nodes* may develop.

Diagnosis is confirmed with a *skin biopsy*. Treatment may include *PUVA*, *radiotherapy*, nitrogen mustard, *anticancer drugs*, and *corticosteroid drugs*.

mydriasis

Dilation (widening) of the pupil of the eye. Mydriasis occurs in the dark; with emotional arousal; after the use of certain eye-drops (for example those containing *atropine*); and also after drinking alcohol.

mydriatic drugs

A group of drugs used to treat *uveitis* and to dilate the pupil during examination of the inside of the eye and for surgery. Mydriatics work by relaxing the circular muscles of the *iris*, causing the pupil to dilate. Common mydriatic drugs include *tropicamide*, *cyclopentolate*, *homatropine*, and *phenylephrine*. (See also *cycloplegia*; *miotic drugs*.)

myectomy

Surgical removal of part or all of a muscle. Myectomy may be performed to treat severely injured and infected muscles or to remove a *fibroid* (an operation called a *myomectomy*) from the muscular wall of the uterus.

myel-

A prefix denoting a relationship to bone marrow (as in *multiple myeloma*) or to the spinal cord (as in *myelitis*). The prefix "myelo-" has the same meaning.

myelin

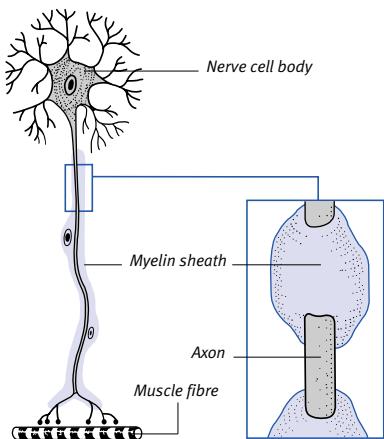

The fatty material made of *lipid* (fat) and protein that forms a protective sheath around some nerve fibres and increases the efficiency of nerve impulse transmission. (See also *demyelination*.)

myelitis

Inflammation of the *spinal cord*. It is often caused by a viral infection. In transverse myelitis, the spinal cord becomes inflamed around the middle of the back. Common symptoms are back pain and gradual *paralysis* of the legs; in some cases, the paralysis becomes permanent. (See also *poliomyelitis*.)

myelocele

Another name for *myelomeningocele*.

**The myelin nerve sheath**

The axon is the conducting fibre of a nerve. To transmit impulses more efficiently, some nerve axons have a myelin sheath.

myelofibrosis

An alternative term for *myelosclerosis*.

myelography

X-ray examination of the spinal cord, nerves, and other tissues within the spinal canal after injection of a contrast medium (a substance that is opaque to X-rays). The procedure has now been replaced by *CT scanning* and *MRI*.

myeloid leukaemia

See *leukaemia, chronic myeloid*.

myeloma, multiple

See *multiple myeloma*.

myelomatosis

See *multiple myeloma*.

myelomeningocele

A congenital abnormality seen in *spina bifida*. An affected baby has a raw swelling over the spine, containing an exposed, malformed section of the *spinal cord* and its *meninges* (protective membranes).

myopathy

A disease or disorder of the *spinal cord*.

myeloproliferative disorders

Conditions characterized by the abnormal proliferation of one or more blood cell groups within the *bone marrow*. (See *leukaemia; polycythaemia*.)

myosclerosis

An increase of fibrous tissue within the *bone marrow* (also called *myelofibrosis*), which interferes with the ability of the

marrow to produce blood cells. Myosclerosis may be primary (with no obvious cause) or secondary (resulting from another bone marrow disease).

The main symptoms of myosclerosis are those of *anaemia*. In addition, enlargement of the *spleen*, night sweats, loss of appetite, and weight loss commonly occur. In secondary myosclerosis, the underlying disease may cause other symptoms.

Treatment of primary myosclerosis includes *blood transfusions* to relieve the symptoms. A few people, however, may develop acute *leukaemia*. Treatment of secondary myosclerosis depends on the underlying cause.

myiasis

Infestation by fly larvae; the condition is primarily restricted to tropical areas. In Africa, the tumbu fly lays eggs on wet clothing left outside; the larvae hatch and penetrate the skin to cause swellings like boils. Other flies lay eggs in open wounds, on the skin, or in the ears or nose. Sometimes, larvae penetrate deeply into the tissues. Intestinal infestation can occur after eating food that has been contaminated.

Myiasis of the skin is treated by applying drops of oil to the swelling. The larva comes to the surface, where it can be carefully removed. In deeper tissues, surgery may be required. Intestinal myiasis is treated with a *laxative*. Preventive measures include keeping flies away from food, keeping open wounds covered, and ironing clothes that have been dried outdoors.

myo-

A prefix denoting a relationship to muscle (as in *myocarditis*).

myocardial infarction

Sudden death of part of the *heart* muscle due to a blockage in the blood supply to that area of the heart. The disorder is popularly known as a *heart attack*. Myocardial infarction is the most common cause of death in the UK.

CAUSES

The usual cause is *atherosclerosis* of the coronary arteries. In this condition, plaques (fatty deposits) develop on the artery walls; a clot may then form over a plaque and block an artery (see *Features of myocardial infarction* box, overleaf).

Men are more likely to have a heart attack than women, and smokers are at greater risk than nonsmokers. Other

risk factors include increased age, an unhealthy diet, obesity, and disorders such as *hypertension* (high blood pressure) and *diabetes mellitus*.

SYMPTOMS

There is a sudden, crushing pain that starts in the centre of the chest and may spread into the arms or up to the jaw. Breathlessness, restlessness, clammy skin, and nausea and/or vomiting may also occur. In some cases, the first symptom is sudden collapse and loss of consciousness. A few people have only mild symptoms or have none at all; this type of heart attack is known as a *silent myocardial infarct*.

The damage to the heart tissue may cause immediate *heart failure* (reduced pumping efficiency) or *arrhythmias* (irregular heartbeat). *Ventricular fibrillation* is the most dangerous form of arrhythmia; it prevents the heart from pumping effectively and, if untreated, is fatal within a few minutes.

DIAGNOSIS

Diagnosis is made from the patient's history, together with an *ECG*. Tests are also carried out to measure levels of certain *enzymes*, and of a protein called *troponin*, which are released into the blood from damaged heart muscle.

TREATMENT

A myocardial infarction is a medical emergency. A person who suspects that he or she is having a heart attack should chew an *aspirin* tablet, which will help to dissolve the clot in the artery. He or she should then be taken to hospital as soon as possible.

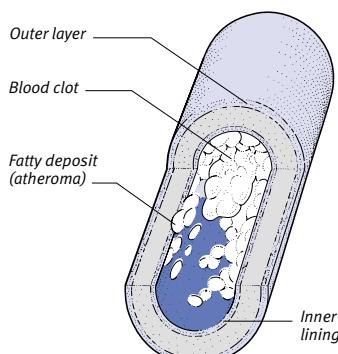

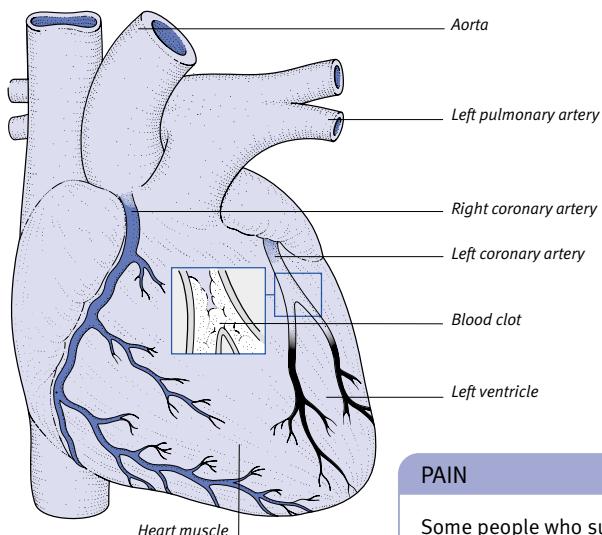

Initially, *oxygen* and *diamorphine* are given in order to relieve the pain and intravenous *thrombolytic drugs* may be given to dissolve the blood clot (unless there is a risk that the drugs will cause excessive bleeding).

Afterwards, patients are monitored in an intensive care or coronary care unit so that any complications, such as *heart failure*, *arrhythmias* (see *arrhythmia, cardiac*), or rupture of a heart valve can be detected and treated as early as possible. If thrombolytic drugs have failed to restore blood flow in the affected artery, surgery may be considered (see *angioplasty, balloon; coronary artery bypass graft*).

On leaving hospital, patients may be advised to take aspirin, *beta-blocker drugs* to protect the heart muscle, and *statin* drugs to lower blood *cholesterol*. *ACE inhibitors* are also given to treat heart failure or impaired function of the left ventricle. In addition, people will

FEATURES OF MYOCARDIAL INFARCTION

Myocardial infarction (heart attack), in which an area of heart muscle is deprived of blood and suffers tissue death as a result, causes severe pain and can be fatal. Most cases result from atherosclerosis of the coronary arteries, a condition in which plaques (patches of fatty deposits) collect inside the arteries.

Atherosclerosis
Plaques of atheroma develop on the inner lining of the arteries, restricting the blood flow. The plaques develop a fibrous covering, which may rupture or become roughened. Platelets (tiny blood cells) may then stick to the plaque and trigger the formation of a blood clot. The clot may completely block the artery, causing a sudden stoppage of blood flow to the heart.

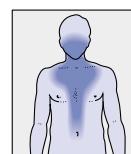

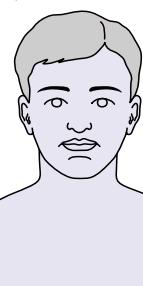

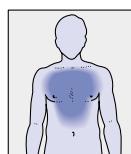

RISK FACTORS

- Uncontrollable factors include family history of heart disease, increasing age, and being male.
- Cigarette smokers have a substantially increased risk of dying of myocardial infarction.
- High blood pressure is a major risk factor, and the risk increases the higher the pressure.
- The risk of atherosclerosis and coronary artery disease increases dramatically in those who are more than 30 per cent overweight.
- A raised blood cholesterol level (for which there may be a genetic tendency) increases the risk. A high-fat diet is also a factor.
- Physical inactivity is also a major risk factor.

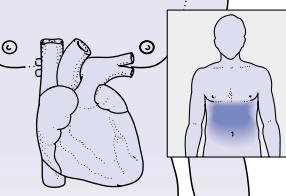

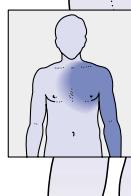

PAIN

Some people who suffer myocardial infarction have a history of angina pectoris, in which blood flow through the coronary arteries is impaired but the resulting chest pain is relieved by rest. The pain of infarction usually comes on suddenly, and ranges from a tight ache to intense, crushing agony. It lasts for longer than 10 minutes, and is not relieved by rest.

Central chest
A feeling of pressure in the central chest, ranging from mild to severe, occurs in almost every myocardial infarction that is due to coronary obstruction.

Jaw to back
In some cases, pain radiates up into the jaw and through to the back. Sometimes, it occurs only in these places.

Upper abdomen
More rarely, pain may be felt in the upper abdomen. If it occurs only here, it may be mistaken for another disorder.

undergo a *rehabilitation* programme to help them return to full activity and to increase awareness of risk factors.

myocardial ischaemia

An insufficient blood supply to the *heart* muscle. It is usually caused by narrowing or blockage of the coronary blood vessels (which supply the heart muscle), due to *atherosclerosis* (an accumulation of fatty

deposits on the walls of arteries). Myocardial ischaemia causes the heart muscle to be deprived of oxygen, and may give rise to problems such as *angina pectoris* and *myocardial infarction* (heart attack).

myocarditis

Inflammation of *heart* muscle, usually due to coxsackievirus infection. It is also a characteristic feature of *rheumatic fever*.

SYMPTOMS

There are often no symptoms. Rarely, there may be a serious disturbance of the heartbeat, breathlessness, chest pain, and *heart failure*. In severe cases of myocarditis, death may result from *cardiac arrest*.

DIAGNOSIS AND TREATMENT

Myocarditis may be suspected from the patient's history and from a physical

examination. An *ECG* will show characteristic abnormalities of the heartbeat. Diagnosis also involves *echocardiography* and *blood tests*.

There is no specific treatment. Bed rest is usually recommended and *corticosteroid drugs* may be prescribed.

myocardium

The middle of the three layers of muscle that make up the wall of the heart. The myocardium is composed of cardiac muscle. (See also *cardiomyopathy*; *myocardial infarction*; *myocardial ischaemia*; *myocarditis*.)

myoclonus

Rapid, uncontrollable jerking or spasm of one or more muscles, either at rest or during movement. Myoclonus may be associated with a muscular or nervous disorder, but it also occurs in healthy people; for example, when the limbs twitch before sleep.

myofascial pain syndrome

See *temporomandibular joint syndrome*.

myoglobin

An oxygen-carrying pigment found in muscles. Myoglobin consists of a combination of iron and protein. It stores oxygen, releasing it when it is needed by the muscles.

Myoglobin may be released into the urine, causing *myoglobinuria*. Slight myoglobinuria may result from prolonged exercise. Severe myoglobinuria is usually due to the release of myoglobin from a large area of damaged muscle, and may cause *kidney failure*.

myoma

A noncancerous muscle *tumour*. (See also *fibroid*.)

myomectomy

Surgical removal of a *myoma*. The term is also used to describe the surgical removal of *fibroids* from the uterus.

myometrium

The muscular wall of the *uterus*. It is composed of smooth *muscle* and lined with *endometrium*. The myometrium contracts strongly during *childbirth* in order to dilate the cervix and push the fetus (and the *placenta*) out of the uterus. It also undergoes much smaller contractions during menstrual periods, which help to expel blood and tissue (see *menstruation*).

myopathy

A disease of *muscle* that is not caused by disease of the nervous system. A myopathy may be an inherited disorder, such as *muscular dystrophy*; it may also be caused by chemical poisoning, a chronic disorder of the *immune system*, or a *metabolic disorder*.

myopia

An error of *refraction*, commonly called shortsightedness, in which distant objects appear blurred. It is caused by the eye being too long from front to back. As a result, images of distant objects are focused in front of the retina.

Myopia, which tends to be inherited, usually appears around puberty, increasing until the early 20s. If it starts in early childhood it may become severe. The condition is detected during a *vision test*. Treatment is with *concave glasses* (or *contact lenses*) or by *photorefractive keratectomy* or *LASIK*.

myosin

A major protein component of *muscle* fibres. Together with *actin*, it provides the mechanism for muscles to contract. The myosin molecules slide along the actin filaments in order to make the muscle fibres shorten.

myositis

Inflammation of *muscle* tissue, causing pain, tenderness, and weakness. Types include *myositis ossificans*, *polymyositis*, and *dermatomyositis*.

myositis ossificans

A *congenital* (present from birth) or *acquired* condition in which bone is deposited in muscles. The congenital form is rare. The first symptoms are painful swellings in the muscles, which gradually harden and extend until the affected child is encased in a rigid sheet. There is no treatment, and death results.

The acquired form may develop after a bone injury, especially around the elbow; it causes severe pain and a swelling that hardens. Treatment with *diathermy*, and gentle, active movements, may be helpful.

myotomy

A surgical procedure that involves cutting into a *muscle*.

myotonia

Inability of a *muscle* to relax after the need for contraction has passed. It is a

feature of *myotonic dystrophy*, a form of *muscular dystrophy*.

myringitis

Inflammation of the eardrum. Myringitis occurs in *otitis media*.

myringoplasty

Surgical closure of a perforation (hole) in the eardrum (see *eardrum, perforated*) by means of a tissue graft (see *grafting*).

myringotomy

A surgical opening made through the eardrum to allow drainage of the middle-ear cavity. It is usually performed to treat persistent *glue ear* in children. A *grommet* may be inserted into the eardrum at the same time.

myxoedema

A condition in which the skin and other body tissues (most noticeably in the face) thicken and coarsen. Myxoedema is usually due to *hypothyroidism*. The term "myxoedema" is sometimes used of adult hypothyroidism.

myxoma

A noncancerous, jellylike tumour composed of soft mucous material and loose fibrous strands. Myxomas usually occur singly, and may sometimes grow very large. They may develop under the skin, in the abdomen, or, very rarely, in the heart chambers. In this last case, thrombi (blood clots) may form, and the blood flow through the heart may be obstructed. Myxomas can usually be successfully removed by surgery.

myxovirus

One of a group of *RNA*-containing *viruses* that are responsible for various human and animal diseases. There are two families of myxovirus: the *paramyxovirus* and the *orthomyxovirus*.

N

nabilone

An *antiemetic drug* derived from *marijuana*. Nabilone is used to treat patients suffering from the nausea and vomiting caused by *anticancer drugs* that have not responded to other treatments.

nabothian cyst

A *cyst* (a small fluid-filled swelling or lump) that develops on the cervix (the neck) of the uterus when the ducts of a mucous gland become obstructed. A nabothian cyst, which is also known as a nabothian follicle, is harmless and requires no treatment.

NAD

The abbreviation for nicotinamide adenine dinucleotide, which is a coenzyme (an organic compound that plays an essential role in a reaction catalyzed by an *enzyme*) derived from *nicotinic acid*. NAD acts as a hydrogen acceptor (forming NADH) in the chemical process that produces energy within cells.

nadolol

A *beta-blocker drug* used to treat *hypertension* (high blood pressure), *angina pectoris* (chest pain due to impaired blood supply to the heart muscle), and certain types of *arrhythmia* (irregularity of the heartbeat). Nadolol is also used to control symptoms of *hyperthyroidism* (overactivity of the thyroid gland).

Possible side effects are typical of other beta-blocker drugs; they include a reduction in the patient's capacity for strenuous exercise and aggravation of any existing symptoms of lung disease and *peripheral vascular disease*.

Naegeli syndrome

A rare inherited condition that has its onset in the first few years of life. Symptoms include weblike skin *pigmentation*, diminished function of the sweat glands, hypodontia (fewer teeth than normal), *hyperkeratosis* (thickening of the outer layer of skin) affecting the palms and soles, and blistering. Naegeli syndrome

has an autosomal dominant pattern of inheritance (see *genetic disorders*) and affects both males and females.

naevus

A type of blemish on the skin. There are two main groups of naevus: pigmented naevi, which are caused by an abnormality in or overactivity of melanocytes (skin cells that produce the brown pigment *melanin*); and vascular naevi, which result from an abnormal collection of blood vessels near the surface of the skin.

PIGMENTED NAEVI

The most common type of pigmented naevus is a freckle, which is a small, flat, light-brown to dark-brown area that may occur on any part of the body exposed to the sun. The tendency to develop freckles on exposure to the sun is inherited; they are more common in people with fair skin and red hair. A *lentigo*, sometimes called an age spot or liver spot, is a light-brown spot similar to a freckle. These spots most commonly affect people over the age of 40 and appear both on covered and on sun-exposed areas of the body. *Café au lait spots* are another type of light-brown pigmented naevus.

Another common type of pigmented naevus is a mole, which is sometimes called a melanocytic naevus. Moles are brown to dark-brown in colour and usually measure less than 1 cm in diameter. Moles can form anywhere on the body and a tendency to develop them sometimes runs in families. Moles may appear soon after birth (see *birthmark*) or during childhood and early adolescence; almost all adults have between ten and 20 moles by the time they are 30. Most moles are noncancerous, but, rarely, a mole may undergo changes that make it cancerous (see *melanoma, malignant*). Red-brown naevi that occur in childhood are juvenile melanomas (see *melanoma, juvenile*).

Some naevi have a bluish coloration. Many black and Asian infants are born with blue-black spots on their lower backs (see *Mongolian blue spot*).

VASCULAR NAEVI

Port-wine stains and strawberry marks (see *haemangioma*) are vascular naevi. These types of naevi are usually present at birth. A port-wine stain is visible as an irregularly shaped red patch and may be distressing, especially if it affects the individual's face. The mark is usually permanent. Strawberry marks are common birthmarks and appear as raised, red swellings; they usually disappear by the time a child is about five years old.

A *spider naevus* is another example of a vascular naevus. These are common in children and pregnant women.

TREATMENT

Most naevi are harmless. If, however, a naevus suddenly appears, grows, bleeds, or changes colour, medical advice should be sought immediately to exclude *skin cancer*. Permanent birthmarks can be treated with *laser treatment*.

nail

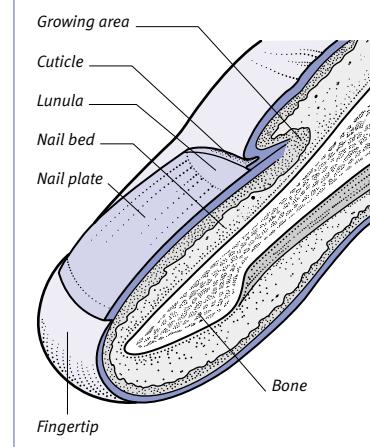

A hard, curved plate, found on each of the fingers and toes, composed of *keratin* (a tough protein that is also the main constituent of skin and hair). Nails grow from an area called the nail bed. At the base of each nail, a half-moon shape (the lunula) is crossed by a flap of skin known as the cuticle. The surrounding skin is the nail fold. A fingernail takes about six months to grow from its base to its tip, although there are seasonal growth variations; and toenails take twice as long.

DISORDERS

The nails are susceptible to damage through injury, usually as a result of crushing or pressure on the nail. Nails may also be damaged by bacterial or fungal infections, especially *tinea* and *candidiasis* (thrush). In *paronychia*, it is the nail folds that are infected. Sometimes the nails can become abnormally

ANATOMY OF A NAIL

The nail bed is the area from which the nail grows. At the base of each nail, a half-moon shape, the lunula, is crossed by a flap of skin, the cuticle. The skin that surrounds the nail is the nail fold. The nail is composed of keratin, a tough protein also found in skin and hair.

N

thick and curved, a condition known as *onychogryphosis*. This mainly affects the big toes of elderly people.

The nails may also be affected by skin diseases. Examples of the effects of skin disease on the nails include pitting of the nails in *alopecia areata*; pitting and separation of the nail from its bed in *psoriasis*; and scarring of the nails in *lichen planus*. Certain nail abnormalities may be signs of more generalized illness. Brittle, ridged, concave nails are a sign of iron-deficiency anaemia (see *anaemia, iron-deficiency*) and fibrous growths on the nail are a sign of *tuberous sclerosis*. Splinterlike black marks develop beneath the nails in particular *bleeding disorders*, indicating bleeding into the nail bed.

Abnormalities of nail colour may also indicate disease. A greenish discolouration may be caused by a bacterial infection under the nail; blue nails may be a sign of respiratory or heart disease; and yellow nails that are hard and curved develop in the lung disorder *bronchiectasis* and in *lymphoedema* (an accumulation of lymph in the tissues). Nails may also become discoloured by smoking (due to nicotine) and by the use of nail polish.

Treatment of nail disorders can be difficult. Creams and lotions seldom penetrate sufficiently; oral medication may take months to be effective.

nail-biting

A common habit in children during their early years at school. Most children grow out of it, although nail-biting sometimes continues as a nervous habit in adolescents and adults. Persistent nail-biting may make the nails unsightly and cause pain and, sometimes, bleeding.

Various preparations with an unpleasant taste can be painted on the nails as a preventive measure.

nalidixic acid

An *antibiotic drug* used in the prevention and/or treatment of *urinary tract infections*. Possible side effects of nalidixic acid include nausea, vomiting, increased sensitivity to sunlight, blurred vision, drowsiness, and dizziness.

naloxone

An opioid antagonist (a drug that counteracts the effects of opioid *analgesic drugs*). Naloxone reverses the breathing difficulty caused by high doses of opioid drugs given during surgery. It may also be given to people who have taken an

overdose of an opioid drug. Naloxone may be given to newborn babies who are affected by opioid drugs used to relieve the mother's pain during childbirth.

Possible side effects of naloxone include nausea, vomiting, abdominal cramps, diarrhoea, and tremors.

naltrexone

An opioid antagonist (a drug that counteracts the effects of opioid *analgesic drugs*) that is used in the treatment of opioid addiction. Naltrexone works by blocking the action of opioid drugs and precipitating withdrawal symptoms in opioid-dependent people. The drug may be given to former addicts to help to prevent relapse. (See also *drug abuse; drug dependence*.)

nandrolone

An anabolic steroid (see *steroids, anabolic*) sometimes used in the treatment of certain types of aplastic anaemia (see *anaemia, aplastic*). Nandrolone is also used illegally by some body builders and athletes to increase their protein production and, therefore, muscle bulk.

Possible side effects of nandrolone include swollen ankles, nausea and vomiting, and *jaundice* (yellowing of the skin and the whites of the eyes). Nandrolone may cause irregular menstruation and abnormal hair growth, in women.

nappy rash

An inflammatory skin condition common in babies, causing soreness and a red rash in the skin covered by a nappy.

CAUSES AND SYMPTOMS

Nappy rash is most commonly caused by urine or faeces irritating the skin. It usually occurs only where the skin and the soiled nappy have been in direct contact; it does not spread to creases in the baby's skin. Nappy rash becomes worse if the baby's nappy is not changed frequently or if the nappy area is not cleaned thoroughly. Perfumed skin products and some washing powders used to clean fabric nappies can also result in a rash.

Nappy rash may also be caused by a fungal infection of the skin, such as *candidiasis* (thrush), or, less commonly, by a bacterial infection, such as *impetigo*. A rash caused by infection affects the whole nappy area, including the creases in the baby's skin.

Discomfort from the rash may make a baby irritable. A severe rash may progress to blistering.

TREATMENT

If nappies are changed frequently and the affected area is regularly cleaned and covered in a barrier cream (such as zinc and castor oil cream), nappy rash generally clears up within a few days. In more severe cases, an ointment containing a mild *corticosteroid drug* may be prescribed to suppress the inflammation. If the area has become infected, oral or topical *antibiotic drugs* or *antifungal drugs* may also be given.

naproxen

A *nonsteroidal anti-inflammatory drug* (NSAID) that is used to relieve pain in the joints and stiffness in *arthritis* (including juvenile arthritis). Naproxen is also prescribed to speed recovery following injury to soft tissues, such as muscles or ligaments.

Side effects of naproxen may include nausea, abdominal pain, and *peptic ulcer*.

naratriptan

A *serotonin agonist* drug used in the treatment of acute attacks of *migraine*.

narcissism

Intense self-love. A narcissistic personality disorder is characterized by an exaggerated sense of self-importance, constant need for attention or praise, inability to cope with criticism or defeat, and poor relationships with other people. People with a narcissistic personality believe themselves to be unique, special, and superior to others; in addition, they may lack concern for the wellbeing or problems of others.

narcolepsy

A *sleep* disorder characterized by chronic daytime drowsiness with recurrent episodes of sleep occurring throughout the day. The exact cause of narcolepsy is unknown, although it can run in families. The condition usually develops before the age of 20.

SYMPTOMS

People who suffer from narcolepsy tend to fall asleep at any time of the day, often when they are carrying out a monotonous task. Sleep may occur at inappropriate times, such as while eating. Narcoleptic attacks may last from a few seconds to more than an hour. In narcolepsy, the REM (rapid eye movement) state of sleep is entered abnormally rapidly. Affected people can be awakened easily but may fall asleep again a short time afterwards.

Some people with narcolepsy have vivid hallucinations just before falling asleep. Others find that they are unable to move while they are falling asleep or waking up (see *sleep paralysis*). About three in four people with narcolepsy also have cataplexy, in which there is a temporary loss of strength in the limbs that causes the person to fall to the ground. Cataplexy is sometimes triggered by an emotional response, such as fear or laughter.

TREATMENT AND OUTLOOK

Treatment of narcolepsy usually involves regular naps, along with *stimulant drugs* to control drowsiness and *antidepressant drugs* to suppress cataplexy.

Although narcolepsy is usually a life-long condition, in some cases there is spontaneous improvement over time.

narcosis

A state of stupor, usually caused by an opioid *analgesic drug* or other chemical. Narcosis resembles sleep, being marked by reduced awareness and diminished ability to respond to external stimulation. However, unlike someone who is sleeping, a person in narcosis cannot be roused completely.

narcotic drugs

The former name for *opioid drugs*. (See also *analgesic drugs*.)

N

nasal congestion

Partial blockage of the nasal passage by the swelling of the *mucous membrane* that lines the *nose*. Nasal congestion is sometimes accompanied by the accumulation of thick nasal mucus, which further impedes breathing. Nasal congestion produces the feeling of a stuffy, "full" nose. There is a frequent desire to blow the nose, but blowing usually has little effect on the congestion.

CAUSES

Nasal congestion is a symptom of the common cold (see *cold, common*) and hay fever (see *rhinitis, allergic*). In these conditions, the swelling is due to inflammation of the membrane lining the inside of the nose. The swelling may become persistent in disorders such as chronic *sinusitis* or *nasal polyps*. The congestion may also be caused by certain drugs, such as *methyldopa* (an *antihypertensive drug*).

TREATMENT

Placing the head over a basin of hot water, possibly containing aromatic oils such as menthol or eucalyptus, and inhaling the steam for several minutes can help loosen the mucus.

Decongestant drugs that are taken as drops and sprays should be used sparingly, but tablets and syrups may be recommended for long-term use. Persistent nasal congestion should be investigated by a doctor.

nasal discharge

The emission of fluid from the *nose*. Nasal discharge is commonly caused by inflammation of the *mucous membrane* lining the nose and is often accompanied by *nasal congestion*.

A discharge of mucus may indicate hay fever (see *rhinitis, allergic*), a cold (see *cold, common*), or an infection that has spread from the nearby sinuses (see *sinusitis*). A persistent runny discharge may be an early indication of a tumour (see *nasopharynx, cancer of*).

Bleeding from the nose (see *nosebleed*) is usually caused by injury or by a foreign body in the nose. In rare cases, bleeding from the nose may be a sign of an underlying *bleeding disorder* or a tumour. A discharge of cerebrospinal fluid from the nose may follow a fracture at the base of the skull (see *skull, fracture of*).

nasal obstruction

Blockage of the nasal passage on one or both sides of the *nose*, which interferes with breathing. The most common cause is inflammation of the *mucous membrane* lining the passage (see *nasal congestion*). Other causes include deviation of the *nasal septum*; *nasal polyps*; a *haematoma* (a collection of clotted blood), which is usually caused by injury; and, rarely, a cancerous tumour. In children, enlargement of the *adenoids* is a common cause of nasal obstruction.

nasal polyp

A growth in the lining of the *nose*, usually attached by a small stalk. Large or numerous nasal polyps may cause *nasal obstruction*, a runny nose, and an impaired sense of smell.

CAUSES

The exact cause of nasal polyps is not known. However, they are more common in people with *asthma* or *rhinitis* (a condition in which the membrane that lines the nose and throat becomes inflamed). Although nasal polyps rarely occur in children, they do sometimes develop in those children who have the inherited condition *cystic fibrosis*.

DIAGNOSIS

Nasal polyps are diagnosed by physical examination and sometimes also by

endoscopy (inspection and examination of the nasal cavity using a viewing instrument). Most nasal polyps are non-cancerous; however, a *biopsy* (removal of a small sample of tissue for microscopic analysis) may be performed to exclude the possibility of cancer.

TREATMENT

Nasal polyps do not need treatment unless they are interfering with breathing, are cancerous, or are causing other symptoms. Small nasal polyps may be treated by using a corticosteroid nasal spray (see *corticosteroid drugs*), which shrinks the polyps over a few weeks. Larger or cancerous polyps may be removed during an endoscopic procedure or by surgery. In certain people, polyps may recur after treatment.

nasal septum

The dividing partition in the *nose*. The nasal septum consists of cartilage (connective tissue formed of collagen) at the front and bone at the rear, both of which are covered by *mucous membrane*.

DISORDERS

A deviated septum (twisting of the septum to one side) may be present from birth or caused by injury. The condition is rarely troublesome, but surgery may be needed if breathing is obstructed.

Injury may also lead to formation of a *haematoma* (a collection of clotted blood) between the cartilage of the septum and the wall of one of the nasal cavities. A haematoma may obstruct breathing and may become infected, causing an *abscess* (collection of pus) that may require surgical drainage. Occasionally, an abscess develops on a child's septum without prior injury.

Rarely, a hole may be eroded in the nasal septum by *tuberculosis*, *syphilis*, *Wegener's granulomatosis*, or as a result of snorting *cocaine*.

Naseptin

A brand name for a combination of chlorhexidine (an *antiseptic* for the skin) with *neomycin* (an *antibiotic drug*). Naseptin cream is used to eliminate organisms, such as staphylococci, from the inside of the nostrils.

nasogastric tube

A narrow plastic tube that is passed through the nose, down the oesophagus (gullet), and into the stomach.

WHY IT IS USED

Nasogastric tubes are commonly used to suck or drain digestive juices from

the stomach when there is a blockage in the intestine (such as in *pyloric stenosis*) or it is not working properly (as may occur after an abdominal operation). A nasogastric tube is also used to give liquid nourishment to patients who cannot eat (see *feeding, artificial*), to obtain specimens of stomach secretions for examination, and to wash out the stomach after a drug overdose or after swallowing poison (see *lavage, gastric*).

HOW IT IS USED

Inserting the tube is a quick, simple procedure that causes little discomfort and does not require an anaesthetic. After it has been lubricated, the tube is passed into one nostril and then, while the patient is swallowing, slid down the throat and into the stomach. To ensure that the tube is in the stomach, a sample of fluid is withdrawn through a syringe and may be tested for acidity. The stomach contents are then either allowed to drain or sucked out through a syringe or a suction device. Fluids for lavage or feeding may be introduced through a funnel. If the tube is to be left in place for some time, the protruding end is taped to the patient's face.

nasolacrimal duct

A channel that drains tears into the nose. The nasolacrimal duct forms part of the *lacrimal apparatus*.

nasopharynx

The passage that connects the nasal cavity behind the *nose* to the top of the throat behind the *soft palate*. The nasopharynx is part of the respiratory tract and forms the upper section of the *pharynx*. During swallowing, the nasopharynx is sealed off by the soft palate pressing against the back of the throat, thereby preventing food from entering.

The nasopharynx contains the lower openings of the *eustachian tubes* (passages connecting the back of the nose to the middle ear). In children, it also contains the *adenoids*, which can enlarge to block the nasopharynx, forcing the child to breathe through the mouth.

nasopharynx, cancer of

A cancerous tumour that originates in the *nasopharynx* (the uppermost part of the throat, behind the nose) and usually spreads to the nasal cavity, nasal sinuses, base of the skull, and neck *lymph nodes*.

CAUSES AND INCIDENCE

Cancer of the nasopharynx is rare in the West but relatively common in the Far

East; the reasons for this are not clear. It occurs most often in people between the ages of 30 and 60.

Factors that increase the risk of this cancer include diet (a high intake of salt-cured fish); smoking; and viral infections, especially infection with the *Epstein-Barr virus*. People who inhale hardwood dust or nickel dust at work over a long period are also at increased risk and should take precautions.

SYMPOTMS

Initially, cancer of the nasopharynx may not cause any symptoms. It may remain unnoticed until the tumour spreads to a lymph node, causing a painless swelling in the neck.

If symptoms do develop, they may include facial swelling, recurrent nosebleeds, a runny nose, and discomfort on swallowing. Loss of the sense of smell, double vision, deafness, paralysis of one side of the face, voice change, and severe facial pain may also develop if nearby nerves are affected.

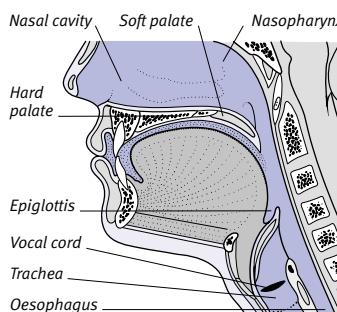

DIAGNOSIS AND TREATMENT

Diagnosis is through *endoscopy* (internal examination and inspection using a viewing tube), during which a *biopsy* (removal of a small sample of tissue for microscopic analysis) can also be taken. An *MRI* scan (a technique that produces cross-sectional or three-dimensional images of internal body structures) and *X-rays* are required to assess the extent of the tumour and the involvement of nearby structures.

Treatment is usually with *radiotherapy*, but, in some cases, the tumour may be surgically removed. If the tumour is treated early, the outlook can be good.

LOCATION OF THE NASOPHARYNX

The nasopharynx forms the upper part of the pharynx and connects the nasal cavity to the top of the throat.

natriuretic peptide

See *atrial natriuretic peptide*.

natural childbirth

See *childbirth, natural*.

natural immunity

A type of *immunity* (protection against disease) that is manifested by a species not previously sensitized to the disease in question either through infection or through *vaccination*.

The mechanisms that are involved in natural immunity are still poorly understood. This condition, however, is not believed to be stimulated by specific *antigens* (substances that trigger an immune response), as is the case with acquired immunity. Natural immunity (also known as innate immunity) is inherited and present at birth.

natural killer cells

A specific type of *lymphocyte* (a type of white blood cell) that is able to destroy cells infected with viruses as well as some types of *cancer* cell. Natural killer cells, also known as NK cells, constitute the *immune system*'s first line of defence against cancerous or infected cells. NK cells are neither T nor B lymphocytes (unlike *killer T-cells*, for example).

N

naturopathy

A form of *complementary medicine* based on the principle that disease occurs as a result of the accumulation of waste products and toxins in the body; symptoms are thought to reflect the attempts of the body to rid itself of these substances. Practitioners of naturopathy believe that health is maintained by avoiding anything artificial or unnatural in the diet or in the environment.

nausea

The sensation of needing to vomit. Although nausea may occur without *vomiting*, the causes are the same.

navel

A popular term for the *umbilicus*, the depression in the abdomen that marks the point at which the umbilical cord was attached to the fetus.

navicular bone

A foot bone that articulates with the head of the talus (one of the bones in the *ankle joint*) and with three of the bones in the tarsus (which makes up the back of the foot and the ankle).

nebulizer

An aerosol device used to administer drugs, such as *bronchodilators*, especially in the emergency treatment of *asthma*. Usually an electric pump sends a stream of air or oxygen across a chamber that contains the drug. This stream of air disperses the drug into a fine mist, which is then conveyed to the face mask and inhaled by the user.

neck

The part of the body that supports the head and serves as a passageway between the head (and brain) and the rest of the body. The neck contains many important structures: the *spinal cord* (which carries nerve impulses to and from the brain); the *trachea* (windpipe); the *larynx* (voice-box); the *oesophagus* (gullet); the *thyroid* and *parathyroid glands*; *lymph nodes*; and several major blood vessels. Seven spinal vertebrae are located in the neck; they are surrounded by a complex system of muscles.

DISORDERS

Torticollis (wry neck), in which the head is twisted to one side, may result from injury to a neck muscle or from skin *contracture* (shrinkage) after burns or other injuries. *Fractures* and *dislocations* of vertebrae in the neck, as well as *whiplash injury*, can cause injury to the spinal cord, causing paralysis or even death (see *spinal injury*).

Degeneration of the joints between the neck vertebrae may occur as a result of *cervical osteoarthritis*, resulting in neck pain, stiffness, and sometimes tingling and weakness in the arm and hand. Similar symptoms may also be caused by a *disc prolapse*. In *ankylosing spondylitis*, fusion of the vertebrae may result in permanent neck rigidity.

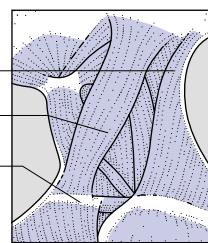

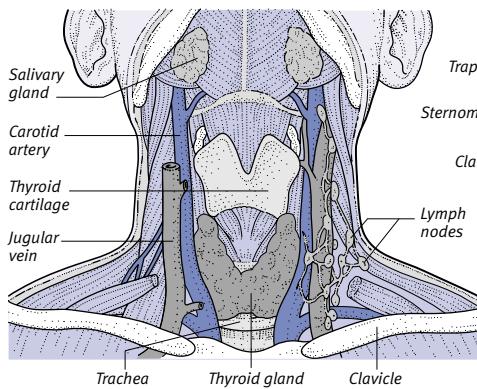

Cervical rib is a rare congenital defect in which there is a small extra rib in the neck. This condition often causes no symptoms until middle age, when it may result in pain, numbness, and a pins-and-needles sensation in the forearm and hand.

Neck pain of unknown origin is very common. However, as long as there are no neurological symptoms (such as loss of sensation or a decrease in muscle power), the condition is unlikely to be serious and usually disappears over the course of a few weeks. However, any condition causing a large swelling in the neck (such as enlargement of the thyroid gland) may interfere with breathing or swallowing.

ANATOMY OF THE NECK

The neck contains many important structures, including the larynx, thyroid and parathyroid glands (embedded in the back of the thyroid), many lymph nodes, and carotid arteries. The upper seven vertebrae of the spine are in the

neck; a complex system of muscles is connected to these vertebrae, the clavicles, the upper ribs, and the lower jaw. Contraction of these muscles allows the head to turn and the jaw to open and close.

Muscles of the side of the neck
Muscles on the side (here, the left side) and back of the neck support and move the head.

neck dissection, radical

A surgical procedure for the removal of cancerous *lymph nodes* in the neck. The operation is often part of the treatment for cancer of the tongue, the tonsils, or other structures in the mouth and throat.

Under general anaesthetic (see *anaesthesia, general*), a flap of skin on the affected side of the neck is raised to expose the underlying sternomastoid muscle. The muscle is cut just above the clavicle (collarbone) and lifted up. All the components of the lymphatic system in the neck (the lymph vessels as well as the lymph nodes) are then removed, together with the internal jugular vein, the lower salivary gland, and other surrounding tissue.

neck rigidity

Marked stiffness of the neck caused by *spasm* of the muscles in the neck and spine. Neck rigidity is an important clinical sign of *meningitis* (inflammation of the membranes that envelop the brain and spinal cord). Severe neck rigidity may cause the head to arch backwards, especially in babies.

necrobiosis lipoidica

A skin condition, usually associated with *diabetes mellitus*, in which reddened patches with yellowish centres develop, most commonly on the shins. The skin in the centre of the patches becomes thin and may ulcerate.

necrolysis, toxic epidermal

A severe, blistering rash in which the surface layers of the skin peel off, exposing large areas of red, raw skin. The condition carries a risk of widespread infection and loss of body fluids and salts.

The most common cause of toxic epidermal necrolysis is an adverse reaction to a drug, particularly a *barbiturate*, *sulphonamide*, or *penicillin*. The condition usually clears up when the causative drug is discontinued. Intravenous fluid replacement is sometimes necessary.

In newborn babies, the condition may be due to a *staphylococcal infection* and is called scalded skin syndrome. Treatment is with *antibiotic drugs* and fluid replacement.

necrophilia

A rare sexual perversion in which orgasm is achieved by means of sexual acts with dead bodies.

necropsy

A little-used medical term for an *autopsy* (postmortem examination of a body).

necrosis

The death of tissue cells. Necrosis can occur as a result of *ischaemia* (inadequate blood supply), which may lead to *gangrene* (tissue death); infection; or damage by extreme heat or cold, noxious chemicals, or excessive exposure to X-rays or other forms of *radiation*.

The appearance of the dead tissue depends on the cause of the necrosis and on the type of tissue affected. In necrosis due to *tuberculosis*, the dead tissue is soft, dry, and cheeselike. Fatty tissue beneath the skin that has died as a result of damage or infection develops into tough scar tissue that may form a firm nodule.

necrotizing fasciitis

A rare but serious infection of tissues beneath the skin by a type of streptococcal bacterium (see *streptococcal infections*) and other bacteria. Necrotizing fasciitis is most likely to occur as a complication of surgery. Initial symptoms of the infection are inflammation and blistering of the skin. The infection spreads very rapidly and the bacteria release enzymes and toxins (poisons) that can cause extensive destruction of deeper tissues and damage to internal organs. Urgent treatment with *antibiotic drugs* and surgical removal of all infected tissue are essential. The infection is life-threatening.

nedocromil

A drug similar to *sodium cromoglicate* that is used to prevent *asthma attacks*.

needle aspiration

See *biopsy*.

needle exchange

A health scheme that enables intravenous drug abusers to exchange used hypodermic needles for new, sterile ones. The scheme is aimed at reducing the risks of infections, such as *HIV* and *hepatitis*, that are transmitted by the sharing of contaminated needles.

needlestick injury

Accidental puncture of the skin by a contaminated hypodermic needle. Hospital staff are most likely to be at risk. Needlestick injuries carry the risk of serious infections, such as *HIV* and *hepatitis*, and need immediate medical attention. The wound should be cleaned thoroughly; *blood tests* may be needed to determine whether infection has been transmitted.

nefopam

An *analgesic drug* used to relieve moderate pain caused, for example, by injury, surgery, or cancer. Nefopam reduces the perception of pain by the brain. Unlike most analgesics that act on the brain, it neither interferes with breathing nor causes dependence.

The possible side effects of nefopam include nausea, dry mouth, nervousness, and difficulty sleeping.

negativism

The tendency to resist or oppose advice, suggestions, or commands. There are two principal types of negativism: active negativism and passive negativism. In active negativism, the individual does the opposite of what he or she is requested to do; such behaviour is seen in toddlers and is uncommon in adult life, although it may be a feature of *catatonia*. In passive negativism, the person does not cooperate simply by failing to do something that has been suggested. This often occurs in *depression* and may also be a feature of *schizophrenia*.

neisserial infections

Infections caused by *bacteria* belonging to the *NEISSERIA* genus. *NEISSERIA GONORRHOEAE* (*gonococcus*) causes *gonorrhoea* (a common *sexually transmitted infection*) in humans. *NEISSERIA MENINGITIDIS* (*meningococcus*), is the causative agent of the condition *meningococcal meningitis* (inflammation of the membranes covering the brain and spinal cord).

Nelson's syndrome

A rare disorder of the *endocrine system* that causes increased skin pigmentation. Nelson's syndrome results from enlargement of the *pituitary gland*, which can follow removal of the *adrenal glands* (to treat *Cushing's disease*).

Nelson's syndrome is treated by *hypophysectomy* (removal or destruction of the pituitary gland).

nematodes

The scientific name for a group of cylindrically shaped worms (see *roundworms*); some are human parasites.

neologism

The act of making up new words that have a special meaning for the inventor. The term neologism also refers to the invented word itself. Persistent neologism can be a feature of speech in people with *schizophrenia*.

neomycin

An *antibiotic drug* used to treat ear, eye, and skin infections, often in combination with other drugs. Neomycin is also given to prevent infection of the intestine prior to surgery. Possible adverse effects include a rash and itching.

neonatal death

The *death* of a live-born infant in the first four weeks of life. Neonatal death is classified as early or late: early neonatal deaths are deaths in the first week of life; late neonatal deaths are those occurring between the end of the first week of life and 27 days after birth. About half of all neonatal deaths in the UK are attributed to *prematurity*; about a quarter to congenital malformations; and the remainder to various causes, including infection and difficulties with delivery. (See also *infant mortality*; *stillbirth*.)

neonatal hypoglycaemia

An abnormally low blood glucose level (see *hypoglycaemia*) in an infant that is under four weeks of age. Neonatal hypoglycaemia commonly causes problems in the first 24 hours of life. Persistent low glucose levels may result in permanent damage to the brain (see *cerebral palsy*).

CAUSES AND INCIDENCE

Neonatal hypoglycaemia is uncommon in healthy babies carried to full term. The condition is likely to occur in premature infants and those of low birth weight, due to their reduced reserves of *glycogen* (main form of the body's stored carbohydrate). It is also more common in babies whose mothers had *diabetes mellitus* during pregnancy. These babies produce the extra insulin they require before delivery, but their glucose levels fall after birth. Also at risk of neonatal hypoglycaemia are infants with inborn errors of metabolism (see *metabolism, inborn errors of*) and those who are unwell at birth. Difficulties with *breastfeeding* during the first days of life may also cause the condition to develop.

SYMPTOMS AND SIGNS

Neonatal hypoglycaemia is usually characterized by jitteriness, *seizures*, irritability, floppiness, *apnoea* (interruption in breathing), and poor feeding.

DIAGNOSIS AND TREATMENT

A diagnosis of neonatal hypoglycaemia is confirmed using *blood tests* to check blood glucose levels.

In babies at increased risk of the condition, preventive treatment involves the immediate establishment of regular feeding, ideally breast-feeding. Hypoglycaemia that is severe enough to cause symptoms requires an intravenous infusion of glucose along with, if possible, treatment of the underlying cause.

neonatal jaundice

See *jaundice, neonatal*.

neonatal urticaria

See *urticaria, neonatal*.

neonate

A newly born infant, specifically up to the age of 27 days. (See also *newborn*.)

neonatology

The branch of *paediatrics* concerned with the care of *newborn* infants and the treatment of disorders that occur during the first few weeks of life. Such problems may be short-term (such as those associated with *prematurity* or low birth weight) or lifelong (such as *spina bifida*).

neoplasia

A medical term for the process of *tumour* formation, characterized by progressive, abnormal cell multiplication. The term neoplasia does not necessarily imply that the new growth is cancerous; neoplasia also results in noncancerous tumours.

neoplasm

A medical term for a *tumour* (any new abnormal growth). Neoplasms may be cancerous or noncancerous.

neostigmine

A drug that is used in the treatment of *myasthenia gravis* (a rare autoimmune disorder that causes muscle weakness). Neostigmine increases the activity of *acetylcholine*, a *neurotransmitter* (a chemical released from nerve endings) that stimulates the contraction of muscles.

Possible side effects of neostigmine include nausea and vomiting, increased salivation, diarrhoea, abdominal cramps, blurred vision, muscle cramps, sweating, and twitching.

nephrectomy

The surgical removal of one or both of the *kidneys*.

WHY IT IS DONE

One of the most common reasons for nephrectomy is to remove a cancerous tumour (see *kidney cancer*). A kidney may also be removed if it is not functioning properly because of injury, infection, or the presence of stones (see *calculus, urinary tract*) or if it is causing severe *hypertension* (high blood pressure). Nephrectomy may also be necessary if a kidney is so badly injured that bleeding cannot be stopped.

HOW IT IS DONE

Nephrectomy takes place under general anaesthetic (see *anaesthesia, general*). An incision is made along the lower edge

of the ribs, from the spine to the front of the abdomen, in order to expose the kidney. The ureter (the tube that carries urine from the kidney to the bladder) and the renal blood vessels are tied off, then the kidney is removed. The incision is stitched up after insertion of a drainage tube, which is left in place for between 24 and 48 hours.

OUTLOOK

On removal of a single kidney, the remaining kidney takes over the workload. If both kidneys are removed, the patient requires regular *dialysis* (artificial purification of blood) or a *kidney transplant*.

nephritis

Inflammation of one or both of the *kidneys*. Nephritis may be caused by an infection (see *pyelonephritis*), by abnormal responses of the *immune system* (see *glomerulonephritis*), or by drugs – for example, penicillin. (See also *Disorders of the kidney* box.)

nephroblastoma

A type of *kidney cancer* that mainly affects children.

nephrocalcinosis

Deposits of *calcium* within the tissue of one or both of the *kidneys*. Nephrocalcinosis is not the same as kidney stones (see *calculus, urinary tract*), in which particles of calcium develop inside the drainage channels of the kidney.

Nephrocalcinosis may occur in any condition in which the level of calcium in the blood is raised – for example, in *hyperparathyroidism* (overactivity of the parathyroid gland) and *renal tubular acidosis* (in which the kidney produces urine of lower-than-normal acidity). Nephrocalcinosis may also occur as a result of taking excessive amounts of certain *antacid drugs* or *vitamin D*.

Treatment is of the underlying cause in order to prevent further calcification.

nephrolithotomy

The surgical removal of a kidney stone (see *calculus, urinary tract*) by cutting into the main part of the *kidney*.

Nephrolithotomy may be performed through an abdominal incision, an incision in the back, or using *pyelolithotomy* (a surgical procedure in which a kidney stone is removed through an incision at the renal pelvis). Instruments are used to grasp and remove the calculus; the breaking up of large calculi may be necessary before removal.

It is now often possible to avoid surgery by using *lithotripsy* (a procedure that uses ultrasonic waves to break up calculi for excretion in the urine).

nephrology

The medical speciality concerned with the normal functioning of the *kidneys* and with the causes, diagnosis, and treatment of kidney disease.

Methods of investigating the kidneys include kidney *biopsy* (removal of a small sample of tissue for microscopic analysis), *kidney function tests*, and *kidney imaging* techniques, such as *ultrasound scanning* and *intravenous urography*.

Treatment of kidney disorders may involve drugs (for example, to control high blood pressure, inflammation, or infection) and surgery (for the treatment of stones or tumours). In advanced cases, regular *dialysis* (artificial purification of the blood) or a *kidney transplant* may be required. (See also *Disorders of the kidney* box.)

nephron

The functional microscopic unit of the *kidney* that consists of a glomerulus (a filtering unit made up of a cluster of capillaries) and a tubule. Each kidney contains about one million nephrons.

The nephrons filter waste products from the blood and modify the amount of salt and water excreted in the urine, according to the body's needs. This process involves blood filtration in the glomerulus followed by further processing of the filtrate as it flows through the various parts of the tubule: the proximal convoluted tubule, the *loop of Henlé*, and the distal convoluted tubule.

nephropathy

A term for any disease of, or damage to, the *kidneys*. The term is usually combined with a word that indicates the cause of the damage, for example *diabetic nephropathy*, *obstructive nephropathy*, *hypertensive nephropathy*, and *toxic nephropathy*. The treatment and outlook are dependent on the cause. (See also *Disorders of the kidney* box.)

nephrosclerosis

Hardening of the arterioles and arteries within the *kidney*, usually as a result of *atherosclerosis* (the deposition of fatty material within blood vessels).

nephrosis

See *nephrotic syndrome*.

nephrostomy

The introduction of a small tube into the *kidney* to drain urine to the abdominal surface, thereby bypassing the ureter and bladder. Nephrostomy is sometimes performed after an operation (typically removal of a kidney stone) on the ureter or the kidney–ureter junction.

nephrotic syndrome

A collection of symptoms and signs resulting from damage to the glomeruli (the filtering units of the *kidney*), which causes severe *proteinuria* (leakage of protein from the blood into the urine), low blood levels of protein, and swelling.

CAUSES

Nephrotic syndrome may occur as a result of *diabetes mellitus*, *amyloidosis* (accumulation of amyloid, an abnormal protein, in the tissues), or any type of *glomerulonephritis* (inflammation of the glomeruli). The conditions may also be due to severe *hypertension* (high blood pressure), reactions to poisons (such as *mercury* or *cadmium*), or adverse reactions to drugs, such as *gold* or *penicillamine*.

Nephrotic syndrome may also be a complication of an infection elsewhere in the body, such as *hepatitis B* or *malaria*. In children, the syndrome is most commonly due to a condition known as minimal change glomerulonephritis.

SYMPTOMS

The symptoms of nephrotic syndrome appear gradually over days or weeks and worsen as more and more protein is lost in the urine. Early signs include frothy urine and decreased urine production. The main symptom is swelling of the legs and face as a result of *oedema* (accumulation of fluid in the tissues). Fluid may also collect in the chest cavity, resulting in *pleural effusion* and shortness of breath, or in the abdomen, causing *ascites*. Lethargy and loss of appetite (leading to weight loss) may also occur.

DIAGNOSIS AND TREATMENT

Diagnosis involves *blood tests*; the urine must also be examined under a microscope and the amount and type of protein lost assessed over a 24-hour period (see *urinalysis*). In most cases, a kidney *biopsy* (removal of a small sample of tissue for microscopic analysis) is also required to establish the exact cause and help with treatment decisions.

Treatment is aimed at the underlying condition. A low-sodium diet may be recommended and *diuretic drugs* may be given to reduce oedema. Protein may need to be given intravenously, but the

effects are short lived. *Corticosteroid drugs* may also be prescribed and are often effective in cases of nephrotic syndrome in childhood.

OUTLOOK

The outlook for someone with nephrotic syndrome depends on the extent of the kidney damage. Recurrent episodes may occur even after treatment. Problems with excessive blood clotting are common and may require treatment with *anticoagulant drugs*. Infections may occur as a result of *immunoglobulin* loss into the urine. Nephrotic syndrome is usually associated with raised cholesterol, which increases the risk of *myocardial infarction* (heart attack) due to *atherosclerosis* (fatty deposits on the artery walls). In the most severe cases, chronic *kidney failure*, and eventually an irreversible loss of kidney function, may develop.

nephrotoxic

A term meaning toxic (poisonous) to *kidney* cells, resulting in damage to or destruction of the cells.

nerve

A bundle of nerve fibres travelling to a common location. Nerve fibres, which are also known as axons, are the filamentous projections of many individual *neurons* (nerve cells).

STRUCTURE

The most obvious nerves in the body are the peripheral nerves, which extend from the *central nervous system* (consisting of the *brain* and the *spinal cord*) to other parts of the body. Of these, 12 pairs of *cranial nerves* link directly to the brain and 31 pairs of *spinal nerves* join the spinal cord. In the shoulder and hip regions, the spinal nerves join to form plexuses, from which branch the main nerves to the limbs, such as the median nerve in the arm and the sciatic nerve in the leg. Most nerves divide at numerous points to send branches to all parts of the body, particularly to the sense organs, the skin, the skeletal muscles, the internal organs, and the glands.

FUNCTION

Nerve fibres may have a sensory function, carrying information from a receptor or sense organ towards the central nervous system (CNS), or they may have a motor function, carrying instructions from the CNS to a muscle or a gland. The messages are carried by electrical impulses propagated along the fibres. Some nerves carry only sensory or motor fibres, but most carry both.

DISORDERS

Nerve function is sensitive to cold, pressure, and injury (see *nerve injury*). The peripheral nerves can be damaged by a variety of disorders, including infection, inflammation, poisoning, nutritional deficiencies, and metabolic disorders (see *neuropathy*). (See also *radiculopathy*.)

nerve block

The injection of a local anaesthetic (see *anaesthesia, local*) around a nerve in order to produce loss of sensation in a part of the body supplied by that nerve. For example, the palm of the hand may be anaesthetized by giving injections at sites up the arm, thereby blocking the ulnar and median nerves.

WHY IT IS DONE

A nerve block is performed when it is not possible to inject anaesthetic directly into the tissues being treated because the area is painfully inflamed or because there is a risk of spreading infection.

The technique may also be used to anaesthetize a large area or an area not suitable for injection because it is deep within the body or is covered with bone.

TYPES

Spinal nerve block A nerve may be blocked as it leaves the cord. This happens both in *epidural anaesthesia*, which is used mainly in childbirth, and in *spinal anaesthesia*, which is used for surgery on the lower abdomen and limbs.

Caudal block In a caudal block, an anaesthetic is injected around the nerves leaving the lowest part of the spinal cord. It produces a loss of sensation in the buttock and genital areas and is occasionally used in childbirth.

Pudendal block A pudendal nerve block involves the injection of an anaesthetic into nerves passing under the pelvis into the floor of the vagina. This type of nerve block is sometimes used during childbirth in a *forceps delivery*.

nerve conduction studies

Electrical tests carried out to assess the extent of nerve damage caused by disorders of the peripheral nervous system (see *neuropathy*). In the test, an electrical stimulus is applied to a nerve; the speed at which the nerve responds to the stimulus and transmits its signal is recorded by specialized equipment.

nerve injury

Damage or severance of conducting fibres within a *nerve* as a result of trauma, resulting in the loss of skin

sensation and muscle power. (See *neuropathy* for nerve damage from causes other than injury.)

Nerves may be damaged in many different injuries, including knife wounds, bullet wounds, penetrating injuries (such as from flying glass), or from accidental contact with powered devices (such as rotary saws and propellers).

PERIPHERAL NERVE INJURY

If injury to a peripheral nerve (a nerve outside the brain or spinal cord) results in severance of some, but not all, of the individual fibres within the nerve, the cut fibres degenerate on both sides of the injury. This leads to loss of power in the muscles and loss of sensation in the skin area supplied by the fibres.

In cases of partial severance in which the ends of the severed fibres are still aligned, new fibres can regenerate along channels left by the degenerated ones. These new fibres begin to grow within a few days of injury, but they grow slowly (at a rate of about 1 mm per day).

If there is total severance of a nerve, the individual fibres try to regenerate but, with no directing channels, simply bunch up to form a lump of tissue. In such cases, function does not recover.

Regenerating nerve fibres sometimes pass down the wrong channels. So, when function is restored, actions may differ from what was intended (for example, an attempt to move the index finger may move the middle finger as well). Movement skills and the interpretation of sensations may need to be relearned.

BRAIN AND SPINAL CORD INJURY

Nerve tracts within the brain and spinal cord are structurally different from the peripheral nerves, and severed fibres in these tracts do not regenerate. Vision cannot be restored if, for example, the *optic nerves* are cut.

TREATMENT

Surgery can sometimes repair a severed nerve, but such treatment is possible only for peripheral nerves. In *microsurgery*, the neurosurgeon ensures that the severed fibres are meticulously brought together and stitched into place using delicate needles and sutures. Careful realignment of the nerve ends gives the fibres the best chance of regenerating along the correct channels. However, even with the best surgical repair, recovery is rarely complete.

A programme of *physiotherapy* is needed to keep paralysed muscles healthy and free from *contracture* (abnormal shortening) during the recovery period.

nerve, trapped

Compression or stretching of a *nerve*, causing numbness, tingling, weakness, and, sometimes, pain in the area supplied by the nerve. Common examples of a trapped nerve include *carpal tunnel syndrome*, in which pressure on the median nerve as it passes through the wrist causes symptoms in the thumb, index, and middle fingers; a *disc prolapse*, in which pressure on the nerve root leading from the spinal cord produces symptoms in the back and legs; and *crutch palsy*, in which the radial nerve presses against the humerus (upper arm bone), producing symptoms in the wrist and hand.

A damaged nerve may take some time to heal. In severe cases, surgical decompression to relieve pressure on the nerve may be necessary.

nervous breakdown

A nontechnical term used to describe unusual behaviour (such as episodes of tearfulness or shouting and screaming) that may be part of a crisis of severe *anxiety*, *depression*, or other psychiatric illness. The condition affects the sufferer's ability to cope with everyday life.

nervous energy

A nontechnical term for the increased drive and activity of individuals who are always restless, anxious, and on the go.

nervous habit

A nontechnical term for a minor repetitive movement or activity. A nervous habit can consist of involuntary twitches and facial tics, such as in *Gilles de la Tourette's syndrome* and some forms of *dyskinesia*. Voluntary nervous habits, such as *nail-biting* and *thumb-sucking*, are common in young children, but usually disappear naturally with time. All nervous habits increase during periods of tension or anxiety and may be severe in some forms of *depression*, *anxiety disorder*, or drug withdrawal.

nervous system

The body system that gathers and stores information. It is in control of the body. (See *Nervous system* box, overleaf.)

STRUCTURE

The *brain* and *spinal cord* form the *central nervous system* (CNS), which consists of billions of interconnected *neurons* (nerve cells). The input of information to the CNS comes from the sense organs. Motor instructions are sent out to

skeletal muscles, the muscles controlling speech, internal organs and glands, and the sweat glands in the skin. This information is carried along *nerves* that fan out from the CNS to the entire body, together making up what is known as the *peripheral nervous system* (PNS).

Each nerve is a bundle consisting of the axons (filamentous projections) of many individual neurons.

FUNCTION

There are also functional divisions. Two of the most important are the *autonomic nervous system*, which is concerned with the automatic regulation of internal body functions, and the *somatic nervous system*, controlling the muscles responsible for voluntary movement.

The overall function of the nervous system is to gather and analyse information about the external environment and the body's internal state and to initiate appropriate responses aimed at satisfying certain drives.

The most powerful drive is for survival. Many survival responses, which range from avoiding physical pain and danger to shivering in response to the cold, are initiated unconsciously and automatically by the nervous system. Other drives are more complex, revolving around a need to experience positive emotions (such as pleasure and excitement) and to avoid negative emotions (such as pain, anxiety, and frustration).

The nervous system functions largely through automatic responses to stimuli (see *reflex*), but it can also improve its performance through *learning*, which relies on *memory*. Voluntary actions can be initiated via activity in conscious areas of the brain. Certain functions (such as visual perception, memory, thought, and speech production) are extremely complex and still not fully understood.

DISORDERS

Disorders of the nervous system may be caused by damage to or dysfunction of any of its parts (see *disorders of the brain*; *spinal cord*; *neuropathy*; *nerve injury*). They may also be due to impaired sensory, analytical, or memory functions (see *vision*, *disorders of*; *deafness*; *numbness*; *anosmia*; *agnosia*; *amnesia*), or motor functions (see *aphasia*; *dysarthria*; *ataxia*).

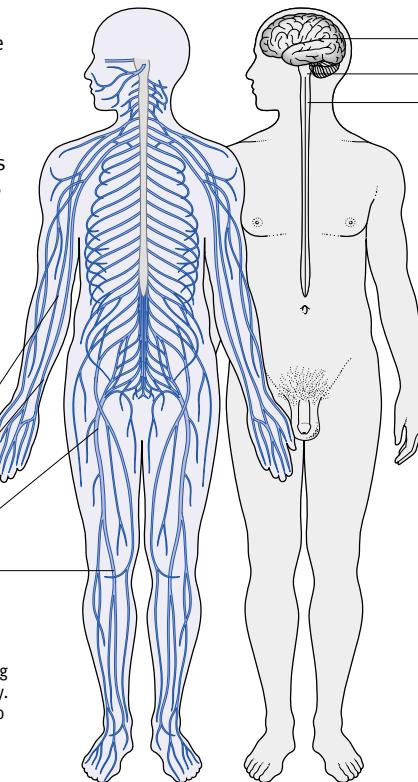

netilmicin

An *antibiotic drug* usually prescribed only to treat serious infection in hospital, when other antibiotic drugs have proved ineffective. In rare cases, netilmicin can damage the inner ear or the kidneys.

NERVOUS SYSTEM

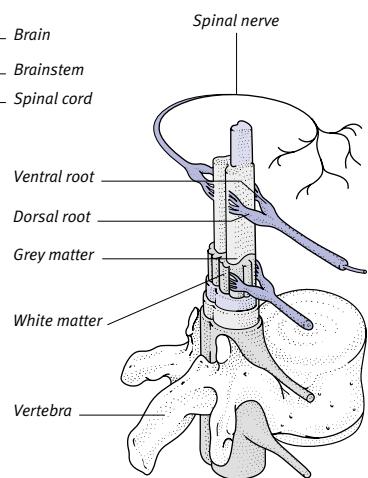

The nervous system detects and interprets changes in conditions inside and outside the body and responds to them. The central nervous system analyses information and initiates responses; the peripheral nervous system gathers information and carries the response signals. Some responses are involuntary; others are dictated by conscious thought. All nervous system activity consists of signals passed through pathways of interconnected neurons (nerve cells).

Median nerve
Ulnar nerve
Femoral nerve
Posterior tibial nerve

Peripheral nervous system

This system comprises all the nerves connecting the brain and spinal cord to the rest of the body. Of these, 31 pairs (the spinal nerves) connect to the spinal cord and 12 pairs (cranial nerves) connect to the brain. The main nerves of the limbs are labelled.

Structure of the spinal cord

The grey matter contains nerve cell bodies; white matter contains their conducting fibres. On joining the cord, spinal nerves split into two. The dorsal root carries sensory fibres; the ventral root carries motor fibres.

Central nervous system

This system consists of the brain and spinal cord, protected by the skull and spine. The CNS receives input from sense organs and receptors and sends signals to muscles and glands, via the peripheral nervous system.

HOW IT WORKS

Some possible events in response to a finger touching a hot object are shown. A receptor sends a message, via a sensory fibre, to the spinal cord. This triggers a signal that travels, via a motor fibre, back to a muscle, which contracts to move the finger away from the heat. This action is called a reflex arc. Other signals pass to the brain.

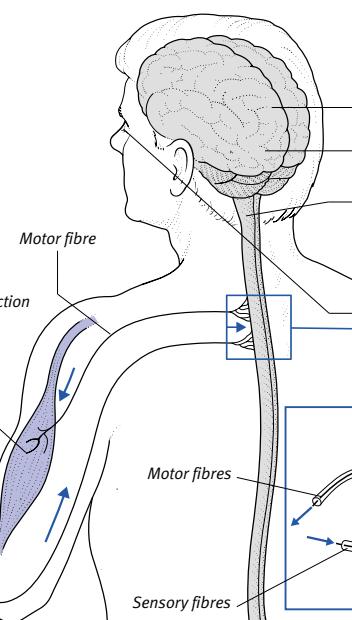

Sensory receptors

Motor fibre
Muscle action

Sensory fibre

Sensory and motor fibres

Although the sensory and motor fibres carry signals in opposite directions, along part of their lengths they may occupy exactly the same nerve.

Brain

When impulses reach the cerebral cortex, pain is felt. Other activity (concerned, for example, with memorizing the painful stimulus) may also be initiated.

Cerebral cortex

Brainstem

Eye movement

Signals arriving at the brainstem may cause more action, such as the eyes moving towards the stimulus.

Nerve fibres to brain

Grey matter

Spinal cord

The signal entering the spinal cord passes to other nerve cells by separate connections.

nettle rash

A common name for *urticaria*.

neuralgia

Pain caused by irritation of, or damage to, a *nerve*. The pain usually occurs in brief bouts, may be severe, and can often be felt shooting along the affected nerve.

TYPES AND CAUSES

Some types of neuralgia are features of a disorder. *Migraine* sufferers commonly experience a form of neuralgia comprising attacks of intense, radiating pain around the eye. Postherpetic neuralgia is a burning pain that may recur at the site of an attack of *herpes zoster* (shingles) for months or even years after the illness.

Other types of neuralgia result from disturbance of a particular nerve. In glossopharyngeal neuralgia, intense pain is felt at the back of the tongue and in the throat and ear, all of which are areas supplied by the glossopharyngeal nerve. The cause is unknown. The same is true of *trigeminal neuralgia*, a severe paroxysm of pain affecting one side of the face supplied by the trigeminal nerve.

TREATMENT

Neuralgia may be relieved by *analgesic drugs* (painkillers), such as *paracetamol*. Glossopharyngeal, trigeminal, and post-herpetic neuralgia may respond to treatment with *carbamazepine* or other *anticonvulsant drugs*, or to *tricyclic antidepressant drugs*.

neural tube defect

A once common developmental failure affecting the *spinal cord* or *brain* of the *embryo*. The neural plate, which develops along the back of the embryo by about the third week of pregnancy, then folds to form the neural tube that later becomes the brain, the spinal cord, and their coverings (the *meninges*). If the neural tube does not form properly, defects in any of these parts can result.

TYPES AND SYMPTOMS

The most serious neural tube defect is *anencephaly* (failure of the skull and brain to develop), which is fatal before birth or soon afterwards. More common is *spina bifida*, in which the vertebrae do not form a complete ring around the spinal cord. Spina bifida can occur anywhere on the spine, but it is most common in the lower back.

There are different forms of spina bifida. In *spina bifida occulta*, the only defect is a failure of the bony arches behind the spinal cord to fuse, which is sometimes associated with a tuft of hair

over the area or a dimple in the skin. This may cause no problems, although there may be tethering of the spinal column, which may need releasing surgically.

If the bone defect is more extensive, there may be a meningocele (a protrusion of the meningeal membranes) or a myelomeningocele (a malformation in which part of the spinal cord and the meninges overlying it are completely exposed). Myelomeningocele is likely to cause severe handicap, with paralysis of the legs, loss of sensation in the lower body, and paralysis of the anus and bladder, causing incontinence (see *incontinence, faecal; incontinence, urinary*). The higher up the spine the malformation is, the more severe the handicap.

Associated problems include *hydrocephalus*, in which extra fluid forms in the brain; insertion of a shunt to relieve the pressure is often needed in the first few weeks of life. However, some children will also have *cerebral palsy*, *epilepsy*, or *learning difficulties*. Children with neural tube defects are at particular risk of developing *meningitis*, a serious infection of the membranes covering the brain and spinal cord.

CAUSES

The cause of neural tube defects is not fully understood, but they tend to run in families, which suggests that genetic factors are involved. Certain types of *anticonvulsant drug* are associated with neural tube defects if they are taken by women during pregnancy.

TREATMENT AND OUTLOOK

Surgery is usually performed a few days after birth. In mild cases, the defect can usually be corrected completely; but in myelomeningocele, some handicap will remain and affected children usually need lifelong care. *Physiotherapy* and mobility aids may be useful to maintain activity and allow as great a degree of independence as possible.

Children with extensive damage to the brain and/or spinal cord usually have a reduced life expectancy.

PREVENTION

The risk of a neural tube defect can be substantially reduced if the mother takes *folic acid* supplements before conception and during the early part of the pregnancy. A mother who has previously had a child affected by a neural tube defect should seek specialist advice before planning another pregnancy. In such cases, a higher dose of folic acid may be recommended in order to reduce the risk of having another affected child.

Blood tests and *ultrasound scanning* in pregnancy can help to detect neural tube defects before birth. Over the last 25 years, there has been a substantial decline in the numbers of babies born with these defects.

neurapraxia

A type of *nerve injury* in which the outward structure of a nerve appears intact, but some conducting fibres have been damaged and thus do not transmit signals normally.

neurasthenia

An outdated term that literally means “nervous exhaustion”. The term neurasthenia was once used to describe a number of physical and mental symptoms, such as insomnia, loss of energy, aches and pains, *depression*, irritability, and reduced concentration.

neuritis

A term that literally means inflammation of a *nerve*. True nerve inflammation may be caused by infection (for example, by a virus in *herpes zoster* or by a bacterium in *Hansen's disease*). The term neuritis is also often applied to nerve damage or disease from causes other than inflammation. It has become virtually synonymous with *neuropathy*.

neuroblastoma

A cancerous tumour that develops from nervous tissue in the *adrenal glands* or in part of the sympathetic nervous system (see *autonomic nervous system*). Neuroblastomas from the sympathetic nervous system usually develop in the sympathetic nerves along the back wall of the abdomen. Less commonly, tumours originate in the sympathetic nerves of the chest or neck. The tumours often spread to other sites in the body.

INCIDENCE AND CAUSE

Neuroblastomas are the most common extracranial (outside the skull), solid tumour of childhood. Most cases develop during the first ten years of life, especially in the first five. The disorder is slightly more common in boys than in girls.

The cause of these tumours is not known, although a genetic factor is thought to be involved.

SYMPTOMS

The symptoms of neuroblastoma may be present from birth or may develop gradually during childhood. Typical symptoms of the condition include a lump in the abdomen, tiredness, weight

loss, aches and pains, pallor, and irritability. In some cases, there is also diarrhoea, *hypertension* (high blood pressure), and flushing of the skin.

If a tumour spreads through the body, other symptoms, such as bone pain or, if the lymph nodes are affected, swellings in the neck or armpits, may occur. *Anaemia* (a reduced level of the oxygen-carrying pigment *haemoglobin* in the blood) may result if the cancer spreads to the bone marrow.

DIAGNOSIS

The diagnosis of a neuroblastoma is made from *MRI* and *CT scanning* (techniques that produce cross-sectional or three-dimensional images of internal body structures), blood tests, urine tests, and *biopsy* (removal of a small sample of tissue for analysis) of the bone marrow and any accessible tumours.

TREATMENT AND OUTLOOK

If possible, the tumour is surgically removed; this is not possible if it has grown around the large blood vessels in the abdomen, however. Treatment is primarily with *anticancer drugs (chemotherapy)*. *Radiotherapy* and a *bone marrow transplant* are other treatments that may also be considered.

The outlook varies because neuroblastomas range from being relatively harmless to aggressively cancerous. Even if the tumour is widespread at the time of diagnosis, however, cure rates may still reach 30 per cent.

neurocutaneous disorders

A group of conditions characterized by abnormalities of the skin and of the nerves and/or the *central nervous system*.

The best known of the neurocutaneous disorders is *neurofibromatosis*, in which there are brown patches on the skin and numerous fibrous nodules on the skin and nerves. Another example is *tuberous sclerosis*, which is characterized by small skin-coloured swellings over the cheeks and the nose, mental deficiency, and epilepsy.

neurodermatitis

An itchy, *eczema*-like skin condition caused by repeated scratching. (See also *lichen simplex*.)

neuroendocrinology

The study of the interactions between the *nervous system* and the *endocrine system* that control internal body functions and the body's response to the external environment.

neurofibromatosis

A *genetic disorder* that causes numerous soft, noncancerous growths, known as neurofibromas, to appear throughout the body. These tumours grow from nerve tissue and develop along nerve pathways. If the condition is severe, it can be very disfiguring.

TYPES AND CAUSES

There are two types of neurofibromatosis. The more common of the two, known as neurofibromatosis 1, is usually apparent in early childhood. The other type, neurofibromatosis 2, is extremely rare and the symptoms do not usually appear until adulthood.

Both types are caused by an abnormal gene that shows an autosomal dominant pattern of inheritance.

SYMPTOMS

In neurofibromatosis 1, numerous pale-brown, flat patches with irregular edges, which are known as *café au lait* spots, develop on the skin. The growths under the skin feel soft to the touch and range in size from hardly noticeable to large bumps. In addition there may be numerous freckles in the armpit and the groin areas.

Adults with neurofibromatosis 2 tend to develop tumours in the inner ear, which can affect hearing, but they rarely have tumours under the skin.

COMPLICATIONS

Complications may occur when the growing tumours press on surrounding organs or nerves. For example, vision may be affected if a tumour develops on the optic nerve, which connects the eye to the brain. Tumours can also cause curvature of the spine. Some children with neurofibromatosis may develop epilepsy or have learning problems. In rare cases, tumours become cancerous.

TREATMENT

There is no cure for neurofibromatosis, and its progression cannot be slowed. However, surgical removal of neurofibromas may be carried out if there are complications or if large, disfiguring tumours are causing distress. Anyone with this disorder, and parents of an affected child, may wish to seek *genetic counselling* when planning a pregnancy.

OUTLOOK

In mild cases, life expectancy is normal, but if the tumours are extensive and become cancerous, lifespan is reduced.

neuroleptic drugs

An alternative name for *antipsychotic drugs*.

neurology

The medical discipline concerned with the study of the *nervous system* and its disorders. Neurologists are trained to examine the nerves, reflexes, motor and sensory functions, and muscles to determine a disorder's cause and extent. They are specialists in the treatment of conditions, such as *migraine* and *Parkinson's disease*, that have a neurological basis, and in the care and support of patients with progressive disorders such as *multiple sclerosis* and *muscular dystrophy*. (See also *neuropathology*; *neurosurgery*.)

neuroma

A noncancerous tumour of *nerve* tissue. In most cases, the cause is unknown; rarely, a neuroma develops as a result of damage to a nerve.

A neuroma may affect any nerve in the body. Symptoms vary according to the nerve involved. In most cases, there is intermittent pain in the areas of the body supplied by the affected nerve. The same areas may also become numb and weak if the neuroma develops in a confined space and presses on the nerve.

If symptoms are troublesome, the tumour may be surgically removed. (See also *acoustic neuroma*.)

neuron

The medical term for a *nerve* cell.

STRUCTURE

A typical neuron consists of a cell body, several branching projections called dendrites, and a filamentous projection called an axon (also known as a *nerve fibre*). An axon branches at its end to form terminals through which nerve signals are transmitted to target cells.

Most axons are coated with a layered insulating *myelin* sheath, which speeds the transmission of nerve signals. The myelin sheath is punctuated along its length by gaps called *nodes of Ranvier*, which help this process. Because the myelin sheath is nonconductive, ion exchange (depolarization) only occurs at a node; signals leap from node to node along the length of the axon.

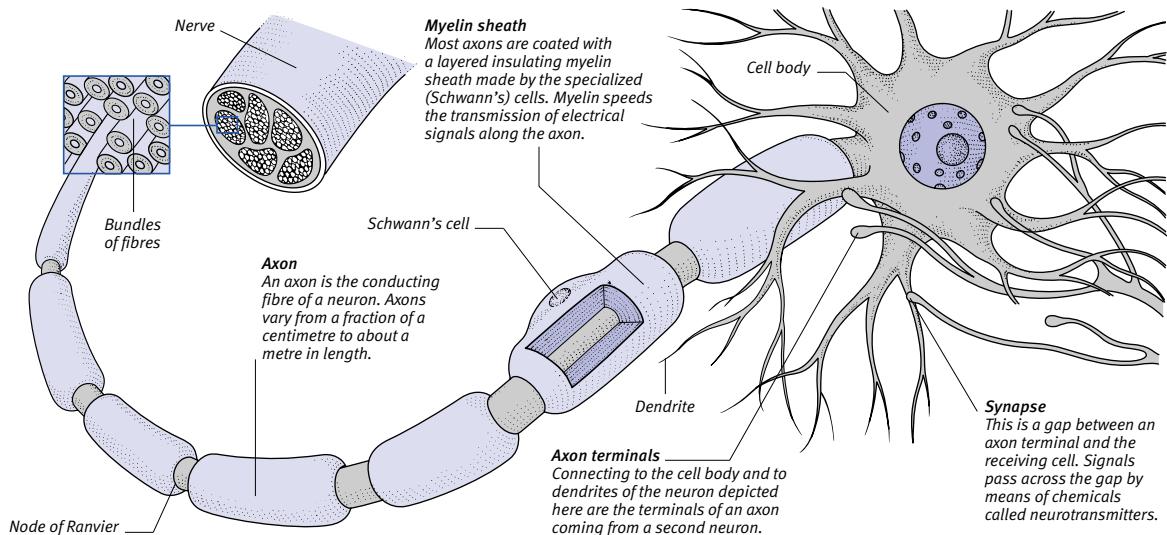

FUNCTION

The nervous system contains billions of neurons, of which there are three main types: sensory neurons, which carry signals from sense receptors into the *central nervous system* (CNS); motor neurons, which carry signals from the CNS to muscles or glands; and interneurons, which form all the complex electrical circuitry within the CNS itself.

STRUCTURE OF A NEURON

A neuron (nerve cell) consists of a cell body and several branching projections, which are called dendrites. Every neuron has a filamentous projection called an axon (nerve fibre). Axons vary greatly in length – from a fraction of a centimetre to about a metre. An axon branches at its end

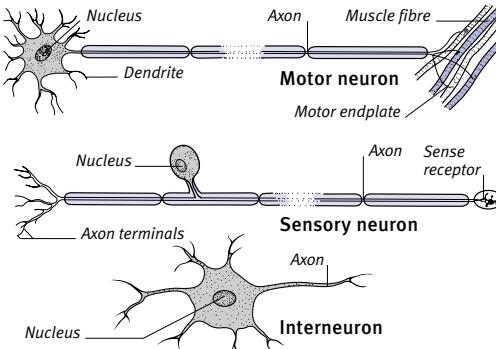

to form terminals, via which signals are transmitted to target cells, such as the dendrites of other neurons, muscle cells, or glands. Bundles of the axons of many neurons are known as nerves or, when they are located within the brain or spinal cord, as nerve tracts or pathways.

BASIC TYPES OF NEURON

N

Sensory neurons carry signals from sense receptors along their axons into the central nervous system (CNS). Motor neurons carry signals from the CNS to muscles or glands; the axon terminals form a motor endplate. Interneurons form all the complex interconnecting electrical circuitry within the CNS itself. For each sensory neuron in the body, there are about 10 motor neurons and 99 interneurons.

Neuron in a cell culture
A sensory neuron from an adult dorsal root ganglion.

When a neuron transmits ("fires") a nerve impulse, a chemical called a *neurotransmitter* is released from the axon terminals at *synapses* (junctions with other neurons). This neurotransmitter may make a muscle cell contract, cause an endocrine gland to release a hormone, or affect an adjacent neuron.

Different stimuli excite different types of neurons to fire. For example, physical stimuli such as cold, pressure, or light of a certain wavelength may excite sensory neurons. Most neurons' activity is controlled by the effects of neurotransmitters

released from adjacent neurons. Certain neurotransmitters generate a sudden change in the balance of electrical potential inside and outside the cell (an "action potential"), which occurs at one point on the cell's membrane and flows at high speed along it. Others stabilize neuronal membranes, preventing an action potential. Thus, a neuron's firing pattern depends on the balance of excitatory and inhibitory influences acting on it.

LIFESPAN

If the cell body of a neuron is damaged or degenerates, the cell dies and is

never replaced. A baby is born with the maximum number of neurons, and this number decreases continuously throughout life. However, because people are born with a very large number of neurons, problems normally only arise when disease, injury, or persistent alcohol abuse affects the CNS, and dramatically increases the rate at which neurons are lost.

If a peripheral nerve is damaged, its individual nerve fibres have the ability to regenerate themselves (see *nerve injury; neuropathy*).

neuropathic joint

A joint that has been damaged by inflammation and a series of injuries, which pass unnoticed due to a loss of sensation in the joint resulting from *neuropathy* (nerve damage caused by disease). Neuropathic joints develop in a number of conditions, including *diabetes mellitus* and untreated *syphilis*.

SYMPTOMS

When sensation to pain is lost, abnormal stress and strain on a joint do not stimulate the protective reflex spasm of the surrounding muscles; this failure of the protective reflex allows exaggerated movement that can lead to damage within and around the joint. *Osteoarthritis*, swelling, and deformity are features of a neuropathic joint.

TREATMENT AND OUTLOOK

An orthopaedic *brace* or *caliper splint* may be necessary to restrict any abnormal movement of the joint. Occasionally, *arthrodesis* (a surgical operation to fuse a joint) is performed. The nerve damage is irreversible.

neuropathology

The branch of *pathology* that is concerned with the causes and effects of disorders of the *nervous system*. (See also *neurology*.)

neuropathy

Disease or inflammation of, or damage to, the peripheral *nerves*, which connect the *central nervous system* (the brain and the spinal cord), to the muscles, glands, sense organs, and internal organs. The term *neuritis* is now used more or less interchangeably with *neuropathy*.

TYPES

Most nerve cell axons (the conducting fibres that make up nerves) are insulated by a sheath of the fatty substance *myelin*. Most neuropathies arise from damage to, or irritation of, either the axons or their myelin sheaths. This may cause the passage of nerve signals to be slowed or blocked completely.

Various types of neuropathy are described according to the site and the distribution of the damage. For example, a distal neuropathy starts with damage at the far end of a nerve (the end farthest from the brain or spinal cord). A symmetrical neuropathy affects nerves at the same places on each side of the body. Some neuropathies are described according to the underlying cause of the condition, for example *diabetic neuropathy*, *entrapment neuropathy*, or *alcoholic neuropathy*.

Polyneuropathy (also known as polyneuritis) refers to damage to several nerves; mononeuropathy (or mononeuritis) indicates damage to a single nerve. The term *neuralgia* describes pain caused by irritation or inflammation of a particular nerve.

CAUSES

There are some cases of neuropathy that have no obvious cause. Among the many specific causes are *diabetes mellitus*, dietary deficiencies (particularly of the B vitamins), excessive alcohol consumption, and metabolic upsets such as *uraemia*. Other causes include *Hansen's disease* (leprosy), *lead poisoning*, or poisoning by drug overdose.

Nerves may become acutely inflamed after a viral infection, such as in *Guillain-Barré syndrome*. Neuropathies may also result from *autoimmune disorders* (disorders in which the immune system attacks the body's own healthy tissues) such as *rheumatoid arthritis*, *systemic lupus erythematosus*, or *polyarteritis nodosa*. In these disorders, there is often damage to the blood vessels supplying the nerves. Neuropathies may occur secondarily to cancerous tumours, such as lung cancer, or with *lymphomas* and *leukaemias*. There is also a group of inherited neuropathies, the most common being *peroneal muscular atrophy*.

SYMPTOMS

The symptoms of neuropathy depend on whether it affects mainly sensory nerve fibres or mainly motor nerve fibres. Damage to sensory nerve fibres may cause numbness, tingling, sensations of cold, and pain, which often starts in the hands and feet and spreads towards the centre of the body. Damage to motor fibres may cause muscle weakness and muscle wasting. Damage to nerves of the *autonomic nervous system* may lead to blurred vision, impaired or absent sweating, faintness, and disturbance of gastric, intestinal, bladder, and sexual functioning, including incontinence and impotence.

Some neuropathies are linked with particular symptoms; for example, diabetic neuropathy can cause severe pain.

DIAGNOSIS

In order to determine the extent of the damage, *nerve conduction studies* are carried out together with *EMG* tests, which record the electrical activity in muscles. Diagnostic tests such as *blood tests*, *MRI* scans (a technique that produces cross-sectional or three-dimensional images of body structures), and nerve

or muscle *biopsy* (removal of a small sample of tissue for microscopic analysis) may also be required.

TREATMENT AND OUTLOOK

Treatment is aimed at the underlying cause. For example, vitamin injections may be given to correct a nutritional deficiency; blood sugar levels are carefully controlled to reduce the risk of further nerve damage and promote recovery in people with *diabetes mellitus*.

If the cell bodies of the damaged nerve cells have not been destroyed, full recovery from the neuropathy is possible. (See also *radiculopathy*.)

neuropsychiatry

The branch of medicine that deals with the relationship between psychiatric symptoms and neurological disorder (see *neurology*). This may include the effects of head injury and alcohol on the brain or specific disorders such as brain tumours, infections, inherited illnesses, and disorders causing brain damage in childhood. *Brain imaging* techniques are often used to demonstrate abnormalities of structure and function in disorders with psychiatric symptoms.

neurosis

An old term for a range of psychiatric disorders in which there was no loss of contact with reality (unlike *psychosis*). Disorders classed as neurotic included mild forms of *depression*, *anxiety*, *hypochondriasis*, and *dissociative disorders*.

neurosurgery

The specialty concerned with the surgical treatment of disorders of the *brain*, *spinal cord*, or other parts of the *nervous system*. Many generalized nervous system disorders do not respond to surgical treatment, but neurosurgery can deal with most conditions in which a localized structural change interferes with nerve function. Improvements in monitoring techniques and control of post-operative complications, such as swelling of the brain, have reduced the risk of serious problems developing.

Conditions treated by neurosurgery include *tumours* of the brain, spinal cord, or meninges (the membranes surrounding the brain and spinal cord); *brain abscesses*; trauma to part of the nervous system, such as that caused by a penetrating wound; abnormalities of the blood vessels supplying the brain, such as an *aneurysm* (a balloonlike swelling at a weak point in an artery);

bleeding inside the skull (see *extradural haemorrhage*; *intracerebral haemorrhage*; *subdural haemorrhage*); a number of birth defects (such as *neural tube defects* and *hydrocephalus*); certain types of *epilepsy*; and nerve damage caused by illness or accidents. Neurosurgery may also be performed to relieve *pain* that would otherwise be untreatable.

neurosypphilis

Infection of the *brain* or *spinal cord* that occurs in untreated *syphilis* many years after initial infection.

Damage to the spinal cord due to neurosyphilis may cause *tabes dorsalis*, a condition characterized by poor coordination of leg movements when walking, urinary incontinence, and intermittent pains in the abdomen and limbs. Damage to the brain may cause *dementia*, muscle weakness, and, in rare cases, total paralysis of the limbs.

neurotic

Suffering from *neurosis* (any of a range of psychiatric disorders in which there is no loss of contact with reality).

neurotoxin

A chemical that damages nervous tissue. The principal effects of neurotoxic nerve damage are numbness, weakness, or paralysis of the part of the body supplied by the affected nerve.

Neurotoxins occur in the venom of certain snakes (see *snake bites*) and are released by some bacteria (such as those that cause *tetanus* and *diphtheria*). Some chemical poisons, such as arsenic and lead, are neurotoxic; certain drugs, such as *nitrofurantoin*, may cause neurodamage in high doses or in susceptible people.

neurotransmitter

A chemical released from a nerve ending that transmits impulses from one *neuron* (nerve cell) to another neuron or to a muscle cell.

ACTION

When a nerve impulse reaches a nerve ending, neurotransmitters are released from synaptic vesicles and cross a tiny gap (a synapse) to reach the target cell. Here, they cause channels in the target cell to open, letting through charged particles that stimulate an impulse in the cell. Alternatively, neurotransmitters may inhibit nerve impulses.

Scores of different chemicals fulfil this function in different parts of the *nervous system*. Many neurotransmitters

also function as hormones, being released into the bloodstream to act on distant target cells.

TYPES AND FUNCTIONS

One of the most important neurotransmitters is *acetylcholine*, which causes skeletal muscles to contract when it is released by neurons connected to the muscles. Acetylcholine is also released by neurons that control the sweat glands and the heartbeat and transmits messages between neurons in the brain and neurons in the spinal cord. Interference with the action of acetylcholine on skeletal muscles is the cause of *myasthenia gravis*. It is thought that depletion of the nerve cells that release acetylcholine in the brain may be a factor in *Alzheimer's disease*.

Another chemical, *noradrenaline* (nor-epinephrine), aids the nervous control of heartbeat, blood flow, and the body's response to stress. This substance is made by the adrenal glands as well as being produced by neurons.

The neurotransmitter *dopamine* plays an important role in parts of the brain that control movement. A malfunction of the neurons that respond to dopamine is thought to underlie *Parkinson's disease*.

Serotonin is one of the main neurotransmitters found in the parts of the brain concerned with conscious processes.

Another group of neurotransmitters are called neuropeptides. This group includes the *endorphins*, which are used by the brain to control sensitivity to pain.

neutropenia

An abnormally low number of *neutrophils* (a type of white blood cell) in the blood, which results in an increased susceptibility to infection. Symptoms may include a sore throat and fever. Neutropenia can be due to aplastic anaemia (see *anaemia, aplastic*), *agranulocytosis*, acute leukaemia (see *leukaemia, acute*), or drugs such as *anticancer drugs*.

neutrophil

A type of phagocyte (a cell in the *immune system*). Neutrophils are a very important part in the immune system, and their role is to engulf and destroy invading bacteria.

newborn

A general term for an infant at birth and during the first few weeks of life.

APPEARANCE OF A NEWBORN BABY

A full-term newborn baby weighs, on average, 3.5 kg, measures 51 cm long,

and is well prepared for survival. The newborn baby may have an oddly shaped skull or a swollen skull as a result of the transition from the uterus to the outside world. Such differences are normal, and they usually disappear relatively quickly.

In a newborn baby, other structures, such as the long bones in the legs, are not yet fully formed. The eyelids are puffy and vision is poor even when the eyes are wide open. The umbilical cord, which is cut at delivery, shrivels and falls off within about ten days to form the navel. The skin is often covered with vernix, a greasy substance that protects the skin in the uterus. Premature babies may have downy hair, called *lanugo* hair, all over the body; this hair disappears after about a month. Blisters, or small white bumps, can sometimes be seen on the lips of a newborn baby; these are due to vigorous sucking. The genitals may appear large in relation to the rest of the body.

At birth, there are changes in the structure of the heart that result in all the blood circulating through the lungs (see *fetal circulation*).

The baby has primitive *reflexes*, such as a grasp reflex, which were important to survival; although, these disappear with increasing age.

MEDICAL EXAMINATION

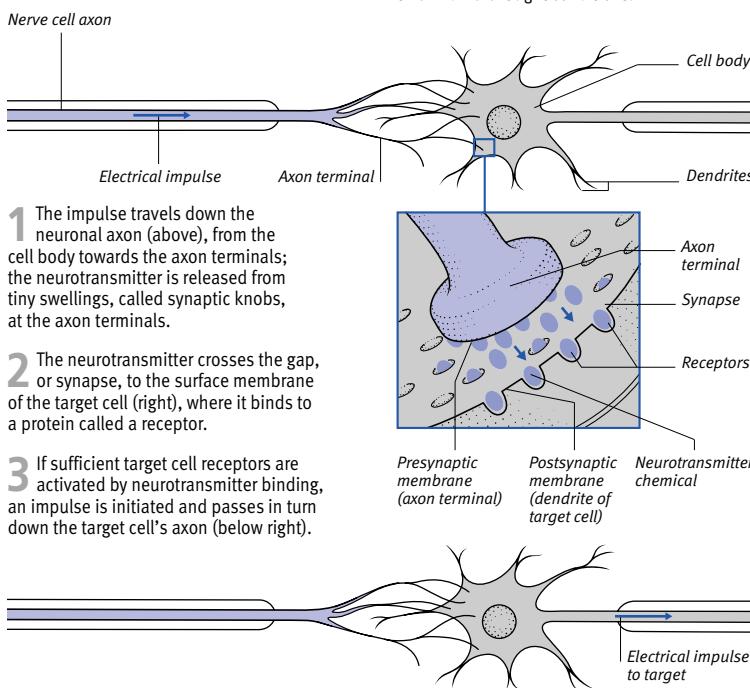

Immediately after birth, the newborn baby is usually given straight to the mother unless there is concern about its condition. Later, it is checked by the nurse, midwife, or doctor in attendance. This usually includes checking the heart rate with a *stethoscope* and establishing that breathing is normal.

The *Apgar score* and other tests are performed to confirm that the baby is in good health. The baby's sex, weight, length, and head circumference are noted and a check is made for any obvious *birth defect*. The vernix is wiped off and the baby is then usually given back to the mother to hold. If very small or sick, the baby may need to be monitored in a neonatal unit.

Within 24 hours of birth, the baby is given a complete medical examination. The skull, eyes, face, abdomen, heart, spine, hips, genitals, and limbs are checked, and the baby's posture, movements, behaviour, cry, reflexes, and responsiveness are noted. The doctor or midwife will confirm that the baby has passed urine and *meconium* (faeces). During the second week of life, blood

HOW NEUROTRANSMITTERS WORK

When an electrical impulse travels down a nerve cell axon, it causes the release of a chemical neurotransmitter at the axon terminals. The chemical released is not the same in every case; acetylcholine, noradrenaline (norepinephrine), dopamine, and serotonin are all important examples.

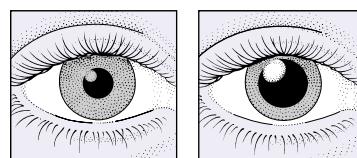

tests are performed to check for *phenylketonuria* (an inherited enzyme defect) and *hypothyroidism* (underactivity of the thyroid gland). Other tests may also be performed, depending on family history and the baby's health.

CONDITIONS IN THE NEWBORN

Some babies suffer injury during birth (see *birth injury*), such as *cephalhaemato* (a swelling of part of the head caused by bleeding between the scalp and the skull).

Jaundice (a yellowing of the skin and the whites of the eyes; see *jaundice, neonatal*) is an extremely common condition that occurs in newborn babies, especially if the baby is breast-fed. Usually appearing on the second or third day of life, the jaundice usually disappears over the next few days. In most cases, neonatal jaundice is harmless; however, the condition may be serious

Example of neurotransmitter activity
Neurotransmitters enable the pupil to change size in different light conditions.

new variant CJD

One form of *Creutzfeldt–Jakob disease*.

NGU

An abbreviation for the condition *nongonococcal urethritis*.

niacin

See *vitamin B complex*.

nickel

A metallic element that is present in the body in minute amounts. Nickel is thought to activate certain *enzymes* (substances that promote biochemical reactions) and it may also play a part in stabilizing chromosomal material in the nuclei of cells.

Disease due to a deficiency of nickel is unknown. Exposure to nickel may cause *dermatitis* (inflammation of the skin). *Lung cancer* has been reported in workers in nickel refineries.

niclosamide

An *anthelmintic drug* used to treat *tapeworm infestation*. Niclosamide causes the tapeworm to loosen its grip on the inner wall of the intestine. The worm is then passed out of the body in the faeces. Side effects of niclosamide include abdominal pain, lightheadedness, and itching.

nicorandil

A *potassium channel activator drug* used in the prevention and long-term treatment of *angina pectoris* (chest pain due to inadequate blood supply to the heart). Side effects, which include flushing, nausea, vomiting, and dizziness, are mainly due to nicorandil's *vasodilation* (widening of the blood vessels) effects and usually wear off with continued treatment. Rarely, mouth ulcers and muscle pain can occur.

nicotinamide

See *vitamin B complex*.

nicotinamide adenine dinucleotide

See *NAD*.

nicotine

A stimulant drug found in tobacco that is responsible for tobacco dependence. After inhalation, nicotine in tobacco smoke passes rapidly into the bloodstream. Nicotine in chewing tobacco is absorbed more slowly via the lining of the mouth. The drug stimulates the nervous system until it is broken down by the liver and excreted in the urine.

EFFECTS

Nicotine acts primarily on the *autonomic nervous system*, which controls involuntary body activities such as heart rate. The effects of the drug vary from one person to another and also depend on dosage and past usage. In someone who is not used to smoking, even a small amount of nicotine may slow the heart rate and cause nausea and vomiting. However, in habitual smokers, the drug increases the heart rate and narrows the blood vessels, the combined effect of which is to raise blood pressure. Nicotine also stimulates the *central nervous system*, thereby reducing fatigue, increasing alertness, and improving concentration.

Regular use of tobacco results in tolerance to nicotine, so that a higher intake is needed for the same effects.

WITHDRAWAL

Because most regular smokers are physically dependent on nicotine, the act of stopping smoking often causes withdrawal symptoms such as headaches, fatigue, drowsiness, and difficulty in concentrating. *Nicotine replacement therapy*, such as the use of nicotine skin patches and chewing gum, can be effective in aiding withdrawal from nicotine. (See also *smoking*.)

N**nicotine replacement therapy**

Preparations containing *nicotine* that are used in place of cigarettes as an aid to stopping *smoking*. Nicotine products are available in the form of *sublingual* tablets (placed under the tongue), chewing gum, skin patches, nasal spray, or inhalers.

Side effects of such preparations may include nausea, headache, palpitations, cold- or flulike symptoms, hiccups, and vivid dreaming. Nicotine replacement therapy should be used as part of a complete package of measures, including the determination to succeed.

nicotinic acid

A form of niacin (see *vitamin B complex*). Apart from its use as a vitamin supplement, nicotinic acid is also prescribed as a *lipid-lowering drug* and as a *vasodilator drug*. High doses are used to treat certain types of *hyperlipidaemia* (a metabolic disorder in which there are high levels of fats in the blood). Nicotinic acid derivatives are used to improve circulation in disorders such as *peripheral vascular disease*.

Adverse effects of nicotinic acid are more common with high doses and include flushing, dizziness, nausea, palpitations, and itching.

NIDDM

The abbreviation for noninsulin-dependent *diabetes mellitus* (type 2 diabetes).

nifedipine

A *calcium channel blocker* drug used mainly to prevent and treat *angina pectoris* (chest pain due to inadequate blood supply to the heart). Nifedipine is also frequently used to treat *hypertension* (high blood pressure) and disorders affecting the circulation, such as *Raynaud's disease*.

Possible side effects of nifedipine include swelling of the hands and feet as a result of *oedema* (accumulation of fluid in tissues), flushing of the skin, headache, and dizziness.

night blindness

The inability to see well in dim light. Many people with night blindness have no discernible eye disease. The condition may be an inherited functional defect of the *retina* (the light-sensitive inner layer at the back of the eye), an early sign of *retinitis pigmentosa* (degeneration of the light-sensitive cells of the retina), or a result of *vitamin A* deficiency.

nightmare

An unpleasant, vivid dream, sometimes accompanied by a sense of suffocation. Nightmares occur during REM (rapid eye movement) sleep in the middle and later parts of the night and they may be clearly remembered if the dreamer awakens completely during the course of the nightmare.

Nightmares are especially common in children aged between eight and ten and are particularly likely to occur when the child is unwell or anxious. In adults, nightmares may be a side effect of certain drugs, including *beta-blocker drugs* and *benzodiazepine drugs*. Repeated nightmares may be associated with traumatic experiences. However, there is no specific relationship with psychiatric illness.

Nightmares should not be confused with *hypnagogic hallucinations*, which occur while falling asleep, nor with *night terror*, which occurs in NREM (nonrapid eye movement) sleep and is not remembered on waking.

night terror

A disorder, occurring mainly in children, that consists of abrupt arousals from sleep in a terrified state. Night terror (or sleep terror) usually starts between the ages of four and seven, gradually disappearing in early adolescence.

Episodes of night terror occur during NREM (nonrapid eye movement) sleep, usually half an hour to three and a half hours after falling asleep. Sufferers wake up screaming, in a semiconscious state, and remain frightened for some minutes. They do not recognize familiar faces or surroundings and usually cannot be comforted. Physical signs of agitation, such as sweating or an increased heart rate, are common. The sufferer gradually falls back to sleep and has no memory of the event the following day.

Though distressing to parents, night terror in children has no serious significance. However, in adults, it is likely to be associated with an *anxiety disorder*.

nipple

The small prominence at the tip of each breast. Women's nipples contain tiny openings through which milk can pass. The nipple and the areola, the surrounding dark area, both increase in size during pregnancy. Involuntary muscle in the nipple allows it to become erect.

DISORDERS

Structural defects of the nipple are rare. One or both nipples may be absent or there may be additional nipples along a line extending from the armpit to the groin. An inverted nipple is usually a harmless abnormality of development, which can be corrected by drawing out the nipple between finger and thumb daily for several weeks. Nipple inversion that develops in older women is mostly due to aging, but *mammography* may be advisable to rule out the possibility of *breast cancer*.

Cracked nipples, common during *breast-feeding*, may lead to infective *mastitis* (inflammation of the breast tissue). Washing, drying, and moisturizing the nipple daily can help to prevent cracking.

Papilloma of the nipple is a non-cancerous swelling attached to the skin by a stalk. *Paget's disease of the nipple* appears initially as persistent *eczema* of the nipple and is due to a slow-growing cancer arising in a milk duct. Surgical treatment is required.

Discharge from the nipple occurs for various reasons. A clear, straw-coloured discharge may develop in early pregnancy; a milky discharge may occur after breast-feeding is over. *Galactorrhoea* (milk discharge in someone who is not pregnant or breast-feeding) may be due to a hormone imbalance or, rarely, a *galactocele* (cyst under the areola). A discharge containing pus indicates a *breast abscess*.

A bloodstained discharge may be due to a noncancerous breast disorder such as *fibroadenosis* (general lumpiness of the breast) or a cancerous tumour.

nitrate drugs

COMMON DRUGS

- Glyceryl trinitrate • Isosorbide dinitrate
- Isosorbide mononitrate

A group of *vasodilator drugs* used to treat or prevent attacks of *angina pectoris* (chest pain due to impaired blood supply to the heart) and to treat severe *heart failure* (reduced pumping efficiency).

Possible side effects of nitrate drugs include headaches, flushing of the skin, and dizziness. *Tolerance* (the need for greater amounts of a drug for it to have the same effect) may develop when some nitrate drugs are taken regularly. To avoid this, a change in dosage, frequency, or timing of the drug, or prescription of a different nitrate drug, may be required.

nitrazepam

A *benzodiazepine drug* used in the short-term treatment of *insomnia*. Nitrazepam is long-acting and may cause a hangover effect, with drowsiness and lightheadedness, the following day. Regular use over several weeks can lead to reduced effectiveness as *tolerance* develops.

Nitrazepam can lead to drug dependence and to withdrawal symptoms, such as nervousness and restlessness. (See also *nitrate drugs; nitrites*.)

nitric oxide (NO)

A gas that is produced both outside the body as a pollutant (for example, in car exhaust fumes) and inside the body, where it takes the form of a molecule that acts as a messenger between cells.

Nitric oxide causes blood vessels to dilate, affecting the flow of oxygenated blood and regulating blood pressure. Overproduction of nitric oxide is associated with various disorders, including *toxic shock syndrome*, and *rheumatoid arthritis*; underproduction may cause *impotence* and *angina*. The control of nitric oxide is an important element of many drug treatments.

nitrites

Salts of nitrous acid (a nitrogen-containing acid). To preserve meat, sodium nitrite is added in small amounts, together with potassium nitrate and salt, to inhibit the growth of potentially harmful bacteria. In large amounts, nitrites can cause dizziness, nausea, and vomiting.

nitrofurantoin

An *antibiotic drug* that is used in the treatment of *urinary tract infection*. Nitrofurantoin should be taken with food to reduce the risk of stomach irritation, which can cause abdominal pain and nausea. More serious side effects, such as breathing difficulty, numbness, and jaundice (yellowing of the skin and the whites of the eyes), occur rarely.

nitrogen

A colourless, odourless gas that makes up 78 per cent of the Earth's atmosphere. Atmospheric nitrogen has no biological action.

Nitrogen gas cannot be utilized by the body, but compounds of nitrogen are essential to life. The most important of such compounds are *amino acids*, the building blocks of *proteins*, which represent the fundamental structural substances of all cells and tissues. Humans cannot make certain amino acids (called *essential amino acids*), which must be obtained from the diet in the form of animal and plant proteins. The proteins are then broken down by digestion into their constituent amino acids to be absorbed and reconstituted into the specific proteins needed by the body. These processes of protein breakdown and reconstitution produce a variety of nitrogen-containing waste products, primarily *urea*, which are excreted by the body in the urine. (See also *nitrate drugs; nitrites*.)

nitroglycerine

A former name for *glyceryl trinitrate*, a *nitrate drug*.

Nitrolingual Pumpspray

The brand name for an aerosol preparation of *glyceryl trinitrate*. This is sprayed under the tongue to treat *angina pectoris* (chest pain due to impaired blood supply to the heart muscle).

nitroprusside

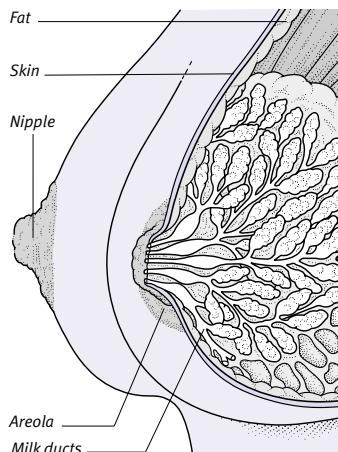

An *antihypertensive drug* given as an infusion in the emergency treatment of *hypertension* (high blood pressure).

nitrous oxide

A colourless gas, also called laughing gas, that has a sweet smell and the chemical formula N₂O. Nitrous oxide is used with oxygen to provide *analgesia* (pain relief) and light anaesthesia (see *anaesthesia, general*) at the site of a serious accident or during childbirth, dental procedures, and minor surgery. For major

LOCATION OF THE NIPPLE

The protrusion at the tip of the breast, surrounded by the areola. Milk ducts emerge at the nipple.

surgery, which requires deeper anaesthesia, a nitrous oxide and oxygen mixture needs to be combined with other drugs.

The advantages of the combination of nitrous oxide and oxygen over other agents are its rapid action and nonflammability. Adverse effects of nitrous oxide may include nausea and vomiting during the recovery period.

nits

The eggs of *lice*. Both head lice and *pubic lice* produce eggs, which they stick to the base of hairs growing from their host's head or pubic area. Nits are tiny, measuring only about 0.5 mm in diameter. They are light brown when newly laid and white when hatched. Hatching takes place within about eight days of being laid. Louse infestations are frequently identified by the presence of nits.

nocardiosis

An infection caused by a funguslike bacterium present in soil. The infection, which is acquired through inhalation, usually starts in the lung and spreads to the brain and tissues under the skin. Nocardiosis is rare, except in people with *immunodeficiency disorders* or those already suffering from a serious disease.

The resulting illness, similar to pneumonia with fever and cough, fails to respond to short-term *antibiotic drug* treatment, and progressive lung damage occurs. Brain abscesses may follow.

Nocardiosis is diagnosed by microscopic examination of sputum. Treatment, which may have to be continued over several months, is with *sulphonamide drugs*, often in conjunction with other antibiotic drugs, such as *trimethoprim*.

nocturia

The disturbance of sleep at night by the need to pass *urine*. In most people, a moderately full bladder does not usually disturb sleep, although light sleepers are more likely to wake with an urge to empty their bladders. Drinking alcohol in the evening stimulates urine production and may result in nocturia.

A common cause of nocturia in men is enlargement of the prostate gland (see *prostate, enlarged*), which obstructs the normal outflow of urine and causes the *bladder* to empty incompletely. In women, a common cause is *cystitis* (inflammation of the bladder), in which irritation of the bladder wall increases its sensitivity so that smaller volumes of urine trigger a desire to urinate. A common cause of nocturia in both sexes is *heart failure* (reduced pumping efficiency of the heart), leading to the retention of excess fluid in the legs during the day, which is absorbed into the bloodstream while lying down at night and is carried to the kidneys to make more urine.

Less common causes of nocturia include *diabetes mellitus*, in which greater volumes of urine are produced both during the day and night; chronic *kidney failure*, in which the normal ability of the kidney to produce a reduced quantity of more concentrated urine at night is lost; and *diabetes insipidus*, in which the kidneys fail to concentrate the urine due to the lack of a pituitary hormone.

nocturnal emission

Ejaculation that occurs during sleep, commonly called a "wet dream". Nocturnal emission is normal in male adolescents and may also occur in adult men.

nocturnal enuresis

See *enuresis, nocturnal*.

nodal

Pertaining to a *node* (a small, rounded knot of tissue).

node

A small, rounded mass of tissue. The term commonly refers to a *lymph node* (a normal structure in the lymphatic system) or to the *sinoatrial node* or *atrioventricular*

node within the conducting system of the heart. (See also *Bouchard's node*; *Heberden's node*; *nodule*; *singer's nodes*.)

nodule

A small lump of tissue. A nodule may protrude from the skin's surface or form deep under the skin. Nodules may be hard or soft. (See also *rheumatoid nodules*; *surfer's nodules*.)

noise

Any sound, particularly one that is disordered and irregular, that is unwanted or interferes with the ability to hear. (See also *noise-induced hearing loss*.)

noise-induced hearing loss

Loss of *hearing* caused by prolonged exposure to excessive noise or by brief exposure to intensely loud noise.

Exposure to a sudden, extremely loud noise (above 130 decibels) can cause immediate and permanent hearing loss. Normally, muscles in the middle *ear* respond to loud noise by repositioning the *ossicles* (bones that pass vibrations to the inner ear) to damp down the noise. If these reflexes have no time to respond, the full force of the vibrations is carried to the inner ear, severely damaging delicate hair cells in the cochlea. Loud noises can even rupture the *eardrum*.

More commonly, noise damage occurs by prolonged exposure to lower levels of noise. Any noise above 85 to 90 decibels may cause gradual destruction of the cochlea's hair cells, leading to permanent hearing loss. Prolonged exposure to loud noise leads initially to a loss of the ability to hear certain high tones. Later, deafness extends to all high frequencies, and speech perception is impaired. Eventually, lower tones are also affected.

Sounds at 85 to 90 decibels or above may initially cause pain and temporary deafness. Prolonged *tinnitus* (ringing or buzzing in the ears) occurring after a noise has ceased is an indication that some damage has probably occurred.

PREVENTION

People who cannot avoid exposure to loud noise (for example, workers using pneumatic drills) should wear ear protection and have their hearing monitored regularly (see *hearing tests*).

noma

Also called *cancrum oris*, noma is the death of tissue in the lips and cheeks due to bacterial infection. The condition is largely confined to young, severely mal-

nourished children in developing countries. Noma can also occur in the last stages of *leukaemia* (cancer of the blood).

The first symptom is inflammation of the gums and the inner surface of the cheeks. Without treatment, this leads to severe ulceration (with a foul-smelling discharge), eventual destruction of the bones around the mouth, and loss of teeth. Healing occurs naturally after a time, but scarring may be severe.

Antibiotic drugs and improved nutrition halt the progress of the disease. Plastic surgery may be used to reconstruct damaged bones or to improve facial appearance.

nonaccidental injury

See *child abuse*.

nongonococcal urethritis

Inflammation of the *urethra* (the tube that carries urine from the bladder to be excreted) due to a cause other than *gonorrhoea*. Nongonococcal urethritis (NGU) was previously known as non-specific urethritis (NSU). Worldwide, the condition is a very common type of *sexually transmitted infection*.

CAUSES

Almost half of all cases of nongonococcal urethritis are known to be caused by *CHLAMYDIA TRACHOMATIS* (see *chlamydial infections*); others may be caused by the virus that causes *herpes simplex*, the protozoan *trichomonas* (see *trichomoniasis*), or other microorganisms. In some cases, the cause remains unknown.

SYMPTOMS

Symptoms generally appear one to five weeks after infection, usually in week two or three. In men, the infection may cause a urethral discharge, which may be accompanied by stinging on passing urine. There may be redness, crusting, and soreness at the urethral opening. However, often no symptoms are present.

The equivalent condition in women, sometimes called nonspecific genital infection, may not cause symptoms unless there are complications. However, a woman who has the infection can pass it on to her sexual partners.

DIAGNOSIS AND TREATMENT

Diagnosis is made from a swab taken from the urethra and a urine sample; both enable identification of the causative organism. *Antibiotic drugs*, such as doxycycline, are the usual treatment.

With treatment, the infection usually clears up in about a week. Follow-up visits may be advised after treatment as

the infection can recur. Sexual partners must be tested and treated if necessary in order to prevent reinfection.

COMPLICATIONS

In men, *epididymitis* (inflammation of the epididymis in the testes), *prostatitis* (inflammation of the prostate gland), and *urethral stricture* (narrowing of the urethra) can occur as complications of nongonococcal urethritis. *Reiter's syndrome* (in which there is arthritis and conjunctivitis as well as the urethritis) occurs as a complication in some men who develop nongonococcal urethritis.

In women, *pelvic inflammatory disease* and infection in the *Bartholin's glands* may occur. *Ophthalmia neonatorum*, a type of conjunctivitis, sometimes develops in babies born to women who have chlamydial cervicitis at delivery.

non-Hodgkin's lymphoma

See *lymphoma, non-Hodgkin's*.

noninvasive

A term used to describe any medical procedure that does not involve penetration of the skin or entry into the body through any natural opening. Examples of noninvasive procedures include *CT scanning* and *echocardiography*.

The term is sometimes also applied to noncancerous tumours that do not spread throughout body tissues.

non-nucleoside reverse transcriptase inhibitors

A type of *antiretroviral drug* that is used to delay the progression of *HIV* infection. (See also *AIDS*.)

nonoxinol 9

A *spermicide* used in contraceptive preparations such as gels, foams, and creams.

nonspecific urethritis

The former term for the condition *nongonococcal urethritis*.

nonstarch polysaccharide (NSP)

Another name for dietary fibre (see *fibre, dietary*).

nonsteroidal anti-inflammatory drugs

COMMON DRUGS

COX-2 INHIBITORS • Celecoxib • Etodolac
• Meloxicam • Rofecoxib

OTHER NSAIDS • Aceclofenac • Acemetacin
• Aspirin • Azapropazone • Benorilate
• Benzylamine • Diclofenac • Diflunisal
• Felbinac • Fenbufen • Fenoprofen

- Flurbiprofen • Ibuprofen • Indometacin
- Ketoprofen • Mefenamic acid • Nabumetone
- Naproxen • Phenylbutazone • Piroxicam
- Sulindac • Tenoxicam • Tiaprofenic acid

A group of drugs, also known as NSAIDs, that produce *analgesia* (pain relief) and reduce inflammation in joints and soft tissues such as muscles and ligaments.

WHY THEY ARE USED

Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used to relieve symptoms caused by types of arthritis, such as *rheumatoid arthritis*, *osteoarthritis*, and *gout*. They do not cure or halt the progress of disease but help to improve mobility of the affected joints and relieve pain and stiffness. NSAIDs are also used in the treatment of back pain, menstrual pain, headaches, pain following minor surgery, and injuries to soft tissue.

HOW THEY WORK

NSAIDs reduce pain and inflammation by blocking the action of the enzyme cyclooxygenase (COX), which is involved in the body's production of *prostaglandins* (chemicals that cause inflammation and trigger transmission of pain signals to the brain, but that also protect the stomach lining). Most NSAIDs block both COX-2 (providing the anti-inflammatory effect) and COX-1 (leading to stomach irritation). COX-2 inhibitors were developed to block COX-2 alone, thereby reducing the risk of stomach irritation.

POSSIBLE ADVERSE EFFECTS

NSAIDs may cause a range of side effects, including nausea, indigestion, bleeding from the stomach, *fluid retention*, and, occasionally, *peptic ulcer*. They may also worsen *heart failure* or *kidney failure*. COX-2 inhibitors cause less gastrointestinal irritation than other NSAIDs.

Noonan's syndrome

An inherited condition that shares many features with *Turner's syndrome*, but in which there is a full complement of chromosomes. Noonan's syndrome can affect both males and females. Features include congenital heart disease (see *heart disease, congenital*), *webbing* of the neck, *ptosis* (drooping eyelids), *myopia* (shortsightedness), feeding problems in infants, *short stature*, *hypotonia* (poor muscle tone), hearing difficulties, delayed speech development, delayed *puberty*, and undescended testes (see *testis, undescended*) in males.

In terms of inheritance, Noonan's syndrome demonstrates an autosomal dominant pattern (see *genetic disorders*).

There is a family history of the condition in approximately half of all cases; the remainder are due to new *mutations*. There is no treatment for the condition as a whole, but many of its features (such as undescended testes and heart problems) may be treated successfully.

noradrenaline

Also known as norepinephrine, a *hormone* secreted by certain nerve endings (principally those of the *sympathetic nervous system*) and by the medulla (the central region) of the *adrenal glands*.

Noradrenaline's primary function is to help maintain a constant blood pressure by stimulating certain blood vessels to constrict (narrow) when blood pressure falls. For this reason, it may sometimes be administered by injection in the emergency treatment of *shock* or severe bleeding. (See also *adrenaline*.)

norepinephrine

An alternative term for *noradrenaline*.

norethisterone

A *progestogen drug* used primarily as an ingredient of some *oral contraceptives* and HRT preparations. Norethisterone is sometimes prescribed to postpone menstruation. It is also used to treat *premenstrual syndrome*, menstrual disorders such as *menorrhagia* (heavy periods), *endometriosis*, and certain types of *breast cancer*. Norethisterone is given by injection as a long-acting contraceptive.

Possible side effects include swollen ankles, weight gain, depression and, rarely, *jaundice* (yellowing of the skin and the whites of the eyes).

norfloxacin

An *antibiotic drug* used in the treatment of *urinary tract infections*.

norgestrel

See *levonorgestrel*.

Noriday

A brand name for *norethisterone* tablets, which are progesterone-only *oral contraceptives*.

normocytic anaemia

Any form of *anaemia* in which the amount of *haemoglobin* (oxygen-carrying pigment) in the blood is reduced, due to a reduction in the total number of *red blood cells*, but the size and haemoglobin content of the individual cells is normal. Normocytic anaemia can develop as a

result of chronic diseases (such as *renal failure* or chronic inflammatory joint diseases such as *rheumatoid arthritis*), or as a result of a problem in the bone marrow itself. (See also *microcytic anaemia*.)

nose

The uppermost part of the respiratory tract and the organ of *smell*.

STRUCTURE

The nose is an air passage connecting the nostrils at its front to the *nasopharynx* (the upper part of the throat) at its rear. The *nasal septum*, which is made of cartilage at the front and bone at the rear, divides the passage into two chambers.

The bridge of the nose is formed from two small nasal bones and from cartilage. The roof of the nasal passage is formed by bones at the base of the skull; the walls by the maxilla (upper jaw); and the floor by the hard palate. Three conchae (thin, downward-curving plates of bone) covered with *mucous membrane* project from each wall.

Air-filled, mucous membrane-lined cavities (called *paranasal sinuses*) open into the nasal passage. There is an opening in each wall to the nasolacrimal duct, which drains away tears. Projecting into the roof of the nasal passage are the hairlike endings of the *olfactory nerves*, responsible for the sense of smell.

FUNCTION

One important function of the nose is to filter, warm, and moisten inhaled air before it passes into the rest of the respiratory tract. Just inside the nostrils, small hairs trap large dust particles and foreign bodies. Smaller dust particles are filtered from the inhaled air by the microscopic hairlike projections of the conchae. The mucus on the conchae flows inwards, carrying microorganisms and other foreign bodies back towards the nasopharynx to be swallowed and destroyed in the stomach.

The nose also detects smells by means of the olfactory nerve endings, which, when stimulated by inhaled vapours, transmit this information to the olfactory bulb in the brain. (See also *nose disorders* box.)

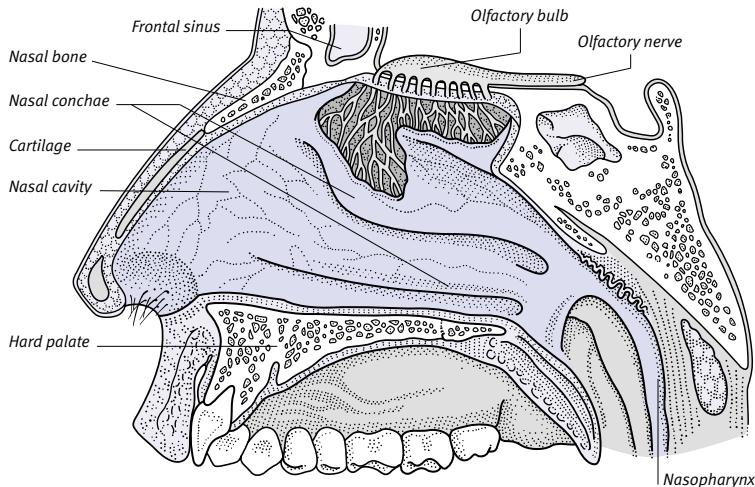

nosebleed

Loss of blood from the *mucous membrane* that lines the nose. Nosebleeds are common in children, but the bleeding is usually minor and stops by itself. Nosebleeds are also common, but in some cases serious, in people over the age of 50. In this age group, bleeding

ANATOMY OF THE NOSE

The nose is involved in breathing and the sense of smell. It is a hollow passage that connects the nostrils and the top of the throat. It warms and

moistens air and traps particles to prevent them from being inhaled. The upper part contains the receptors that transmit sensations of smell.

may come from the back of the nose and be hard to stop. If the blood is swallowed, bleeding may not be seen.

CAUSES

Nosebleeds often occur spontaneously. In dry environments or during the winter months, the membranes lining the nose may become dry and cracked, causing bleeding to occur. Nosebleeds may also occur if the lining of the nose is injured by a blow to the nose or by nose-picking or forceful nose-blowing. In children, nosebleeds often occur as a result of rough play.

A foreign body in the nose or an infection in the upper respiratory tract may also result in a nosebleed. In people over the age of 50, the small blood vessels in the nose may be more fragile and therefore more likely to rupture and cause bleeding.

Rarely, recurrent nosebleeds are a sign of an underlying disorder, such as *hypertension* (high blood pressure), a bleeding disorder such as *thrombocytopenia*, or a tumour of the nose or paranasal sinuses. Nosebleeds may also be caused by drugs that prevent blood clotting (see *anticoagulant drugs*).

TREATMENT

The vast majority of nosebleeds are short-lived and do not require specific treatment. A nosebleed can usually be stopped by pressing on the soft part of

the nose (pressing both sides together) for about 15 minutes. If membranes in the nose are dry or cracked, rubbing water-based ointment on the area may help to prevent nosebleeds.

A nosebleed that persists for more than about an hour requires medical attention. Treatment for a serious nosebleed may involve nasal sponges placed into the nostrils to absorb the blood or the insertion and inflation of a balloon catheter to stop the bleeding. If the cause is not obvious, the nasal passages may be examined with a viewing instrument to look for ruptured blood vessels or a tumour (see *endoscopy*). Alternatively, imaging techniques such as *X-rays* or *MRI* (a technique that produces cross-sectional or three-dimensional images of body structures) may be used. Treatment will then be of the underlying cause. Occasionally, surgery is required to tie off leaking blood vessels.

nose, broken

Fracture of the nasal bones or dislocation of the cartilage that forms the bridge of the nose. A blow from the side may knock the bones or cartilage out of position or cause displacement of the *nasal septum* (the dividing partition inside the nose). A frontal blow tends to splay the bones of the nose outwards, depressing the bridge. The fracture is

DISORDERS OF THE NOSE

The nose is susceptible to a wide range of disorders. Infections and allergic conditions, leading to stuffiness or sneezing, are common. Due to its prominent position, the nose is also prone to injury.

Infection

The common cold (see *cold, common*), a viral infection, causes inflammation of the lining of the nasal passages and excessive production of mucus, leading to nasal congestion. Small *boils* (infected hair follicles) sometimes occur just within the nostril, where they may cause pain. Backward spread of infection from the nose may cause *cavernous sinus thrombosis*, a serious condition that, without antibiotic drugs, can be fatal.

Tumours

Noncancerous tumours of blood vessels, known as *haemangiomas*, may affect the nasal cavity in babies. Many

disappear spontaneously before puberty. *Basal cell carcinoma* and *squamous cell carcinoma* (types of skin cancer) may occur in or around the nostril. The nose may also be invaded by cancers originating in the sinuses.

Injury

Because of its prominent position, the nose is also particularly prone to injury. Fracture of the nasal bones (see *nose, broken*) is a common sports injury that can lead to deformity and may require corrective surgery. *Nosebleeds* are also common, particularly in children; they may be caused by fragile blood vessels, infection of the lining of the nose, or a blow to the nose.

Drugs

Repeated sniffing of cocaine interferes with the blood supply to the mucous membrane lining the nose and can cause perforation of the nasal septum. Persistent taking of snuff can irritate or damage the nasal lining.

Allergies

Hay fever (see *rhinitis, allergic*) is one of the most common allergies and may be brought on by a reaction to various allergens, such as pollens, animal dander, house mites, or fungal spores.

Obstruction

A *nasal polyp* (a projection of swollen mucous membrane) may block a nostril, causing a feeling of congestion. Young children frequently insert foreign bodies, such as beads, peas, or pebbles, into their nostrils. Objects can become stuck, leading to obstruction and discharge.

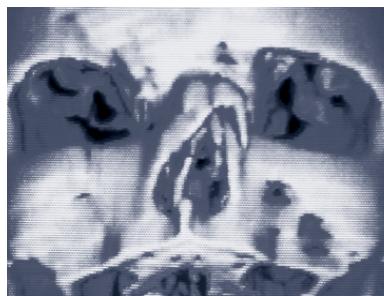

INVESTIGATION

To inspect the inside of the nose, the doctor uses a speculum in order to open up the nostrils. If a fracture is suspected, X-rays are taken. If cancer is suspected, a nasal endoscopy and a biopsy are performed.

usually accompanied by severe swelling of overlying soft tissue. A fractured nose is painful and remains tender for about three weeks after the injury.

TREATMENT

Resetting is usually carried out either before the swelling has started or when it has subsided, usually about ten days after the injury. Occasionally, a displaced bridge can be carefully manipulated into position under a local anaesthetic (see *anaesthesia, local*). However, a general anaesthetic (see *anaesthesia, general*) is usually needed. A plaster splint is sometimes required during healing.

CT scan showing broken nose

In this three-dimensional image of the skull, a fracture of the nasal bone is clearly visible. The damaged bone is asymmetrical and has a V-shaped notch on the right-hand side.

nose reshaping

See *rhinoplasty*.

nosocomial

A term that means associated with hospitals. A nosocomial infection, for example, is an infection acquired by a patient during a stay in hospital.

notifiable diseases

Medical conditions that must be reported to the local health authority. The notification of certain potentially harmful infectious diseases enables public health physicians to monitor and control the spread of infection and records to be kept of disease patterns.

Examples of notifiable infectious diseases are *food poisoning*, *viral hepatitis*, *measles*, *malaria*, *pertussis* (whooping cough), *tetanus*, *tuberculosis*, *meningitis*, *mumps*, and *rubella* (German measles). Similar information is also collected on cancers, occupational diseases, birth defects, and other noninfectious health problems. (See also *prescribed diseases*.)

NREM sleep

The abbreviation for nonrapid eye movement *sleep*, the period of sleep during which the brain is less active. NREM sleep occurs alternately with

REM sleep throughout the night. An average cycle of sleep is made up of three-quarters NREM sleep and one-quarter REM sleep.

NSAID

The abbreviation for *nonsteroidal anti-inflammatory drugs*.

NSU

The abbreviation for nonspecific urethritis, the former term for *non-gonococcal urethritis*.

nuchal thickness scan

Ultrasound scanning performed in early pregnancy in order to identify fetuses at high risk of *chromosomal abnormalities*, such as *Down's syndrome*. The scan investigates the thickness of the nuchal fold, an area of skin at the back of the neck. Excessive thickness of the nuchal fold is an indication that there may be chromosomal abnormalities.

nuclear energy

The energy that is released as a result of changes in the nuclei (see *nucleus*) of atoms. Nuclear energy is also known as atomic energy and it is principally released in the form of heat, light, and ionizing *radiation*, such as gamma rays.

Nuclear energy is released in certain natural processes, examples of which include the spontaneous decay of radioactive substances, such as uranium ores, and the nuclear reactions that power the sun. Nuclear energy is also released in specifically designed devices, for example in nuclear reactors.

nuclear magnetic resonance

See *MRI*.

nuclear medicine

Techniques that use radioactive substances (see *radioactivity*) in the detection and treatment of disease.

Radioactive materials, which may be injected, inhaled, or swallowed, are taken up by body tissues or organs in different concentrations, and an instrument called a *gamma camera* is used to detect and map the distribution of radiation within the body (see *radionuclide scanning*). The technique uses only minuscule quantities of radiation.

In techniques for treatment, higher doses of radiation are used. Diseased tissues are destroyed by exposure to an external radioactive source or by insertion of a radioactive substance into a body cavity (see *radiotherapy; interstitial radiotherapy; intracavitary therapy*).

N

nucleic acid

A substance found in all living matter that has a fundamental role in the propagation of life. Nucleic acids provide the inherited coded instructions (or “blueprint”) for an organism’s development; they also provide apparatus by which these instructions are carried out.

TYPES

There are two types of nucleic acid: deoxyribonucleic acid (DNA) and ribonucleic acid (RNA). In all animal and plant cells, including human cells, DNA permanently holds the coded instructions, which are first translated and then implemented by RNA. DNA is the main constituent of *chromosomes*, which are carried in the nucleus of the cell.

STRUCTURE

DNA and RNA are similar in structure, both comprising long, chainlike molecules. However, DNA usually consists of two intertwined chains, whereas RNA is generally single-stranded.

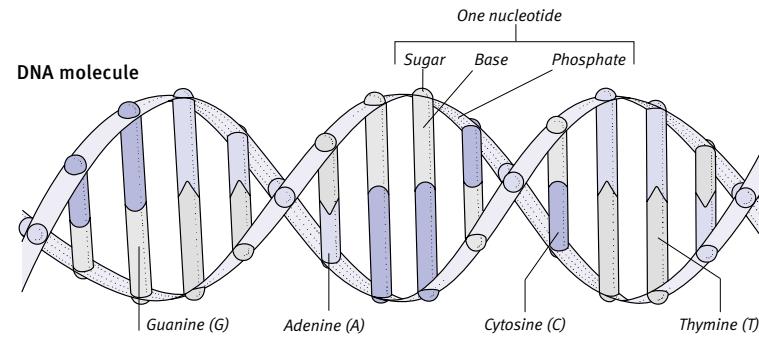

The basic structure of DNA is like a rope ladder; the chains form the two sides, and interlinking structures in between form the rungs. The ladder twists into a spiral shape called a double helix.

NUCLEIC ACIDS

Two types of nucleic acid are found in body cells: DNA and RNA, both of which are long, chainlike molecules (strands). DNA consists of two intertwined strands (a double helix), and RNA is usually just a single strand.

Nucleic acids are made up of units called nucleotides, each consisting of a sugar, a phosphate group, and a base.

There are four different bases in DNA: adenine (A), cytosine (C), guanine (G), and thymine (T). These bases pair up, adenine with thymine and cytosine with guanine, to form the characteristic double helix structure of DNA. RNA is like a single strand of DNA but has a base called uracil (U), instead of thymine, which pairs with adenine.

Each DNA chain has a “backbone” consisting of a string of sugar and phosphate chemical groups. Attached to each sugar is a chemical called a base, which can be any of four types (adenine, thymine, guanine, and cytosine) and forms half a rung of the DNA ladder. The four bases can occur in any sequence along the chain. The sequence, often many millions of individual bases long, provides the code for the activities of the cell (see *genetic code*). Because the two bases that form each rung of the ladder conform to certain pairings, known as base pairs (adenine pairs with thymine; and guanine with cytosine) the sequence of bases on one chain determines the sequence on the other. This is of fundamental importance for the copying of DNA molecules when a cell divides.

RNA is like a single strand of DNA; the main difference is that the base thymine is replaced by another base, uracil, and the sugar and phosphate chain is chemically slightly different.

FUNCTION

DNA controls a cell’s activities by specifying and regulating the synthesis of *enzymes* (substances that promote biochemical reactions) and other proteins in the cell. Different *genes* (sections of DNA) regulate the production of different proteins. For a particular protein to be made, an appropriate section of DNA acts as a template for an RNA chain. This “messenger” RNA then passes out of the

nucleus into the cell cytoplasm (a thick fluid that forms the bulk of the cell), where it is decoded to form proteins (see *protein synthesis*).

When a cell undergoes mitotic (see *mitosis*) division, identical copies of its DNA must go to each of the two daughter cells. The structure of DNA makes this process possible. Starting at one end of the molecule, the two chains “unzip”. As they do so, two more chains are formed (side by side with the original chains) by the linking of free, unlinked nucleotides that are present in cells. Because only certain base pairings are possible, the new double chains are identical to the original DNA molecule. Thus a dividing cell provides an exact copy of its DNA to its daughter cells. Each of a person’s cells carries the same DNA replica that was present in the fertilized ovum, thus the DNA message passes from one generation of cells to the next.

nucleoside reverse transcriptase inhibitors

An *antiretroviral drug* used to delay the progress of HIV infection. (See also *AIDS*.)

nucleotide

A compound that consists of a base, linked to a sugar and a phosphate group. The *nucleic acids* DNA and RNA are chains of linked nucleotides. There are four different bases in DNA, adenine, cytosine, guanine, and thymine, which

always pair up, adenine with thymine and cytosine with guanine, to form the characteristic double helix of DNA. RNA is like a single strand of DNA but has uracil as a base instead of thymine. The sugar molecule in DNA is deoxyribose; in RNA it is ribose.

nucleus

The central core, structure, or focus of any of a variety of objects or structures.

CELL NUCLEUS

The nucleus of a living *cell* is a roughly spherical unit at the centre of the cell. It contains the *chromosomes* (composed mainly of *nucleic acid*), which are responsible for directing the cell's activities, and is surrounded by a membrane. The membrane has small pores through which various substances can pass between the nucleus and the cytoplasm, a thick fluid that forms the bulk of the cell. Usually, the nucleus has one nucleolus, a smaller dense region with no membrane concerned with protein manufacture.

NERVE NUCLEUS

A nerve nucleus is a group of *neurons* (nerve cells) within the brain and the spinal cord that work together to perform a particular function.

ATOMIC NUCLEUS

The nucleus of an atom is composed of protons and neutrons and accounts for almost the total mass of the atom, but only a tiny proportion of its volume. *Nuclear energy* is produced through changes in atomic nuclei.

nulliparous

A term that refers to a woman who has never given birth to a live infant, including a woman who has never conceived. (See also *grand multipara*; *multiparous*.)

numbness

Loss of sensation in part of the body caused by interference with the passage of impulses along sensory *nerves*.

CAUSES

Numbness can occur naturally (such as when blood supply to a nerve in the leg is cut off temporarily by sitting cross-legged); it can be induced artificially (for example by a dentist anaesthetizing a nerve before filling a tooth); or it may be the result of a disorder of the *nervous system* or its blood supply.

Multiple sclerosis can cause loss of sensation in any part of the body through damage to nerve pathways in the central nervous system (CNS). In a *neuropathy*, the peripheral nerves (nerves outside

the CNS) are damaged. In a *stroke*, pressure on, or reduced blood supply to, nerve pathways in the brain often causes loss of feeling on one side of the body.

Severe cold, as in *frostbite*, causes numbness by direct action on the nerves. Numbness is a symptom of *Raynaud's disease*, a disorder of the blood vessels in which exposure to cold causes the small arteries supplying nerves in the fingers and toes to contract suddenly.

Numbness may indicate psychological disorders, such as *anxiety*, *panic attack*, or a hysterical *conversion disorder*.

DIAGNOSIS AND TREATMENT

Examination usually reveals an area of sensory loss or impairment corresponding to the skin distribution of a single peripheral nerve, several nerves, or a sensory area in the CNS. The distribution of the affected area may suggest the site and mechanism of the nerve damage. Treatment depends on the cause.

nummular

Round, flat, and disc-shaped. The term may also be used to describe a structure or condition that features round, flat, disc-shaped abnormalities. For example, nummular eczema is a skin disorder defined by the appearance of characteristic coin-shaped patches of itchy skin.

nurse

A person trained and experienced in the scientific basis of nursing. He or she is entrusted with the care of the sick and the carrying out of medical and surgical duties. Worldwide, nurses must meet certain prescribed standards of education and clinical competence. They must generally undergo a period of training in a hospital and pass a final examination in order to qualify in the profession.

The term nursing may also be used interchangeably with *breast-feeding*. (See also *doctor*; *midwifery*.)

nutrient

An essential dietary factor, such as carbohydrates, proteins, certain fats, vitamins, and minerals. (See *Essential nutrients* boxes, overleaf.)

nutrition

The scientific study of food and the processes of digestion and assimilation. Nutritionists look at the ways in which various types of food are used by the body, the chemical components of different foods, and the effects of eating certain foods on health. The knowledge

gained by nutritionists from studying the effects of diet on health in different countries has led to the development of guidelines to ensure a healthy, balanced diet that can reduce the risk of ill health.

A BALANCED DIET

A good diet supplies adequate quantities of the main nutrients: *proteins*, *carbohydrates*, *fats and oils*, *vitamins*, *minerals*, dietary fibre (see *fibre, dietary*), and water. Each one of these elements makes an important contribution to health, but it is important that they are consumed in the correct proportions, with carbohydrates forming the bulk of the diet and fats only a relatively small proportion.

The daily diet should include foods from each of the five main food groups. Bread, potatoes, pasta, and other complex carbohydrates provide energy, plenty of dietary fibre, some minerals, and vitamins in the B group (see *vitamin B complex*). Milk and dairy foods provide protein and are a good source of *calcium* and certain vitamins, such as B_{12} , A, and D; low-fat versions are useful for reducing the overall fat intake in the diet. Meat, fish, and pulses provide protein, *iron*, B vitamins, and some minerals. A variety of fruit and vegetables should be eaten, ideally five portions each day. Fruit and vegetables provide fibre and carbohydrate and are rich in vitamins and minerals. Fatty and sugary foods (such as sweets, cakes, and chips), although providing *energy*, have little other nutritional value and should be limited in the diet. Consumption of saturated fats should be kept to an absolute minimum.

In addition to foods from the main groups, the diet should contain plenty of water, as much as eight glasses a day. The need for water is increased by diarrhoea, vomiting, and taking *diuretic drugs*. Drinks that contain sugar, caffeine, or alcohol should be consumed in moderation. Sugar contributes to tooth decay; carbonated drinks, even those low in sugar, can damage the teeth because they are acidic. Excessive intake of caffeine can cause palpitations and insomnia.

ENERGY REQUIREMENTS

The body needs a constant reserve of energy to function properly. Energy from food is measured in units called kilojoules (kJ) or kilocalories (kcal), which are usually referred to simply as calories.

The number of calories needed by an individual depends on how much energy their body uses. This depends partly on how efficiently the body's cells use energy, which is genetically determined,

ESSENTIAL NUTRIENTS		
Proteins	The main structural component of tissues and organs. We need proteins for growth and repair of cells. Each protein contains hundreds and sometimes thousands of units called amino acids in specific combinations. In the body there are 20 different amino acids; 12 of these can be manufactured by the body itself	and the remaining eight can only be obtained by eating a balanced diet. A vegetarian diet that contains eggs, milk, and cheese provides sufficient amounts of all the essential amino acids. A vegan diet, which also excludes dairy products, needs careful planning in order to prevent a deficient intake of protein (see <i>Vegetarianism</i>).
Carbohydrates	The two carbohydrate food groups, sugars (simple carbohydrates) and starches (complex carbohydrates), are the main energy sources that are required for metabolism (chemical processes that take place in cells).	Complex carbohydrates should make up at least half of the diet. Complex carbohydrates found in cereals and fruit are rich in fibre and nutrients. Refined carbohydrates such as sugar and white flour should be kept to a minimum.
Fats	Fats provide energy for metabolism and are a structural component of cells. Most people in developed countries eat too much fat; fats should constitute no more than 30 per cent of total calorie intake. There are three types of dietary fats: saturated fats (found mostly in meat and dairy products), monounsaturated fats (found in olive oil and avocados), and polyunsaturated fats (found in fish and vegetable oils). Saturated fats	tend to increase the amounts of unwanted types of cholesterol in the blood whereas polyunsaturated fats and monounsaturated fats have the opposite effect. Studies have indicated that a high level of low-density lipoprotein cholesterol in the blood is associated with coronary artery disease. Our bodies naturally produce enough cholesterol for our needs; excess is mostly due to eating too much saturated fat.
Fibre	This is the indigestible structural material that is found in plants. Although fibre passes through the intestine unchanged, it is an essential part of a healthy diet. A diet low in fibre may lead to constipation, diverticular disease, and other disorders.	High-fibre diets (including plenty of fruit, raw vegetables, grains and cereals) provide bulk without excess calories. Low-fibre diets tend to be high in refined carbohydrates and fats, and thus increase the risk of developing obesity, heart disease, and some cancers.
Water	Our bodies are composed of about 60 per cent water. Water constitutes a high proportion of many foods, particularly fruit and vegetables, and is essential to maintain	metabolism (chemical processes in cells) and normal kidney and bowel function. Water is also the major component of the volume of blood in the circulation.
Vitamins	Regulators of metabolism. Vitamins ensure the healthy functioning of the brain, nerves, muscles, skin, and bones. Although vitamins do not supply energy, some enable energy to be released from the food. A healthy, balanced diet contains enough vitamins for most people's needs, and supplements are not	usually necessary. Indeed, some vitamins that are stored in fats (A, D, E, and K) are dangerous if taken in excess. The body can store only relatively small amounts of water-soluble vitamins (B and C), but even on a very restricted diet, vitamin deficiency is rare until several months have elapsed.
Minerals	A balanced diet provides enough minerals for most people. Calcium is necessary for the maintenance of healthy teeth and bones. Other minerals, such as zinc and magnesium, are needed in minute amounts to control cell metabolism.	The only mineral commonly required as a supplement is iron, which is used to prevent anaemia in women who have heavy periods. Sodium chloride (salt) is needed to maintain fluid balance; excess may cause high blood pressure.

and on the level of physical activity. The rate at which the body uses energy simply to maintain basic processes such as breathing and digestion is called the basal metabolic rate (BMR). Extra calories are needed for all other activities; energetic sports increase calorie requirement. Energy requirements also depend on gender (for example, an average woman requires about 2,000 kcal daily, compared with about 2,500 kcal for an average man) and age (a growing teenager requires more calories than an adult and the BMR declines with increasing age). A pregnant woman needs more calories than a nonpregnant woman.

If more calories are consumed than are needed, the excess energy is stored as fat and weight is gained. Weight loss occurs if demands for energy exceed calorie intake. (See also *energy requirements; metabolism*.)

nutritional disorders

Nutritional disorders may be caused by a deficiency or excess of one or more *nutrients*, or by the presence of a *toxin* (poisonous element) in the diet.

NUTRITIONAL DEFICIENCY

A diet deficient in *carbohydrates* is usually also deficient in *protein*, leading to protein–calorie malnutrition, which most often occurs as a result of severe poverty and famine (see *kwashiorkor; marasmus*).

Inadequate intake of protein and calories may also occur in people who restrict their diet excessively to lose weight (see *anorexia nervosa*), hold mistaken beliefs about diet and health (see *food fad*), or lose interest in food due to *alcohol dependence* or *drug dependence*.

Deficiency of specific nutrients is commonly associated with a disorder of the digestive system, such as *coeliac disease*, *Crohn's disease*, or pernicious anaemia (see *anaemia, megaloblastic*).

NUTRITIONAL EXCESS

Obesity results from taking in more *energy* from the diet than is used up by the body. It is a major threat to health and is associated with disorders such as *coronary artery disease*, *hypertension* (high blood pressure), and *stroke* (damage to part of the brain due to interruption to its blood supply). An excessive intake of saturated fat is thought to be a factor in cardiovascular disease and in certain *cancers*. Nutritional disorders may also result from excessive *minerals* and *vitamins*.

TOXINS

Naturally occurring toxins can interfere with the digestion, absorption, and/or utilization of nutrients or cause specific

FOOD SOURCES OF ESSENTIAL NUTRIENTS

The tables list a selection of foods that are good sources of carbohydrate, protein, fat or fibre, together with the amount of the nutrient concerned in 100 g of each food. The figures given

PROTEIN	
Food	Protein content (g of protein per 100g of food)
Yeast extract	40
Beef, lean, roast	31
Tuna, canned	28
Wheatgerm	27
Cheese, cheddar	26
Chicken, lean, roast	26
Peanuts, shelled, roasted	24
Cod, grilled	17
Soya beans	14
Cottage cheese, low-fat	13
Eggs, boiled	12
Brazil nuts	12
Tofu (soft)	9
Chick peas	9

CARBOHYDRATE	
Food	Carbohydrate content (g of carbohydrate per 100g of food)
Sugar, white	100
Sugar, brown	100
Rice, white, uncooked	87
Cornflakes	87
Pasta, uncooked	84
Brown rice	81
Honey	81
Flour, white	80
Apricots, dried, stoned	67
Chocolate, milk	57
Beans, haricot, uncooked	45
Bread, white	45
Bread, wholemeal	37
Prunes	34

here are averages, because the exact nutrient content of many foods depends on variable factors such as the method of preparation. (See also *vitamins; minerals*.)

FAT	
Food	Fat content (g of fat per 100g of food)
Coconut oil (saturated fat)	92
Butter and margarine	81
Brazil nuts, shelled	67
Peanuts, shelled, roasted	49
Sausage, pork, cooked	42
Beef, lean with fat, roast	40
Low-fat spread	39
Cream, whipping	38
Cheese, cheddar	32
Chocolate, milk	30
Egg yolk	30
Olive oil (saturated fat)	14
Corn oil (saturated fat)	13
Sunflower oil (saturated fat)	9

FIBRE	
Food	Fibre content (g of fibre per 100g of food)
Bran	44
Apricots, dried, stoned	24
Prunes	14
Peas, boiled	12
Blackcurrants	9
Brazil nuts	9
Bread, wholemeal	9
Peanuts, shelled, roasted	8
Sweetcorn	6
Celery	5
Tofu	4
Broccoli	4
Lentils	2
Bread, white	2

disorders due to their toxic effects. For example, the *ergot* fungus on rye can cause ergotism, symptoms of which include *gangrene* (tissue death) of the toes and fingers, *seizures*, and mental disorders.

Industrial pollutants, pesticides, fertilizers, and various other chemicals may also contaminate food.

nymphomania

An outdated term for a condition in which a woman has an insatiable appetite for sexual activity with many partners. The equivalent behaviour in men is called satyriasis or Don Juanism. It was said to be caused by intense *narcissism* and feelings of inferiority.

nyctagmus

A condition in which there is involuntary movement of the eyes. This movement is usually horizontal, but can be vertical or rotatory. In almost all cases, both eyes move together.

TYPES

In the most common type, jerky nystagmus, the eyes repeatedly move slowly in one direction and then rapidly in the other. This may also occur as a normal effect of attempting to follow a sequence of objects rapidly passing the eyes, such as when looking out of the window of a moving vehicle. This phenomenon is known as "optokinetic nystagmus". Less commonly, nystagmus is "pendular", with the eyes moving evenly up and down or from side to side.

CAUSES

Nystagmus may be congenital (present at birth), in which case the cause is unknown. Because a steady gaze is impossible, there is almost always a moderate to severe defect of visual acuity. The condition also occurs in *albinism* and as a result of any very severe defect of vision present at birth, such as congenital *cataract*.

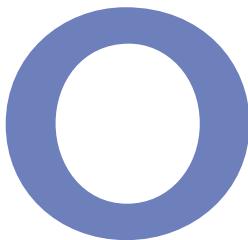

Persistent nystagmus appearing later in life usually indicates a nervous system disorder (such as *multiple sclerosis*, a *brain tumour*, or an *alcohol-related disorder*), or a disorder of the balancing mechanism in the inner ear. Adult-onset nystagmus is occasionally seen as an occupational disorder in people who work in poor light, such as coal miners.

INVESTIGATION AND TREATMENT

Electronystagmography, which is a method of recording eye movements, may be used to differentiate between the different types of nystagmus. Treatment is of the underlying cause, if possible.

nystatin

An *antifungal drug* used in the treatment of *candidiasis* (thrush). Nystatin may be taken as a tablet, liquid, pessary, cream, or ointment and can be safely used during pregnancy. High doses taken orally may cause diarrhoea, nausea, vomiting, and abdominal pain.

oat cell carcinoma

A form of *lung cancer*, also known as *small cell carcinoma*.

obesity

An increasingly common condition in which a large amount of excess fat has accumulated in the body. An obese person is defined as having a *body mass index (BMI)* (calculated from height and weight) of over 30. A BMI of between 25 and 30 is overweight, but not obese.

CAUSES

Obesity is usually caused by the regular consumption of more food than is needed for energy. Energy requirements are determined partly by metabolic rate (see *metabolism*) and partly by level of physical activity. Genetic factors may play a significant part in obesity. However, environmental influences (such as eating and exercising patterns) are also important. In a small minority of cases, obesity is due to an underlying disorder, such as *hypothyroidism* (underactivity of the thyroid gland), *Cushing's syndrome*, damage to the *hypothalamus* (the area of the brain responsible for controlling the appetite), or the effects of drug treatment (such as with *corticosteroid drugs*).

COMPLICATIONS

Obesity substantially increases the risk of serious illness. *Hypertension* (high blood pressure), *stroke*, and type 2 *diabetes mellitus* are much more likely to occur in obese people. *Coronary artery disease* is also more common in the obese, particularly in men under 40. Obesity is also associated with an increased risk of some cancers, including cancer of the colon, rectum, breast, and uterus. Extra weight may aggravate *osteoarthritis* due to strain on the joints.

TREATMENT

The first line of treatment is a weight-reducing diet (see *weight reduction*) plus regular exercise. Fad diets may cause a dramatic weight loss within a short period of time but, in almost all cases, the weight is quickly regained when normal eating habits are resumed.

Appetite suppressant drugs are rarely used because of their side effects. *Orlistat*, a drug that prevents absorption of fat from the intestine, is effective only while being taken. Side effects include diarrhoea and vitamin deficiencies.

Radical procedures are sometimes considered for severely obese people who have failed to lose weight using routine methods. *Wiring of the jaws* may be carried out to restrict food intake. An operation in which part of the stomach is stapled together to reduce its capacity may be performed. Intestinal bypass operations are occasionally performed to reduce the length of the digestive tract and allow less food to be absorbed. However, due to the risk of adverse effects, such procedures are only considered if obesity is seriously endangering a person's health.

obsessive-compulsive disorder

A psychiatric condition, often known as OCD, in which an individual is dogged by persistent ideas (obsessions) that lead to repetitive, ritualized acts (compulsions). The disorder, which usually starts in adolescence, is rare. However, minor obsessional symptoms probably occur in about one sixth of the population, particularly at times of stress.

CAUSES

OCD may have a genetic element, but environmental factors also play a part. Personality traits of orderliness and cleanliness are thought to be related, as is a tendency to neurotic symptoms. Certain brain damage, especially that of *encephalitis*, can cause obsessional symptoms. Tests on people with OCD show overactivity in frontal areas of the brain.

SYMPOTMS

Obsessions are recurrent thoughts or feelings that come into the mind seemingly involuntarily. Although people who are affected regard such thoughts as senseless, they are unable to ignore or resist them. Thoughts of violence, fears of being infected by germs or dirt, and constant doubts (for example, whether the front door is shut or the oven turned off) are the most common obsessions. In obsessional rumination, there is constant brooding over a word, phrase, or unanswerable problem.

Compulsions are repetitive, apparently purposeful acts that are carried out in a ritualized fashion. They are performed for the purpose of warding off fears or relieving anxiety. Handwashing, counting, and checking are the most common.

Compulsive acts may have to be performed so many times that they seriously disrupt work and social life.

The disorder is often accompanied by *depression* and *anxiety*. If severe, a person may become housebound.

TREATMENT

Many sufferers respond well to *behaviour therapy*, sometimes combined with anti-depressant drugs (see *selective serotonin reuptake inhibitors*). Most recover within a year, but symptoms may recur under stress. For the most severely affected, OCD can be a lifelong problem.

obstetrics

The branch of medicine concerned with *pregnancy* and *antenatal care*, *childbirth*, and *postnatal care*. Obstetrics also involves the study of the structure and function of the female *reproductive system*. (See also *gynaecology*.)

obstructive airways disease

See *pulmonary disease*, *chronic obstructive*.

obstructive jaundice

A type of *jaundice* (yellowing of the skin and the whites of the eyes) resulting from an obstruction to the flow of *bile* (an alkaline liquid that carries waste products away from the *liver*) between the liver and the small intestine. Causes include *gallstones* and cancer of the pancreas (see *pancreas, cancer of*).

obstructive sleep apnoea

A type of *sleep apnoea* due to obstruction of breathing by repeated blockage of the upper airway during sleep.

occipital lobe

One of the two areas of *brain* tissue that lie beneath the occipital bone at the back of the brain. The occipital lobe is primarily concerned with vision.

occiput

The lower back part of the head, where it merges with the neck.

occlusion

Blockage of a passage, canal, opening, or vessel in the body. Occlusion may be caused by disease (for example, a *pulmonary embolism*) or may be medically induced. The term also describes eye-patching for the treatment of *amblyopia* (a defect of visual acuity) in children.

In dentistry, occlusion is the relationship between the upper and lower teeth when the jaw is shut. In an ideal occlu-

sion: the upper incisors and canines (front teeth) slightly overlap the lower ones; the front two upper incisors are aligned centrally with the front two lower incisors; the remaining upper teeth are positioned in an alternating pattern relative to the equivalent lower teeth; and the outer ridges of the lower premolars and molars (back teeth) fit into the hollows in the corresponding upper teeth. Very few people have an ideal occlusion, but in the majority the arrangement of the teeth allows efficient biting and chewing of food. (See also *malocclusion*; *retinal artery occlusion*; *retinal vein occlusion*.)

occult

Hidden or obscure. For example, the term occult blood is often used to describe blood in a sample of faeces that is not visible to the naked eye but can be detected by chemical tests.

occult blood, faecal

The presence in the *faeces* of blood that cannot be seen by the naked eye, but can be detected by chemical tests (see *faecal occult blood test*).

Faecal occult blood tests are widely used in screening for cancer of the colon (see *colon*, *cancer of*). Finding faecal occult blood may also be a sign of various gastrointestinal disorders including *oesophagitis* (inflammation of the gullet); *gastritis* (inflammation of the stomach lining); *stomach cancer*; cancer of the intestine (see *intestine*, *cancer of*); rectal cancer (see *rectum*, *cancer of*); *diverticular disease* (in which pouches form in the wall of the intestine); *polyps* in the colon; *ulcerative colitis* (inflammation and ulceration of the lining of the colon and rectum); or irritation of the stomach or intestine by drugs such as aspirin. (See also *rectal bleeding*.)

occupational disease and injury

Illnesses, disorders, or injuries that are the result of exposure to chemicals or dust, or are caused by physical, psychological, or biological factors that occur in the workplace. Serious occupational diseases are far less common than formerly, but still make up an important group of conditions. They include the following main categories.

DUST DISEASES

The term *pneumoconiosis* is used to refer to *fibrosis* (formation of scar tissue) in the lung due to inhalation of industrial dusts, such as coal. *Asbestosis* is a lung

condition associated with asbestos in industry. Allergic *alveolitis* (inflammation of the tiny air sacs in the lungs) is caused by inhalation of organic dusts (often containing fungal spores) (see *farmer's lung*).

CHEMICAL POISONING

Industrial chemicals can damage the lungs if they are inhaled, or other major organs if they enter the bloodstream through the lungs or skin. Examples of harmful chemicals include fumes of cadmium, beryllium, lead, and benzene. Carbon tetrachloride and vinyl chloride are causes of liver disease. Many of these compounds can cause kidney damage.

OCCUPATIONAL SKIN DISEASE

Work-related skin disorders include contact *dermatitis* (skin inflammation), which results either from allergy or from direct irritation by chemicals in contact with the skin, and *squamous cell carcinoma*, which may be caused by exposure to tar.

INFECTIOUS DISEASES

Rare infectious diseases that are more common in certain jobs include *brucellosis* and *Q fever* (acquired from livestock), *psittacosis* (acquired from birds), and *leptospirosis* (caused by a bacterium excreted in rat's urine). People who work with blood or blood products are at increased risk of viral hepatitis (see *hepatitis*, *viral*) and *AIDS*, as are healthcare professionals.

RADIATION HAZARDS

The nuclear industry and some healthcare professions use measures to reduce the danger from *radiation hazards*. Exposure to certain types of radiation increases the risk of cancer.

OTHER DISORDERS

Other occupational disorders include *writer's cramp*, *carpal tunnel syndrome*, and *singer's nodes*. *Raynaud's phenomenon* is associated with the handling of vibrating tools. Deafness may be caused by exposure to excessive noise.

occupational medicine

A branch of medicine that deals with the effects of various occupations on health and with an individual's capacity for particular types of work. It includes prevention of *occupational disease and injury* and the promotion of health in the working population.

Epidemiology is used to analyse patterns of sickness absence, injury, illness, and death. Clinical techniques are used to monitor the health of a particular

workforce. Assessment of psychological stress and hazards of new technology are part of the remit.

Occupational health risks are reduced by dust control, appropriate waste disposal, use of safe work stations and practices, limiting exposure to harmful substances, and screening for early evidence of occupational disorders.

occupational mortality

Death due to work-related disease or injuries. Annual death rates (deaths per million at risk) vary widely between occupations, ranging from very low levels in clothing and footwear manufacture to very high levels in industries such as the offshore oil and gas industries. The pattern of deaths varies over time as industrial standards change. Certain diseases that take many years to develop may reflect occupational practices that have since been improved.

occupational therapy

Treatment comprising individually tailored programmes of activities to help people who have been disabled by illness or accident to improve their function and ability to carry out everyday tasks. Occupational therapy also involves recommending aids and changes to the home that help to increase an individual's independence.

octreotide

A somatostatin analogue, a hormone that acts on the *pituitary gland*. Given by injection, octreotide is used mainly in the treatment of *acromegaly* (a rare disorder that causes abnormal enlargement of certain body parts) and hormone-secreting intestinal tumours. Octreotide is also used to prevent complications following pancreatic surgery.

Side effects of octreotide may include various gastrointestinal disturbances such as nausea, vomiting, abdominal pain and bloating, flatulence, and diarrhoea.

ocular

Relating to or affecting the *eye* and its structures; also the eyepiece of an optical device, such as a *microscope*.

oculogyric crisis

A state in which the eyes are fixed, usually upwards, for minutes or hours. The crisis may occur with muscle spasm of the tongue, mouth, and neck, and is often triggered by stress. It may occur following *encephalitis* (inflammation of

the brain) and in *parkinsonism* (a movement disorder), or may be induced by drugs such as *phenothiazine* derivatives.

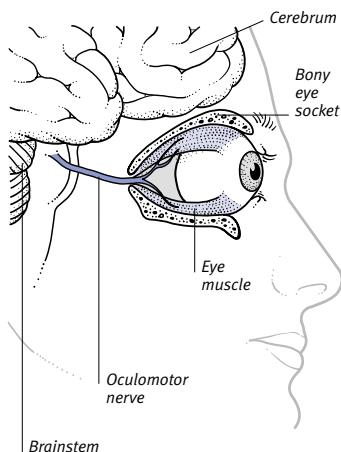

oculomotor nerve

The third *cranial nerve*, controlling most of the muscles that move the eye. The oculomotor nerve also supplies the muscle that constricts the pupil, that which raises the upper eyelid, and the ciliary muscle, which focuses the eye.

The oculomotor nerve may be damaged due to a fracture to the base of the skull or a tumour. Symptoms of damage to the oculomotor nerve include *ptosis* (drooping of the upper eyelid), *squint*, dilation of the pupil, inability to focus the eye, double vision, and a slight protrusion of the eyeball. (See also *trochlear nerve*; *abducent nerve*.)

LOCATION OF THE OCULOMOTOR NERVE

The oculomotor nerve originates high in the brainstem and passes forward through a slit in the bony eye socket to reach the muscles that move the eye and eyelids.

OD

The abbreviation for an overdose (see *drug overdose*).

odontoid

The peglike process on the second cervical *vertebra* (one of the vertebral bones in the neck) on which the first cervical vertebra rests. The odontoid is dislocated during judicial hanging, and the resultant pressure on the *spinal cord* is the cause of death.

oedema

Abnormal fluid accumulation in body tissues that may be localized (as in swelling from an injury) or generalized (as in *heart failure*).

WATER BALANCE IN THE BODY

Water accounts for roughly three fifths of body weight and is constantly exchanged between blood and tissues. The pressure of blood being pumped around the body forces water out of the capillaries (tiny blood vessels) and into the tissues. By a reverse process, which depends on the water-drawing power of the proteins in the blood (see *osmosis*), water is reabsorbed into the capillaries and lymphatic vessels from the tissues. Normally, these two mechanisms are in balance, keeping the distribution of water between the blood and tissues more or less constant.

The action of the kidneys and hormones, including *ADH*, regulate the total amount of fluid in the body. Any excess is excreted from the body as urine.

CAUSES OF OEDEMA

Various disorders can disrupt these processes. Heart failure leads to congestion in the veins, which creates backward pressure in the capillaries. This overcomes osmotic pressure in the capillaries and causes more fluid than normal to be forced into the tissues. Backward pressure can also be created by a tumour pressing on veins, causing oedema in the area drained by the obstructed vein.

In *nephrotic syndrome*, an abnormal loss of protein from the blood reduces osmotic pressure and prevents enough fluid being drawn from the tissues into the blood. *Kidney failure* prevents salt being excreted from the body, allowing it to accumulate in the tissues and attract water to it.

Other disorders that can cause oedema include *cirrhosis* of the liver, which leads to blood congestion in the veins

Appearance of oedema

This photograph shows the characteristic swelling that occurs with oedema and the dimpling of the skin when it is pressed.

of the liver, lowers blood protein (and therefore osmotic pressure), and causes salt retention. A deficiency of protein in the diet, as may occur in alcoholics, can also reduce osmotic pressure.

Injury or inflammation may lead to oedema by causing capillaries to leak. The blockage of lymphatic vessels may result in *lymphoedema*.

Oedema may also be caused by certain drugs, such as *corticosteroid drugs*, that have an action on the kidneys, resulting in salt retention.

SYMPOTMS

Symptoms of generalized oedema, such as swelling around the base of the spine (in bedridden people) or in the ankles, occur when excess body fluid increases by more than 15 per cent. In severe cases, fluid accumulates in large body cavities, such as the peritoneal cavity of the abdomen in *ascites* or the pleural cavity of the lungs in *pleural effusion*. In *pulmonary oedema*, the air sacs of the lungs become waterlogged, causing breathlessness.

TREATMENT

The underlying cause of the oedema should be remedied. If this is not possible, symptoms can be relieved by excretion of the excess fluid. Output of urine by the kidneys is increased by restricting dietary salt and by the use of *diuretic drugs*.

Oedipus complex

A psychoanalytic term defined as the unconscious sexual attachment of a child for the parent of the opposite sex, which is manifested by the consequent jealousy of, and desire to eliminate, the parent of the same sex.

oesophageal atresia

A rare *birth defect* in which the oesophagus forms into two separate sections during embryonic development. A short section of the *oesophagus* is absent, the part of the oesophagus above the gap terminates in a pouch, and the lower part of the oesophagus, projecting upwards from the stomach, may also be blind-ended. In most cases, however, the upper or lower section of oesophagus connects with the trachea (windpipe) to form an abnormal channel, called a *tracheoesophageal fistula*.

The condition may be suspected before birth if the mother has *polyhydramnios* (excess amniotic fluid); this indicates that the fetus is unable to swallow the amniotic fluid as normal.

SYMPTOMS

The infant cannot swallow saliva or milk, and drools and regurgitates milk continually. If there is an upper tracheo-oesophageal fistula, milk may be sucked into the lungs, provoking coughing fits and *cyanosis* (a bluish skin coloration).

TREATMENT AND OUTLOOK

Immediate surgery is needed in order to join the blind ends of the oesophagus and close the fistula. In some cases, more than one operation may be necessary. If surgery is successful, the baby should develop normally.

oesophageal dilatation

A procedure to stretch the *oesophagus* when it has been narrowed by disease (see *oesophageal stricture*) and swallowing is difficult.

Endoscopy is used to locate the obstruction. The narrowed area is then stretched by passing bougies (cylindrical rods with olive-shaped tips) down the oesophagus, or by using a *balloon catheter* (a fine tube with an inflatable balloon at the end).

oesophageal diverticulum

A saclike protrusion of part of the wall of the *oesophagus*. There are two types: a pharyngeal pouch (also known as a Zenker's or pulsion diverticulum), and a mid-oesophageal diverticulum (also known as a traction diverticulum).

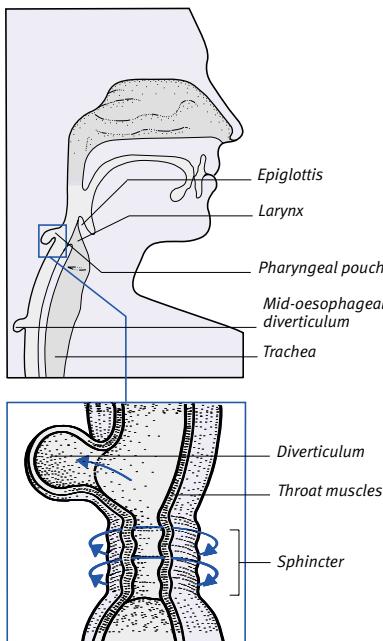

PHARYNGEAL POUCH

This type is located at the top of the oesophagus, at its entrance from the pharynx (throat). The pouch usually projects backwards. The cause is a failure of the sphincter (circular muscle) at the entrance to the oesophagus to relax during the act of swallowing, due to muscular incoordination. Instead, the sphincter resists the passage of food. As the powerful throat muscles used for swallowing work against this resistance, part of the lining of the oesophagus is forced through the oesophageal wall, forming the diverticulum.

Once the diverticulum is formed, it gradually enlarges. Food and fluids become trapped in it and may spill into the trachea (windpipe), causing coughing and recurrent chest infections. The condition is usually treated surgically.

MID-OESOPHAGEAL DIVERTICULUM

This disorder consists of a pouch that is formed further down the oesophagus. It rarely causes symptoms and may only be discovered accidentally. It does not usually require treatment.

**Location of oesophageal diverticula**

A pharyngeal pouch forms at the top of the oesophagus as a reaction to the sphincter's failure to relax during swallowing. A mid-oesophageal diverticulum is a pouch further down the oesophagus. It is usually symptomless.

oesophageal spasm

Uncoordinated muscle contractions in the *oesophagus*, which cause intermittent swallowing difficulties and chest or upper abdominal pain. The spasm may be due to reflux *oesophagitis* but often occurs for no apparent reason. Women are more commonly affected than men.

A barium swallow (see *barium X-ray examinations*) and *endoscopy* may be used to rule out a more serious condition, such as cancer. Treatment is of any underlying cause.

oesophageal speech

A technique for producing speech after surgical removal of the *larynx* (voicebox) (see *laryngectomy*). Air is trapped in the *oesophagus* and is gradually expelled while the tongue, palate, and lips form distinguishable sounds.

oesophageal stricture

Narrowing of the *oesophagus* that may cause pain, swallowing difficulties, regurgitation of food, and weight loss.

CAUSES

Oesophageal stricture may be due to cancer of the oesophagus (see *oesophagus, cancer of*) or to any of numerous noncancerous causes. These include per-

sistent reflux *oesophagitis*, in which constant irritation from gastric acid causes inflammation and swelling followed by the formation of fibrous scar tissue and narrowing. In *Plummer-Vinson syndrome*, a web of tissue forms in the upper oesophagus in association with iron deficiency anaemia (see *anaemia, iron deficiency*). A Schatzki ring (a non-cancerous fibrous ring found in the lower oesophagus) can also cause difficulty swallowing. Prolonged use of a *nasogastric tube* may inflame the oesophagus, leading to a stricture, as may swallowing a corrosive liquid.

DIAGNOSIS AND TREATMENT

A barium swallow (see *barium X-ray examinations*) may help to confirm the diagnosis. *Endoscopy* (passage of a viewing instrument down the oesophagus) is used to look at the narrowed area, and a *biopsy* (removal of a sample of tissue for microscopic analysis) is carried out to exclude the possibility of cancer.

In some cases, the narrowed area can be stretched by *oesophageal dilatation*. In cases where the narrowing is caused by cancer, or in very rare cases where there is severe narrowing over a long segment of oesophagus (usually due to the swallowing of corrosives), the affected area may have to be removed surgically. The stomach can then be drawn up into the chest or the missing oesophagus replaced with a section of colon.

oesophageal varices

Widened veins in the walls of the lower *oesophagus* and, sometimes, the upper part of the stomach.

CAUSE

Oesophageal varices develop as a consequence of *portal hypertension* (an increase in blood pressure in the portal vein that is usually caused by liver disease). Blood in the portal vein, passing from the intestines to the liver, meets resistance due to liver disease, and is diverted into small veins in the walls of the oesophagus and stomach. The increased blood pressure causes the veins to balloon outwards.

SYMPTOMS

There are generally no symptoms until an episode of bleeding, which results in repeated episodes of haematemesis (vomiting of blood) and the passage of black faeces. There are usually other symptoms of chronic liver disease.

TREATMENT

To control acute bleeding, urgent endoscopic injection of a sclerosant to seal

off the affected veins is required. Alternatively, banding (in which tight rubber bands are placed over the base of each enlarged vein) may be used. Replacement of lost blood and intravenous injection of drugs to constrict the blood vessels, such as octreotide and terlipressin, are also carried out. Creation of a shunt (a surgically created passage) to direct blood away from the varices may also be considered. Despite treatment, an episode of bleeding may still prove fatal.

oesophagitis

Inflammation of the *oesophagus*. There are two main types: corrosive oesophagitis, caused by accidental or intentional swallowing of caustic chemicals, and reflux oesophagitis, caused by regurgitation of the stomach's contents.

CORROSIVE OESOPHAGITIS

Chemicals that are likely to cause severe corrosive oesophagitis include many cleaning and disinfecting products. The oesophagus may rupture, with fatal consequences; alternatively it may heal but may result in an *oesophageal stricture* (narrowing of the oesophagus).

REFLUX OESOPHAGITIS

Reflux oesophagitis is due to poor function of the muscles in the lower oesophagus, which permits the stomach's acidic contents to rise back into the oesophagus (see *acid reflux*). The main symptom, heartburn, may be worsened by alcohol, smoking, and obesity. Poor function of the lower oesophagus may be linked with a *hiatus hernia*, in which the top part of the stomach slides back and forth through the muscular diaphragm between the chest and the abdomen.

COMPLICATIONS

Barrett's oesophagus is a complication of reflux oesophagitis in which cells that normally line the stomach extend up into the oesophagus. It may lead to cancer. Severe, chronic oesophagitis can cause an *oesophageal stricture*.

TREATMENT

The treatment for most cases of persistent reflux oesophagitis is a change of diet and lifestyle: weight loss, avoiding heavy meals, limiting alcohol intake, and stopping smoking. *Antacid drugs* help to reduce acidity. Surgical treatment (such as *minimally invasive surgery*) may be necessary for a hiatus hernia.

oesophagogastroduodenoscopy

Examination of the upper digestive tract using an endoscope (see *gastroscopy*).

oesophagogastrectomy

Examination of the *oesophagus* and also the stomach with the use of an endoscope (see *gastroscopy*).

oesophagoscopy

Examination of the *oesophagus* using an endoscope (see *gastroscopy*).

oesophagus

The muscular tube that carries food from the throat to the stomach. The oesophagus is part of the digestive tract (see *digestive system*).

STRUCTURE

The top end of the oesophagus is the narrowest section of the entire digestive tract. It is encircled by a sphincter (circular muscle) that is normally closed but can open to allow the passage of food. A similar sphincter operates where the oesophagus joins the stomach. The oesophageal walls consist of strong muscle fibres arranged in bundles: some

circular, and others longitudinal. The inner lining of the oesophagus consists of smooth, squamous epithelium that is made up of flattened cells.

FUNCTION

Powerful waves of contractions (*peristalsis*) pass through the muscles in the oesophageal wall, propelling food and liquids down towards the stomach and intestines for digestion. Gravity plays little part in getting food into the stomach, making it possible to drink while upside down. (See also *swallowing*).

oesophagus, cancer of

A malignant tumour, most common in people over the age of 50, that mainly affects the middle or lower *oesophagus* and leads to swallowing difficulties. Smoking and heavy alcohol intake are risk factors; people with certain disorders of the oesophagus (such as *Barrett's oesophagus*) are also at increased risk.

SYMPTOMS

The tumour is often present for some time before it begins to cause symptoms. Early symptoms may include pain on, and difficulty in, swallowing foods and/or liquids. The patient's condition progressively worsens to a point where food is immediately regurgitated and there is rapid weight loss. Regurgitated fluid spilling into the *trachea* (windpipe) often causes respiratory infections.

DIAGNOSIS, TREATMENT, AND OUTLOOK

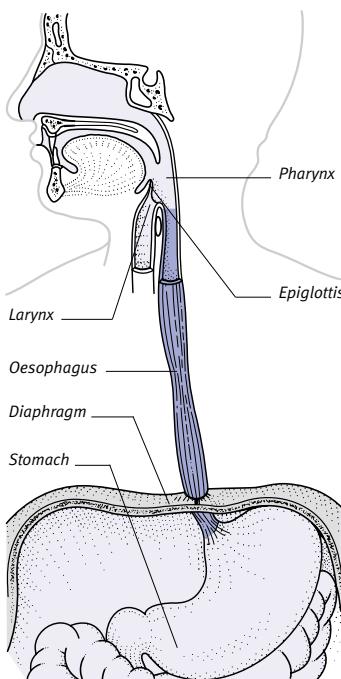

Diagnosis usually involves a barium swallow (see *barium X-ray examinations*) to detect an obstruction in the oesophagus and a *biopsy* (removal of a small sample of tissue for microscopic analysis) taken during *endoscopy*.

Treatment depends on whether or not the cancer has spread to surrounding structures. Removal of the oesophagus may be possible in some localized, and early diagnosed, cancer. *Radiotherapy* may cause regression of the cancer, relieve symptoms, and occasionally cure older patients who might not be suitable for major surgery. Permanent insertion of a rigid tube (a stent) through the tumour, or laser treatment to burn through it, can help temporarily to relieve symptoms and improve nutrition.

The outlook depends on whether the cancer has spread at the time of diagnosis. In cases in which there is no spread and surgery is carried out successfully, 50 per cent of patients survive for more than five years. If the cancer is more widespread, less than a quarter of patients survive longer than one year.

ANATOMY OF THE OESOPHAGUS

A muscular tube that propels food to the stomach from the throat. The upper and lower ends are bounded by sphincters – muscular valves that open to allow food to pass through.

DISORDERS OF THE OESOPHAGUS

Several disorders affect the oesophagus, many of which cause *swallowing difficulties* and/or chest pain.

Infection and inflammation

Infections of the oesophagus are rare but may occur in immunosuppressed patients whose defences are weakened. The most common are *herpes simplex* and *candidiasis* (thrush) spreading downwards from the mouth. Both cause pain on swallowing. *Oesophagitis* (inflammation of the oesophagus) is usually due to reflux of stomach contents, causing heartburn. A more severe form, corrosive oesophagitis, can occur as a result of swallowing caustic chemicals. Both types may cause an *oesophageal stricture* (narrowing of the oesophagus) with difficulty in swallowing. *Barrett's oesophagus* is a complication of long-term reflux oesophagitis; it may lead to cancer.

Congenital defects

Oesophageal atresia (the congenital absence of a section of the oesophagus, with the remaining sections ending in dead ends) requires urgent surgical treatment. Babies are occasionally also born with weblike constrictions of the oesophagus. These are rarely serious enough to require treatment, but they can be broken down with a dilator.

Tumours

Tumours of the oesophagus are relatively common. The initial symptom

is usually difficulty in swallowing. The majority of oesophageal tumours are cancerous (see *oesophagus, cancer of*).

Injury

Severe vomiting and retching can tear the oesophageal lining and, in extreme cases, lead to rupture. A swallowed *foreign body* can also cause injury, even perforation, if it penetrates the oesophageal wall.

Other disorders

Oesophageal varices (dilated blood vessels) at the junction of the stomach and oesophagus may be associated with *cirrhosis*. An *oesophageal diverticulum* is a protruding sac in which food may collect, causing difficulty in swallowing. In *oesophageal spasm*, the oesophageal muscles contract uncontrollably. In *achalasia*, the sphincter at the junction between the oesophagus and stomach fails to relax to allow the passage of food, causing pain on swallowing and sometimes regurgitation of food.

INVESTIGATION

Disorders of the oesophagus are investigated by barium swallow (see *barium X-ray examinations*) and by endoscopy during which a biopsy (tissue sample) can be taken for microscopic examination.

oestradiol

See *estradiol*.

oestriol

See *estriol*.

oestrogen drugs

COMMON DRUGS

- Conjugated oestrogens • Diethylstilbestrol
- Estradiol • Estriol • Estrone • Estropipate
- Ethynodiol dihydrogesterone • Mestranol

A group of synthetically produced drugs that are used in *oral contraceptives* and additionally to supplement or replace the body's own *oestrogen hormones* in *hormone replacement therapy (HRT)*. Oestrogen drugs are often used with *progestogen drugs*.

WHY THEY ARE USED

Oestrogens suppress the production of *gonadotrophin hormones*, which stimulate cell activity in the *ovaries*. They are used in HRT to treat, or sometimes to prevent, menopausal symptoms and disorders. Oestrogens may also be used to treat female *hypogonadism* (underactivity of the ovaries), abnormal menstrual bleeding, and prostatic cancer (see *prostate, cancer of*).

POSSIBLE ADVERSE EFFECTS

Oestrogens may cause breast tenderness and enlargement, bloating, weight gain, nausea, reduced sex drive, depression, migraine, and bleeding between periods. Most of the side effects subside after two or three months. Oestrogens can also increase the risk of abnormal

blood clotting and susceptibility to *hypertension* (high blood pressure).

Oestrogen drugs should not be taken during pregnancy because they may adversely affect the fetus.

oestrogen hormones

A group of *hormones* that are essential for normal female sexual development and healthy functioning of the reproductive system. In women, they are produced mainly in the *ovaries* and also in the *placenta* in pregnancy. Small amounts are produced in the *adrenal glands* in both men and women, but oestrogens have no specific function in men. When levels are low, oestrogen hormones can be replaced with *oestrogen drugs*.

oestrogen–progestogen pill

An alternative name for the combined pill (see *oral contraceptives*).

oestrone

See *estrone*.

ofloxacin

A *quinolone* antibiotic used to treat skin, soft tissue, and lower *respiratory tract* and *urinary tract infections*. It is usually taken in tablet form to treat infections that have not responded to other drugs but is also given by intravenous infusion for severe *systemic* infections. Side effects may include nausea, vomiting, diarrhoea, and abdominal pain.

oils

See *fats and oils*.

ointment

A greasy preparation that is used as a vehicle to apply drugs in dry skin conditions such as *eczema* or to protect or lubricate the skin.

olanzapine

An *antipsychotic drug* used for the treatment of *schizophrenia*.

olecranon

The bony projection at the upper end of the *ulna* (the inner bone of the forearm) that forms the point of the elbow.

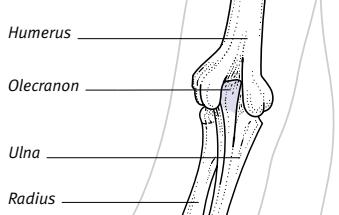

olecranon bursitis

Inflammation of the small, fluid-filled pad that cushions the *olecranon* at the tip of the elbow. The condition causes pain and swelling but usually clears up after a few days of rest and avoiding pressure on the joint. (See also *bursitis*.)

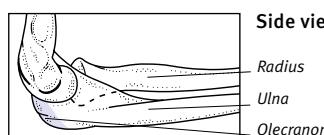

LOCATION OF THE OLECRANON

This is the curved projection at the upper end of the ulna. It acts to prevent elbow overextension.

View from behind

Side view

olfactory bulb

The swelling at the end of each *olfactory nerve* that deals with the sense of smell. These bulbs lie on the brain's lower surface, just above the roof of the nose.

olfactory nerve

The first *cranial nerve*, which conveys sensations of smell as nerve impulses from the nose to the brain. Each of the two olfactory nerves has receptors in the mucous membrane lining the nasal cavity. These receptors detect smells and send signals along nerve fibres, which pass through tiny holes in the roof of the nasal cavity and combine to form the olfactory bulbs. From here, nerve fibres come together to form the olfactory nerve, which leads to the olfactory centre in the brain. Sense of smell may be lost or impaired due to damage to the olfactory nerves, usually as a result of head injury.

oligo-

A prefix meaning few, scanty, or little, as in *oligospermia* (the presence of too few sperm in the semen).

oligodendrogloma

A rare and slow-growing type of primary *brain tumour* that originates in the oligodendroglial cells that support brain cells. Oligodendrogloma mainly affect young or middle-aged adults. Surgical removal of the tumour can, in some cases, lead to a total cure.

oligohydramnios

A condition in which an insufficient amount of *amniotic fluid* surrounds a fetus in the uterus.

CAUSES

Amniotic fluid is produced partly by the *placenta*, but mainly from the urine produced by the fetus. Oligohydramnios may occur if the placenta is not functioning properly, which can occur in severe *pre-eclampsia*, or if there is an abnormality of the kidneys or bladder of the fetus. Reduced quantities of amniotic fluid may also result from leakage due to a premature rupture of the amniotic membranes.

TREATMENT AND OUTLOOK

Oligohydramnios may be suspected if the woman's uterus is smaller than expected; diagnosis is confirmed using *ultrasound scanning*.

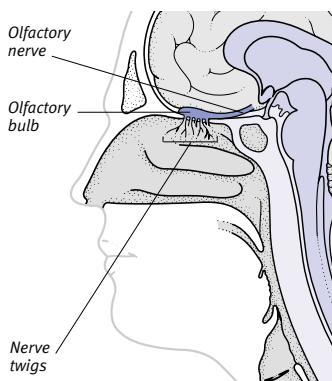

In some cases, the underlying disorder can be treated, but this may not be possible (particularly if the fetus is not developing normally). If oligohydramnios occurs early in pregnancy, it usually results in *miscarriage*. In later pregnancy, the pressure of the uterus on the fetus may cause a deformity such as *talipes* (club-foot).

oligospermia

A temporary or permanent deficiency in the number of *sperm* in the *semen*. This condition is also known as oligo-

LOCATION OF THE OLFACTORY NERVE

Each olfactory bulb lies on top of a thin bony plate in the roof of the nose and connects to the brain via an olfactory nerve. Nerve twigs pass through the bony plate to enter the nasal lining.

zoospermia. It may be a cause of *infertility*, especially when other disorders of the sperm are also present.

CAUSES

Normally, there are more than 20 million sperm per millilitre of semen. A low sperm count can be due to various disorders, including hormonal disorders, *orchitis* (inflammation of a testis), undescended testis (see *testis, undescended*), and, infrequently, a *varicocele* (varicose vein in the scrotum). Smoking, alcohol abuse, and some drugs may also reduce the sperm count.

TREATMENT

Treatment of oligospermia is for the underlying cause. If the cause is a hormone deficiency, *gonadotrophin hormones* may be prescribed. If infertility is a problem, *artificial insemination* within the uterus or *in vitro fertilization* (IVF) with *intracytoplasmic sperm injection* may be successful. (See also *azoospermia*.)

oliguria

The production of low quantities of *urine* in proportion to the volume of fluid taken in. The condition may be caused by excessive sweating; in some cases, it is a sign of *kidney failure*.

olive oil

An oil, obtained from the fruit of the olive tree *OLEA EUROPAEA*, that may be used to soften earwax or to treat *cradle cap* in babies. Olive oil is high in monounsaturated fat (see *fats and oils*); it is an important part of a *Mediterranean diet*.

Ollier's disease

See *dyschondroplasia*.

-oma

A suffix denoting a tumour, which may be cancerous or noncancerous, as in *lipoma* and *carcinoma*.

omega-3 fatty acids

A group of polyunsaturated fatty acids that are found mainly in oily fish (such as mackerel, herring, and sardines). Omega-3 fatty acids are also found in certain vegetable oils (such as rapeseed oil and soya oil) and nuts such as walnuts and peanuts.

Omega-3 fatty acids have been found to lower raised levels of *triglycerides* (a type of fat) in the blood. Fish-oil preparations containing omega-3 fatty acids are used to treat severe hypertriglyceridaemia, in which levels of triglycerides in the blood are greatly elevated (see

hyperlipidaemias). The principal side effects are nausea and belching, but these are uncommon.

omentum

A double fold of fatty membrane in the abdomen (peritoneum) hanging in front of the intestines that acts as a fat store.

omeprazole

A *proton pump inhibitor* drug used to treat *peptic ulcer*, *reflux oesophagitis* (inflammation of the gullet), and *Zollinger-Ellison syndrome*. Possible adverse effects include rashes, headache, nausea, diarrhoea, and constipation.

omphalocele

An alternative name for *exomphalos*.

onchocerciasis

A tropical disease, also called river blindness, caused by infestation with the worm *ONCHOCERCA VOLVULUS*. The disease, a type of *filariasis*, affects millions of people in some regions of Africa and Central and South America.

CAUSES AND SYMPTOMS

Onchocerciasis is transmitted from person to person by small, fiercely biting, black simuliid flies. These flies, which breed in, and always remain near, fast-running streams, ingest microfilariae (tiny worms) and inject their larvae into human skin, where they multiply and spread around the body under the skin (see the illustrated box).

The dead larvae can cause an allergic reaction resulting in inflammation and the formation of fibrous tissue. When this occurs in the eye, the damage is permanent and leads to blindness. Symptoms of the condition include itchy, swollen patches; they usually arise about a year after infestation.

TREATMENT AND PREVENTION

Treatment involves taking *anthelminthic drugs*, which quickly kill the microfilariae. Such treatment needs to be repeated annually because the adult worms are not affected. Travellers to areas where the disease is prevalent should take measures to discourage *insect bites*.

oncogenes

Genes found in every cell of the body that control growth, repair, and replacement. Activation of an oncogene is a factor in the development of cancerous cells. *Mutations* (structural changes) in oncogenes, resulting from damage by *carcinogens*, can cause a cell to grow uncontrollably and infiltrate and destroy normal tissues (see *cancer*). Factors known to encourage oncogene mutation include ultraviolet light, radioactivity, tobacco smoke, alcohol, asbestos, and some chemicals. In addition, some viruses can activate oncogenes.

oncology

The study of the causes, development, characteristics, and treatment of *tumours*, particularly *cancers* (malignant tumours).

Because there are many different types of tumours, developing in virtually any tissue in the body, oncology encompasses a wide range of experimental techniques and investigative approaches. These include surveying the frequency and distribution of tumours, testing new treatments, investigating the biochemical processes involved in tumour formation, and studying abnormal genes that are associated with tumours. Doctors specializing in the study and treatment of cancer are known as oncologists.

ondansetron

A *serotonin antagonist* drug used to control the nausea and vomiting that occur following an operation or that are induced by *radiotherapy* or *anticancer drugs*. Ondansetron is taken in the form of tablets or suppositories or is given by injection. Side effects may include constipation, headache, and hiccups.

onychogryphosis

Abnormal thickening, hardening, and curving of the nails that occurs mainly in elderly people. It may be associated with *fungal infection* or poor circulation, or it may occur for no apparent reason.

onychogryphosis

This thickening, hardening, and overgrowth of the toenails occurs mainly in elderly people. It can also affect the fingernails.

onycholysis

Separation of the nail from its bed: a feature of many skin conditions, including *psoriasis* and *dermatitis*.

oocyte

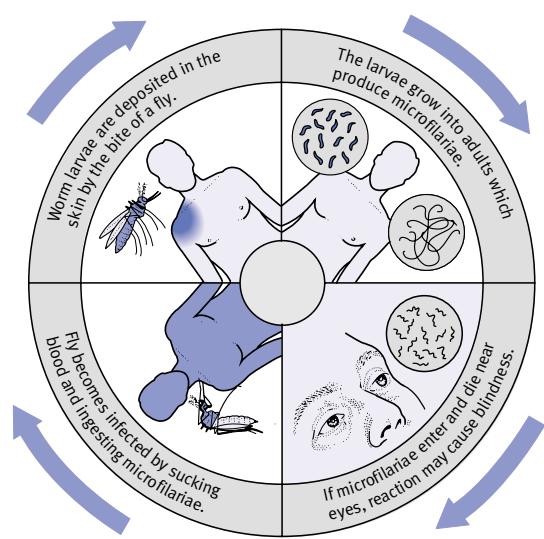

One of the cells that are found in the *ovary* that, after undergoing *meiosis* (a type of cell division), form ova (egg cells; see *ovum*).

oogenesis

The process by which mature ova (egg cells; see *ovum*) are produced in the female's ovary. At birth, a female has her entire lifetime's complement of

LIFE-CYCLE OF ONCHOCERCIASIS

The infestation is spread by a fly that ingests microfilariae (tiny worms) from an infested person. The worms grow into larvae inside the fly and are deposited in the skin of a new human host when the fly bites. In the new host, the larvae develop into adults, which produce microfilariae that migrate around the body.

OOPHORECTOMY

oogonia (cells that divide by *meiosis* to develop firstly into *oocytes* and eventually into mature ova).

oophorectomy

Removal of the *ovaries*, usually done to treat *ovarian cysts* or cancer (see *ovary, cancer of*). A partial oophorectomy may be performed to preserve ovarian function in premenopausal women. In a *hysterectomy*, both ovaries may be removed if disease has spread from the uterus, or as a preventive measure. The ovaries may be removed as part of the treatment for *breast cancer* if growth of the tumour depends on hormones produced by the ovary. If both ovaries are removed before the onset of the menopause, *hormone replacement therapy (HRT)* may be needed.

-opathy

A suffix denoting disease or disorder, as in *neuropathy* (a disorder of the nerves).

open-angle glaucoma

An alternative name for chronic simple *glaucoma*, a gradual buildup of excessive fluid pressure in the eye.

open chest massage

Rhythmic compression that is applied directly to the heart through an incision in the chest wall in order to restart arrested heart action (see *cardiac arrest*). Open chest massage, which is also known as internal *cardiac massage*, is an emergency measure for the purpose of maintaining the circulation. It is not commonly performed.

open fracture

A type of *fracture*, also known as a compound fracture, in which the broken bone penetrates the overlying skin. An open fracture carries a greater risk of infection than a closed fracture because the skin has been punctured.

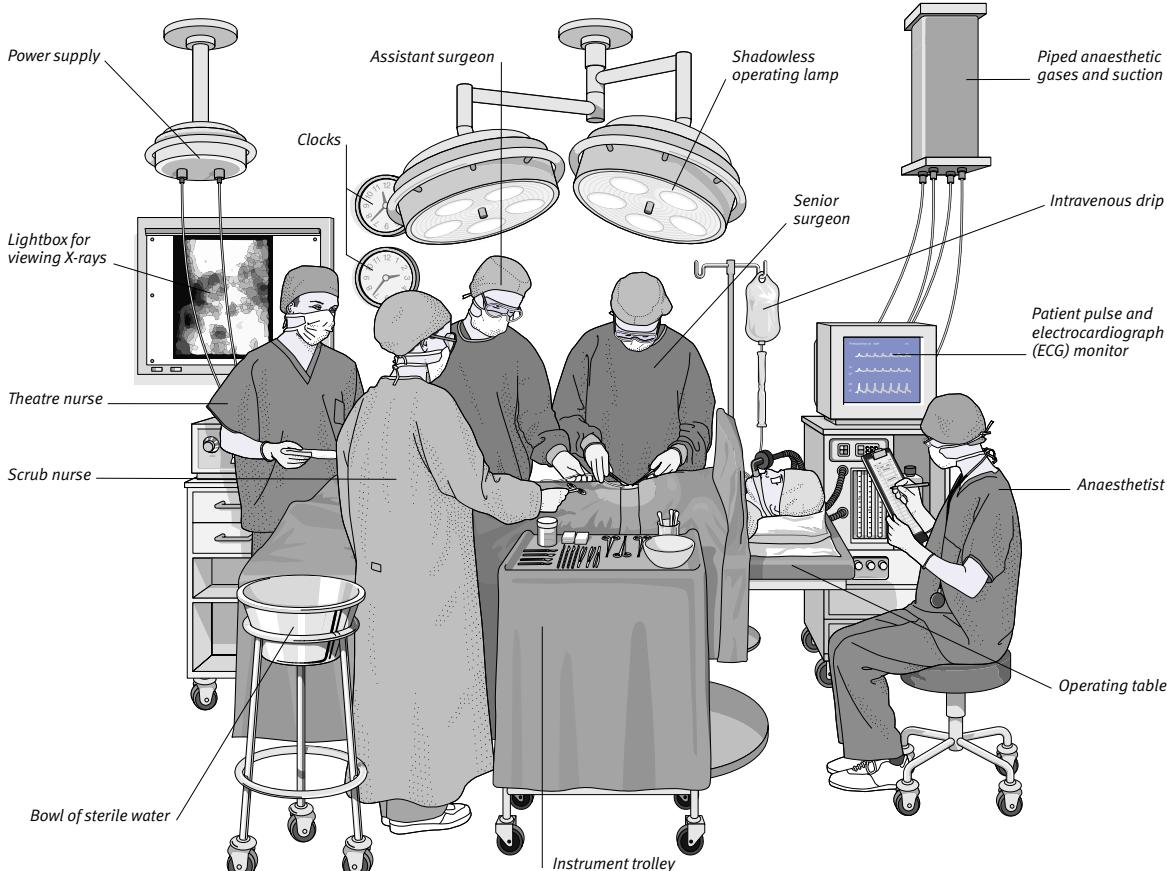

open heart surgery

Any operation on the *heart* in which it is stopped temporarily and its function taken over by a mechanical pump (a *heart-lung machine*). The main forms of open heart surgery include the correction of congenital heart defects (see *heart disease, congenital*), surgery for the repair of narrowed or leaky heart valves (see *heart-valve surgery*), and *coronary artery bypass* surgery.

OPERATING THEATRE

The operating table can be raised, lowered, and tilted in any direction to allow optimum access to the patient. For some operations, it is best for the surgeon to stand but, during delicate procedures, such as microsurgery, the surgeon

usually sits. The operating lamp is designed to give brilliant focal illumination without causing any shadow. The anaesthetic apparatus can maintain breathing in patients who have been given a muscle-relaxant drug.

Once the heart–lung machine has been connected, the heart is isolated, and the defects repaired. Surgical hypothermia is used to keep the heart cool and help prevent damage to the heart muscle from lack of oxygen (see *hypothermia, surgical*). Various techniques that enable procedures to be performed on a beating heart without the need to use a heart–lung machine are now becoming available.

operable

A term applied to a condition that is suitable for surgical treatment, such as an accessible noncancerous tumour. (See also *inoperable*.)

operating theatre

A specialized room in which surgical procedures are performed. An operating theatre is one of a suite of rooms, attached to an anaesthetic room and a recovery area. The risk of infection of open wounds during surgery is reduced by a ventilation system that continually provides clean, filtered air, and surfaces that are easily washable. Surgeons, assistants, and nurses use sterile brushes and bactericidal soaps to scrub their hands and forearms before putting on sterile gowns and gloves.

The operating theatre has a range of equipment, including shadowless operating lights; lightboxes for viewing X-ray images or scans; anaesthetic machines (see *anaesthesia, general*); and a *diathermy* machine, which is used for the control of bleeding. A *heart–lung machine* may also be used.

operation

A surgical procedure usually carried out with specialized instruments; but sometimes only the hands are used (as in the manipulation of a simple fracture).

ophryosis

Spasm (involuntary contraction) of the muscles of the eyebrow.

ophthalmia

An old term for *ophthalmitis*.

ophthalmia neonatorum

A type of eye inflammation and a discharge (*ophthalmitis*) that occur in newborn infants, usually as a result of being infected with the sexually transmitted diseases *gonorrhoea* or *chlamydia* at birth. Treatment of ophthalmia neonatorum is with *antibiotic drugs*.

ophthalmitis

A term that is used to describe any inflammatory eye disorder. Types of ophthalmitis include *ophthalmia neonatorum* and sympathetic ophthalmitis, a rare condition in which a penetrating injury to one eye is followed by severe *uveitis* (inflammation of the iris and choroid) that can lead to blindness in the other eye. Sympathetic ophthalmitis can be treated with *corticosteroid drugs*, but it is sometimes necessary to remove the injured eye in order to preserve the sight of the other.

ophthalmology

The study of the eye and the diagnosis and treatment of the disorders that affect it. Ophthalmology covers assessment of vision, prescription of glasses or contact lenses, and surgery for eye disorders, such as *cataracts* and *glaucoma*. (See also *eye, examination of, optician; optometry; orthoptics*.)

ophthalmoplegia

Partial or total paralysis of the muscles that move the eyes. Ophthalmoplegia may be caused by a disease that affects the eye muscles themselves, such as *Graves' disease*, or by a condition that affects the brain or the nerves supplying the eye muscles, such as *stroke*, a *brain tumour*, *encephalitis* (inflammation of the brain), or *multiple sclerosis*.

ophthalmoplegic migraine

A type of *migraine* (a severe headache that is often accompanied by visual disturbances) in which movement of an eye is affected. Movement of the pupil may or may not also be affected.

ophthalmoscope

An instrument that is used to examine the inside of the eye. The ophthalmoscope contains a deflecting prism or a perforated angled mirror, which allows illumination and viewing of the entire area of the back of the eye, including the light-sensitive *retina*.

ophthalmoscopy

A noninvasive procedure in which a doctor uses an *ophthalmoscope* to examine the inside of the eye. The ophthalmoscope is used first to direct a beam of light into the eye and then to examine various structures, such as the light-sensitive *retina*; the retinal blood vessels; the head of the *optic nerve*; and the jelly-like *vitreous humour*.

opiate

Any drug derived from, or chemically similar to, *opium*.

opioid

A type of *analgesic drug* (painkiller) used in the treatment of moderate to severe pain. Opioids, also known as narcotic drugs, may be abused for their euphoric effects; abuse may cause *tolerance* (the need for greater amounts of a drug to get the same effect), and physical and psychological *drug dependence*. Opioids in common use include *codeine*, *diamorphine*, *morphine*, and *pethidine*.

opisthotonus

A form of *spasm* in which the head is bent backwards and the back is arched. Opisthotonus may occur in people with *tetanus* or *meningitis* or as a result of a severe brain injury.

opium

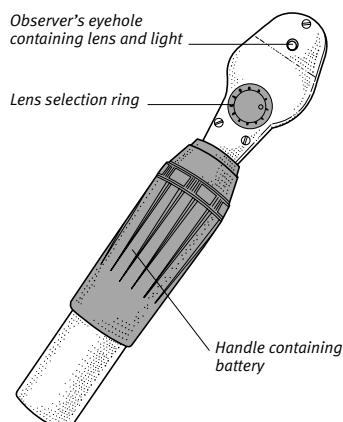

A substance obtained from the unripe seed pods of the poppy plant *PAPAVER SOMNIFERUM*. Opium has an analgesic (pain-relieving) effect and may also cause sleepiness and euphoria. Opium and its derivatives, such as *codeine* and *diamorphine*, are known as *opiates* or *opioids*.

opportunistic infection

Infection by organisms that rarely have serious or widespread effects in people of normal health, but which can cause serious illness or widespread infection

OPHTHALMOSCOPE

An ophthalmoscope allows viewing of the entire area of the back of the eye, including the retina.

in a person whose *immune system* is impaired. Malfunction of the immune system can be caused by diseases such as *AIDS* and *leukaemia* or by *chemotherapy*.

Opportunistic infections include a variety of viral, bacterial, protozoal, and fungal infections, including *tuberculosis*, *herpes simplex*, *pneumonia*, *cryptococcosis*, and *candidiasis* (thrush). Treatment of the infection is with the appropriate antimicrobial drugs.

oppositional defiant disorder

A type of behavioural disorder that usually appears in childhood or early adolescence. Typically, an affected child shows hostile, argumentative behaviour that includes loss of temper, defiance of rules, and swearing. While to some extent such behaviour is a common feature of adolescence, when law-breaking or violence occur the condition is considered pathological.

optic atrophy

A shrinkage or wasting of the *optic nerve* fibres due to disease or injury to the optic nerve. The optic nerve is responsible for carrying electrical impulses from the light-sensitive layer of the eye, the *retina*, to the brain, where the information is processed to produce *vision*.

Damage to the fibres of the optic nerve leads to blurring of vision and may result in total visual loss. Damage to the optic nerve cannot be reversed. Optic atrophy may occur without prior signs of nerve disease.

Ischaemic optic atrophy is a type of optic atrophy in which damage to optic nerve fibres is caused by an impaired blood supply. Leber's hereditary optic atrophy is a rare *genetic disorder*, most common in males, that causes degeneration of the optic nerve. The nerve degeneration first becomes apparent between 15 and 45 years of age.

Optic atrophy may be diagnosed by viewing the eye using an *ophthalmoscope*. The optic disc (the point where the optic nerve leaves the back of the eye) appears pale or white. *Vision tests* may also be performed.

If the underlying cause of the atrophy is identified and treated successfully, any further damage to the optic nerve can be prevented.

optic disc

The area on the *retina* (the light-sensitive layer at the back of the eye) where nerve fibres from the eyeball join the

optic nerve. The optic disc is also known as the blind spot because of its lack of light-sensitive cells.

optician

A person who fits and sells *glasses* and *contact lenses*. An ophthalmic optician, or optometrist, examines the eyes for *myopia* (shortsightedness), *hypermetropia* (longsightedness), *presbyopia* (loss of focusing power with age), or *astigmatism* (uneven curvature of the cornea). Opticians also screen for eye disorders, such as *glaucoma*, and refer patients to ophthalmologists. (See also *ophthalmology*; *optometry*).

optic nerve

The second *cranial nerve*; the nerve of *vision*. The two optic nerves each consist of about one million nerve fibres that transmit impulses from the *retina* (the light-sensitive layer at the back of the eye) to the *brain*. The optic nerves converge behind the eyes, where fibres from the inner halves of the retina cross over. Nerve fibres from the right halves of both retinas go to the right side of the occipital lobes in the brain; and those from the left halves of the retinas go to the left side.

Disease or injury occurring at a particular point on an optic nerve leads to loss of a specific part of the visual field.

Disorders of the optic nerve include *optic atrophy*, *optic neuritis* (nerve inflammation) and *papilloedema* (caused by pressure on the nerve from disease in the eye socket or by a *brain tumour*).

optic neuritis

Inflammation of the *optic nerve*, often causing sudden loss of part of the visual field. Attacks are sometimes accompanied by pain on moving the eyes. Vision usually improves within six weeks, but some optic nerve fibres will be damaged. Recurrent attacks usually lead to permanent loss of visual acuity.

Most cases are thought to be due to demyelination of the optic nerve fibres in *multiple sclerosis*. The condition may also result from inflammation or infection of tissues around the optic nerve.

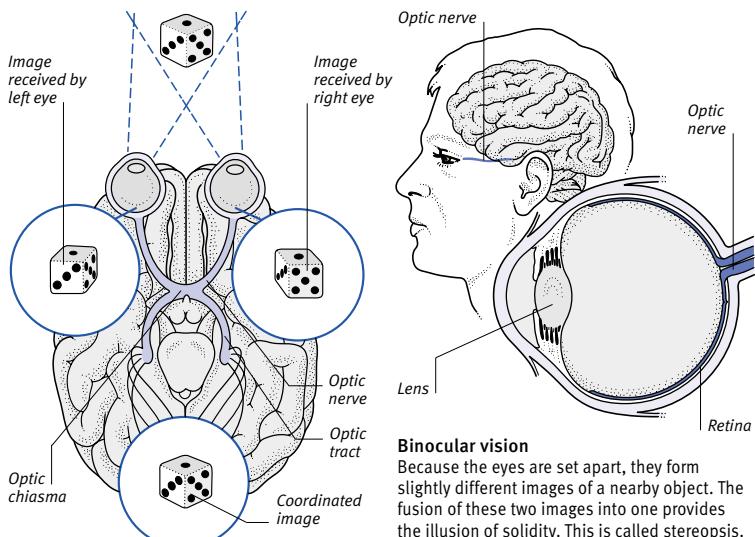

Corticosteroid drugs may help to restore vision, but have little effect on long-term outcome. (See also *optic atrophy*.)

Opticrom

A brand name for eye-drops containing *sodium cromoglicate*, an *antiallergy drug* used to treat allergic *conjunctivitis*.

THE FUNCTION OF THE OPTIC NERVE

Each optic nerve is a bundle of long fibres that relays electrical signals from the nerve cells in one of the retinas towards the brain. The optic nerves meet at the optic chiasma, where the information transmitted by both optic nerves is routed to the appropriate parts of the brain via the optic tracts. The brain coordinates this information into a complete visual picture.

optimum dose

The amount of an agent, such as a drug, that will produce a desired effect without causing unwanted side effects.

optometry

The practice of assessing *vision* to establish whether glasses or contact lenses are needed to correct a visual defect, as carried out by an optometrist. Disorders of the eye may require treatment by an ophthalmologist. (See also *ophthalmology; optician*.)

oral

Concerning the *mouth*.

oral contraceptives

COMMON DRUGS

OESTROGENS • Ethinylestradiol • Mestranol

PROGESTOGENS • Desogestrel • Gestodene

• Levonorgestrel • Norethisterone

• Norgestimate

A group of oral drug preparations containing one or more synthetic female *sex hormones* that are taken by women in a monthly cycle to prevent pregnancy.

TYPES

“The pill” commonly refers to the combined or the phased pill, which both contain an *oestrogen drug* and a *progestogen drug*, and the *minipill* (or progestone-only pill), which contains only a progestogen. The combined pill is taken for three weeks out of every four; the minipill is taken continuously.

EFFECTIVENESS

When oral contraceptives are taken correctly, the number of pregnancies among women using them for one year is less than 1 per cent. However, actual failure rates may be up to four times higher, particularly for the minipill, which has to be taken at the same time each day.

If vomiting or diarrhoea occurs after a pill has been taken, the woman should follow the drug manufacturer’s advice for a missed pill. If a woman taking oral contraceptives has missed two consecutive menstrual periods, she should have a *pregnancy test*.

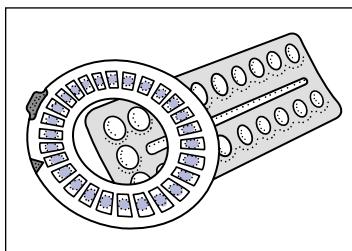

HOW THEY WORK

Combined and phased pills increase oestrogen and progesterone levels. This interferes with the production of two hormones, *luteinizing hormone* (LH) and *follicle-stimulating hormone* (FSH), which in turn prevents ovulation. The minipill works partly by making the mucus lining of the *cervix* (the neck of the womb) too thick to be penetrated by *sperm*.

HOW ORAL CONTRACEPTIVES WORK

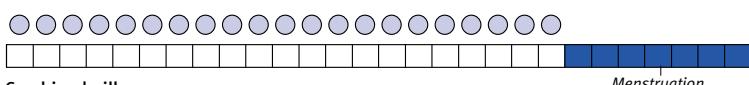

Combined pills (including phased pills) increase the levels of oestrogen and progesterone in the body, which interferes with the production by the pituitary gland of two *gonadotrophin hormones* called follicle-stimulating hormone (FSH) and luteinizing hormone (LH). This action in turn prevents ovulation.

The progestone-only pill (the minipill) works partly by making the mucus that lines the inside of the cervix (neck of the uterus) so thick that it is impenetrable to sperm.

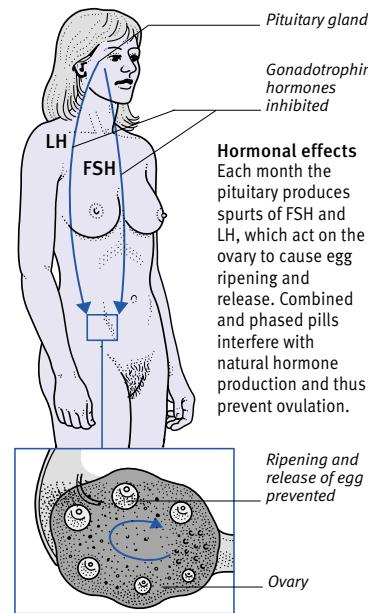

Pill packaging

Most oral contraceptives come in packs, called calendar packs, that clearly indicate which day of the week each pill should be taken.

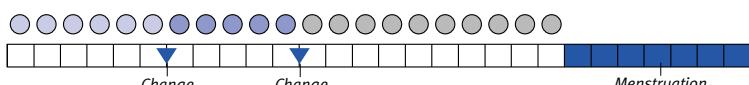

Combined pill

These pills contain an oestrogen and a progestogen drug in fixed doses. A course usually consists of one pill per day for 21 days,

Effects on eggs

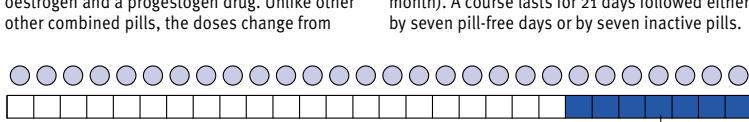

FSH normally brings about egg ripening and LH causes the egg’s release from the ovary; combined pills prevent this.

Phased pill

These are combined pills, containing both an oestrogen and a progestogen drug. Unlike other combined pills, the doses change from

followed by seven pill-free days, during which bleeding may occur. A new course is then started, whether or not bleeding has occurred.

Minipill

These pills contain only a progestogen drug in a fixed dose. The pills are taken continuously: one every day with no pill-free days in between.

phase to phase (different times during the month). A course lasts for 21 days followed either by seven pill-free days or by seven inactive pills.

Bleeding usually occurs during the last few days of each cycle. The minipill has a slightly higher failure rate than combined pills.

ADVANTAGES

Oestrogen-containing pills can help protect against uterine and ovarian cancer, ovarian cysts, endometriosis (in which fragments of uterine lining are dispersed, usually around the pelvic cavity). They also tend to make menstrual periods regular, lighter, and relatively pain-free.

POSSIBLE ADVERSE EFFECTS

Possible side effects of oestrogen-containing (combined) pills include nausea, weight gain, depression, breast tenderness, increased appetite, reduced sex drive, leg cramps, abdominal cramps, headaches, and dizziness. They can also cause occasional spotting (slight blood

loss) in between periods, early in the cycle. More seriously, there is a small increase in the risk of *thrombosis* (an abnormal blood clot) occurring that may lead to a *stroke* or a *pulmonary embolism*. Oestrogen-containing pills may also aggravate heart disease, or they may cause *gallstones*, *jaundice*, and, very rarely, *liver cancer*. There is a small increase in the long-term risk of breast cancer occurring for women taking the combined pill.

CONTRAINdications

Oestrogen-containing pills are generally not recommended for use by women with *liver disease*, *migraine*, worsening *otosclerosis* (an ear disorder), or women at increased risk of thrombosis. They are not usually prescribed to a woman with a personal or family history of significant heart or circulatory disorders or to a woman who suffers from unexplained vaginal bleeding.

Combined or phased pills may interfere with milk production and should not be taken during breast-feeding.

Certain drugs, such as some *antibiotic drugs* or *anticonvulsant drugs*, may impair the effectiveness of oral contraceptives; a doctor should always be consulted. (See also *contraception*.)

oral hygiene

Measures that are used to keep the mouth and teeth clean and to reduce the risk of tooth decay (see *caries*, *dental*), *gingivitis* and other gum disorders, and *halitosis* (bad breath). Oral hygiene includes regular, thorough *toothbrushing* and flossing (see *floss*, *dental*) in order to remove *plaque* (a sticky coating that forms on the teeth and consists of saliva, bacteria, and food debris). *Disclosing agents* can be used to help to reveal areas of plaque buildup. Dentures are brushed on all surfaces and soaked in cleansing solution.

Professional treatment to remove *calculus* (a mineral deposit that forms on teeth) and stubborn plaque by scaling and polishing is usually carried out by a dentist or dental hygienist during a routine check-up. In *periodontal disease*, treatment may be needed more often.

oral phase

A term that is used in *psychoanalytic theory* to refer to the earliest stage of a person's psychosexual development. The oral phase is thought to last from birth to about 18 months of age. (See also *anal phase*; *genital phase*.)

oral rehydration therapy

See *rehydration therapy*.

oral surgery

The branch of surgery concerned with the treatment of deformity, injury, or disease of the teeth, the jaws, and other parts of the mouth. Procedures include the extraction of impacted wisdom teeth (see *impaction*, *dental*) and *alvelectomy* (removal of tooth-bearing bone from the jaw).

More complicated oral surgery includes: repair of a broken jaw; *orthognathic surgery*, (which is carried out to correct deformities of the jaw); plastic surgery in order to correct *cleft lip and palate*; and the removal of some noncancerous tumours from the mouth.

oral syringe

See *syringe*, *oral*.

orange peel effect

See *peau d'orange*.

orbit

The socket in the *skull* containing the eyeball, protective fat, blood vessels, muscles, and nerves. The *optic nerve* passes from the eye to the *brain* through an opening in the back of the orbit.

DISORDERS

A severe blow to the face may fracture the orbit, but the eyeball is often undamaged because it is squeezed back-

wards by protective muscles during reflex blinking. Fractures can often heal without treatment, but some may cause deformity and therefore require corrective surgery. In rare cases, bacterial infection spreads from a *sinus* or the face to cause *orbital cellulitis*.

orbital cellulitis

Bacterial infection of the tissues within the eye socket, or *orbit*. Usually, the infection originates in a nearby sinus, but sometimes it spreads in the blood from a facial infection. The affected eye protrudes and is extremely painful and red. There is also severe swelling of the lids and conjunctiva (the membrane lining the inside of the lids and covering the white of the eye).

Orbital cellulitis is a serious disorder. The eye may be damaged; there is also a slight risk that the infection may spread inwards to involve the brain. Treatment is with high doses of *antibiotic drugs*.

orchidectomy

The surgical removal of one or both of the *testes*. Orchidectomy may be performed for testicular cancer (see *testis*, *cancer of*) or gangrene caused by torsion (see *testis*, *torsion of*), or to reduce production of the male hormone *testosterone* in the treatment of cancer of the prostate gland (see *prostate*, *cancer of*).

Removal of only one testis does not affect sex drive, potency, or the ability to have children.

orchidopexy

An operation to bring down an undescended testis (see *testis*, *undescended*) into the scrotum. Orchidopexy is usually performed in boys before the age of two in order to reduce the risk of later *infertility* or testicular cancer (see *testis*, *cancer of*).

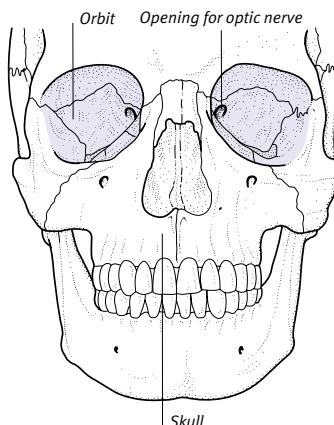

orchitis

Inflammation of a *testis*. Orchitis may be caused by the *mumps* virus, particularly if infection occurs after puberty. Swelling and severe pain in the affected testis are accompanied by high fever. In *epididymo-orchitis*, the tube that carries sperm from the testis is also inflamed.

Treatment is with *analgesic drugs* (painkillers) and *ice-packs* to reduce swelling; *antibiotic drugs* may be given, but not for mumps orchitis. The condition usually begins to subside within seven days but is occasionally followed by shrinking of the testis.

LOCATION OF ORBIT

The orbits are the deep cavities in the skull that enclose and protect the eyeballs and the muscles that move the eyes.

orf

A skin infection occasionally transmitted to humans from sheep. Caused by a *pox* virus, orf usually produces a single persistent, fluid-filled blister on the arm or hand. The antiviral drug idoxuridine may hasten recovery.

organ

A collection of various *tissues* integrated into a distinct structural unit to perform specific functions. For example, the brain consists of nerve tissue and support tissue that is organized to receive, process, and send out information.

organ donation

The agreement of a person (or of his or her family) to the surgical removal of one or more of the organs for use in *transplant surgery*.

Most organs that are commonly used for transplantation, such as the heart, lungs, liver, and kidneys, are removed immediately after death. Heart and lung function is sometimes maintained by machine after *brain death* has been certified until the organs have been removed. Living donors may be able to give a kidney, but usually only to a close relative (see *tissue-typing*).

Although it is not legal in the UK, in some countries, organ donors are paid for their organs. People can facilitate use of their organs after death by informing relatives and carrying a donor card. (See also *corneal graft*; *heart-lung transplant*; *heart transplant*; *heart-valve surgery*; *kidney transplant*; *liver transplant*.)

organelle

One of various specialized structures contained within a body *cell*.

organic

Related to a body *organ*; having organs or an organized structure; or related to *organisms* or to substances from them.

In medicine, the term indicates the presence of disease in the body.

In chemistry, the term refers to certain compounds that contain carbon. (See also *inorganic*.)

organic brain syndrome

See *brain syndrome*, *organic*.

organic disease

A term used to refer to any disorder that is associated with changes in the structure of an organ or tissues. (See also *functional disorder*.)

organism

A general term for an individual animal or plant. *Bacteria* and *viruses* are disease-causing *microorganisms*.

organ of Corti

A structure involved in hearing that is situated in the *cochlea* of the inner ear. Sensory hair cells in the organ of Corti vibrate in response to sounds and translate them into electrical impulses that travel via the cochlear nerve to the brain.

organomegaly

Abnormal enlargement of the body's internal organs, such as *hepatomegaly* (enlargement of the liver).

organophosphates

Highly poisonous agricultural insecticides that are harmful when absorbed through the skin, by inhalation, or by swallowing. Among the many possible symptoms are nausea, vomiting, abdominal cramps, diarrhoea, blurred vision, excessive sweating, headache, confusion, and twitching. In cases of severe poisoning, breathing difficulty, palpitations, seizures, and unconsciousness may occur. If left untreated, death may result.

Treatment may include washing out the stomach (see *lavage*, *gastric*) or removing soiled clothing and washing contaminated skin. Injections of *atropine* may be administered, and *oxygen therapy* and/or artificial *ventilation* may be needed. With rapid treatment, people may survive doses that would otherwise have been fatal. Long-term effects of organophosphates in sheep dips are thought to be responsible for debilitating illness with neural, muscular, and mental symptoms.

orgasm

Intense sensations produced by a series of muscular contractions at the peak of sexual excitement. Orgasm usually lasts for about three to ten seconds but can last up to a minute in women.

In men, contractions of the muscles of the inner pelvis massage semen into the *urethra*; the semen is then forcefully propelled through the urethral orifice (see *ejaculation*).

Orgasm in women is associated with irregular contractions of the voluntary muscles of the walls of the *vagina* and, in some women, of the *uterus*, followed by relief of congestion in the pelvic area. Some women experience multiple orgasms if stimulation is continued.

Orgasm is usually followed by a refractory phase during which there is no physical response to further sexual stimulation. Both men and women may experience problems with orgasm (see *ejaculation*, *disorders of*; *orgasm, lack of*).

orgasm, lack of

Inability to achieve orgasm during sexual activity. The problem is more common in women than men. In either sex, failure to achieve orgasm may be due to inhibited sexual desire (see *sexual desire*, *inhibited*) or inability to become aroused or maintain arousal (see *frigidity*; *impotence*). In men, there may be a problem achieving orgasm despite normal arousal (see *ejaculation*, *disorders of*).

In women, lack of orgasm is the most common sexual problem, affecting up to 50 per cent of women at some time in their lives. Some are unable to achieve orgasm under any circumstances, others experience orgasm only occasionally.

For both sexes, contributory factors include problems with sexual technique or a relationship, lack of familiarity with sexual responses, psychological problems (such as anxiety, early sexual trauma, or inhibitions), and the fear of becoming pregnant.

Sex therapy, *relationship counselling*, and *psychotherapy* may be helpful.

orifice

A term used in anatomy to refer to any opening in the body, especially an entrance or outlet of a body cavity. An example of an orifice is the mouth.

orlistat

An anti-obesity drug used with a slimming diet to treat severe obesity. Unlike *appetite suppressants*, orlistat acts on the gastrointestinal tract, preventing the digestion of fats by lipases (*pancreatic enzymes*). Instead of being absorbed, the fats pass out of the body in faeces.

Side effects are gastrointestinal in nature and can be minimized by reducing fat intake. Flatulence and faecal urgency are common. Deficiencies of fat-soluble vitamins may develop with prolonged use of orlistat.

ornithosis

A disease of birds, caused by the microorganism *CHLAMYDIA PSITTACI*, that can cause *psittacosis* in humans.

oro-

A prefix pertaining to the *mouth*.

orphan drugs

Drugs that have been developed to treat rare conditions but are not manufactured generally.

orphenadrine

A *muscle-relaxant drug* used to treat the movement disorder *Parkinson's disease*. Side effects of orphenadrine include a dry mouth and blurred vision.

ORT

The abbreviation for *oral rehydration therapy*. (See also *rehydration therapy*.)

ortho-

A prefix meaning normal, correct, or straight, as in *orthopaedics*, a branch of surgery concerned with correcting disorders of the bones and joints.

orthodontic appliances

Fixed or removable devices, commonly known as braces, worn to correct *malocclusion* (an abnormal relationship between the upper and lower teeth) or to reposition overcrowded or *buck teeth*. Usually fitted during childhood and adolescence, a brace moves teeth using sustained gentle pressure.

A fixed appliance has brackets attached to the teeth through which an arch wire is threaded and tightened to exert pressure. These are usually kept in place for about a year, after which time a retainer plate may be needed to hold the teeth in place until tooth and jaw growth has finished.

Removable appliances, which consist of a plastic plate with attachments that anchor over the back teeth, are used when only one or a few teeth need correcting. They apply force by means of springs, wire bows, screws, or rubber bands fitted to the plate.

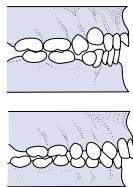

orthodontics

A branch of *dentistry* concerned with prevention and treatment of *malocclusion* (an abnormal relationship between the upper and lower teeth). The procedures are usually performed while teeth are developing and relatively manoeuvrable but can also be of benefit in adulthood.

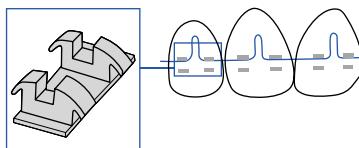

An orthodontist may first make models of the teeth (see *impression, dental*) and take *X-rays* of the head and jaws. Certain teeth, often premolars, may be extracted to make room for the remaining teeth. Poorly positioned teeth are then moved by gentle pressure exerted by *orthodontic appliances*.

HOW ORTHODONTIC APPLIANCES WORK

The tooth sockets are remarkably responsive to sustained pressure against the teeth. Orthodontic appliances, which may be fixed or removable, provide such pressure. Even gentle pressure applied in a particular direction will move teeth. As they move, bone is remodelled so that the new position is stable.

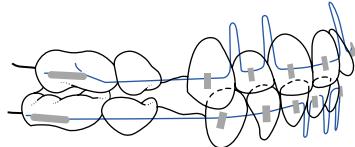

Overcrowding
This is frequently associated with malocclusion (poor alignment between upper and lower teeth). Some teeth have to be extracted to make room for others to be straightened.

FIXED APPLIANCES**Appearance of brackets and wires**

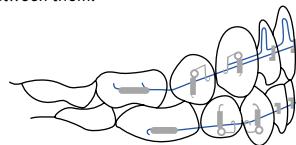

Brackets are fixed appliances cemented to the outer surface of the teeth; they have slots into which arch wires can be fitted.

**Repositioning a tooth**

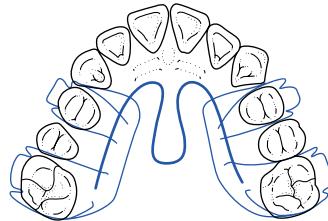

By careful design of the arrangement of wires and spring, force can be exerted in any direction to move a tooth into the desired position.

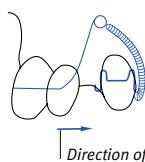

1 Teeth are removed to create space and an appliance made to correct the alignment of the remaining teeth and to close gaps between them.

2 Once the teeth in the upper and lower jaws are completely aligned, the appliance is adjusted to tip or rotate the teeth in order to achieve a good appearance and bite.

REMOVABLE APPLIANCES

Arrangement of wires over teeth
These are easier to keep clean than fixed appliances and are less obtrusive, but they may interfere with speech; their efficiency relies on patients using them as directed. This type exerts pressure to push the teeth at the sides outwards.

Bow device
This simple wire spring acts by exerting force to straighten the tooth. Many bow devices are more complicated.

A removable bow
One of the many forms of orthodontic wire appliance, this bow device exerts pressure on the teeth at the sides, which straightens and moves them outwards.

orthognathic surgery

Operations to correct deformities of the jaw and the severe *malocclusion* (abnormal relationship between the upper and lower teeth) that is associated with them.

Orthognathic surgery is performed under general anaesthesia. A jaw that projects too far can be shortened by removing a block of bone from each side and manoeuvring the front of the jaw backwards. A jaw that is too short can be reshaped by dividing the

bone on each side, sliding the front of the jaw forwards, and inserting bone grafts (taken from elsewhere in the body) into the gaps. After repositioning, the jaw bones often require wiring together (see *wiring of the jaws*) until they have healed.

orthomyxovirus

One of a family of *viruses* that includes the microorganisms responsible for respiratory tract diseases, especially *influenza*.

orthopaedics

The branch of surgery concerned with disorders of the *bones* and *joints* and their associated *muscles*, *tendons*, and *ligaments*. Orthopaedic procedures include setting broken bones and applying casts; treating slipped discs, dislocations, arthritis, and back problems; treating bone tumours and birth defects of the skeleton; and repairing or replacing hip, knee, or finger joints. (See also *brace*, *orthopaedic*; *collar, orthopaedic*.)

orthopnoea

Difficulty in breathing when lying flat. Orthopnoea is a symptom of *heart failure* (the heart is no longer pumping blood efficiently) and *pulmonary oedema* (an accumulation of fluid in the lungs), and also occurs with *asthma* and chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*).

orthoptics

Techniques used mainly in children to measure and evaluate *squint*, including eye exercises, assessment of monocular and binocular vision, and measures to combat *amblyopia* (lazy eye).

orthostatic hypotension

Also called postural hypotension, low blood pressure that occurs on standing. Orthostatic hypotension may be caused by treatment with *antihypertensive drugs* or the failure of nerves that control the diameter of the blood vessels, often as a result of *diabetes mellitus*.

orthotics

Use of appliances to support or correct weakened or deformed limbs, joints, or other parts of the body.

os

An anatomical term for a bone. Os also refers to an opening in the body, as in the cervical os (entrance to the *uterus*).

Osgood–Schlatter disease

Painful enlargement and tenderness of the tibial tuberosity, the bony prominence of the *tibia* (shin) just below the knee. The condition occurs most commonly in boys aged between 10 and 14 years of age. It may be the result of excessive, repetitive pulling of the *quadriceps muscle* at the front of the thigh due to repeated exercise. There is usually pain above and below the knee, which is worse during strenuous activity, and the tibial tuberosity is tender

when touched. The disorder often clears up without treatment as long as sporting activity is restricted; severe pain may require *physiotherapy* or immobilization in a plaster *cast*.

Osler's disease

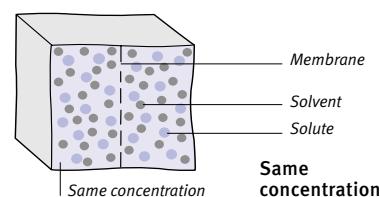

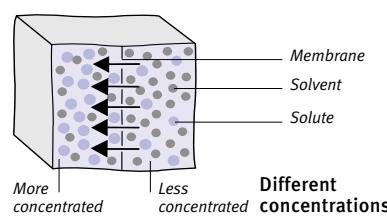

A rare inherited condition in which capillaries (tiny blood vessels) in the skin and mucous membranes, such as those lining the mouth and nose, become dilated, forming red spots. The condition, which is also known as hereditary haemorrhagic telangiectasia, is an autosomal dominant *genetic disorder*.

The lesions may bleed easily. Nosebleeds are a common symptom and may begin in childhood. Lesions may also develop in the digestive tract, causing recurrent bleeding leading to *anaemia*; in the lungs, causing blood to be coughed up; or in the brain, causing tissue damage and seizures.

Anaemia can be counteracted with iron supplements. In some cases, laser treatment is used to seal the lesions.

osmosis

The passage of a solvent from a weaker solution to a more concentrated one through a semipermeable membrane. All body cells are surrounded by such membranes, which allow water, salts, simple sugars (such as *glucose*), and *amino acids* (but not proteins) to pass through. Therefore, osmosis plays an important part in regulating the distribution of water and other substances that are present in body tissues.

Osmosis

If two solutions, each consisting of different concentrations of a solute (e.g. salt) in a solvent (e.g. water), are separated by a semipermeable membrane, solvent moves from the weaker to the stronger solution until the two solutions attain equal concentration.

osmotic diuresis

An increased output of *urine* by the *kidneys* due to the presence of one or more substances in the urine that draw water from the blood into the urine. Excessive amounts of *glucose* in the urine, as a result of *diabetes mellitus*, can produce this effect; another possible cause is treatment with one of the osmotic *diuretic drugs*, such as *mannitol*.

osseous

Bony or bonelike. The term "osseous" is sometimes used to refer to the bony parts of the inner *ear*. (See also *bone*.)

ossicle

A small bone, especially any of the three tiny bones in the middle *ear* (malleus, incus, and stapes) that are involved in conducting sound from the eardrum to the inner ear.

ossification

The process by which *bone* is formed, renewed, and repaired, which starts in the embryo and continues throughout a person's life. There are three main situations in which ossification occurs: bone growth, during which new bone forms at the *epiphyses* (ends) of bones; bone renewal as part of normal regeneration; and bone repair, which occurs following a *fracture*.

In newborn babies, the *diaphysis* (bone shaft) has begun to ossify and is composed mainly of bone tissue, while the epiphyses are made of cartilage that gradually hardens. In children, growth plates produce new cartilage to lengthen the bones and further bone forms at secondary ossification centres in the epiphyses. By the age of 18, the shafts, growth plates, and epiphyses have all ossified and fused into continuous bone, allowing no further growth.

Ossopan

A brand name for hydroxyapatite, a *calcium* supplement used in the treatment of *osteoporosis* (loss of bone tissue).

osteitis

Inflammation of *bone*. The most common cause is infection, usually by bacteria (see *osteomyelitis*). Other causes of osteitis include *Paget's disease* and *hyperparathyroidism* (overactivity of the parathyroid glands).

osteitis deformans

An alternative term for *Paget's disease*.

oste-

A prefix that is used to denote a relationship to bone, as in *osteoporosis*, which is a condition that causes the bones to become thin and weaken.

osteoarthritis

A common *joint* disease, osteoarthritis is characterized by degeneration of the cartilage that lines the joints or by formation of *osteophytes* (bony outgrowths), leading to pain, stiffness, and occasionally loss of function. Osteoarthritis is the most common form of *arthritis*. *Cervical osteoarthritis* is a particular form of osteoarthritis that affects mainly the joints between the cervical *vertebrae* (the bones in the neck).

CAUSES AND SYMPTOMS

Osteoarthritis is due to inflammation and destruction of the cartilage that

occurs at joint surfaces and changes to the bone beneath. This condition is most likely to occur in the weight-bearing joints as well as in any joints that have previously suffered some kind of damage. However, these are not the only causes. Genetic factors may be involved in cases in which osteoarthritis affects the joints.

Evidence of osteoarthritis can be seen on *X-rays* of almost everyone over the age of 60; however, not all of these people have symptoms. Factors that lead to the development of osteoarthritis at an earlier age include excessive wear of, or injury to, a joint; congenital deformity or misalignment of the bones in a joint; *obesity*; or inflammation from another disease such as *gout*. Severe osteoarthritis affects about three times as many women as men.

Affected joints become enlarged and distorted by *osteophytes*, which are responsible for the gnarled appearance of arthritic hands. Weakness and shrinkage of surrounding muscles may occur if severe pain prevents the joint from being used regularly.

TREATMENT

There is no cure for osteoarthritis. Pain can be relieved by *analgesics* and *nonsteroidal anti-inflammatory drugs*; injection of *corticosteroid drugs* into an affected joint or of *hyaluronic acid* into an affected knee may temporarily relieve the symptoms; *physiotherapy* to improve muscle strength around the affected joints can help to limit the deterioration that otherwise results from joint instability. In overweight people, weight loss often provides relief of symptoms. If the condition is severe, various aids are available that can make coping at home easier. Surgery for osteoarthritis, including *arthroplasty* and *arthrodesis*, is only undertaken if the pain and disability are too severe to cope with.

osteopathia, hypertrophic pulmonary

A *bone* disorder almost always associated with *lung cancer*. Symptoms include pain and swelling of the wrists and ankles, accompanied by clubbing of the fingers. The condition will disappear if the underlying cancer is treated successfully. Symptoms can be partially relieved with *nonsteroidal anti-inflammatory drugs*.

osteoblastoma

A painful, noncancerous *bone tumour* that is characterized by the formation of *osteoid tissue* and primitive bone. Osteoblastomas most commonly occur in the spine of a young person.

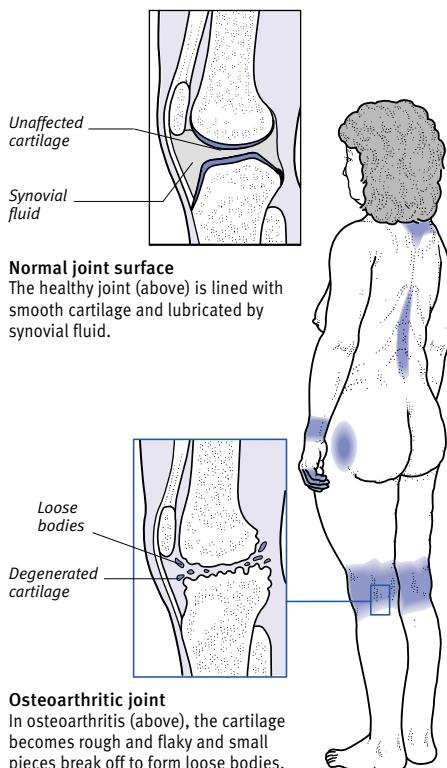

osteochondritis dissecans

Degeneration of a *bone* just under a joint surface, causing fragments of bone and cartilage to become separated; this may cause the joint to lock. The condition commonly affects the knee and usually starts in adolescence. Symptoms include aching discomfort and intermittent swelling of the affected joint.

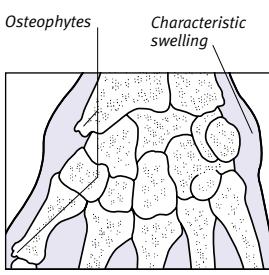

If a fragment has not completely separated from the bone, the joint may be immobilized in a plaster *cast* to allow reattachment to occur. Loose bone or cartilage fragments in the knee are removed during *arthroscopy*. Disruption to the smoothness of the joint surface increases the risk of *osteoarthritis*.

OSTEOARTHRITIS

Osteoarthritis differs from rheumatoid arthritis and has a better outlook. It is characterized by degeneration of cartilage or by formation of bony outgrowths (osteophytes). It results from excessive wear on joints or to slight deformity or misalignment of bones in a joint. Inflammation from a disease, such as gout, may also lead to osteoarthritis. Weight-bearing joints, such as those in the neck, the lower back, the knees, and hips, are the areas most commonly affected.

X-ray signs of osteoarthritis
In this X-ray of a knee joint, there is narrowing of the joint space with osteophyte production and an increase in density of the bone ends.

Osteophytes
These are outgrowths of new bone that tend to occur at the margins of the joint surfaces in osteoarthritis.

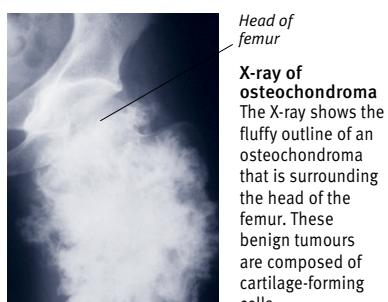

osteochondritis juvenilis

Inflammation of an *epiphysis* (growing end of bone) occurring in children and adolescents. Osteochondritis juvenilis causes pain, tenderness, and restricted movement if the epiphysis forms part of a joint. The inflammation leads to softening of the bone, which may result in deformity. The condition may be due to disruption of the bone's blood supply. There are several types of osteochondritis juvenilis: *Perthes' disease*; Scheuermann's disease, which affects several adjoining vertebrae; and other types that affect certain bones in the foot and wrist.

The affected bone may need to be immobilized in an orthopaedic *brace* or *plaster cast*. In Perthes' disease, surgery may be required to prevent more deformity. The bone usually regenerates within three years and rehardens, but deformity may be permanent and increases the risk of *osteoarthritis* in later life.

osteochondroma

A noncancerous *bone* tumour, which is formed from a stalk of bone capped with cartilage, and appears as a hard round swelling near a joint. An osteochondroma develops in late childhood and early adolescence, usually from the side of a long bone near the knee or shoulder. The tumour causes problems only if it interferes with the movement of tendons or the surrounding joint, in which case surgical removal may be necessary. Large osteochondromas can interfere with skeletal growth, and may cause deformity.

osteochondrosis

See *osteochondritis juvenilis*.

osteodystrophy

Any generalized bone defect caused by *metabolic disorders*. Types of osteodystrophy include *rickets*; *osteomalacia*; and

bone cysts and bone mass reduction associated with chronic *kidney failure* or *hyperparathyroidism* (overactivity of the parathyroid glands). In adults, an osteodystrophy is usually reversible if the underlying cause is treated before bone deformity occurs.

osteogenesis imperfecta

A *congenital* condition characterized by abnormally brittle *bones* that are unusually susceptible to *fractures*.

CAUSE AND SYMPTOMS

The condition is caused by an inherited defect in the *connective tissue* that forms the basic material of bone. Severely affected infants are born with multiple fractures and a soft skull and they do not usually survive. Other sufferers have many fractures during infancy and childhood, often as a result of normal handling and activities, and it may be difficult to distinguish the condition from *child abuse*.

A common sign of osteogenesis imperfecta is that the whites of the eyes are abnormally thin, making them appear blue. Sufferers may also be deaf as a result of *otosclerosis*. In very mild cases, osteogenesis imperfecta may not be detected until adolescence or later.

TREATMENT AND OUTLOOK

There is no specific treatment for the condition. Fractures are immobilized and usually heal quickly, but they may cause shortening and deformity of the limbs, resulting in abnormal, stunted growth. Skull fractures may cause brain damage or death. Parents may have *genetic counselling* to estimate the risk of the condition occurring in future children. Severe cases can be diagnosed prenatally by *ultrasound scanning*.

osteogenic sarcoma

See *osteosarcoma*.

osteoid osteoma

A *bone* disorder in which a tiny abnormal area of bone, usually in a long bone, causes deep pain, which is typically worse at night. The condition is cured by removing the area of bone. (See also *osteoma*.)

osteoma

A hard, noncancerous, usually small tumour that may occur on any bone in the body. Surgical removal of the osteoma may be necessary if it causes symptoms through pressing on surrounding structures.

osteomalacia

The softening, weakening, and demineralization (loss of essential minerals) of an adult's *bones* as a result of a deficiency of *vitamin D*. *Rickets* is the equivalent disease in children.

The development and maintenance of healthy bone requires an adequate intake of calcium and phosphorus from the diet, but these minerals cannot be absorbed by the body without a sufficient amount of vitamin D. This vitamin is obtained from certain foods and from the action of sunlight on the skin.

CAUSES

Osteomalacia can be caused by a variety of factors, including: insufficient vitamin D in the diet (for example, due to lack of butter, fish, eggs, or fish-liver oils); insufficient exposure to sunlight; or inadequate absorption of vitamin D from the intestine (see *malabsorption*), caused by a disorder such as *coeliac disease*, or following intestinal surgery. Rare causes include *kidney failure*, *acidosis* (increased acidity of body fluids), and certain inherited *metabolic disorders*.

Osteomalacia is uncommon in developed countries, but it may affect people who have poor diets (especially dark-skinned people who have little exposure to sunlight).

SYMPTOMS

Osteomalacia causes bone pain, especially in the neck, legs, hips, and ribs. In addition, muscle weakness, particularly at the hips, can make it very difficult to stand up and to climb stairs. If the blood calcium level is very low, there may be *tetany* (muscle spasms) in the hands, feet, and throat. Weakened bones are vulnerable to distortion and fractures, which are often painless.

TREATMENT

Treatment is with a diet rich in vitamin D and regular supplements. Calcium supplements may also be given.

osteomyelitis

Infection, usually by bacteria, of *bone* and *bone marrow*. It is relatively rare in developed countries but is more common in children, most often affecting the long arm and leg bones and vertebrae; in adults, it usually affects the vertebrae. The condition may be either acute or chronic.

ACUTE OSTEOMYELITIS

In acute osteomyelitis, the infection (which is usually caused by the bacterium *STAPHYLOCOCCUS AUREUS*) enters the bloodstream via a skin wound or as a

result of infection elsewhere in the body. The infected bone and marrow become inflamed; pus forms, causing fever, severe pain and tenderness in the bone, and inflammation and swelling of the skin over the affected area.

Prompt treatment with high doses of *antibiotic drugs*, initially given intravenously and continued over several weeks or months, usually cures acute osteomyelitis. If the condition fails to respond, surgery has to be performed to remove infected and dead bone and drain away any pus.

CHRONIC OSTEOMYELITIS

Chronic osteomyelitis may develop if acute osteomyelitis is neglected or fails to respond to treatment; after a compound fracture; or due to infection of the bone with *Mycobacterium tuberculosis*, which causes *tuberculosis*.

The condition causes constant pain in the affected bone. Complications include persistent deformity and, in children, arrest of growth in the affected bone. Involvement of the spine can result in damage to the spinal cord if the condition is not treated. In the later stages of the disease, *amyloidosis* (abnormal deposits of a starchy substance in vital organs) may develop.

Chronic osteomyelitis requires surgical removal of all affected bone, sometimes followed by a *bone graft*; antibiotic drugs are also prescribed.

osteopathy

A system of diagnosis and treatment that recognizes the role of the musculoskeletal system in the healthy functioning of the body. The basic principle of osteopathy is that all body systems operate in unison, and that disturbances in one system can alter the functions of some others. The osteopath uses manipulation, rhythmic stretching, and pressure to restore movement to the joints. He or she also uses traditional diagnostic and therapeutic procedures to diagnose and treat dysfunction.

osteopenia

Any decrease in *bone* mass below the normal level. The term is used particularly to refer to a decrease in mass that occurs when the body makes too little new bone to compensate for normal bone lysis (breakdown or destruction). Osteopenia can occur throughout the skeleton or may be confined to a specific area, such as the bones adjacent to a diseased or damaged joint.

osteopetrosis

A very rare inherited disorder in which *bones* harden and become denser. Deficiency of one of the two types of bone cell responsible for healthy bone growth results in a disruption of normal bone structure. In its mildest form, there may be no symptoms. More severe forms result in abnormally high susceptibility to *fractures*; stunted growth; deformity; and *anaemia*. Pressure on nerves may cause blindness, deafness, and facial paralysis.

Most treatments for osteopetrosis aim to reduce the severity of symptoms. Bone marrow transplants of cells from which healthy bone cells might develop are undertaken in some cases.

osteophyte

An outgrowth of *bone* at the boundary of a joint. The formation of osteophytes is a characteristic feature of *osteoarthritis* that contributes to the deformity and restricted movement of affected joints.

osteoporosis

A disease in which there is loss of bone tissue (and so loss of bone density), causing bones to become brittle and fracture easily.

CAUSES

Thinning of the bones is a natural part of the aging process. However, women are especially vulnerable to loss of bone density after the *menopause*, because their *ovaries* no longer produce *oestrogen hormones*, which help maintain bone mass.

Other causes of osteoporosis include premature removal of the ovaries; a diet that is deficient in calcium; certain hormonal disorders, such as an overactive thyroid gland (see *hyperthyroidism*); long-term treatment with *corticosteroid drugs*; and prolonged immobility. Osteoporosis is most common in heavy smokers and drinkers, and in very thin people.

SYMPTOMS

Osteoporosis may go undiagnosed for many years. The first sign is often a fracture, typically at the wrist or the top of the *femur* (thigh bone), after what may have been a trivial injury. One or several *vertebrae* may fracture spontaneously and cause the bones to crumble, leading to progressive height loss and/or pain due to compression of spinal nerve roots.

DIAGNOSIS AND TREATMENT

Osteoporosis is confirmed by the use of *bone densitometry*. Bone loss can be minimized by adequate dietary calcium and regular, sustained exercise to build the bones and maintain their strength.

Bisphosphonate drugs may be used to prevent and treat bone loss following the menopause. Long-term *hormone replacement therapy* (HRT) is now usually only advised for women who cannot take other treatments or in whom other treatments have been unsuccessful. Women who have gone through a premature menopause before the age of 40 may be advised to have HRT until the age of 50 to protect them against osteoporosis; for these women, the health risks of HRT are thought to be less than normal.

osteosarcoma

A cancerous tumour of the bone that can spread to the lungs and, less commonly, to other areas. An osteosarcoma usually develops in people between the ages of ten and 25, generally in a long bone of the arm or leg, often around the knee. Osteosarcomas may also be seen in elderly people as a rare complication of *Paget's disease* or of previous treatment with *radiotherapy*. The tumour causes pain and swelling of the affected bone if it occurs near the surface.

In the past, amputation of the affected limb was inevitable. However, the outlook has improved due to a combination of *chemotherapy* and surgery in which the diseased bone is replaced with a custom-made *prosthesis*.

osteosclerosis

Increased *bone density*, which is visible on *X-rays* as an area of extreme whiteness. Localized osteosclerosis may be caused by a severe injury that compresses the bone, the joint disorder *osteoarthritis*, chronic *osteomyelitis* (bone infection), or an *osteoma* (noncancerous bone tumour). Osteosclerosis occurs throughout the body in the inherited bone disorder *osteopetrosis*.

osteotomy

Surgery to alter the alignment or length of a *bone*, by cutting it. Osteotomy is used to correct *hallux valgus* (a deformity of the big toe) that has caused a *bunion*; *coxa vara* (a deformity of the hip); or deformity caused by congenital hip dislocation (see *hip, congenital dislocation of*). Osteotomy is also used to straighten a long bone that has healed crookedly after a *fracture*, or to shorten the uninjured leg if a fractured leg has shortened during healing (see *leg, shortening of*).

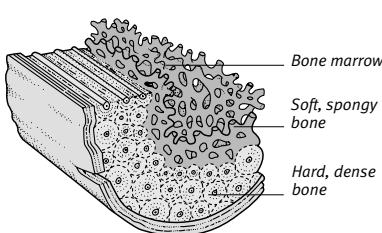

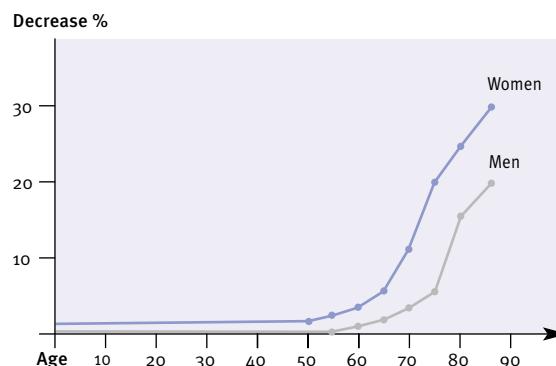

ostium

An anatomical term for an opening.

OSTEOPOROSIS

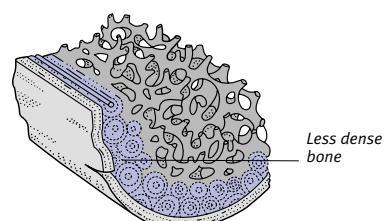

In osteoporosis, the density of bones decreases, and their brittleness increases, although there is no change in size or composition. Women past the menopause are the most commonly affected because their ovaries no longer produce oestrogen, which helps to maintain bone mass. The risk of the condition is greater in a woman who undergoes the menopause early, or whose mother had osteoporosis.

Bone loss with age
The graph on the right shows how the percentage of bone lost increases in both sexes from age 50 onwards, with the losses particularly marked in women after the menopause. By age 80, up to half of all women have sustained at least one fracture due to osteoporosis, a much higher proportion than in men.

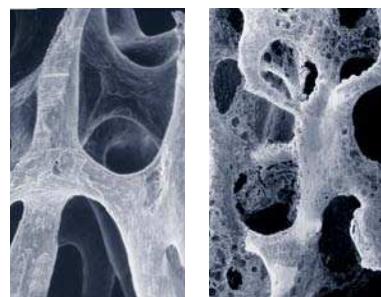

Normal bone cross-section

Bone consists of fibres of collagen (a protein), which give elasticity, and calcium, which gives hardness.

Osteoporotic bone

Thinning is mainly due to loss of collagen, which takes calcium with it. Both hard and spongy bone tissues are affected.

Bone tissue affected by osteoporosis

When compared with normal bone tissue (left), the osteoporotic bone (right) is far less dense and appears thin and brittle.

-ostomy

A term that is used to describe a surgical opening (for example, *colostomy*) or a junction of two hollow organs.

otalgia

The medical term for *earache*.

OTC drug

See *over-the-counter drug*.

otitis externa

Inflammation of the outer-ear canal, commonly due to infection (see *Ear infections* box, overleaf). It usually causes swelling, a discharge, and, in some people, *eczema* around the opening of the ear canal. The ear may be itchy and painful and blocked with pus, causing deafness.

CAUSES

Generalized infection of the canal, and sometimes of the pinna (external ear), may be due to a fungal or bacterial infection. The ear may also sometimes become inflamed as part of a generalized skin disorder such as *atopic eczema* or *seborrhoeic dermatitis*.

TREATMENT

Often, the only treatment required is to keep the ear clean and dry until the

infection has cleared. Locally acting preparations that contain *antibiotic drugs*, *antifungal drugs*, or *corticosteroid drugs* may be used. Oral antibiotics may be given to treat bacterial infections if they are severe.

otitis media

Inflammation of the middle *ear*, the cavity between the eardrum and the inner ear, (see *Ear infections* box, overleaf).

CAUSES

This condition is due to a viral or bacterial infection that has usually travelled up the *eustachian tube*, the passage that runs from the back of the nose to the middle ear. The tube may become blocked by inflammation or enlarged *adenoids*, causing fluid and/or pus to accumulate in the middle ear rather than draining away through the tube. Children, particularly those under seven years, are especially susceptible to otitis media because of the shortness of their eustachian tubes; some children have recurrent attacks.

SYMPTOMS

Acute otitis media can cause sudden severe earache, a feeling of fullness in the ear, deafness, *tinnitus* (ringing or buzzing in the ear) and fever. The

eardrum may burst, discharging pus and relieving pain, in which case healing usually occurs within a few weeks.

DIAGNOSIS AND TREATMENT

The condition is diagnosed by examination of the middle ear with an *otoscope*; the eardrum appears red and may bulge outwards. Treatment is with *analgesic drugs* (painkillers). *Antibiotic drugs* may be prescribed if the infection is bacterial.

COMPLICATIONS

A complication of otitis media is *glue ear*, in which a thick fluid builds up in the ear and affects hearing. Glue ear may follow severe or recurrent otitis media, which occurs mainly in children.

In rare cases, the infection spreads inwards to cause *mastoiditis* (inflammation of the mastoid bone in the skull).

oto-

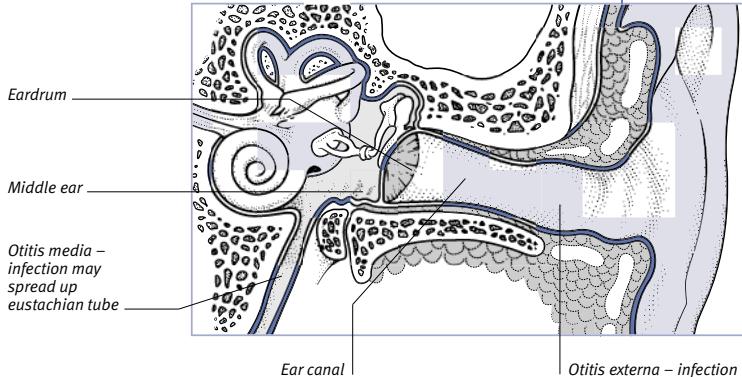

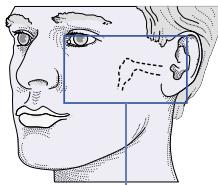

Pertaining to the *ear*, as in *otorrhoea* (discharge from the ear).

otoacoustic emission

An echo emitted by the inner *ear* in response to sound. The emission is produced only by a normally functioning ear and is recorded in a test to detect impaired hearing.

EAR INFECTIONS: OTITIS MEDIA AND OTITIS EXTERNA

Inflammation of the middle ear (otitis media) or ear canal (otitis externa) usually results from infection and may cause earache. Otitis media is more common in children and may be acute (with sudden onset of pain) or chronic (continuing over a long period).

Otitis media

This usually occurs through spread of infection from the back of the nose to the middle ear via the eustachian tube.

Otitis externa

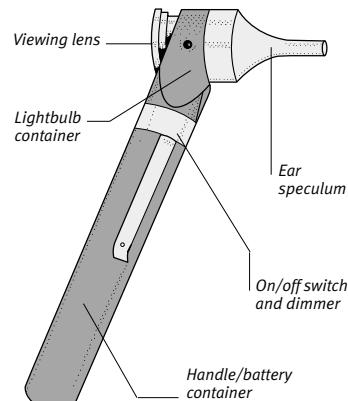

The ear canal is susceptible to infection if it is moist (after swimming) or damaged by attempts to remove earwax.

freely, it can transmit sound vibrations to the inner ear. Alternatively, a *hearing-aid* can markedly improve hearing.

otoscope

An instrument, also called an auroscope, for examining the outer-ear canal and the eardrum. An otoscope illuminates and magnifies the inside of the ear. Otoscopy (examination using an otoscope) is performed in order to detect physical abnormalities such as inflammation or pus in the outer-ear canal (see *otitis externa*) and distortion or rupture of the eardrum.

OTOSCOPE

otomycosis

A fungal *ear* infection that causes inflammation of the ear canal and the external ear (see *otitis externa*).

otoplasty

Cosmetic surgery on the external *ear* usually carried out to make protruding ears lie closer to the head. Otoplasty may also be performed to construct a missing ear in a child born with part or all of one missing, or to reconstruct a damaged ear.

otorhinolaryngology

A surgical speciality, also known as ENT surgery, concerned with diseases of the *ear*, *nose*, and *throat*. ENT specialists treat *sinus* problems, *otitis media*, *tonsillitis*, minor hearing loss, *otosclerosis*, *Ménière's disease*, airway problems in children, uncontrollable nosebleeds, and cancer of the *larynx* (voicebox) and *sinuses*.

otorrhoea

A discharge of pus or other fluid from the *ear* (see *ear*, *discharge from*).

otosclerosis

A disorder of the middle *ear* that causes progressive *deafness*. The condition usually develops in both ears.

CAUSES AND INCIDENCE

Otosclerosis occurs when overgrowth of bone immobilizes the *stapes* (the innermost one of the three tiny bones in the middle ear). As a result, sound vibrations are prevented from passing along the bone to the inner ear.

Otosclerosis frequently runs in families, and symptoms usually start to appear in early adulthood. The condition affects more women than men, and often develops during pregnancy.

SYMPTOMS AND SIGNS

To an affected person, sounds are muffled but can be distinguished more easily if there is background noise.

Hearing loss progresses slowly over 10 to 15 years and is often accompanied by *tinnitus* (ringing in the ears) and, more rarely, *vertigo* (a spinning sensation). A degree of sensorineural deafness may develop, making high tones difficult to hear and causing the sufferer to speak loudly.

DIAGNOSIS AND TREATMENT

The condition is diagnosed by *hearing tests*. It can be cured by *stapedectomy*, a surgical procedure in which the *stapes* is replaced by a tiny piston, which moves through a hole created in the inner ear. Because the piston can move

ototoxicity

Toxic damage to the structures of the inner *ear*. High doses of certain drugs, such as *aminoglycoside* antibiotics, may cause this type of ear damage, resulting in impaired hearing and balance.

Otrivine

A brand name for *xylometazoline*, a *decongestant drug* that is used in the treatment of allergic *rhinitis* to relieve nasal congestion. Otrivine is available as a nasal spray or drops.

out-of-body experience

A feeling of leaving one's body and observing oneself from another dimension. The experience, which is thought to be due to disturbance of brain function, is reported by some patients following a general anaesthetic or a medical emergency.

outpatient treatment

Medical care on a same-day basis in a hospital or clinic.

ovarian cyst

An abnormal, fluid-filled swelling in an *ovary*. Ovarian cysts are common and, in the majority of cases, non-cancerous; however, the likelihood of a cyst being cancerous increases with age. In some cases, both of the ovaries have multiple cysts due to a hormonal disorder (see *ovary, polycystic*).

TYPES

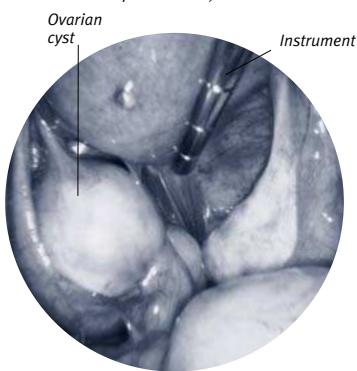

The most common type, a *follicular cyst*, is one in which the egg-producing follicle enlarges and fills with fluid. Cysts may also occur in the *corpus luteum*, a mass of tissue that forms from the follicle after *ovulation*. Other types of cysts include *dermoid cysts* and mucous or serous *cystadenomas* (see *adenoma*), which can become very large. In some cases, an ovarian cyst may be due to *ovarian cancer*, particularly in postmenopausal women.

SYMPTOMS

Ovarian cysts often produce no symptoms, but some may cause abdominal swelling or discomfort, pain on intercourse, or irregularities of menstruation including *amenorrhoea*, *menorrhagia*, and *dysmenorrhoea*. Severe abdominal pain, nausea, and fever may develop if twisting or rupture of a cyst occurs. Surgery is required to treat these conditions.

DIAGNOSIS AND TREATMENT

An ovarian cyst may be discovered during the course of a routine *pelvic examination* and its position and size confirmed by *ultrasound scanning*. In many cases, simple ovarian cysts (thin-walled or fluid-filled cysts) disappear without treatment. Complex cysts (such as dermoid cysts) usually require surgical removal. In some cases, aspiration (withdrawal by suction) of fluid under

Laparoscopic view of an ovarian cyst

This photograph shows an ovarian cyst (centre left) that has formed at the ovary as a result of *endometriosis*, a condition in which fragments of uterine tissue locate in other parts of the body.

the guidance of ultrasound, or during *laparoscopy*, may be possible. If an ovarian cyst is particularly large, the ovary may need to be removed by surgery (see *oophorectomy*).

ovary

One of a pair of almond-shaped glands situated on either side of the *uterus* immediately below the opening of the *fallopian tubes*. Each ovary contains numerous cavities called *follicles*, in which egg cells (see *ovum*) develop. The ovaries also produce the female sex hormones *oestrogen* and *progesterone*.

ovary, cancer of

A malignant growth of the *ovary*. The cancer may be primary (arising in the ovary) or secondary (due to the spread of cancer from another part of the body).

INCIDENCE AND CAUSES

Ovarian cancer can occur at any age but is most common in women over 50 and in those who have never had children. A family history of cancer of the ovary, breast, or colon, especially in close relatives under 50, is an important risk factor. Having taken *oral contraceptives* in the past substantially reduces the risk.

SYMPTOMS

In most cases, ovarian cancer causes no symptoms until it is widespread. The first symptoms may include vague discomfort and swelling in the abdomen; nausea and vomiting; and abnormal vaginal bleeding. The swelling may be due to the tumour itself or to *ascites* (excess fluid in the abdominal cavity).

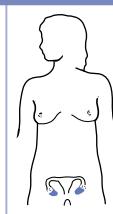

DIAGNOSIS AND TREATMENT

Diagnosis of ovarian cancer involves a physical examination, *ultrasound scanning*, and *blood tests* to measure levels of a substance produced by the tumour. The tumour is usually surgically removed, along with the uterus (see *hysterectomy*) and the unaffected ovary. In younger women whose cancer is found early, it is sometimes possible to perform less radical surgery and preserve fertility. The extent of spread within the abdomen is assessed during surgery.

Surgery is followed by *chemotherapy*, unless the cancer was found at a very early stage. Platinum-based drugs, which are combined with *paclitaxel*, are usually given. Survival rates depend on the type of tumour and how advanced it is at the time of diagnosis; as the disease is often quite advanced, less than one in four women survive for more than five years.

ANATOMY OF THE OVARY

Each ovary consists of glandular cells and egg-producing follicles. After ovulation, each follicle forms a *corpus luteum*.

ovary, disorders of

Diseases and abnormalities of the ovaries can occur for various reasons. Absence of ovaries, or their failure to develop normally, is rare and is usually due to a chromosomal abnormality (see *Turner's syndrome*). Oophoritis (inflammation of an ovary) may result from infections such as *gonorrhoea* or *pelvic inflammatory disease*. *Ovarian cysts* are common and usually noncancerous. *Poly囊 ovarian syndrome* is due to an imbalance of sex hormones. Ovarian cancer (see *ovary, cancer of*) occurs mainly in women over 50. Ovarian failure causes premature *menopause* in about 5 per cent of women.

ovary, polycystic

An ovary with multiple *ovarian cysts*. Symptomless ovarian cysts are present in about a quarter of the female population. In some women, however, ovarian cysts are associated with menstrual disorders and/or other symptoms; in these cases the condition is known as *polycystic ovary syndrome*.

overbite

Overlapping of the lower front *teeth* by the upper ones. A slight degree of overbite is normal as the upper jaw is larger than the lower jaw. In *malocclusion*, overbite may be greater than normal or the lower teeth may project in front of the upper teeth (prognathism).

overbreathing

A common name for *hyperventilation*.

overcrowding, dental

Excessive crowding of the *teeth* so that they are unable to assume their normal positions in the jaw.

CAUSES

Dental overcrowding is commonly inherited and may occur because the teeth are too large for the jaw or the jaw is too small to accommodate the teeth. Overcrowding may also be caused, or aggravated, by premature loss of primary molar (back) teeth; this can cause the permanent teeth replacing them to move out of position and crowd the teeth further forward.

SYMPOTMS

Overcrowded teeth may lead to *malocclusion* (abnormal relationship between the upper and lower teeth) or may prevent certain teeth from erupting through the gum (see *impaction, dental*). The teeth can be difficult to clean, increasing the risk of dental decay (see *caries, dental*) and *periodontal disease*.

TREATMENT

Teeth may need to be extracted to allow room for others or for cosmetic reasons. Usually, an *orthodontic appliance* is fitted to the remaining teeth until they are positioned correctly.

**Overcrowded teeth**

The top and bottom front teeth are crowded together because the molars, just behind them, have grown too far forward.

overdose

See *drug poisoning*.

overflow incontinence

A type of incontinence (see *incontinence, urinary*) in which urine leaks from the bladder, or a type of faecal incontinence in which semi-liquid faeces leak out around impacted faeces in constipation (see *incontinence, faecal*). Overflow urinary incontinence most

commonly occurs in cases of long-term *urinary retention*, which is caused by an obstruction at the outlet of the bladder. Treatment is generally of the underlying problem.

over-the-counter (OTC) drug

A drug that can be bought without a prescription at a pharmacy or other shop, such as a supermarket.

overuse injury

Also called *repetitive strain injury*, a term for any injury caused by repetitive movement of part of the body. Symptoms include pain and stiffness in the affected joints and muscles.

Examples include *epicondylitis*: painful inflammation of one of the bony prominences at the elbow, caused by the pull of the attached forearm muscles during strenuous activities (see *golfer's elbow; tennis elbow*). Overuse injuries of the fingers, thumb, and wrist joints may affect assembly-line and keyboard workers, and musicians; injuries of the neck may affect violinists.

Rest usually relieves the symptoms. A change in the technique used during the activity may prevent recurrence.

overweight

Weighing more than the recommended weight for a particular height. (See also *obesity*.)

ovulation

The development and release of an *ovum* (egg; the female reproductive cell) from a follicle within an *ovary*. During the first half of the menstrual cycle (see *menstruation*), *follicle-stimulating hormone* (FSH) causes several ova to mature in the ovary. At mid-cycle, *luteinizing hormone* (LH) causes one ripe ovum to be released for potential fertilization.

Signs of ovulation include a rise in body temperature, changes in the consistency of the cervical mucus, and sometimes mild abdominal pain (see *mittelschmerz*). A yellow mass of tissue known as the corpus luteum develops from the follicle after *ovulation* and releases progesterone during the second half of the cycle.

After the release of the ovum, it travels along the *fallopian tube* and, if *fertilization* does not occur, it soon degenerates. Regular menstruation usually means that ovulation is occurring; exceptions to this occur around *puberty* and approaching the *menopause*.

ovum

The egg cell (the female cell of reproduction). An ovum contains a nucleus suspended in cytoplasm (a gel-like substance) and it is surrounded by a protective layer that is known as the *zona pellucida*.

About one million immature ova are present in each *ovary* at birth, but only about 200 per ovary mature to be released at *ovulation*. A *fertilized ovum* develops into an *embryo*.

ovum, blighted

A *zygote* (a fertilized egg cell) in which development has stopped at an early stage. This condition results in the appearance of an empty sac in the uterus, with no fetus visible on *ultrasound scanning*; blighted ovum is a common cause of *miscarriage*.

Ovysmen

A brand-name *oral contraceptive* containing *ethinylestradiol* (a synthetic form of the female sex hormone estradiol) and *levonorgestrel* (a progestogen drug).

oxalate

A substance that is synthesized by the body as well as being derived from certain foods, such as spinach, rhubarb, and tea. When blood oxalate levels are raised, kidney stones (see *calculus, urinary tract*) may develop.

oxazepam

A *benzodiazepine drug* used as a short-term treatment for *anxiety*. Oxazepam may cause dependence if it is taken regularly for more than two weeks (see *drug dependence*).

oximeter

An instrument that measures the amount of oxygenated haemoglobin (see *oxyhaemoglobin*) in the blood. A pulse oximeter is a photoelectric sensor attached either to a finger or to an ear to measure oxygen saturation continuously. Oximetry is used to monitor a patient during certain procedures, and always during *general anaesthesia*; it is also used to help diagnose and monitor many lung diseases.

oxrenolol

A *beta-blocker drug* that is used in the treatment of *hypertension* (high blood pressure), *angina* (chest pain due to insufficient blood supply to the heart), and cardiac *arrhythmias* (irregular heart-

beat). Oxprenolol may also be used to relieve symptoms of *anxiety* and control those of *hyperthyroidism* (overactivity of the thyroid gland).

oxybutynin

A drug used to treat frequent urination (see *urination, frequent*) and urge incontinence (see *incontinence, urinary*) by relaxing bladder muscle and increasing bladder capacity. Common side effects include dry mouth and blurred vision.

oxygen

A colourless and odourless gas that makes up 21 per cent of the Earth's atmosphere. Oxygen is essential for almost all forms of life, including humans, because it is necessary for the metabolic "burning" of foods to produce energy. This is a process that takes place in body cells and is known as *aerobic metabolism*.

Oxygen is absorbed through the lungs and into the blood, where it binds to the *haemoglobin* in red blood cells. As oxygen-rich blood circulates around the body, the oxygen is released from the red blood cells into the body tissues.

Additional supplies of oxygen are used to treat conditions such as severe *hypoxia* (inadequate oxygen in the body tissues) or *bronchitis*. High-pressure oxygen (see *hyperbaric oxygen treatment*) is sometimes used to treat *decompression sickness* or *carbon monoxide poisoning*. (See also *ozone*.)

oxygen concentrator

An appliance used in *oxygen therapy* that separates oxygen from the air and mixes it back in at a greater concentration. This oxygen-enriched air is delivered through a tube for prolonged inhalation. The appliance is used by people who have persistent *hypoxia* (inadequate oxygen in body tissues) due to severe chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*). (See also *hyperbaric oxygen treatment*.)

oxygen therapy

The process of supplying a person with oxygen-enriched air to relieve severe *hypoxia* (inadequate oxygen in body tissues). The oxygen is usually delivered through a face-mask or a nasal cannula (a length of narrow plastic tubing with two prongs that are inserted into the nostrils). The oxygen concentration of the air may be varied in accordance

with the patient's needs. Piped oxygen is used in hospitals; oxygen in cylinders can be used when the patient is moving from place to place. Long-term therapy for people with persistent hypoxia, which results from diseases such as chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*) or *pulmonary fibrosis*, may involve the use of an *oxygen concentrator*. (See also *hyperbaric oxygen treatment*.)

oxyhaemoglobin

The substance formed when the *iron* in haem, the pigment in the *haemoglobin* of red blood cells, combines chemically with oxygen. Oxyhaemoglobin gives the blood in the arteries its bright red colour. This compound is the form in which oxygen is transported from the lungs to the tissues, where the oxygen is released (see *respiration*).

oxymetazoline

A *decongestant drug* used in the treatment of *allergic rhinitis* (hay fever), *sinusitis*, and the common *cold*.

oxytetracycline

A tetracycline *antibiotic drug* that is used to treat *chlamydial infections* such as *nongonococcal urethritis*. It is also used for a variety of other infective conditions, including *bronchitis* and *pneumonia*; the drug may also be used to treat severe *acne*.

Side effects may include nausea, vomiting, diarrhoea, skin rash, and increased sensitivity of the skin to sunlight. Oxytetracycline may discolour developing teeth and is not given to children under 12 or pregnant women.

oxytocin

A *hormone* produced by the *pituitary gland*. Oxytocin causes uterine *contractions* during labour and stimulates milk-flow in *breast-feeding* women.

Synthetic oxytocin is used for *induction of labour*. It is given by intravenous infusion to produce uterine contractions. It is also often given with ergometrine as a single dose after delivery to prompt placental separation and expulsion, to reduce blood flow, or to empty the uterus after an incomplete *miscarriage* or a fetal death.

A possible adverse effect of synthetic oxytocin is abnormally strong, painful contractions. Rare side effects include nausea, vomiting, palpitations, and allergic reactions.

oxyuriasis

An alternative name for *enterobiasis* or *threadworm infestation*.

ozena

A severe and rare form of *rhinitis*, in which the mucus membrane in the nose wastes away and a thick nasal discharge dries to form crusts. Ozena often causes severe *halitosis* (bad breath).

ozone

A form of oxygen, ozone (O_3) is a poisonous, faintly blue gas that is produced by the action of electrical discharges (such as lightning) on oxygen molecules (O_2) and by interactions between hydrocarbon pollutants and sunlight.

Ozone occurs naturally in the upper atmosphere, where it screens the Earth from most of the sun's harmful ultraviolet radiation. The ozone layer is being depleted by atmospheric pollutants, allowing increasing amounts of ultraviolet radiation to reach the Earth's surface. This increases the risk of affected populations developing higher rates of certain diseases and conditions, such as *skin cancer* and *cataracts* (see *sunlight, adverse effects of*).

Increased levels of ozone near the ground are an indicator of poor air quality. In these circumstances, the raised levels make the breathing problems of people with allergic lung diseases increasingly likely to worsen, particularly if they exercise.

P

pacemaker

A small device that supplies electrical impulses to the *heart* in order to maintain a regular *heartbeat*.

WHY IT IS USED

A pacemaker is needed when the heart's *sinoatrial node* malfunctions (see *sick sinus syndrome*), when the passage of the electrical impulses that stimulate heart contractions is impaired (see *heart block*), or when the heart rate is intermittently slow and fast or the rhythm is irregular.

TYPES

Pacemakers may be fitted externally, as a temporary measure until a permanent pacemaker can be fitted. They can also be internal (surgically implanted in the chest). Internal pacemakers can either discharge impulses at a steady (fixed) rate or discharge only at times when the heart rate slows or a beat is missed (demand); some types can increase the

heart rate during exercise or change an abnormal rhythm into a normal one. Internal pacemakers are also either single-chambered or dual-chambered. Single-chamber pacemakers work by passing a single wire into the right atrium or right ventricle; dual-chamber pacemakers have two wires, one that passes into the right atrium, and the other into the right ventricle.

pachyderma

Abnormal thickening of the skin. (See also *elephantiasis*.)

Pacinian corpuscle

A specialized form of sensory nerve ending (see *receptor*) found in the dermis (the lower layer of the skin). Pacinian corpuscles detect deep pressure and vibration.

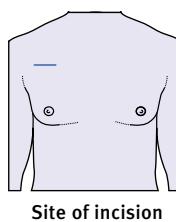

packed red blood cells

A *blood product* comprising blood from which 70 per cent of the *plasma* (the fluid that carries blood cells and other substances) has been removed to leave a high concentration of *red blood cells*. In blood transfusions, packed red blood cells are used much more commonly than "whole" blood (blood that has had nothing removed), especially to treat *anaemia* and *haemolytic disease of the newborn*.

INTERNAL PACEMAKER

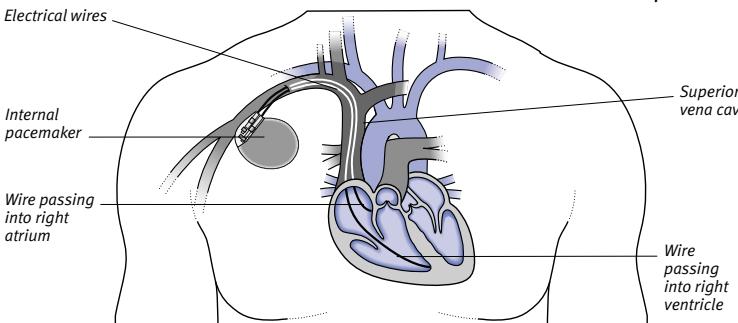

P

An internal pacemaker is inserted just beneath the skin in the chest wall, usually under local anaesthetic. The device weighs only 20–50g, and most are powered by a lithium battery that lasts on average between six and 10 years before needing to be replaced. Each electrical impulse that the pacemaker discharges stimulates the heart into contracting and producing a heartbeat. Some pacemakers deliver continuous impulses; others deliver an impulse only when the heart rate falls too low or in order to override an excessively fast rate.

Site of incision

Dual-chamber pacemaker

newborn; if a smaller volume of blood is transfused, there is less risk of overloading the circulation.

paclitaxel

An *anticancer drug* that is used to treat certain types of cancer, such as ovarian cancer (see *ovary, cancer of*) and *breast cancer*.

The possible side effects of paclitaxel include nausea, vomiting, *anaemia*, and increased susceptibility to infection.

paediatrics

The branch of medicine that concentrates on the development of children and with the diagnosis, treatment, and prevention of childhood diseases and other conditions.

paedophilia

Persistent sexual attraction to, often leading to abuse of, children. Paedophilia is most often seen in men. It is thought to result from a combination of psychological and social factors that affect sexuality. Paedophiles often show *personality disorders* such as antisocial personality disorder, and have little concern for the effect of their behaviour on the child.

Paedophilic activity is illegal; many affected people are only identified once they have been arrested. Treatments are designed to reduce the urge to have sexual relations with children; they include *cognitive-behavioural therapy* and drug treatment to reduce sexual urges. (See also *child abuse; incest*.)

Paget's disease

A common disorder that occurs in middle-aged and elderly people that is characterized by the disruption of *bone* formation. The affected bones become weak, enlarged and thickened, and deformed. Paget's disease is sometimes called *osteitis deformans*,

Paget's disease usually affects the pelvis, skull, collarbone, vertebrae, and long bones of the leg. Normally, the maintenance of healthy bones involves a balance between the actions of cells that break down bone tissue and the activity of cells that create new tissue. In Paget's disease, however, this balance is disturbed. The disorder is thought to be caused by a viral infection; it may run in families.

SYMPTOMS

There are often no symptoms. If symptoms do occur, the most common ones are bone pain and deformity, especially bowing of the legs. Affected bones are susceptible to fracture.

Skull changes may lead to leontiasis ossea (distortion of the facial bones producing a lionlike appearance) and cause damage to the inner-ear bones, sometimes resulting in deafness, *tinnitus* (ringing in the ears), *vertigo* (a spinning sensation), or headaches.

In the spine, enlarged vertebrae may press on the spinal cord, causing pain and sometimes paralysis of the legs. If the disease affects the pelvis, it may cause severe *arthritis* of the hip joints.

Occasionally, *bone cancer* may develop. In rare cases, when many bones are involved, increased blood flow through affected bones may cause *heart failure*.

DIAGNOSIS AND TREATMENT

Paget's disease is diagnosed by *X-rays*, which show areas of porous and thickened bone, and *blood tests*, which reveal abnormal levels of the substances involved in bone formation and breakdown.

Most people do not need treatment, or need only *analgesic drugs* (painkillers). In more severe cases, treatment with drugs such as *bisphosphonates* or *calcitonin* may be prescribed to control the rates of bone breakdown and renewal. The drugs will not reverse any existing deformity, but will slow the progression of the disease. Surgery may be needed to correct deformities or treat arthritis.

Paget's disease of the nipple

A rare type of *breast cancer* in which a tumour develops in the *nipple*. The disease resembles *eczema* and can cause itching and a burning feeling. A non-healing sore may develop. Without treatment, the tumour may spread into the breast. Diagnosis is made with a *biopsy* (sample of tissue).

pain

A localized, unpleasant sensation that can range from a feeling of mild discomfort to an excruciating experience. Pain serves the function of alerting the body to possible causes of injury, or making an affected person (or animal) withdraw from a source of harm. It may be acute (in which it appears and disappears suddenly) or chronic (in which it persists for days, weeks, or even longer).

MECHANISM OF PAIN

Pain results from the stimulation of sensory nerve endings called nociceptors in the skin. Pain receptors are also present in other structures, such as the blood vessels and tendons. Some nociceptors respond only to severe stimulation, such as cutting, pricking, or extreme

heat; others respond to warning stimuli such as firm pressure or stretching. Signals that arise from the nociceptors are transmitted via nerves to the brain. In addition, chemicals called *prostaglandins* trigger inflammation and swelling, and further stimulate the nerve endings.

Pain that may be felt at a point some distance from the cause is known as referred pain (see *pain, referred*).

PSYCHOLOGICAL ASPECTS OF PAIN

Pain is usually associated with distress and anxiety, and sometimes with fear. People vary tremendously in their pain thresholds (the level at which the pain is felt and the person feels compelled to act). The cause and circumstances of the pain may also affect the way it is perceived by the sufferer. The pain of cancer, because of fear of the disease, may seem much greater and cause more suffering than similar pain that results from persistent indigestion. Unexplained pain is often worse because of the anxiety it can cause; once a diagnosis is made and reassurance given, the pain may be perceived as less severe. In some cases, pain may be felt due to emotional reasons rather than any obvious physical cause (see *pain, psychogenic*).

The experience of pain may be reduced or blocked by arousal or strong emotion; for example, an injury sustained during competitive sport or on the battlefield may go unnoticed in the heat of the moment. Some people believe that mental preparation for pain, in advance of situations such as childbirth or in experiments to test pain, can greatly reduce the response.

A person's response to pain is also greatly modified by past experience; the outcome of previous episodes of pain may affect the way in which the individual copes with subsequent pain. Factors such as *insomnia*, *anxiety*, and *depression*, which often accompany incapacitating chronic illness, lower tolerance to pain. Many hospitals now have specialist pain clinics, in which people with severe pain that has proved difficult to control may be assessed and treated. Such patients include those with advanced *cancer* and poorly understood conditions such as facial pain and various types of *neuralgia*.

TREATMENT

Treatment is for the underlying cause of the pain. It may involve *analgesic drugs*, electrical stimulation (*TENS*), surgery, or therapies such as *acupuncture*. (See also *pain relief*; *endorphins*.)

painful arc syndrome

A condition in which pain occurs when the arm is raised between 45 and 160 degrees from the side. The usual cause is an inflamed *tendon* or *bursa* in the *shoulder* joint that is being squeezed between the *scapula* (shoulderblade) and *humerus* (upper-arm bone). Treatment includes *physiotherapy* and injections of *corticosteroid drugs*. (See also *subacromial bursitis*.)

painful heel

See *heel, painful*.

painkillers

See *analgesic drugs*.

painless haematuria

A form of *haematuria* (blood in the urine) that is not associated with pain when urine is passed (see *urination, painful*). Common causes of painless haematuria include *kidney tumours*; tumours in the ureters; *bladder tumours*; or *glomerulonephritis* (inflammation in the tiny filtering units of the kidneys).

pain, psychogenic

Pain that occurs in response to a mental or emotional stimulus rather than having a physical cause. Persistent pain that has no obvious physical cause may be due to a psychological disorder (see *somatization disorder*).

pain, referred

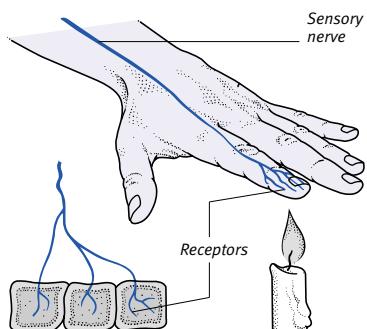

Pain that is felt in a site other than the affected part of the body. This form of pain occurs when the brain cannot distinguish the correct source of the pain signals (see the illustrated box overleaf). Examples of referred pain are pain in the left shoulder or the arm, related to *angina pectoris* (chest pain due to insufficient blood supply to the heart muscle) and *sciatica* (pain that radiates along the sciatic nerve in the leg).

pain relief

The treatment of pain, usually with *analgesic drugs*. *Paracetamol*, *aspirin* and *codeine* are among the most widely used drugs in this group. Pain accompanied by *inflammation* is often alleviated by *non-steroidal anti-inflammatory drugs (NSAIDs)*. Severe pain may require treatment with *opioids*, such as *morphine*. Other types of drug may be used to treat nerve pain, such as *trigeminal neuralgia* or the burning sensation in the feet that may be a feature of *diabetes mellitus*. Examples are

PAIN

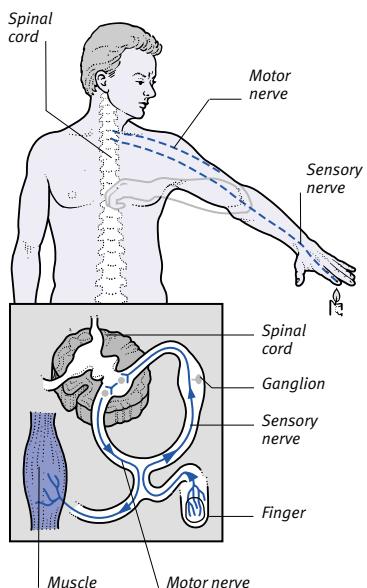

Pain mechanisms exist to provide a useful warning of possible injury or to caution against repeating an action that has led to injury. Certain diseases, such as arthritis and extensive cancer, may set off these same mechanisms, causing chronic pain that has no apparent function.

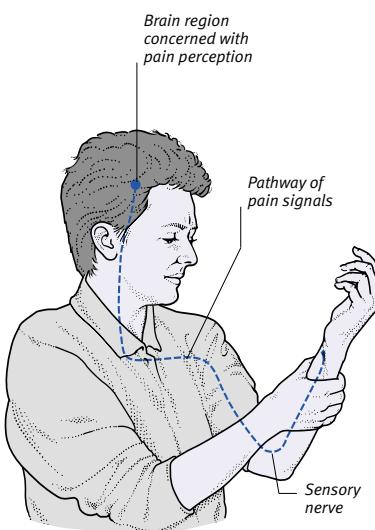

Reflex action

The nerve pathways that warn of noxious stimuli (through the sensation of pain) may also initiate automatic, reflex actions that help prevent harm.

- 1** Receptors in the fingertip detect heat. Signals are sent along a sensory nerve to the spinal cord.

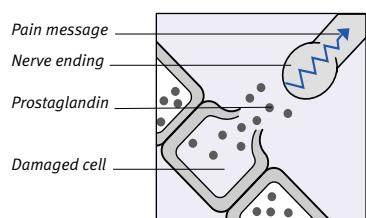

- 2** The signals arriving in the spinal cord pass instantaneously to a motor nerve that connects to a muscle in the arm. The signals received via the motor nerve cause the muscle in the arm to contract, moving the arm away from the source of danger (the flame).

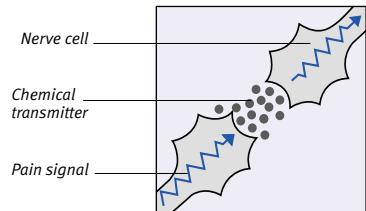

Perception of pain

When an injury occurs, signals pass along nerve pathways concerned with pain, first to the spinal cord and then to the thalamus in the brain; there the pain is perceived.

Initiation of pain signals

Pain signals are set off by stimulation of special nerve endings – by pressure, heat, or the release of chemicals, including prostaglandins, by cells that have been damaged.

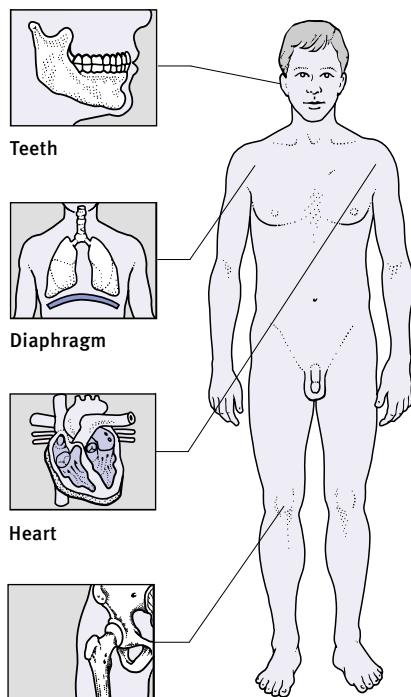

Signal transmission to brain

Within the brain and spinal cord, pain signals pass between nerve cells by means of chemicals that cross the gaps between the cells.

REFERRED PAIN

A referred pain is one felt in a site other than an injured or diseased part. Sensory nerves from certain body areas converge before they enter the brain, causing confusion about the source of pain signals.

Tooth to ear region

A toothache may be felt in the ear, because the same sensory nerve supplies both parts.

Diaphragm to right shoulder

Inflammation of the diaphragm, often due to pneumonia, may be felt as a pain in the right shoulder.

Heart to left arm

Angina, a pain caused by reduced blood supply to the heart muscle, is often felt in the left shoulder or arm.

Hip to knee

Disorders that affect the hip, such as arthritis, may be felt as pain in the knee rather than in the hip.

tricyclic antidepressants (such as amitriptyline) and *anticonvulsant drugs* (such as carbamazepine or gabapentin).

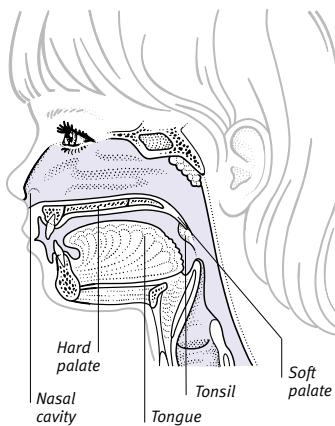

Other methods of pain relief include *massage*, *ice-packs*, *poultices*, *TENS*, *acupuncture*, and *hypnosis*. Surgery to destroy pain-transmitting nerves (such as a *sympathectomy*) is occasionally performed in cases where all other appropriate treatments have failed.

palate

The roof of the mouth, which separates the mouth from the nasal cavity. The palate is covered with a *mucous membrane*. At the front is the hard palate, which is a plate of bone forming part of the *maxilla* (upper jaw). At the rear is the soft palate, which is a flap of muscle and fibrous tissue that projects into the *pharynx* (throat). During the process of swallowing, the soft palate presses against the rear wall of the pharynx, thereby preventing food from escaping into the nose. (See also *cleft lip and palate*.)

LOCATION OF THE PALATE

The palate forms the floor of the nasal cavity and the roof of the mouth, providing a surface against which the tongue can push during chewing and swallowing.

palliative care

Nursing or medical care that is given to relieve the symptoms of illness rather than to treat the cause. Palliative care is often given to people who are in the last stages of a terminal illness (see *dying, care of the*). In these cases, the aim is to minimize unpleasant symptoms

and to provide a comfortable, reassuring environment for the last days or weeks of life. (See also *palliative treatment*.)

palliative treatment

Treatment that relieves the symptoms of a disorder but does not cure it. There is a wide variety of palliative treatments. Examples are *pain relief*, *antiemetic drugs* to relieve nausea and vomiting; *sedative drugs* to relieve insomnia; and other therapies, such as *massage* and *counselling*. (See also *dying, care of the*.)

pallor

Abnormal paleness of the *skin* and *mucous membranes*, particularly noticeable in the face. Pallor may have many possible causes and is not always a symptom of disease.

Pallor may be caused by constriction of small blood vessels in the skin, which may occur in response to shock, severe pain, injury, heavy blood loss, or fainting. This restriction of blood flow to the skin ensures that the brain and other vital organs are adequately supplied with blood and that body heat is conserved (at least temporarily).

Less commonly, pallor may be due to a deficiency of the skin pigment *melanin* that may result from spending too little time in daylight. Abnormally pale skin is also a feature of *albinism*.

Disorders that cause pallor include *anaemia*, *kidney failure*, and *hypothyroidism* (underactivity of the thyroid gland). *Lead poisoning* is a rare cause.

palmar erythema

See *liver palms*.

palpation

A technique used in *physical examination* in which parts of the body are felt with the hands to assess the condition of the skin and underlying organs.

palpitation

An awareness or feeling in the chest of the *heartbeat* or a sensation of having a rapid and forceful heartbeat.

CAUSES

Palpitations are usually felt in tense or frightening situations, or following strenuous exercise. When experienced at rest or during a period of calm, they are usually due to *ectopic heartbeats* and are felt as fluttering or thumping in the chest. This condition is usually due to *alcohol* or *caffeine* consumption, or *smoking*, rather than disease. Palpitations may also be due to cardiac arrhythmias

(irregularities of the heartbeat; see *arrhythmia, cardiac*); *anaemia* (a reduced level of the oxygen-carrying pigment haemoglobin in the blood); or *hyperthyroidism* (overactivity of the thyroid gland), which speeds up the heartbeat.

DIAGNOSIS AND TREATMENT

Recurrent palpitations, or those causing chest pain, breathlessness, or dizziness, may indicate an underlying disorder, and need prompt medical attention. They may be investigated by a 24-hour *ECG* and *thyroid function tests*. Treatment depends on the cause.

palsy

A term applied to certain forms of *paralysis*, such as *Bell's palsy* (the most common form of *facial palsy*).

Paludrine

The brand name for the antimalarial drug *proguanil*.

panacea

A remedy that is claimed to cure all diseases. No such remedy is known.

Panadol

A brand name for the analgesic (pain-killing) drug *paracetamol*.

Pancoast's syndrome

A collection of symptoms that occurs when a growth presses on the *brachial plexus* (the group of major nerves controlling the arm and hand). These symptoms include pain and paralysis in the arm or hand, as well as *Horner's syndrome* if the growth presses on the sympathetic cervical (neck) nerves. Pancoast's syndrome is commonly due to a tumour called Pancoast's tumour, which develops in the upper part of the lung in people with *lung cancer*.

pancreas

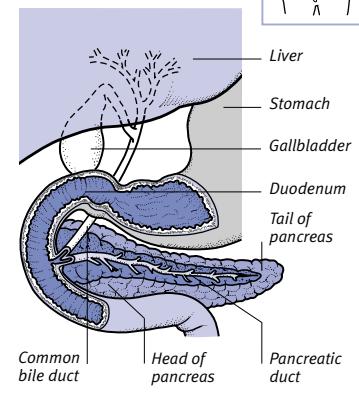

A tapered gland that lies across the back of the abdomen, behind the stomach. The broadest part (which is called the head) is on the right-hand side, in the loop of the duodenum (the first part of the small intestine). The main part (which is called the body) tapers from the head and extends horizontally. The narrowest part (the tail) extends leftwards, towards the spleen.

STRUCTURE AND FUNCTION

The major part of the pancreas is made up of exocrine tissue, which release chemicals through ducts. Embedded within these tissues are "nests" of

LOCATION OF THE PANCREAS

This organ lies behind and under the stomach, except for its head, which lies within the curve of the duodenum.

endocrine cells (known as the *islets of Langerhans*), which secrete hormones into the bloodstream.

The exocrine cells secrete digestive enzymes into a network of ducts that meet to form the main pancreatic duct. This duct joins the common bile duct (which carries bile from the *gallbladder*) to form a small chamber, the ampulla of Vater, which opens into the *duodenum*. Also secreted is *sodium bicarbonate*, which neutralizes stomach acid entering the duodenum.

The islets of Langerhans are surrounded by many blood vessels, into which they secrete the hormones *insulin*, *glucagon*, and somatostatin. These hormones regulate the level of *glucose* in the blood. (See also *Disorders of the pancreas* box.)

pancreas, cancer of

A malignant tumour of the *pancreas*. Pancreatic tumours usually arise in the exocrine tissue, which is responsible for producing digestive juices. They may also occasionally arise from parts of the endocrine system or from the ampulla of Vater (the junction of the common bile duct and the pancreatic duct). The cause of cancer of the pancreas is unknown, but smoking, chronic *pancreatitis*, and a high alcohol intake may contribute.

SYMPOTMS

Symptoms and signs of pancreatic cancer include upper abdominal pain that radiates to the back; loss of appetite; weight

loss; jaundice (yellowing of the skin) if the tumour obstructs the bile ducts; and possibly even *diabetes mellitus*. There may also be indigestion, nausea, vomiting, diarrhoea, and tiredness. In many cases, symptoms do not appear until the cancer has spread (typically to the liver and the lymph nodes in the abdomen).

DIAGNOSIS AND TREATMENT

Diagnosis usually requires ultrasound scanning, *CT scanning* or *MRI* of the upper abdomen, or *ERCP* (endoscopic examination of the pancreatic ducts).

In the early stages, *Whipple's operation* (surgical removal of cancerous tissue), *radiotherapy*, and *anticancer drugs* may provide a cure. In the later stages, little can be done apart from provision of *palliative treatment*, such as pain relief, a *bypass operation* to treat obstruction of the duodenum, or insertion of a *stent* (rigid tube) to relieve jaundice. Most people with advanced pancreatic cancer survive for less than one year.

pancreatectomy

Removal of all or part of the *pancreas*, which may be performed as treatment for *pancreatitis* (inflammation of the pancreas). In rare cases, pancreatectomy is performed as a treatment for *insulinomas* (insulin-producing tumours).

Pancreatectomy may cause a deficiency of pancreatic hormones and digestive enzymes. This situation may lead to *diabetes mellitus*, which needs to receive treatment with insulin therapy, and *malabsorption*, which requires oral supplements of *pancreatin*.

pancreatin

An oral preparation of pancreatic enzymes required for digestion. It is used to prevent *malabsorption*, and it may be needed after *pancreatectomy* or by people who have disorders affecting the pancreas, such as chronic *pancreatitis*, cancer (see *pancreas, cancer of*), or *cystic fibrosis*.

pancreatitis

Inflammation of the *pancreas*, a condition that may be acute or chronic. In acute pancreatitis, the pancreas suddenly becomes inflamed, causing severe abdominal pain. This condition can be life-threatening if left untreated. In chronic pancreatitis, the pancreas is persistently inflamed; this condition leads to a progressive loss of function.

CAUSES

The main causes of acute pancreatitis are alcohol abuse, typically a bout of

heavy drinking, and *gallstones*. Less common causes are injury (such as a violent blow to the abdomen), viral infections (such as *mumps*), surgery on the *biliary system*, or certain drugs, such as *immunosuppressants* and thiazide *diuretic drugs*.

Chronic pancreatitis is usually due to long-term alcohol abuse. Less common causes include *hyperlipidaemia* (a high level of fat in the blood), *cystic fibrosis*, *haemochromatosis* (a condition in which there is excess iron in the body), and severe acute pancreatitis.

SYMPOTMS

An attack of acute pancreatitis usually lasts about 48 hours. Symptoms are a sudden attack of severe upper abdominal pain, which may spread to the back, often accompanied by vomiting. Movement often makes the pain worse, but sitting may help to relieve it. In severe cases, inflammation may affect the whole abdomen (see *peritonitis*); there is also a risk of *shock* (failure of blood circulation), which may be life-threatening.

Chronic pancreatitis usually develops over several years, and may be symptomless in the early stages. When symptoms do appear they are usually the same as those of acute pancreatitis, although the pain may last from a few hours to several days, and attacks may become more frequent over time. If there is no pain, the principal signs may be of *malabsorption* or *diabetes mellitus* due to reduced levels of pancreatic enzymes and insulin, respectively.

COMPLICATIONS

Acute pancreatitis may recur repeatedly. Severe acute pancreatitis may damage the pancreas and lead to *hypotension* (low blood pressure), *heart failure*, *kidney failure*, *respiratory failure*, *pancreatic cysts*, and *ascites* (accumulation of fluid in the abdomen).

Chronic pancreatitis leads to permanent damage to the gland; the tissue is damaged and gradually replaced by scar tissue, and normal function is progressively impaired. Other possible complications include the development of ascites and cysts, as well as *bile duct obstruction*.

DIAGNOSIS AND TREATMENT

A diagnosis may be made using abdominal *X-rays*, *ultrasound scanning*, or *CT scanning* or *MRI* (techniques that produce cross-sectional or three-dimensional images of body structures). In addition, *blood tests* may be used in cases of suspected acute pancreatitis, to detect pancreatic enzymes that have leaked directly into the blood.

DISORDERS OF THE PANCREAS

Serious disruption of pancreatic function occurs only when the secretory tissue of the gland has been damaged or destroyed in advanced disease. The most common pancreatic disorder is *diabetes mellitus*, in which the insulin-producing cells in the gland are destroyed.

Congenital and genetic disorders

About 85 per cent of people with the genetic disorder *cystic fibrosis* produce totally inadequate quantities of pancreatic digestive enzymes, which results in *malabsorption* of fats and proteins. This, in turn, may produce steatorrhoea (excess fat in the faeces) and muscle wasting.

Genetic factors are thought to play some part in diabetes mellitus, although they are not the primary cause of the disease.

Chronic *pancreatitis* (inflammation of the pancreas) may, in rare cases, be hereditary; chronic pancreatitis often causes diabetes.

Infection

Acute pancreatitis may result from certain viral infections, especially with

the *mumps* or *hepatitis* viruses. Other viruses, such as coxsackievirus, may also cause pancreatitis. In some cases, coxsackievirus infection may contribute to the development of diabetes.

Tumour

Pancreatic cancer is one of the fairly common cancers (see *pancreas, cancer of*). It is difficult to diagnose and, in most cases, has spread extensively by the time it is detected.

Trauma

Injury to the pancreas – as a result of a blow to the abdomen, for example – may cause acute pancreatitis. The mechanism by which this occurs is not fully established, but it is believed that pancreatic enzymes (most of which are inactive until they reach the intestine) are released within the gland and then activated, with the result that they digest the pancreas.

Poisons and drugs

Excessive alcohol intake is a common cause of pancreatitis. It can also be caused by various drugs, such as sulphonamides, *oestrogen drugs* (including oestrogen-containing contraceptive pills), and

thiazide diuretic drugs; corticosteroid drugs may also cause pancreatitis.

Autoimmune disorders

The cause of the damage to the pancreas in diabetes mellitus remains controversial. However, there is increasing evidence that, possibly in response to a viral infection, the body's immune system produces antibodies (proteins made by the immune system) that inappropriately attack and destroy the pancreatic cells.

Other disorders

The condition most often associated with pancreatitis, other than alcohol overuse, is *gallstones*. These occasionally block the exit of the pancreatic duct into the duodenum, leading to inflammation of the pancreas.

INVESTIGATION

Diagnosis of pancreatic disorders may involve *ultrasound scanning, CT scanning, or MRI* of the abdomen; tests to measure levels of pancreatic enzymes in the blood or duodenum; and endoscopic examination of the gland (see *ERCP*).

Acute pancreatitis is treated with *intravenous infusion* of fluids and salts and opioid *analgesic drugs* (painkillers). In some cases, the abdominal cavity may be washed out with sterile fluid; *ERCP* (an endoscopic X-ray procedure) may be used to find and remove gallstones; or a *pancreatectomy* (surgical removal of damaged tissue) may be performed.

Treatment for the chronic form is with painkillers, *insulin*, *pancreatin*, and, in some cases, *pancreatectomy*.

pancreatography

Imaging of the pancreas or its ducts using *CT scanning, MRI, ultrasound scanning, X-ray* (after a radiopaque *contrast medium* is injected into the ducts during exploratory surgery), or with *ERCP* (an endoscopic X-ray procedure).

pancytopenia

A simultaneous and severe reduction in the numbers of red blood cells (causing *anaemia*); white blood cells (a condition called *leucopenia*); and platelets, involved in clotting (*thrombocytopenia*).

This condition may be a result of damage to the *bone marrow*, where blood cells are made; such damage may be due to cancer in the marrow, or to destruction of the marrow by *radiotherapy* or *anticancer drugs*. Pancytopenia may also be due to *hypersplenism* (overactivity of the spleen), in which the spleen destroys excessive numbers of blood cells. (See also *aplastic anaemia*; *Fanconi's anaemia*.)

pandemic

A medical term that is applied to a disease that occurs over a large geographical area and that affects a high proportion of the population; a widespread *epidemic*.

panencephalitis

See *subacute sclerosing panencephalitis*.

panic attack

A brief period of acute *anxiety*, often dominated by an intense fear of dying or losing one's reason. Although unpleasant and frightening, panic attacks usually

last for only a few minutes, cause no physical harm, and are rarely associated with any serious physical illness.

Panic attacks are generally a feature of an *anxiety disorder, agoraphobia*, or other *phobias*. In some cases, however, such attacks are associated with a *somatization disorder* or *schizophrenia*.

Attacks are unpredictable at first, but tend to become associated with specific situations, such as being in a cramped lift. Symptoms begin suddenly. They include a sense of breathing difficulty, chest pains, *palpitations*, feeling light-headed, dizziness, sweating, trembling, and faintness. *Hyperventilation* often also occurs. This condition results in carbon dioxide levels in the blood becoming abnormally low, which leads to a *pins-and-needles* sensation and feelings of *depersonalization* and *derealization*. The attacks end quickly.

The symptoms of hyperventilation may be relieved quickly by covering the mouth and nose with a small paper bag and breathing into the bag for a few minutes; this measure restores carbon

dioxide levels to normal. In the longer term, *cognitive-behavioural therapy* and relaxation exercises may be used to help affected people control their anxiety.

panic disorder

A type of *anxiety* disorder characterized by recurrent *panic attacks* that are of intense anxiety and accompanied by distressing physical symptoms.

panniculitis

Inflammation occurring in subcutaneous fat (the layer of fatty tissue just beneath the skin). The inflamed fatty tissue forms multiple tender nodules under the skin. One form of this condition is *erythema nodosum*, in which swellings develop on the legs.

pantothenic acid

A vitamin of the *vitamin B complex*.

papain

A naturally occurring mixture of *enzymes*, including chymopapain, which is found in pawpaws. Papain breaks down proteins and has been used to remove clotted blood and dead tissue from wounds and ulcers.

papilla

Any small, nipple-shaped projection from a tissue's surface, such as the mammary papilla (the breast nipple).

P

papilloedema

Swelling of the head of the *optic nerve*. This condition is also known as optic disc oedema. The nerve swelling is visible with an *ophthalmoscope*. It usually indicates a dangerous rise in the pressure within the skull, which may sometimes be caused by a *brain tumour*.

papilloma

A noncancerous growth of the *epithelium* (the cell layer that forms the surface of the skin and mucous membranes) that resembles a wart and most commonly affects the skin, tongue, larynx, and urinary and digestive tracts. If it does not disappear spontaneously it can be surgically removed.

Papillon–Lefèvre syndrome

A rare *genetic disorder* affecting the skin and gums. Papillon–Lefèvre syndrome results in areas of thickened, cracked skin. In addition, it makes the gums prone to infection from very early in life. Severe gum disease (see *periodontal*

disease) causes the milk teeth to be lost prematurely, and may cause all the adult teeth to be lost by age 20.

papovavirus

A family of viruses that includes papillomaviruses (see *human papillomavirus*).

pap smear

See *cervical smear test*.

papule

A small, solid, slightly raised area of skin. Papules are usually less than 5 mm in diameter. They may be raised or flat; rough or smooth; and pigmented or the colour of the surrounding skin.

par-/para-

Prefixes that have several meanings. They may mean "beside or beyond", as in the parathyroid glands (which lie behind the thyroid); "closely resembling or related to", as in paratyphoid fever (a disease that is very similar to typhoid fever); or "faulty or abnormal", as in paraesthesia (abnormal sensation).

para-aminobenzoic acid (PABA)

A biochemical that used to be the active ingredient of many *sunscreen* preparations, but is now rarely used.

paracentesis

A procedure in which a body cavity is punctured with a needle to remove fluid for analysis, to relieve pressure from excess fluid, or to instil drugs.

paracetamol

An *analgesic drug* that is used to treat mild pain and to reduce fever. Paracetamol may, in rare cases, cause nausea or a rash. An overdose may cause liver damage and can be fatal. An antidote is available, but must be given early.

Papilloma on the tongue

This harmless growth, which resembles a wart, may disappear spontaneously but may need to be removed under local anaesthetic.

paraesthesia

Altered sensation in the skin without any stimulus (see *pins-and-needles*).

paraffinoma

A tumourlike swelling under the skin caused by prolonged exposure to paraffin. Paraffinomas may form in the lungs if paraffin is inhaled.

paraffin, white soft

See *petroleum jelly*.

paraldehyde

A *sedative drug* used to stop prolonged epileptic *seizures*. Paraldehyde can be administered as an *enema* or by injection into a muscle.

paralysis

Complete or partial loss of controlled movement caused by the inability to contract one or more *muscles*. Paralysis may be temporary or permanent, and can affect areas of varying sizes, from a small facial muscle to many of the major muscles in the body. There may also be loss of feeling in affected areas. Paralysis is also known as palsy.

TYPES

The types of paralysis are classified by the areas of the body that are affected and by the effect on the muscles. Paralysis of one half of the body is called *hemiplegia*. If corresponding areas on both sides of the body (such as the legs) are affected, it is known as *diplegia*. If all four limbs and the trunk are affected, the paralysis is called *quadriplegia* or *tetraplegia*. *Paraplegia* is the paralysis of both legs and sometimes part of the trunk. In addition, paralysis may be classified as flaccid, causing floppiness, or spastic, causing rigidity.

CAUSES

The muscles that control body movements are stimulated to contract by impulses originating in the motor cortex of the brain. These impulses travel via the spinal cord and peripheral nerves to reach the muscles. Paralysis may be caused by any form of injury or disorder anywhere along this nerve pathway. Alternatively, it may result from a disorder in the muscle.

Brain disorders A common cause of paralysis is a *stroke*, in which brain tissue is damaged by bleeding from a ruptured blood vessel, or an area of the brain is starved of oxygen due to a clot in the blood vessel supplying that region. The paralysis will occur on the

opposite side of the body to the site of the brain damage because the motor nerves cross over in the *brainstem*.

Hemiplegia may be caused by any brain disorder in which the portion of the brain that controls movement is damaged. Examples of such disorders include a *brain tumour*, *brain abscess*, or *brain haemorrhage*.

Some types of paralysis are caused by damage to parts of the nervous system concerned with fine movement control, such as the *cerebellum* and the *basal ganglia*. *Parkinson's disease* is caused by a lack of *dopamine* in the basal ganglia.

Cranial nerve damage may affect a variety of muscles and functions. For example, damage to the *facial nerve* (the seventh cranial nerve) causes weakness of the facial muscles (see *facial palsy*) and loss of taste.

Spinal cord disorders If the spinal cord becomes damaged or diseased, paralysis will develop in muscles that are supplied by nerves below the affected area. Damage to, or pressure on, the spinal cord may result from fracture of one or more *vertebrae* (which may result from severe injury, as in a road traffic accident) or *disc prolapse* (slipped disc). Diseases affecting the spinal cord include *multiple sclerosis* and *poliomyelitis*.

Peripheral nerve disorders Certain nerve disorders, called *neuropathies*, affect the peripheral nerves and may cause varying degrees of paralysis. Neuropathies may be caused by a variety of conditions, such as *diabetes mellitus* (see *diabetic neuropathy*), vitamin deficiency, liver disease, cancer, and the toxic effects of some drugs or metals (such as lead).

Muscle disorders Certain disorders arising in the muscles, such as *muscular dystrophy*, may cause paralysis. Temporary paralysis sometimes occurs in *myasthenia gravis*.

TREATMENT

The underlying cause is treated, if possible. *Physiotherapy* is given for both temporary and permanent paralysis, to prevent joints from becoming locked in awkward positions. In addition, it retrains and strengthens the muscles and joints in people with temporary paralysis, so that some degree of mobility will be possible after recovery.

For paralysed people who are confined to a bed or a wheelchair, nursing care is essential to avoid the complications that can result from prolonged immobility, such as *bedsores*, *deep vein thrombosis*, *urinary tract infections*, *constipation*, and limb deformities.

paralysis, periodic

A rare, inherited condition that causes intermittent phases of muscle weakness, often associated with raised or lowered blood levels of *potassium*. The disorder shows an autosomal dominant pattern of inheritance (see *genetic disorder*).

Periodic paralysis affects young people, with attacks usually beginning in childhood or adolescence. Episodes of muscle weakness vary in frequency from daily to once every few years and last from a few minutes to a few hours.

Lowered potassium levels may occur after a high-carbohydrate meal or during a period of rest following physical exertion. The diuretic drug *acetazolamide* may be used to prevent attacks; potassium is often given orally to restore muscle strength when an attack occurs.

In other cases, potassium levels are raised; triggers include being cold, having a rest after physical exertion, and pregnancy. *Diuretic drugs* may be given as preventive treatment; a sugary drink may help to relieve an attack.

The condition often clears up without treatment by the age of 40.

paralytic ileus

See *ileus*, *paralytic*.

paramedic

A term for any health-care worker who is trained to work in an auxiliary capacity to medical professionals such as doctors and nurses. The term usually refers to ambulance staff who attend accidents or medical emergencies.

paramyxovirus

One of a family of *viruses* that includes the microorganisms responsible for *croup*, *mumps*, *measles*, and *parainfluenza* (a mild form of *influenza*).

paranoia

A condition in which the central feature is the *delusion* that people or events are especially connected to oneself. The term "paranoia" may also be used to describe feelings of persecution. A paranoid person builds up an elaborate set of beliefs based on the interpretation of chance remarks or events. Typical themes are persecution, jealousy (see *jealousy*, *morbid*), love, and grandeur (belief in one's own superior position and powers).

TYPES AND CAUSES

Paranoia may be *chronic* or *acute*. Chronic paranoia may be caused by brain damage, abuse of *alcohol* or *amphetamines*,

amines, *manic-depressive illness*, or *schizophrenia*. It is also a feature of paranoid *personality disorder*, which is a psychological condition that causes people to be constantly suspicious of the motives of other people.

Acute paranoia, lasting for less than six months, may occur in people who have experienced radical life changes, such as refugees. In shared paranoia (see *folie à deux*), delusion develops because of a close relationship with someone else who has a delusion.

SYMPOTMS

There are usually no other symptoms of mental illness apart from occasional *hallucinations*. In time, however, the anger, suspicion, and social isolation may become severe.

TREATMENT AND OUTLOOK

If acute illness is treated early with *antipsychotic drugs*, the outlook is good. In long-standing cases of paranoia, however, the delusions are usually firmly entrenched, but antipsychotic drugs may make them less debilitating.

paraparesis

Partial *paralysis* or weakness of both legs and sometimes part of the trunk.

paraphimosis

Constriction of the *penis* behind the *glans* (head) by an extremely tight foreskin that has been pulled back, causing swelling and pain. Paraphimosis often occurs as a complication of an abnormally tight foreskin (see *phimosis*).

The problem can often be remedied manually by applying an ice-pack to reduce swelling and then squeezing the glans to return the foreskin to its normal position. Otherwise, an injection or an operation to cut the foreskin may be necessary. *Circumcision* (surgical removal of the foreskin) may be performed to prevent recurrence.

paraplegia

Weakness or *paralysis* of both legs and sometimes of part of the trunk as well, often accompanied by loss of feeling and by loss of urinary control. Paraplegia is a result of nerve damage in the *brain* or *spinal cord*.

parapsychology

The branch of *psychology* dealing with experiences and events that cannot be explained by scientific knowledge. Such phenomena include extrasensory perception (ESP), telepathy (communication

PARASITES: ECTOPARASITES (present in skin or on body surface)		
Common examples	Activities	How acquired
• Head lice • Ticks • Bedbugs • Cat/Dog fleas • Aquatic leeches	Suck host's blood	Through contact with other people (lice, scabies mites, warts), animals (ringworm fungi, ticks), vegetation (ticks, mites), or water (aquatic leeches). Bedbugs live in bedroom walls or mattresses and visit humans at night. Cat and dog fleas may visit humans when the pet is absent.
• Scabies mites	Burrow in skin	
• Ringworm fungi • Wart viruses	Multiply in skin	

PARASITES: ENDOPARASITES (live within body)		
Common examples	Activities	How acquired
• Tapeworms • Flukes • Roundworms • Threadworms • Hookworms	Adults live in human gut, blood vessels, bile ducts, or elsewhere and produce eggs that are passed out of the body.	By eating infected meat, swallowing eggs on food, contaminating fingers with faecal material, or contact with infected water.
• Various disease-causing protozoa, fungi, bacteria, and viruses	Organisms multiply locally or spread throughout the body, causing disease.	By inhalation, water- or food-borne transmission, sexual transmission, or blood-borne infection, among other mechanisms.

of thoughts), telekinesis (movement of objects with the mind), and precognition (being able to see into the future).

Many "paranormal" experiences can probably be explained by mental disturbances; others are probably due to coincidence, self-deception, or fraud.

paraquat

A weedkiller, available in high concentrations for agricultural use, which can be fatal if swallowed, inhaled, or absorbed through the skin. Paraquat poisoning requires urgent medical attention. Symptoms may include breathing difficulty, mouth ulcers, nosebleeds, diarrhoea, and later, respiratory and kidney failure.

Treatments include eating activated charcoal or Fuller's earth. *Haemodialysis* (removal of toxic substances from the blood) may also be used.

parasite

Any organism living in or on another living creature (the host) and deriving advantage from it, while causing the host disadvantage. In contrast, some organisms live on other creatures but have a symbiotic, or mutually beneficial, relationship with their host (see *commensal*).

pathetic system controls everyday functions such as breathing, digestion, and excretion of waste products.

parathion

An agricultural *organophosphate* insecticide that is highly poisonous.

parathyroidectomy

Surgical removal of abnormal tissue from the *parathyroid glands*. Parathyroidectomy may be performed to treat *hyperparathyroidism* (excess secretion of parathyroid hormones). Less commonly, it may be used to treat parathyroid cancer.

If hyperparathyroidism is caused by an *adenoma* (a small, benign tumour), usually only one of the parathyroid glands is involved and needs to be removed. If all the glands are enlarged and overactive, more parathyroid tissue may be removed.

parathyroid glands

Two pairs of oval, pea-sized glands that lie behind the *thyroid gland* in the neck. The glands produce parathyroid hormone (PTH), which helps to regulate the level of calcium in the blood.

Blood calcium levels are monitored continuously by the body because even small variations can impair muscle and nerve function. If the calcium levels drop too low, the parathyroid glands

Parasites obtain nourishment from the host's blood, tissues, or ingested food. The organisms may spend only part of their life-cycle with the host or remain there permanently. Some cause few symptoms, while others cause disease or even death.

Animal parasites of humans include *protozoa*, *worms*, *flukes*, *leeches*, *lice*, *ticks*, and *mites*. *Viruses* and disease-causing *fungi* and *bacteria* are also parasites.

parasitology

The scientific study of *parasites*. Although viruses and many types of bacteria and fungi are parasites, their study is conducted under the title of *microbiology*.

parasuicide

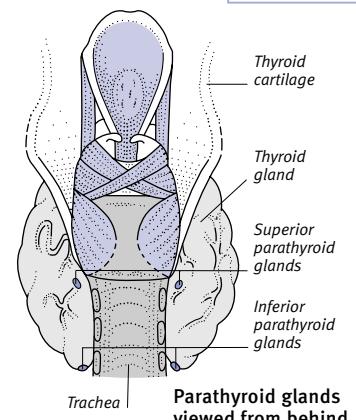

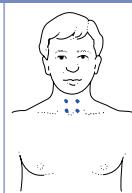

See *suicide, attempted*.

parasympathetic nervous system

One of the two divisions of the *autonomic nervous system*, which controls the automatic activities of organs, glands, blood vessels, and other tissues throughout the body. In contrast to the function of the sympathetic system, which prepares the body for action, the parasymp-

LOCATION OF THE PARATHYROID GLANDS

These glands are embedded in the back of the thyroid gland, in the front of the neck, and are situated on either side of the trachea.

Parathyroid glands viewed from behind

release more PTH (see *feedback*). This response causes the bones to release more calcium into the blood, the intestines to absorb more from food, and the kidneys to conserve calcium; as a result, calcium levels rise rapidly. If the blood level of calcium is too high, the glands reduce their output of PTH.

Some people have only one parathyroid gland or have extra glands in the neck or chest. Rarely, the parathyroid glands may become overactive (a condition called *hyperparathyroidism*), which causes erosion of the bones and stones in the kidneys, ureters, or bladder (see *calculus, urinary tract*). Alternatively, the glands may become underactive (see *hypoparathyroidism*), resulting in *tetany* (painful muscle spasms) or *seizures*.

parathyroid tumour

A growth within a *parathyroid gland*. The tumour may cause excess secretion of parathyroid hormone (PTH), leading to *hyperparathyroidism*. Parathyroid cancers are very rare; most parathyroid tumours are noncancerous *adenomas*. An adenoma that causes hyperparathyroidism will be surgically removed (see *parathyroidectomy*). This usually provides a cure.

paratyphoid fever

An illness identical in most respects to *typhoid fever*, except that it is caused by a different bacterium, *SALMONELLA PARATYPHI*, and is usually less severe.

paraumbilical hernia

A *hernia* occurring near the *navel*. Paraumbilical hernias may occur in obese women who have had several children.

parenchyma

The functional (as opposed to supporting) tissue of an organ.

parenteral

The administration of drugs or other substances by any route other than via the gastrointestinal tract (for example, by injection into a blood vessel).

parenteral nutrition

Intravenous feeding (see *feeding, artificial*).

paresis

Partial *paralysis* or weakness affecting one or more muscles.

parietal

A medical term that is used to refer to the wall of a part of the body.

parity

A term used to indicate the number of pregnancies a woman has undergone that have resulted in the birth of a baby capable of survival.

parkinsonism

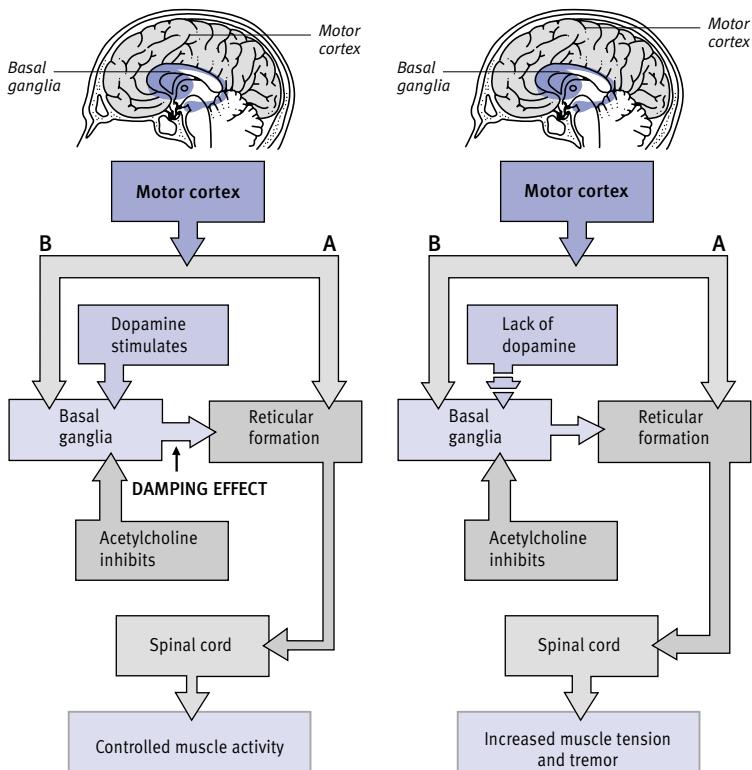

Any neurological disorder that is characterized by *tremor* (typically, this is a "pill-rolling" tremor, which occurs when the thumb is rubbed over the index finger); slow movements; and rigidity. The other characteristic features of the disorder of parkinsonism result

from the slowness of movement. These features include a masklike face, a *festinating gait* (a shuffling, unbalanced style of walking), a monotonous style of speech, and reduced blinking. The most common type of parkinsonism is known as *Parkinson's disease*.

The known causes of parkinsonism include *cerebrovascular disease* (problems involving the blood vessels in the brain); the use of *antipsychotic drugs*, or the abuse of certain *designer drugs*; *carbon monoxide* poisoning; and, rarely, the infection *encephalitis lethargica*.

CAUSE OF PARKINSON'S DISEASE

This disorder results from damage, of unknown origin, to the basal ganglia (nerve cell clusters in the brain). The difference between the healthy state and that of Parkinson's disease is shown in the diagrams below.

Healthy state

During movement, signals pass from the brain's cortex, via the reticular formation and spinal cord (pathway A), to muscles, which contract. Other signals pass, by pathway B, to the basal ganglia; these damp the signals in pathway A, reducing muscle tone so that movement is not jerky. Dopamine, a nerve transmitter made in the basal ganglia, is needed for this damping effect. Another transmitter, acetylcholine, inhibits the damping effect.

Parkinson's disease

In Parkinson's disease, degeneration of parts of the basal ganglia causes a lack of dopamine within this part of the brain. The basal ganglia are thus prevented from modifying the nerve pathways that control muscle contraction. As a result, the muscles are too tense, causing tremor, joint rigidity, and slow movement. Most drug treatments increase the level of dopamine in the brain or oppose the action of acetylcholine.

Parkinson's disease

A neurological disorder that is the most common cause of *parkinsonism*.

CAUSES AND INCIDENCE

Parkinson's disease is caused by degeneration of, or damage to, cells in the *basal ganglia* of the brain. As a result, there is a deficiency of the neurotransmitter *dopamine* (which is needed for the control of movement). The condition occurs mainly in elderly people and is more common in men.

For further information on the processes leading to Parkinson's disease, see the illustrated box, previous page.

SYMPOTMS AND SIGNS

The main symptoms develop gradually, over several months or even years. The disease usually begins as a slight tremor of one hand, arm, or leg, which is worse when the hand or limb is at rest.

Later, both sides of the body are affected, causing stiffness, weakness, and trembling of the muscles. Symptoms include a stiff, shuffling walk that may break into uncontrolled, tiny running steps; constant hand tremors, sometimes accompanied by shaking of the head; a permanent rigid stoop; and an unblinking, fixed expression. Everyday activities such as eating, washing, and dressing become very difficult.

The intellect is unaffected until late in the disease, although the affected person's speech may become slow and hesitant, and the handwriting usually becomes very small. *Depression* is a common complication.

TREATMENT

There is no cure, but drug treatment, *physiotherapy*, and, rarely, surgery can help to relieve symptoms. In the early stages of Parkinson's disease, exercises, special aids in the home (see *disability*), and support can improve the affected person's morale and mobility. Drug treatment is used to minimize symptoms in later stages. These treatments cannot halt the degeneration of brain cells, but can minimize the symptoms by helping to correct the chemical imbalances in the brain.

In some cases, an *anticholinergic drug* such as trihexyphenidyl (benzhexol) may initially be given to reduce tremor. Anticholinergic drugs can be effective for several years, but may cause side effects such as dry mouth, blurred vision, and difficulty in passing urine.

Levodopa, which the body converts into dopamine, is usually the most effective drug. It may, however, cause side

effects such as nausea and vomiting; therefore, the dose is increased gradually, and the drug may be given in combination with benserazide or carbidopa. Levodopa is usually effective for several years, but the effects gradually wear off. Drugs that may be used in conjunction with it, or as substitutes for it, include *amantadine* and *bromocriptine*.

Surgical operations on the brain are occasionally performed, if the affected person is young and otherwise in good health. New therapies that are still being assessed include replacement of damaged tissue with transplanted brain cells, and deep brain stimulation with electrical impulses to reduce tremor.

OUTLOOK

If left untreated, the disease progresses over 10 to 15 years, leading to severe weakness and incapacity. Some sufferers eventually develop *dementia*. Modern drug treatments, however, can provide considerable relief from the symptoms and give affected people a much improved quality of life.

paronychia

An infection of the skin fold at the base or side of the *nail*. The affected area becomes swollen and painful, and there may be a buildup of pus.

Paronychia may be acute (caused by bacteria) or chronic (usually caused by *CANDIDA ALBICANS*). The condition is most common in women, particularly those with poor circulation and whose work involves frequent contact with water. It also affects people with skin disease involving the nail fold.

Treatment is with *antifungal drugs* or *antibiotic drugs*. If pus has collected in the area, it may need to be drained surgically. To prevent the occurrence of paronychia, gloves should be worn for all tasks that involve putting the hands in water, and the hands should be dried thoroughly after washing.

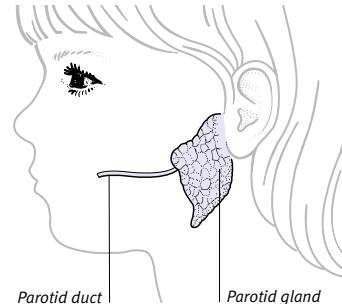

parotid glands

The largest of the three pairs of *salivary glands*. The parotid glands are situated on each side of the face, just above the angle of the jaw and in front of the ear. They secrete saliva into the mouth through a duct that opens into the inner cheek, level with the second molar tooth.

The parotid glands may develop various disorders that can affect all of the salivary glands, such as infections, abscesses (collections of pus), or calculi (stones). One disorder that specifically

LOCATION OF THE PAROTID GLANDS

The glands are situated deep in the angle of the jaw and secrete saliva into the mouth. Mumps may affect other salivary and exocrine glands.

affects these glands is *mumps*, which causes inflammation of one or both glands. Another is a form of noncancerous tumour, *pleomorphic adenoma*, which is slow-growing and painless but may rarely become cancerous.

parotitis

Inflammation of the *parotid glands*, which is often due to infection with the *mumps* virus.

paroxetine

A *selective serotonin reuptake inhibitor* antidepressant drug. Possible side effects of paroxetine include nausea, indigestion, and appetite loss.

paroxysm

A sudden attack, worsening, or recurrence of symptoms or of a disease; a *spasm* or *seizure*.

paroxysmal nocturnal dyspnoea

Acute breathing difficulty that occurs suddenly at night, usually waking the person from sleep. The condition most commonly affects people suffering from congestive *heart failure* with *pulmonary oedema* (a buildup of fluid in the lungs); in these cases, it is caused by fluid leaking out of the blood vessels into the air spaces of the lungs once the person is lying down. It may also occur in people with chronic lung diseases.

paroxysmal tachycardia

A form of tachycardia (abnormally rapid heartbeat) that usually comes on abruptly and stops just as suddenly. It

may be due to irregular muscle contractions in one of the chambers of the heart (see *arrhythmia, cardiac*).

parrot fever

The common name for *psittacosis*.

parturition

See *childbirth*.

parvovirus

The former name for *erythrovirus*.

passive movement

Movement of a person's limbs or body by another person. Passive movement is used in *physiotherapy* to exercise the body if a person has nerve or muscle disorders that prevent voluntary movements.

passive smoking

Involuntary inhalation of tobacco smoke by people who do not smoke. Passive smoking has been shown to increase risks of chest and ear infections in children and of tobacco-induced cancers in adults.

passivity

In *psychology*, a persistent unwillingness or inability to take responsibility for oneself and one's everyday life. Passivity may be a feature of disorders such as *depression* or *dependent personality disorder*. The term has a specific meaning when used in reference to *schizophrenia*: it describes a patient's belief that his or her thoughts, feelings, or actions are controlled by others.

pasteurization

The process of heating foods to destroy disease-causing *microorganisms*, and to reduce numbers of microorganisms that cause fermentation and putrefaction.

Patau's syndrome

A *chromosomal abnormality* in which there are three copies of chromosome 13 rather than the normal two. Patau's syndrome is a *congenital* condition (one that is present from birth). It causes low birth weight and a range of deformities including *cleft palate* or *hare lip*; eye deformities; *micrognathia* (undersized jaw); low-set ears; extra digits (see *polydactyly*); and malformation of the genitalia. There may also be serious deformities of the internal organs, such as heart defects, meningocele (see *neural tube defects*), and *exomphalos* (in which part or all of the intestines protrude through the navel).

Most children with Patau's syndrome die before two years of age, and those that survive have *learning difficulties*. Sometimes, affected children may have a mixture of normal and abnormal cells (see *mosaicism*), and they may have milder forms of the condition.

The condition may be diagnosed at an early stage of pregnancy by a test such as *chorionic villus sampling* or *amniocentesis*. In addition, *genetic counselling* may be offered.

patch test

A method that is used to diagnose the substances that are responsible for the skin disorder *allergic contact dermatitis*. A selection of possible *allergens* are put on a patch and taped to the skin. A skin reaction indicates that there is a sensitivity to a particular allergen.

patella

The kneecap (see *knee*).

patent

A term meaning "open" or "unobstructed" (such as in *patent ductus arteriosus*). The term "patent medicine" is sometimes used to refer to proprietary drugs protected by a patent.

patent ductus arteriosus

A defect of the *heart* in which the *ductus arteriosus* (a channel between the pulmonary artery and the aorta in the fetus) fails to close at birth.

CAUSE

In the fetus, blood that is pumped by the right side of the heart flows through the *ductus arteriosus* and bypasses the lungs (see *fetal circulation*). Normally, the *ductus arteriosus* closes at or shortly after birth, and blood passes from the right ventricle (lower chamber) of the heart to the lungs. In some babies this closure may fail to happen, producing a *patent ductus arteriosus*. In this condition, some of the blood that is pumped by the left side of the heart, and which should go to the rest of the body, is directed via the *ductus* to the lungs. As a result, the heart has to work harder than normal to pump sufficient blood to the body.

SYMPOTMS

Patent ductus arteriosus usually causes no symptoms, unless a large amount of blood is misdirected, in which case the baby fails to gain weight, becomes short of breath on exertion, and may have frequent chest infections. Eventually, *heart failure* may develop.

DIAGNOSIS AND TREATMENT

Diagnosis is made from hearing a heart *murmur*, from *chest X-rays*, and from an *ECG* and *echocardiography*. The drug *indometacin* or surgery may be used to close the duct.

paternity testing

The use of tests, including *DNA* tests and blood tests, to help decide whether a particular man is the father of a certain child. This procedure may be requested, or ordered by a court, in legal situations in which the paternity of a child is disputed.

Blood samples or buccal swabs (cell samples taken from rubbing the inside of the cheek) are taken from the child, from the man who is believed to be the father, and from the mother. There are various methods of testing for paternity: blood samples may be tested for *blood groups*, *histocompatibility antigens* (proteins that normally exist within body tissues, and whose form is inherited from the parents), and/or short lengths of DNA (a technique known as *genetic fingerprinting*); buccal swabs may only be used for DNA tests.

Genetic fingerprinting is the most conclusive method of paternity testing. Particular regions of DNA are examined for structures called genetic markers. If certain markers are present in the child's blood but not in the mother's blood, it follows that they must be determined by genes inherited from the child's biological father. If the man being tested shows the markers in his blood, there is a high probability that he is the biological father; if he does not, he can be excluded from the paternity of the child. No form of paternity testing is 100 per cent accurate in confirming or excluding someone as the father of a child.

patho-

A prefix denoting a relationship to disease.

pathogen

Any agent, but particularly a *microorganism*, that causes disease.

pathogenesis

The processes by which a disorder originates and develops.

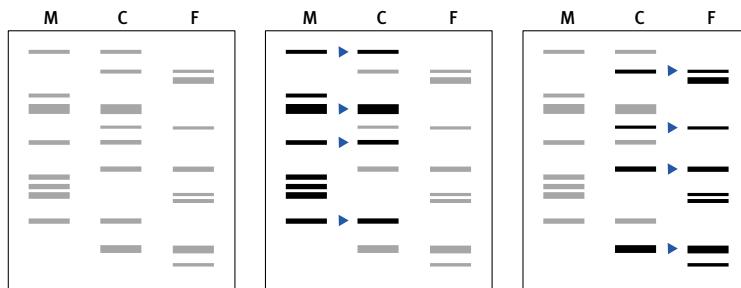

pathognomonic

A medical term applied to a sign or symptom that is characteristic of a disease or disorder and is therefore sufficient by itself to make a diagnosis.

PATERNITY TESTING USING DNA ANALYSIS

DNA analysis (commonly referred to as genetic fingerprinting) is replacing older techniques of paternity testing because it gives a decisive result in more cases. Blood samples are taken from the mother, child, and possible father, and some DNA (hereditary material) from each is specially processed.

PATERNITY ESTABLISHED

pathological fracture

Fracture of a bone weakened by disease, such as by certain forms of *cancer*, *osteoporosis*, and *Paget's disease*.

inations of dead people) to determine causes of death and to determine the effects that a disease or a treatment has had on the body.

pathology, cellular

Also called cytopathology, the branch of *cytology* concerned with the effects of disease on cells.

pathophysiology

The study of the effects of disease on body functions.

-pathy

A suffix that is used to denote a disease or disorder.

PCR

The abbreviation for *polymerase chain reaction*.

peak-flow meter

A piece of equipment that measures the maximum speed at which air can flow out of the lungs. A peak-flow meter is useful in assessing the severity of *bronchospasm* (constriction of the airways in the lungs), because narrowed airways slow the rate at which air can be expelled from the lungs. A peak-flow meter is most commonly used to diagnose *asthma*. In people who already have the disorder, it is used to monitor their condition and assess how they respond to treatment.

The peak flow is measured by taking in a deep breath and breathing out with the maximum force possible through the mouthpiece. The meter has a pointer and a scale on the side; the expelled breath moves the pointer to give a reading on the scale – the higher the reading, the greater the speed at which the air is travelling.

peau d'orange

A condition in which the skin is a normal colour but looks like orange peel. The skin's dimpled appearance is due to *fluid retention* in the nearby lymph vessels. Peau d'orange is not necessarily a sign of disease, although it is, for example, one of the features of *breast cancer*.

pectin

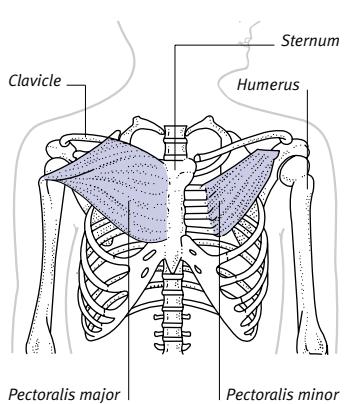

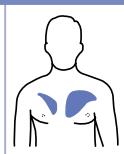

A form of *polysaccharide* found in apples and in the rinds of citrus fruits. Preparations containing pectins may be used to relieve diarrhoea.

pectoral

A medical term that means "relating to the chest", as in the pectoral muscles on either side of the chest. The pectoralis major is a large muscle covering much of the upper front of the chest. The smaller pectoralis minor lies beneath it.

PECTORAL MUSCLES

The major pectoral draws the arm across the body. The minor, which lies beneath it, moves the shoulder and raises some ribs.

pediculosis

Any type of louse infestation (see *lice*; *pubic lice*).

peer review

Processes by which doctors and scientists review the work of colleagues in the same field, to maintain standards.

pellagra

A potentially fatal disorder due to niacin deficiency (see *vitamin B complex*) resulting in *dermatitis*, diarrhoea, and *dementia*.

CAUSES AND INCIDENCE

Pellagra occurs primarily in poor rural communities in parts of the world, such as areas of India, where people subsist on maize. The body is unable to absorb most of the niacin in maize unless the maize is first treated with an alkali such as limewater. Maize is also low in tryptophan, an amino acid that is converted into niacin in the body.

Disorders such as *carcinoid syndrome* (which increases the breakdown of tryptophan) and *Crohn's disease* (which impairs absorption of tryptophan from the small intestine) may cause pellagra.

SYMPOTMS

The first symptoms are weakness, weight loss, lethargy, depression, irritability, and inflammation and itching of skin that is exposed to sunlight. In acute attacks, weeping blisters may develop on the affected skin, and the tongue becomes bright red, swollen, and painful.

DIAGNOSIS AND TREATMENT

Diagnosis is made from the patient's condition and dietary history. Daily intake of niacin and a varied diet usually bring about a cure.

pelvic abscess

An *abscess* (a collection of pus formed after infection with microorganisms) that develops in one of the structures within the pelvis. Pelvic abscesses may be due to *peritonitis* (inflammation of the membrane lining the abdominal cavity) or to localized inflammation resulting from disorders such as *pelvic inflammatory disease*.

pelvic examination

Examination of a woman's external and internal *genitalia*. After examination of the external genitalia, a *speculum* is inserted into the vagina to allow a clear view of the cervix. A *cervical smear test* may be performed. The doctor also carries out a bimanual examination: he or she inserts two fingers into the vagina, feeling the abdomen with the other hand to evaluate the position and size of the uterus and the ovaries and to detect any tenderness or swelling (see *Procedure for a pelvic examination* box, overleaf).

pelvic floor exercises

A programme of exercises to strengthen the muscles and tighten the ligaments at the base of the abdomen. These tissues make up the pelvic floor, which supports the uterus, vagina, bladder, urethra, and rectum. Slackening of the

pelvic floor muscles and ligaments is common following childbirth, and is a part of the aging process.

WHY THEY ARE DONE

Performing pelvic floor exercises, especially during pregnancy and after childbirth, may help to prevent prolapse of the uterus (see *uterus, prolapse of*) and urinary stress incontinence (see *incontinence, urinary*). The exercises may also be of help to women who find achieving *orgasm* difficult.

HOW THEY ARE DONE

The pelvic floor muscles are those that tighten if urine flow is stopped in mid-stream. The exercises involve contracting and relaxing the muscles several times. They can be carried out while standing, sitting, or lying down, by imagining that urine is being passed, contracting and holding the muscles for ten seconds, and then slowly releasing them. This action should be repeated five to ten times, as often as possible; ideally, the exercises should be performed for five minutes in every hour throughout the day. Weighted pessaries may also be used; these help the patient to perform the exercise correctly.

pelvic infection

An infection that affects the female reproductive system. Severe or recurrent pelvic infection is referred to as *pelvic inflammatory disease* (PID).

pelvic inflammatory disease

Inflammation of the internal female reproductive organs. Pelvic inflammatory disease (PID) is usually due to an infection. It is most common in young, sexually active women. PID is a common cause of lower abdominal pain in women. In some cases, however, there are no obvious symptoms, and affected women may be unaware that they have had the condition until they undergo an examination to assess their fertility.

CAUSES

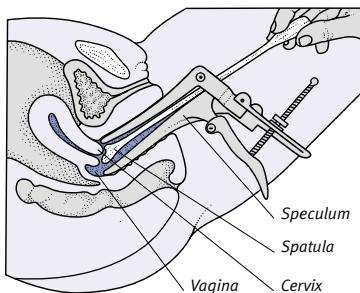

Pelvic inflammatory disease may not have any obvious cause, but it usually occurs as a result of a sexually transmitted infection, such as a *chlamydial infection*. It may also occur after a *miscarriage*, abortion (see *abortion, induced*), or *childbirth*. Use of an *IUD* increases the risk of infection, particularly soon after insertion of the device.

SYMPTOMS AND COMPLICATIONS

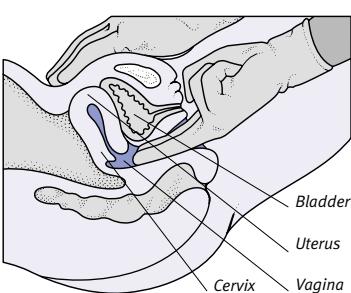

Common symptoms of PID include pain and tenderness in the lower abdomen, fever, and irregular menstrual periods.

PROCEDURE FOR PELVIC EXAMINATION

The examination is usually performed with the woman lying on her back with her knees bent. If the examination is carried out because of uterine prolapse or incontinence, the woman may be asked to lie on her side. The doctor usually begins by inspecting the external genitals for ulceration or swelling and then does an internal examination.

**Use of speculum**

A speculum is inserted into the vagina to hold the vaginal walls apart; this gives the doctor a clear view of both the vagina and cervix. A *cervical smear test*, in which cells are removed with a spatula, may also be performed.

**Manual examination**

The doctor inserts two fingers into the vagina and palpates (feels) the abdomen with the other hand to evaluate the size and position of the uterus and ovaries, and to detect any abnormal pelvic swelling or tenderness.

There may also be a profuse vaginal discharge consisting of blood and/or pus. Pain often occurs after *menstruation* and may be worse during sexual intercourse (see *intercourse, painful*). There may also be malaise, vomiting, or backache. PID may be acute or chronic.

DIAGNOSIS AND TREATMENT

A diagnosis is usually made by an internal *pelvic examination* and examination of swabs from the vagina or cervix to look for infectious organisms. *Laparoscopy* (examination of the abdominal cavity using a viewing instrument) can confirm the diagnosis.

Antibiotic drugs are prescribed to clear the infection, and sometimes *analgesic drugs* (painkillers) may be given. If an IUD is the suspected cause of PID, the device may need to be removed.

OUTLOOK

If PID is detected and treated early, the patient should recover fully. Some affected women, however, have repeated attacks with or without reinfection. A *pelvic abscess* may develop as a complication of the condition. PID may cause *infertility* or increase the risk of *ectopic pregnancy*; this is primarily due to scarring of the fallopian tubes, which prevents eggs from travelling down the tubes to the uterus.

pelvic pain

See *abdominal pain*.

pelvimetry

Assessment of the shape and dimensions of a woman's pelvis. Pelvimetry may be carried out a couple of weeks before *child-*

birth, to determine whether a woman is likely to have difficulty in delivering a baby vaginally. The procedure may also be performed after a vaginal delivery has been unsuccessful and a *caesarean section* has been carried out, to assist in planning a future pregnancy and delivery.

Medical staff can obtain a rough indication of the size of the pelvic outlet by manually checking the distance between the ischial tuberosities (the prominent bones in the lower pelvis) during a pelvic examination. More precise information may be obtained by taking an *X-ray* of the pelvis and then making measurements from the resulting image. However, excessive exposure to X-rays in pregnancy may increase the risk of subsequent *leukaemia* or other cancers in the unborn child, and therefore this procedure is carried out only in rare circumstances.

pelvis

The ring of bones in the lower trunk that supports the trunk, protects the lower abdominal organs, and forms part of the hip joints. Attached to the pelvis are the muscles of the abdominal wall, the buttocks, the lower back, and the insides and backs of the thighs.

STRUCTURE

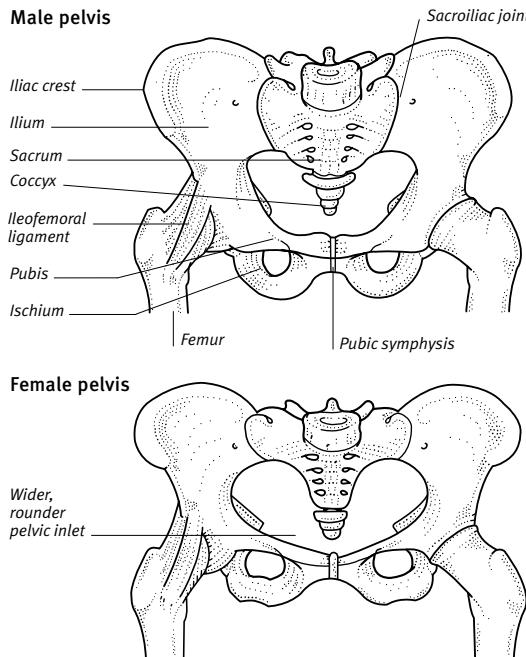

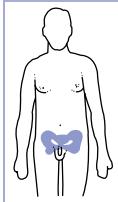

The pelvis consists of two innominate bones (hip-bones). At the back, the hip-bones are joined by rigid joints (the *sacroiliac joints*) to the *sacrum* (the triangular spinal bone below the lumbar vertebrae). At the front, they curve forwards to join at a central point known as the *pubic symphysis*.

Each innominate bone consists of three fused bones: the ilium, ischium, and pubis. The ilium, the largest and uppermost of these bones, consists of a wide, flattened plate with a long, curved ridge (the *iliac crest*) along its upper border. The ischium is the bone that bears much of the body weight when sitting. The pubis is the smallest of the pelvic bones; from the ischium it extends forwards and round to the *pubic symphysis*, where it is joined to the other pubis bone by tough fibrous tissue. All three bones meet in the *acetabulum*, the cup-shaped cavity that forms the socket of the hip joint.

In women, the pelvis is generally shallow and broad, and the *pubic symphysis* joint is less rigid than a man's. These differences facilitate child-birth. In men, the greater body weight needs a larger and more heavily built pelvis for support.

STRUCTURE OF THE PELVIS

A basin-shaped bony structure at the base of the trunk, the pelvis consists of the sacrum and coccyx at the back and, on either side, the hips (each comprising three fused bones: the ilium, ischium, and pubis), which curve round to meet at the front. The pelvis supports the upper half of the body and protects the lower abdominal organs. The female pelvis is shallower and wider.

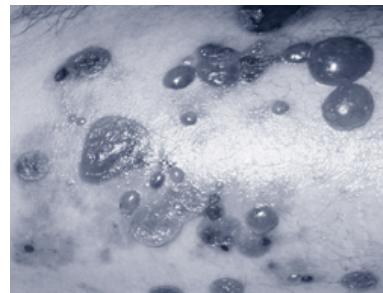

DISORDERS

Fractures of the pelvis may be caused by a direct blow, or by a force transmitted through the femur (thigh-bone). Considerable force is required to cause such a fracture, and it is usually the result of a road traffic accident; motorcycle riders are particularly at risk. The fracture itself often heals without any problems, but it is frequently accompanied by damage to internal organs within the pelvis, and especially to the bladder; such damage may require immediate surgical treatment.

Osteitis pubis (inflammation of the pubic symphysis) is usually caused by repeated stress on the pelvis. It occurs in soccer players due to continually kicking a ball. The symptoms include pain in the groin and tenderness over the front of the pelvis. In most cases, the condition clears up with rest.

pelviureteric junction

The point at which the renal pelvis (the main collecting duct of the *kidney*) narrows to become the *ureter* (the tube that carries urine from the kidney to the bladder). Obstruction to the flow of urine may occur at the pelviureteric junction, and this can result in damage to the kidneys.

pemphigoid

An uncommon, chronic skin disease, mainly affecting elderly people, in which large, sometimes itchy, blisters form on the skin. Pemphigoid is thought to be an *autoimmune disorder* (one in which the body reacts against its own tissues).

pemphigoid

An uncommon, chronic skin disease, mainly affecting elderly people, in which large, sometimes itchy, blisters form on the skin. Pemphigoid is thought to be an *autoimmune disorder* (one in which the body reacts against its own tissues).

Diagnosis is made with a skin *biopsy*. Treatment of the disease is usually with a long-term course of *corticosteroid* or *immunosuppressant drugs*.

pemphigus

A rare, serious skin disease in which numerous *blisters* develop on the skin and in the mouth. Pemphigus primarily affects people aged between 40 and 60. The blisters usually develop in the mouth, then appear on the skin. They rupture to form raw areas that may become infected and later crust over. Skin that appears unaffected may also blister after gentle pressure is applied. If a large area of the body is affected by the disease, there may be severe skin loss, which can lead to bacterial infection and, sometimes, death.

The diagnosis is confirmed by a skin *biopsy*. Treatment of pemphigus is with a long-term course of *corticosteroid drugs* and, in some cases, with *immunosuppressants*. *Antibiotics* may also be prescribed.

penciclovir

An *antiviral drug*. Penciclovir is commonly used in the form of a cream to treat cold sores (see *herpes simplex*).

penicillamine

An *antirheumatic drug* sometimes used to treat *rheumatoid arthritis*. Penicillamine is also used to treat copper or lead poisoning; it is a *chelating agent*, which binds to these metals to form a less harmful compound that can be safely excreted. In addition, it is used to treat *Wilson's disease* (a rare brain and liver disorder caused by a buildup of copper in the tissues), and primary *biliary cirrhosis* (a liver disorder).

The possible adverse effects of penicillamine can include allergic rashes, itching, nausea, vomiting, abdominal pain, loss of taste, blood disorders, and impaired kidney function.

penicillin drugs

COMMON DRUGS

- Amoxicillin • Ampicillin • Benzylpenicillin
- Co-amoxiclav • Co-fluampicil • Flucloxacillin
- Phenoxymethylpenicillin

A group of *antibiotic drugs*. Natural penicillins are derived from the mould *PENICILLIUM*; others are synthetic preparations. Penicillins are used to treat many infective conditions, including *tonsillitis*, *bronchitis*, bacterial *endocarditis*, *syphilis*, and *pneumonia*. They are also given to prevent *rheumatic fever* from recurring. Penicillins destroy bacteria by preventing them from forming normal cell walls.

POSSIBLE ADVERSE EFFECTS

Diarrhoea is a common adverse effect of penicillin drugs. Penicillins may also provoke an allergic reaction (see *allergy*) in susceptible individuals. Allergic symptoms appear immediately after the drug is taken and include *urticaria* (nettle rash),

wheezing, and *angioedema* (swelling of body tissues, occurring especially around the mouth and eyes). In rare cases, penicillins may cause the life-threatening allergic reaction *anaphylactic shock*. Reaction to a penicillin drug requires immediate discontinuation of the drug; urgent medical advice should be sought.

penile implant

A *prosthesis* inserted into the *penis* to help a man suffering from permanent *impotence* to achieve sexual intercourse. The various types include a silicone splint inserted in the tissues of the upper surface of the penis, and an inflatable prosthesis that is inflated by squeezing a small bulb in the scrotum.

penile warts

See *warts, genital*.

penis

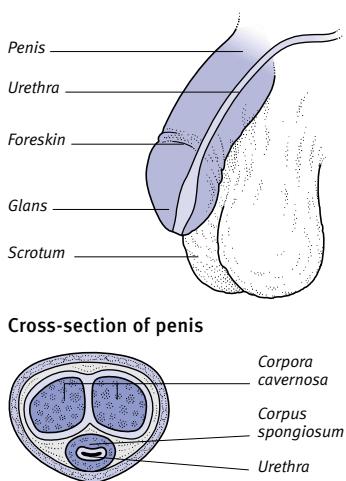

The male sex organ, through which *urine* and *semen* pass.

STRUCTURE AND FUNCTION

The penis consists of three cylindrical bodies of erectile tissue (spongy tissue full of blood vessels) that run along its length. Two of these bodies, the *corpora cavernosa*, lie side by side along the upper part of the penis. The third body, the *corpus spongiosum*, lies centrally beneath them and expands at the end to

ANATOMY OF THE PENIS

The *corpora cavernosa* and the *spongiosum* are the erectile tissues of the penis. A network of nerves controls the blood flow into them.

form the *glans*. Around the erectile tissue is a sheath consisting of fibrous connective tissue that is enclosed by skin. Over the glans, the skin forms a fold called the *foreskin*.

Through the centre of the corpus spongiosum runs the *urethra*, which is a narrow tube that carries urine and semen out of the body through an opening at the tip of the glans.

The principal functions of the penis are the excretion of urine and the discharge of semen during sexual intercourse (see *erection*; *ejaculation*).

DISORDERS

One common problem is *impotence* (failure to attain or maintain an erection). This condition affects most men at some point in their lives, and is usually psychological in origin. However, persistent impotence may be caused by nerve damage associated with *diabetes mellitus*, *alcohol* dependence, *atherosclerosis*, or spinal cord injury.

Balanitis (inflammation of the glans and foreskin) is usually caused by *candidiasis*, although other organisms, including those that cause *gonorrhoea* and *syphilis*, may cause inflammation. *Balanitis* may lead to *phimosis*, in which the foreskin is abnormally tight, or *paraphimosis*, in which the foreskin retracts at erection but is too tight to move back over the glans.

Penile warts (see *warts, genital*) are caused by a sexually transmitted virus. Cancer of the penis (see *penis, cancer of*) is a rare disorder; the incidence is higher in men who have not been circumcised than in those who have.

The most common congenital abnormality of the penis is *hypospadias*, a condition in which the opening to the urethra is located on the underside of the penis. In male *pseudohermaphroditism*, which is also congenital, the penis is very small and there is usually also hypospadias.

Other disorders of the penis include *priapism*, in which an erection is painful and abnormally prolonged, and a condition called *Peyronie's disease*, in which the erect penis bends.

penis, cancer of

A rare type of cancerous tumour that is more common in uncircumcised men with poor personal hygiene. Viral infection and smoking have both been shown to be additional risk factors. The tumour usually starts on the *glans* or on the foreskin as a painless, wartlike lump or a painful ulcer, and develops into a

cauliflowerlike mass. The growth usually spreads slowly, but in some cases it can spread to the *lymph nodes* in the groin within a few months.

Diagnosis is made by a *biopsy* (tissue sample). If the tumour is detected early, surgical removal is usually successful. Otherwise, removal of part or all of the penis may be necessary. *Radiotherapy* and *chemotherapy* may also be used.

pentamidine

An antiprotozoal drug (see *protozoa*) administered by intravenous infusion or nebulizer to prevent and treat *pneumocystis pneumonia* in immunosuppressed people. Pentamidine is also used to treat the tropical disease *leishmaniasis*. Side effects of the drug may include nausea and vomiting, dizziness, flushing, rash, and taste disturbances.

pentazocine

An opioid *analgesic drug* used to relieve moderate or severe pain caused by injury, surgery, cancer, or childbirth. It is rarely used because of its adverse affects, which include dizziness, drowsiness, nausea, vomiting, and, rarely, hallucinations. *Drug dependence* may develop if high doses are taken for prolonged periods.

peppermint oil

An oil obtained from the peppermint plant *MENTHA PIPERITA*. It is prescribed to relieve abdominal colic but may cause heartburn. Peppermint oil is also used as a flavouring in some drug preparations.

peptic ulcer

A raw area that develops in the gastrointestinal tract due to erosion by acidic gastric juice. A peptic ulcer most commonly occurs in the stomach, where it is called a *gastric ulcer*, or the *duodenum* (the first part of the small intestine), where it is known as a *duodenal ulcer*.

CAUSES

The lining of the stomach and duodenum is usually protected from the acid gastric juice by a layer of mucus. If this layer is damaged, the acid can come into contact with the tissues, causing inflammation and erosion. Ulcers can also form in the *oesophagus*, when acidic juice from the stomach enters it (see *acid reflux*).

The major cause of peptic ulcers is infection with *HELICOBACTER PYLORI* bacteria, which can damage the lining of the stomach and duodenum, allowing the acid stomach contents to attack it. The long-

term use of *nonsteroidal anti-inflammatory drugs* (NSAIDs), smoking, alcohol consumption, and excess acid production can also damage the stomach lining. A *stress ulcer* is a peptic ulcer caused by severe physiological stress, such as that due to neurosurgery or to burns (for example, a *Curling's ulcer*). Psychological stress is thought to aggravate an existing ulcer.

For further information on how an ulcer forms and the sites where ulcers may develop, see the illustrated box.

SYMPOTMS

There may be no symptoms, or there may be burning or gnawing pain in the upper abdomen when the stomach is empty. The pain of a duodenal ulcer is often relieved by eating, but usually recurs a few hours later. The pain of a gastric ulcer may be worsened by food.

Other possible symptoms of a peptic ulcer include a loss of appetite, a bloated or full feeling in the abdomen, nausea, and, sometimes, vomiting.

COMPLICATIONS

The most common complication of a peptic ulcer is bleeding as the ulcer penetrates deeper and damages blood vessels. If severe, bleeding may result in haematemesis (vomiting of blood) and *melaena* (black faeces) and is a medical emergency. Chronic bleeding may cause iron-deficiency anaemia. Rarely, an ulcer may perforate the wall of the digestive tract and lead to *peritonitis* (inflammation of the abdominal cavity's lining).

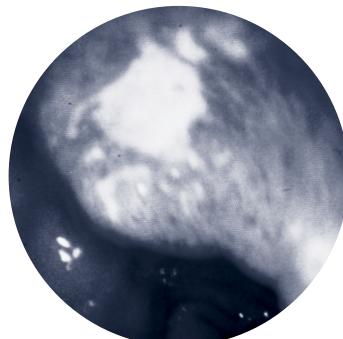

SITES AND CAUSES OF PEPTIC ULCER

A peptic ulcer develops in about one in eight people in the UK at some time in their lives. Some of the mechanisms that are involved in causing ulcers are shown below. A peptic ulcer is investigated using endoscopy, which involves passing a gastroscope (a type of endoscope) through the mouth to view

Gastric ulcer

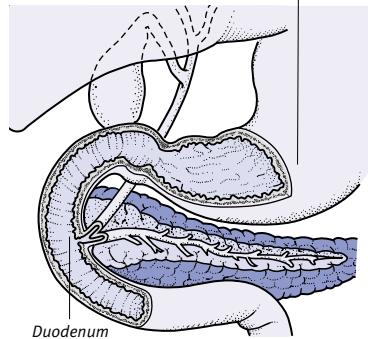

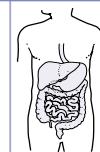

This photograph of an ulcer in the wall of the stomach was taken using a gastroscope passed through the mouth into the stomach.

Duodenal ulcer

In this gastroscopic view of the top of the duodenum, an ulcer is clearly visible as a smooth white area.

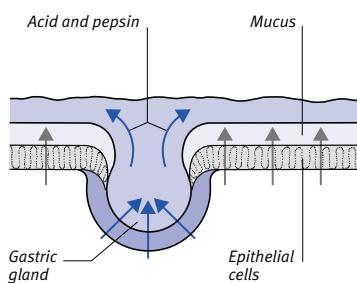

the stomach and duodenum. A sample of the stomach lining may be taken at the same time to look for evidence of *HELICOBACTER PYLORI* infection, the major cause of peptic ulcers; blood tests (to check for antibodies against *HELICOBACTER PYLORI*) and breath tests are also used to confirm its presence.

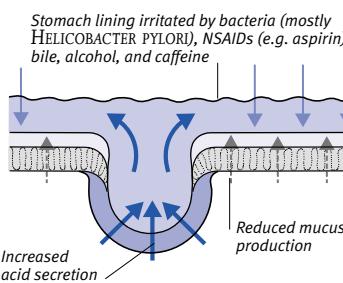

Site of ulcers

Peptic ulcers are most common in the first part of the duodenum or lower half of the stomach; oesophageal ulcers also occur.

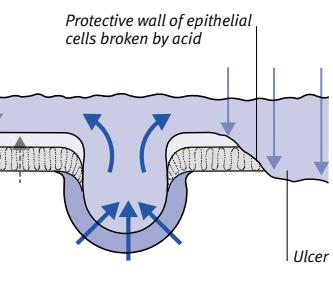

HOW AN ULCER IS FORMED

1 Gastric glands in the lining of the stomach secrete acid and the enzyme pepsin, which help to break down food. The acid and pepsin would quickly eat away the stomach and duodenum if other cells in the lining did not secrete a protective mucus.

2 Most peptic ulcers are due to bacterial infection of the stomach lining, which damages its mucous layer (making it vulnerable to acid) and the cells that control excess acid production. Ulcers can also be caused by NSAIDs or excess alcohol combined with excess production of acid. Smoking is another important irritant factor.

3 If damaging influences overcome the protective factors in the stomach or duodenal lining, the mucous layer and mucus-secreting cells are eroded and an ulcer forms. Stress is probably not a prime cause of ulcers but it is possible it may aggravate an existing ulcer.

Another rare complication is scarring of the tissues that occurs as a result of chronic ulcers. Scar tissue around the pyloric sphincter (the outlet where the stomach opens into the duodenum) may cause narrowing of the outlet. This condition, which is called *pyloric stenosis*, may obstruct the passage of food from the stomach to the duodenum, resulting in vomiting and weight loss.

DIAGNOSIS AND TREATMENT

An ulcer is usually diagnosed by *endoscopy* of the stomach and duodenum, or, less commonly, a barium meal (see *barium X-ray examination*). Tests are carried out to see whether the individual is infected with the *HELICOBACTER* bacterium. If so, a combination of *antibiotics* and an *ulcer-healing drug* will be given as treatment. A further test may be carried out to check that the treatment has been successful. If *HELICOBACTER* is not detected, however, (for example, in cases where the ulcer was due to the use of *NSAIDs*), the *NSAIDs* will be stopped and treatment with *proton pump inhibitors* or *H₂-blockers* will be given.

Surgery is now rarely needed for peptic ulcers, except to treat complications such as bleeding or perforation.

peptide

A protein fragment consisting of two or more *amino acids*. Peptides that consist of very many linked amino acids are called polypeptides; chains of polypeptides are called *proteins*. In the body, peptides occur in forms such as *hormones* and *endorphins*.

perception

The interpretation of a *sensation*. Information is received through the five senses (taste, smell, hearing, vision, and touch), then identified and organized into a pattern by the brain. Factors such as attitude, mood, and expectations affect the final interpretation; for example, a person who is hungry is more likely to notice the sight and smell of food than someone who has just eaten.

Hallucinations are false perceptions that occur in the absence of any type of sensory stimuli.

percussion

A diagnostic technique that involves tapping the chest or abdomen with the fingers and listening to the sound that is produced. From this sound, the doctor can deduce the condition of the internal organs. (See also *examination, physical*.)

percutaneous

A term meaning "through the skin".

perforation

A hole made in an organ or tissue by disease or injury.

pergolide

A drug used to treat *parkinsonism*, a type of neurological disorder resulting from a lack of *dopamine*. It acts by stimulating the *receptors* for dopamine in the brain.

peri-

A prefix meaning "around", as in *pericardium*, the membranous sac that surrounds the heart.

perianal haematoma

A *haematoma* (collection of blood) under the skin around the anus. A perianal haematoma is painful and of sudden onset. It usually disappears with no treatment, but minor surgery may be required to drain the blood.

periapical abscess

See *abscess, dental*.

pericarditis

Inflammation of the *pericardium* (the double-layered membrane surrounding the heart). This disorder often leads to chest pain and fever. There may also be an increased amount of fluid (see *effusion*) in the pericardial space, which separates the two smooth layers of the pericardium. The excess fluid may compress the heart and restrict its action.

Long-term inflammation can cause a condition called constrictive pericarditis, in which the pericardium becomes scarred, thickens, and contracts, and as a result impedes the heart's action.

CAUSES

Causes of pericarditis include infection; *myocardial infarction* (heart attack); cancer spreading from another site; and injury to the pericardium. The disorder may accompany the autoimmune conditions *rheumatoid arthritis* and *systemic lupus erythematosus*, or *kidney failure*.

SYMPTOMS

Pain, behind the sternum (breastbone) and sometimes in the neck and shoulders, may be more severe if the person takes a deep breath, changes position, or swallows. Pain may be relieved by sitting up and leaning forward. There may also be fever. Constrictive pericarditis causes *oedema* (fluid swelling) of the legs and abdomen.

DIAGNOSIS AND TREATMENT

Diagnosis is made from a *physical examination*, from an *ECG* (which records the electrical activity in the heart) and *chest X-rays* or *echocardiography*, which will show any excess fluid around the heart.

If possible, treatment is aimed at the cause. *Analgesic drugs* (painkillers) or *anti-inflammatory drugs* may be given. If there is an effusion, the excess fluid may be drawn off through a needle. In severe constrictive pericarditis, the thickened part of the pericardium may be surgically removed so that the heart can pump freely.

pericardium

The membranous bag that surrounds the *heart* and the roots of the major blood vessels that emerge from it.

The pericardium is made up of two layers. The outer layer is tough, inelastic, and fibrous. It is attached to the diaphragm below and to the sternum (breastbone) in front. The inner layer is separated into two sheets; the innermost one is firmly attached to the heart, and the outer one is attached to the fibrous layer. The smooth inner surfaces of these sheets are separated by a space called the pericardial space, which contains a small amount of fluid that lubricates the heart.

perimenopause

The period immediately preceding the *menopause* (when the ovaries stop producing eggs and *menstruation* ceases). During the perimenopause, levels of *oestrogen* begin to fall. Fluctuations in hormone levels cause menstrual periods to become irregular and results in symptoms such as hot flushes.

perimetry

A visual field test to determine the extent of peripheral vision. (See *eye, examination of*).

perinatal

Relating to the period that extends from just before the birth of a baby to just after. The perinatal period is often defined as the period from the 24th week of pregnancy to the end of the first week after birth.

perinatology

A branch of *obstetrics* and *paediatrics* concerned with the study and care of the mother and baby during pregnancy and just after birth.

Perinatologists are specialists in the management of high-risk pregnancies and births, and in the investigation and treatment of prenatal conditions that might endanger the life or health of the fetus, such as *Rhesus incompatibility*, *spina bifida*, or biochemical disorders. These doctors are also skilled in assessing the function of the placenta and maintaining the health of an expectant mother who may herself be at risk of health problems.

perindopril

One of a class of drugs called ACE inhibitors, which act by widening the blood vessels and thereby ease the workload on the heart. Perindopril may be used to relieve hypertension (high blood pressure) or congestive heart failure.

The drug may have side effects related to widening of the blood vessels, such as *hypotension* (low blood pressure), leading to dizziness or fainting; flushed skin; and headaches.

perineum

The area that is bounded internally by the bony structures that surround the pelvic floor (the muscles that support the pelvis). Internally, the perineum extends from the coccyx at the back to the public symphysis at the front of the body and incorporates the lower parts of the genitourinary and gastrointestinal tracts. Outside the body, the perineum is the area that extends from the genitals to the anus.

periodic fever

An inherited condition that causes recurrent bouts of fever (see *familial Mediterranean fever*).

periodic paralysis

See *paralysis, periodic*.

period, menstrual

See *menstruation*.

periodontal abscess

See *abscess, dental*.

periodontal disease

Any disorder of the periodontium (the tissues that surround and support the teeth). The most common type of periodontal disease is *gingivitis* (gum inflammation). Gingivitis can lead to marginal periodontitis, which often causes the development of a periodontal abscess (see *abscess, dental*).

Periodontal disease

The gums are inflamed and have receded. Many of the teeth are eroded at the base; and the tooth sockets may also be decayed.

periodontics

The branch of dentistry concerned with the structures that surround and support the teeth, particularly the gums.

periodontitis

Inflammation of the periodontium (the tissues surrounding the teeth). There are two types: periapical and marginal.

CAUSES

Periapical periodontitis results from neglected tooth decay (see *caries, dental*). If dental caries is left untreated, areas of enamel and the dentine (softer tissue) beneath them are eventually destroyed, allowing bacteria to enter the tooth pulp. From there, the bacteria spread to the root tip and into the surrounding tissues, sometimes causing the formation of an abscess (see *abscess, dental*), *granuloma*, or *cyst*.

Marginal periodontitis is the major cause of tooth loss in adults. It is a result of untreated *gingivitis* (gum disease), which in turn is usually due to poor *oral hygiene*. In this condition, neglected, inflamed gum tissue at the base of the teeth becomes damaged, and pockets form between the gums and the teeth. A sticky deposit of mucus, food particles, and bacteria (see *plaque, dental*) and a hard, mineralized coating formed from plaque and saliva (see *calculus, dental*) then collect in these pockets. The bacteria in the plaque and calculus attack the periodontal tissues, causing them to become inflamed and then detached from the teeth. The bacteria also eventually erode the bones surrounding the teeth. As a result, the teeth become loose in their sockets and fall out.

SYMPOTMS

Periapical periodontitis may cause localized toothache, especially on biting. An abscess may damage bone and periodontal ligaments, causing the tooth to become loose; a large dental cyst may cause swelling of the jaw.

In marginal periodontitis there are signs of gingivitis, such as red, soft, shiny, tender gums that bleed easily. There is also an unpleasant taste in the mouth and bad breath. The deepening pockets in the gums gradually expose the sensitive dentine in the roots of the teeth, causing the teeth to ache when hot, cold, or sweet foods or liquids are consumed. Occasionally, there is a discharge of pus from the gums, or a periodontal abscess develops.

DIAGNOSIS AND TREATMENT

The diagnosis of periodontitis is by a dental examination to find any pockets and assess their size and depth, and dental X-rays to check for bone loss.

Periapical periodontitis is treated by draining the pus and filling the tooth or alternatively by *root-canal treatment*, in which decayed pulp is removed from a tooth and its root and the cavity is then filled. If the tooth cannot be saved, however, *extraction* is performed.

In the early stages of marginal periodontal disease, regular, scrupulous teeth cleaning can prevent further plaque and calculus formation and thus halt destruction of the tissues surrounding the teeth. For more severe periodontitis, the dentist will remove existing plaque and calculus by *scaling* and *root planing* (smoothing the surface of an exposed root). In some cases, *gingivectomy* (surgical trimming of the gums) may be performed to reduce the size of gum pockets. Surgery may also be carried out in order to remove the diseased lining from the pocket (see *curettage, dental*), so that healthy underlying tissue will reattach itself to the tooth; and the damaged, irregular bone is smoothed. Loose teeth can sometimes be anchored to firmer ones by a method called splinting (see *splinting, dental*).

period pain

See *dysmenorrhoea*.

periosteum

The layer of connective tissue that coats all of the *bones* in the body except the joint surfaces. The periosteum contains small blood vessels and nerves. It produces new bone in the initial stages of healing following a *fracture*.

periostitis

Inflammation of the *periosteum* (connective tissue covering bone). The usual cause is a blow that presses directly on to bone. Symptoms include pain, tenderness, and swelling over the affected area.

peripheral nerves

Nerves that run between the *central nervous system* (CNS, the brain and spinal cord) and particular body tissues. Of these, 12 pairs are *cranial nerves* and 31 pairs are *spinal nerves*. Some peripheral nerves are sensory, carrying messages from sensory organs and nerve endings (see *receptor*) towards the brain and spinal cord; others are motor nerves, carrying signals away from the CNS to stimulate responses in the tissues.

peripheral nervous system

The system of *peripheral nerves*, which fan out from the *central nervous system* (the brain and spinal cord) to the muscles, skin, internal organs, and glands.

peripheral vascular disease

Narrowing of arteries in the legs, and sometimes in the arms, which restricts blood flow and causes pain. In severe cases, *gangrene* (death of tissues supplied by the vessels) may develop.

CAUSES

In most affected people, peripheral vascular disease is caused by *atherosclerosis*, in which fatty deposits form on the inner walls of arteries. The greatest risk factor for developing atherosclerosis is *smoking*. Other risk factors include *hypertension* (high blood pressure), a high-fat diet, and poorly controlled *diabetes mellitus*.

Diseases of the peripheral arteries that are not caused by atherosclerosis include *Buerger's disease* and *Raynaud's disease*.

SYMPTOMS AND COMPLICATIONS

The first symptom of narrowed arteries due to atherosclerosis is usually an aching feeling in the leg muscles (usually in the calf) when walking. The pain may be relieved by resting for a few minutes, but recurs after the same amount of walking as before. Prolonged use of the arms may also cause pain.

Symptoms then become worse until, eventually, pain is present even when the person is at rest. The pain may be severe and continuous, even disrupting sleep. By this stage, the blood supply to the affected leg is dangerously low. The affected limb is cold and numb, with dry, scaly skin, and *leg ulcers* may develop after even minor injuries. In the final stage, *gangrene* (tissue death) develops, initially appearing in the toes and then spreading up the leg.

Sudden arterial blockage sometimes occurs, causing acute *ischaemia* (insufficient blood supply to an organ or tissue). This arterial blockage may be due to the rapid development of a clot on top of a plaque of atherosclerosis, by a dissecting aneurysm (splitting of an arterial wall), or by an embolism arising from a clot formed in the heart and carried to a peripheral artery. It causes sudden, severe

pain. The affected limb becomes cold and pale or blue, with no pulse. Movement and feeling in the limb are lost.

DIAGNOSIS AND TREATMENT

A diagnosis is often based on the results of *Doppler ultrasonography*, which shows the flow of blood through the affected vessels, or *angiography*, which will reveal signs of narrowing or other structural abnormalities.

Exercise and giving up smoking are important aspects of treatment. For peripheral vascular disease of the legs, the affected person needs to take scrupulous care of the feet in order to prevent infection and minimize the risk of gangrene. *Arterial reconstructive surgery*, *bypass* surgery, or balloon *angioplasty* may be needed to widen or bypass the affected blood vessels. *Amputation* is necessary if gangrene has developed.

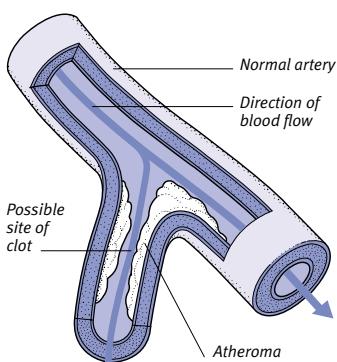

peristalsis

Wavelike movement caused by the rhythmic contraction and relaxation of the smooth muscles in the walls of the digestive tract and the ureters. Peristalsis is responsible for the movement of food and waste products through the digestive system and for transporting urine from the kidneys to the bladder.

In the digestive system, peristalsis in the oesophagus (gullet) moves food towards the stomach, even if the body is

PERIPHERAL VASCULAR DISEASE

The disease usually starts with the formation of atheroma (fatty plaques) in the lining of artery walls. Smokers are among those at highest risk.

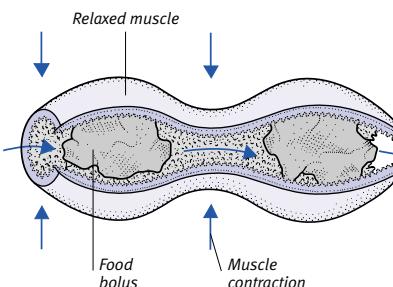

Clot formation

Clots may form on top of the atheroma (plaques), restricting blood flow to tissues, which may lead to pain and tissue death.

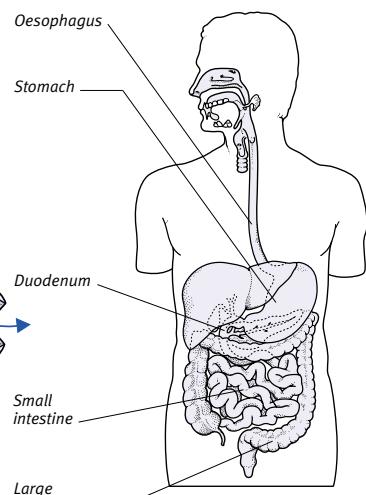

PERISTALSIS

The walls of many body passages contain a special type of muscle called smooth muscle. The muscle fibres contract in sequence, sending waves of contraction along the walls of the passage.

Effect of peristalsis

As each group of muscle fibres in the wall of the intestine contracts, it narrows that part of the passage, squeezing the food bolus into an adjoining section where the muscle fibres are relaxed.

Sites of peristaltic action

Peristalsis occurs most obviously in the digestive tract, shown above, but it also moves urine through the ureters.

turned upside down. In the stomach, similar muscle movements help to mix food with gastric juices and move the partly digested food into the duodenum (the first part of the small intestine). The muscles of the small intestine move in a slow, back-and-forth churning motion that allows more time for the intestine to absorb nutrients. In the large intestine, peristaltic contractions occur only about once every 30 minutes. Two or three times a day, however, usually following a meal, a strong, sustained wave of peristalsis in the colon forces the contents into the rectum, and may prompt the urge to defaecate. (See also the illustrated box.)

peritoneal dialysis

See *dialysis*.

peritoneum

The two-layered membrane that forms a lining in the abdominal cavity and covers and supports the abdominal organs. The peritoneum contains blood vessels, lymph vessels, and nerves. The surface area of the peritoneum is equal to that of the entire skin.

The peritoneum produces a lubricating fluid that allows the abdominal organs to glide smoothly over each other. It also protects the organs against infection. In addition, the membrane absorbs fluid and acts as a natural filtering system; this function is utilized in one form of *dialysis*. The peritoneum may become inflamed as a complication of an abdominal disorder (see *peritonitis*).

peritonitis

Inflammation of the *peritoneum* (the membrane lining the abdominal wall and covering the abdominal organs). Peritonitis is a serious condition.

CAUSES

The inflammation is almost always due to irritation and bacterial infection caused by another abdominal disorder. The most common cause is *perforation* of the stomach or intestine wall, which allows bacteria and digestive juices to move into the abdominal cavity. Perforation is usually the result of a *peptic ulcer*, *appendicitis* (acute inflammation of the appendix), or *diverticulitis* (inflammation of abnormal pouches in the wall of the intestine).

Peritonitis may also be associated with acute *salpingitis* (inflammation of a fallopian tube), *cholecystitis* (inflammation of the gallbladder), or *septicaemia* (blood poisoning).

SYMPOTMS

There is usually severe abdominal pain over part or all of the abdomen. After a few hours, the abdomen feels hard, and *peristalsis* (wavelike contractions of the intestinal muscles) stops (see *ileus, paralytic*). Other symptoms are fever, bloating, nausea, and vomiting. *Dehydration* and *shock* may occur.

DIAGNOSIS AND TREATMENT

Diagnosis is made from a *physical examination*. The affected person will need to be admitted to hospital without delay. Surgery may be necessary to deal with the cause. If the cause is unknown, a *laparoscopy* or an exploratory *laparotomy* may be performed. *Antibiotic drugs* are often given to destroy bacteria, and *intravenous infusions* of fluid may be given to treat dehydration.

OUTLOOK

In most cases, a full recovery is made. Rarely, however, intestinal obstruction, caused by *adhesions* (bands of scar tissue between loops of intestine), may occur at a later stage.

peritonsillar abscess

An abscess (collection of pus) in the soft tissue around the tonsils that occurs as a complication of *tonsillitis*. A peritonsillar abscess, also known as quinsy, causes pain, swallowing difficulties, and jaw stiffness. The tonsils appear asymmetrical. *Antibiotic drugs* and *analgesic drugs* (painkillers) are usually given to help relieve the symptoms, and, in some cases, a small surgical incision may be made to drain the abscess.

permanent teeth

The second set of *teeth*, which usually start to replace the primary teeth at about the age of six. There are 32 permanent teeth: 16 in each jaw. Each set of 16 consists of four incisors, two canines, four premolars and six molars. (See also *eruption of teeth*.)

permethrin

A drug included in preparations used to treat *lice* and *scabies*.

pernicious anaemia

A type of *anaemia* (reduced blood levels of the oxygen-carrying pigment *haemoglobin*) caused by the stomach lining failing to produce intrinsic factor – necessary for vitamin B_{12} absorption. Deficiency of vitamin B_{12} prevents bone marrow from producing normal red blood cells (see *anaemia, megaloblastic*).

pernio

An alternative term for *chilblain*.

peroneal muscular atrophy

A rare, inherited disorder characterized by muscle wasting in the feet and calves and then in the hands and forearms. The condition, which is also known as Charcot–Marie–Tooth disease, is caused by degeneration of some peripheral nerves. It usually appears in late childhood or adolescence.

Muscle wasting stops halfway up the arms and legs, making them look like inverted bottles; sensation may be lost. There is no treatment for the disorder, but it is rare for the sufferer to become totally incapacitated because the disease usually progresses at a very slow rate. Life expectancy is normal.

phenothiazine

A *phenothiazine*-type *antipsychotic drug* that is used to relieve symptoms in psychiatric disorders, such as *schizophrenia*; to sedate agitated or anxious patients; and sometimes for the relief of severe nausea and vomiting.

Possible adverse effects include abnormal movements of the face and limbs, drowsiness, blurred vision, stuffy nose, and headache. Long-term use of the drug may cause the movement disorder *parkinsonism*.

Persantin

A brand name for *dipyridamole*, an *anti-platelet drug*. Persantin prevents abnormal *blood clotting* by inhibiting the activity of platelets (tiny blood cells that aid clotting). The drug is used to prevent recurrence of a *stroke* or *transient ischaemic attack* or to prevent the development of blood clots in people with prosthetic *heart valves*.

persistent vegetative state

A term used to describe a type of indefinite, deep *coma* (unconsciousness and unresponsiveness to stimuli). The condition is caused by damage to areas of the brain that control higher mental functions. Although the eyes may open and close and there may be random movements of the head and limbs, there is no response to stimuli such as pain. Only basic functions, such as breathing and heartbeat, are maintained due to functioning of the *brainstem*. There is no treatment to reverse the situation; with good nursing care, survival for several years is possible.

personality

A term that is used to describe the sum of a person's traits, habits, and experiences. Temperament, intelligence, emotion, and motivation are important aspects. The development of personality seems to depend on the interaction of heredity and environment.

personality disorders

A group of conditions characterized by a failure to learn from experience or to adapt appropriately to changes, resulting in distress, impaired social functioning, and, in some cases, occupational problems. Personality disorders are patterns of abnormal behaviour that may become especially obvious during periods of stress. They are usually first recognizable in adolescence and may continue throughout life, often leading to *depression* or *anxiety*. Personality disorders are not the result of another psychiatric disorder or a result of substance abuse.

TYPES

Specific types of personality disorders are divided into three groups, but there is often overlap between them.

The first group is characterized by eccentric behaviour. Paranoid people show suspicion and mistrust of others; schizoid people are cold emotionally; and schizotypal personalities have behavioural oddities similar to, but less severe than, those of schizophrenia.

In the second group, behaviour tends to be dramatic. Histrionic people are excitable and constantly crave stimulation. Narcissists have an exaggerated sense of self-importance (see *narcissism*). People with antisocial personality disorder (formerly called psychopaths) disregard accepted standards of behaviour and show no concern for other people's feelings and rights. As a result, they often come into contact with the police. People with borderline personality disorder behave very impulsively; their self-image, relationships, and emotions are unstable.

People in the third group show anxiety and fear. Dependent personalities lack the self-confidence to function in an independent way (see *dependence*). People who have avoidant personalities are hypersensitive to criticism and rejection and cautious about new experiences. Those with obsessive-compulsive personalities are very rigid in their habits (see *obsessive-compulsive disorder*).

TREATMENT

Personality disorders are generally difficult to treat. Treatment options include

counselling, *psychotherapy*, and *behaviour therapy*. The treatment may need to be prolonged, however, and affected people may not always comply with guidance from doctors or therapists.

personality tests

Questionnaires designed to define various personality traits or types. Tests may be used to detect psychiatric symptoms, various underlying traits, how outgoing or reserved a person is, and predisposition to developing neurotic illness.

perspiration

The production and excretion of sweat from the *sweat glands*. Perspiration is another name for sweat.

Perthes' disease

Inflammation of an *epiphysis* (growing area) of the head of the *femur* (thigh bone). The disease is a type of *osteochondritis juvenilis*, thought to be due to disrupted blood supply to the bone.

The condition is most common in boys aged between five and ten years, and usually affects one hip. Symptoms include pain in the thigh and groin, and a limp on the affected side. Movement of the hip is restricted and painful.

Diagnosis is made with *X-rays*, which may show flattening, fragmentation, and (in later stages) shrinking of the head of the femur. Treatment of the disease may be rest for a few weeks, followed by splinting of the hip, or surgery to fit the head of the femur more securely into the pelvis. The disease usually clears up by itself within three years, but the hip may be permanently deformed.

pertussis

A highly contagious infectious disease, also called whooping cough. It mainly affects infants and young children and is most dangerous in newborn babies. The main features are bouts of coughing, often followed by a "whoop" as air is drawn back into the lungs.

CAUSE

The main cause is infection with *BORDETELLA PERTUSSIS* bacteria, which are spread in airborne droplets. In affluent countries such as the UK, however, the incidence of pertussis has been greatly reduced by *immunization*.

SYMPTOMS

After an *incubation period* of seven to ten days, the illness starts with a mild cough, sneezing, nasal discharge, fever, and sore eyes. After a few days, the cough becomes

worse. Whooping occurs in most cases. Sometimes the cough can cause vomiting. In infants, there is a risk of temporary *apnoea* (cessation of breathing) following a coughing spasm. The illness may last anything from a few weeks up to three months, although the child is usually only infectious for about three weeks.

COMPLICATIONS

Coughing may cause nosebleeds and bleeding from ruptured blood vessels on the surface of the eyes or *petechiae* (red, flat, pinhead spots) on the face. Other possible complications include *dehydration* from repeated vomiting; *pneumonia*; *pneumothorax* (a form of collapsed lung); *bronchiectasis* (permanent widening of the airways); and *seizures*. Untreated, pertussis may prove fatal.

DIAGNOSIS AND TREATMENT

Pertussis is usually diagnosed from the symptoms. In the early stages of the illness, the antibiotic *erythromycin* is often given to reduce the child's infectivity. Treatment consists of keeping the child warm, giving small, frequent meals and plenty to drink, and protecting him or her from stimuli, such as smoke, that can provoke coughing. If the child becomes blue or persistently vomits after coughing, he or she must be admitted to hospital.

PREVENTION

In the UK, vaccination against pertussis is usually given at two, three, and four months of age, with a booster dose at three to five years.

Possible complications of vaccination include mild fever and fretfulness. Very rarely, an infant may react severely, with high-pitched screaming or seizures.

Communities need to maintain a high level of immunity, through immunization, to protect infants. It should be remembered that the risks from the disease itself are far greater than any risk from the pertussis vaccine.

perversion

See *deviation, sexual*.

pes cavus

See *claw-foot*.

pessary

Any of a variety of devices placed in the vagina. Some types are used to correct the position of the uterus (see *uterus, prolapse of*); others are used as contraceptive devices. The term "pessary" is also used to refer to a dose of medication, in solid form, that is inserted into the vagina, where it dissolves to release the drug.

pesticides

Poisonous chemicals used to eradicate pests. Different types of pesticide include herbicides, insecticides, and fungicides. Pesticide poisoning, particularly in children, may result from swallowing an insecticide or a garden herbicide (see *chlorate poisoning*). Poisoning may also occur in agricultural workers, often as a result of inhalation or of absorption of the chemical through the skin. Exposure to pesticides can also occur indirectly, through eating food in which chemicals have accumulated as a result of crop spraying. (See also *DDT; defoliant poisoning; lindane; paraquat; parathion*.)

petechiae

Red or purple, flat, pinhead-sized spots that occur in the skin or mucous membranes. They do not blanch (go pale) when pressure is applied to them. Petechiae are caused by a localized *haemorrhage* (leakage of blood) from small blood vessels. They occur in *purpura* (a group of bleeding disorders) and, sometimes, in bacterial *endocarditis* (infection of the inner lining of the heart). Petechiae may also arise after periods of excessive straining; in conditions such as *pertussis* (whooping cough), for example.

pethidine

A synthetic opioid *analgesic drug* similar to, but less powerful than, *morphine*. Pethidine is used as a *premedication* and to relieve severe pain after operations or during childbirth. The drug may cause nausea and vomiting, so it is usually given with an *antiemetic drug*. Pethidine can be addictive, making it unsuitable for treating continuing pain.

petit mal

A type of generalized seizure that occurs in *epilepsy*. Petit mal attacks affect children and adolescents but rarely persist into adulthood. Attacks may take place many times a day, and they may sometimes last as long as 30 seconds each. The signs include a momentary loss of awareness, occasionally with drooping eyelids. Treatment for petit mal attacks is with an *anticonvulsant drug*.

petroleum jelly

A greasy substance, also known as *petrolatum* or soft paraffin, that is obtained from petroleum. The jelly is commonly used as an *ointment base*, a protective dressing, and an *emollient*.

PET scanning

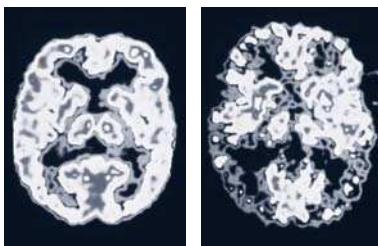

The abbreviation for positron emission tomography. This imaging procedure is a diagnostic technique that is based on the detection of positrons (a type of subatomic particle) emitted by radioactively labelled substances introduced into the body. PET scanning produces images of the metabolic and chemical activity of tissues.

HOW IT WORKS

Certain substances used in biochemical processes in the body, such as glucose or oxygen, are labelled with radioisotopes and then injected into the bloodstream. They are taken up in greater concentrations by tissues that are more active or overactive metabolically. The substances emit positrons, which release photons that are detected by the scanner. A computer then converts this information into images, which are colour-coded to show different levels of tissue activity.

WHY IT IS DONE

PET scans are used to detect brain tumours, locate epileptic activity within the brain, and examine brain function in *Alzheimer's disease* and in mental illnesses such as *depression*.

PET scans of the brain

A scan of a normal brain (left) can be compared to that of a patient with Alzheimer's disease, in which the dark areas on both sides of the brain indicate reduced function and blood flow.

Peutz–Jeghers syndrome

A rare, inherited condition in which *polyps* occur in the gastrointestinal tract and small, flat, brown spots appear on the lips and in the mouth. Occasionally, the polyps bleed, or cause abdominal pain or *intussusception* (the intestine telescopes in on itself causing obstruction).

Tests for the condition include *barium X-ray examination* and *endoscopy*. Bleeding polyps may be removed.

Peyer's patches

Areas of mucosa-associated lymphoid tissue (MALT) situated in the mucous membrane lining the ileum (the last

portion of the small intestine). Peyer's patches form part of the *lymphatic system*, which helps to fight infection.

peyote

A cactus plant found in northern Mexico and the southwest of the United States. Dried blossoms are used to prepare the hallucinogenic drug *mescaline*.

Peyronie's disease

A disorder of the *penis* in which part of the sheath of fibrous connective tissue thickens, causing the penis to bend during erection. The problem commonly makes intercourse difficult and painful. The thickened area can be felt as a firm nodule when the penis is flaccid. Eventually, some of the erectile tissue may also thicken. Men over 40 are most often affected. The cause is unknown.

The disease may improve without treatment. Otherwise, surgical removal of the thickened area and replacement with normal tissue may be carried out.

pH

A measure of the acidity or alkalinity of a solution. The pH scale ranges from 0–14, 7 being neutral; values smaller than this are acid, and values that are larger are alkaline.

The pH of body fluids must be close to 7.4 for metabolic reactions to proceed normally (see *acid-base balance*). If it falls lower than 7.35, the resulting acidity is called *acidosis*; if it rises above 7.45, the result is *alkalosis*.

phacoemulsification

A surgical procedure used to treat *cataract* (an opacity in the lens of the eye). In this procedure, *ultrasound* waves are used in order to break down the lens tissue, and then the broken-down material is removed through a tiny incision in the eye. An artificial lens implant may then be inserted to improve vision. (See also *cataract surgery*.)

phaeochromocytoma

A rare, usually noncancerous, tumour arising in cells in the *medulla* (core) of the *adrenal glands*. These cells secrete the hormones *adrenaline* (epinephrine) and *noradrenaline* (norepinephrine). The tumour causes increased production of the two hormones, which leads to *hypertension* (high blood pressure) and signs of stress, such as anxiety. The disorder is most common in young to middle-aged adults.

SYMPOTMS AND SIGNS

Hypertension is usually the only sign. However, certain conditions or situations (such as pressure on the tumour, emotional upset, change in posture, or taking *beta-blocker drugs*) can cause a surge of hormones. This surge brings on a sudden rise in blood pressure, *palpitations*, headache, nausea, vomiting, facial flushing, sweating, and, sometimes, a feeling of impending death.

DIAGNOSIS AND TREATMENT

Blood tests and *urinalysis* are used to detect excessive levels of epinephrine and norepinephrine and thus make a diagnosis. *CT scanning*, *MRI*, and *radioisotope scanning* may be used to locate the tumours, and they are then usually removed surgically. Follow-up medical checks are required because the condition occasionally recurs.

phagocyte

A cell in the *immune system* that can surround, engulf, and digest *micro-organisms*, foreign particles, and cellular debris. Phagocytes are found in the blood, *spleen*, *lymph nodes*, and alveoli (small air sacs) within the lungs. Some types of white *blood cell*, especially granulocytes and some monocytes, are "free" phagocytes, which are able to migrate through the tissues and engulf harmful organisms and debris.

phalanges

The small bones that make up the fingers, thumb, and toes. The thumb and big toe have two phalanges; all the other fingers and toes have three.

phalanx

A term for any of the bones in the fingers or the toes.

phallus

Any object that may symbolize the *penis*.

phantom limb pain

The *perception* that a limb is still present after it has been amputated. The sensation occurs because impulses from the nerves in the stump are interpreted by the brain as coming from the limb.

phantom pregnancy

See *pregnancy, false*.

pharmaceutical

Any medicinal drug. The term is also used with reference to the manufacture and sale of drugs.

pharmacognosy

The study or knowledge of the pharmaco logically active ingredients of plants.

pharmacokinetics

The term that is used to describe how the body deals with a *drug*. It covers the way in which the drug is absorbed into the bloodstream, how the drug is distributed to different body tissues, and how the drug is broken down for excretion from the body.

pharmacology

The branch of science that is concerned with the discovery and development of *drugs*; their chemical composition; their actions; their uses; and their toxicity. Pharmacodynamics involves the study of the drugs' interactions with, and effects on, living organisms.

pharmacopoeia

Any book that lists and describes most medicinal drugs, especially an official publication. One such example is the British Pharmacopoeia (BP).

A pharmacopoeia provides a description of the sources, preparations, and doses of drugs. There may also be information on how drugs work and on possible adverse effects.

pharmacy

The practice of preparing drugs, and making up and dispensing prescriptions. The term is also used to describe the place, in a hospital for example, where these activities are carried out.

pharyngeal diverticulum

An alternative term for a pharyngeal pouch (see *oesophageal diverticulum*).

pharyngeal pouch

See *oesophageal diverticulum*.

pharyngitis

Acute or chronic inflammation of the *pharynx* (the part of the throat that is situated between the tonsils and the voicebox), causing a sore throat.

CAUSES

The most common cause is a viral infection. Pharyngitis often occurs as part of a cold (see *cold, common*) or *influenza*. It may also be an early feature of glandular fever (see *mononucleosis, infectious*) or *scarlet fever*. Sometimes, the condition is due to a bacterial infection, such as a *streptococcal infection*; a rare but serious bacterial cause is *diphtheria*.

Swallowing substances that can scald, corrode, or scratch the lining of the throat, smoking, and excessive consumption of alcohol may also be the causes of pharyngitis.

SYMPTOMS

As well as a sore throat, there may be discomfort when swallowing, slight fever, earache, and swollen *lymph nodes* in the neck. In severe cases of pharyngitis, there may be a high fever, and the soft palate and throat may swell so much that breathing and swallowing can become difficult.

TREATMENT

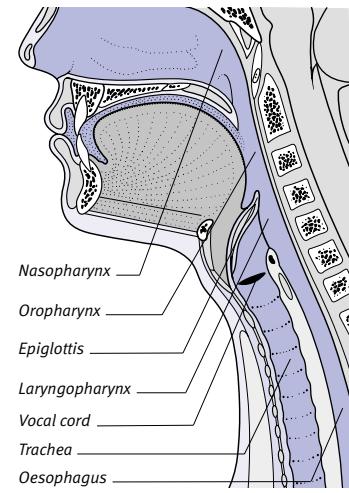

Gargling with warm salt water and taking *analgesic drugs (painkillers)* is usually the only treatment needed. If the sore throat is severe or prolonged, a doctor may take a throat *swab* and prescribe *antibiotic drugs*.

pharynx

The passage that connects the back of the mouth and nose to the *oesophagus*. The upper part of the passage, or *nasopharynx*, connects the nasal cavity to the area situated behind the soft *palate*. The middle part, the *oropharynx*, runs from the nasopharynx to below the tongue. The lower part, called the *laryngopharynx*, lies behind and to each side of the *larynx* (voicebox).

LOCATION OF THE PHARYNX

The pharynx, or throat, plays an essential part in breathing and eating and can change shape to help form vowel sounds in speech. It has a mucous membrane lining.

DISORDERS

The most common disorder affecting the pharynx is acute *pharyngitis* (inflammation of the pharynx), which causes a sore throat. Another common problem is choking due to the presence of a foreign body, such as a fish-bone, that has become lodged in the pharynx.

A rare disorder is *oesophageal diverticulum*. In this condition, a small sac (a pharyngeal pouch) develops in the rear wall of the laryngopharynx.

Cancerous tumours (see *nasopharynx, cancer of; pharynx, cancer of*) are relatively rare in Western countries, but more common in the Far East. Some forms of cancer have been linked with smoking and excessive drinking.

pharynx, cancer of

A cancerous tumour of the *pharynx* (the part of the throat between the tonsils and the voicebox). Pharyngeal cancer usually develops in the *mucous membrane* lining the throat.

CAUSES AND INCIDENCE

In the West, almost all cases of pharyngeal cancer are related to smoking and alcohol. The disorder is more common in men, and incidence rises with age.

Tumours of the nasopharynx (see *nasopharynx, cancer of*) have different causes and symptoms from those that arise lower in the pharynx.

SYMPTOMS

Cancerous tumours of the oropharynx (the middle section of the pharynx) usually cause difficulty in swallowing, often accompanied by a sore throat and earache. Blood-stained sputum may be coughed up. Sometimes, there is only the feeling of a lump in the throat or a visibly enlarged *lymph node* in the neck.

Cancer of the laryngopharynx (the lowermost part of the pharynx) initially produces a sensation of incomplete swallowing; symptoms that develop in the later stages include a muffled voice, hoarseness, and also an increased difficulty in swallowing.

DIAGNOSIS AND TREATMENT

Diagnosis is made by *biopsy*, which is often performed in conjunction with *laryngoscopy, bronchoscopy, or oesophagoscopy*. The growth may be removed surgically or treated with *radiotherapy*. *Anticancer drugs* may also be given.

phenylcyclidine

A drug of abuse, commonly known as angel dust or PCP. It produces euphoria, which sometimes leads to anxiety or

depression. Coordination, speech, and thinking are impaired; the user may have *hallucinations*, and may become violent. Other possible effects include increases in blood pressure and heart rate, dilated pupils, tremor, and reduced sensitivity to pain. High doses of phenylcyclidine may cause *coma*.

Long-term effects include violent behaviour, anxiety, and mental disorders such as severe *depression, paranoia, and schizophrenia* (see *drug-induced psychosis*). There is also a risk of brain damage, and of death due to *seizures* or cardiac or respiratory arrest.

phenelzine

A monoamine oxidase inhibitor *antidepressant drug* usually given when other antidepressant drugs have been found to be ineffective. Possible side effects include dizziness, drowsiness, and rash. When taken with some other drugs or certain foods, such as mature cheese, broad beans, and yeast extract, phenelzine can cause a dangerous rise in blood pressure.

Phenergan

A brand name for the antihistamine drug *promethazine*.

phenobarbital

A *barbiturate drug* that is used mainly as an *anticonvulsant*. Phenobarbital may be used with *phenytoin* in the treatment of *epilepsy*. Possible side effects of the drug include drowsiness, clumsiness, dizziness, excitement, and confusion.

phenol

A strong *antiseptic*, also called carbolic acid. Liquids or ointments that contain phenolic compounds are used to cleanse wounds and inflamed skin, while phenol in an oil base can be injected into haemorrhoids in order to shrink them. Phenol is also found in chemical substances such as *disinfectants*; in this form, it is highly toxic.

phenothiazine drugs**COMMON DRUGS**

- Chlorpromazine • Fluphenazine
- Methotriptazine • Perphenazine
- Pipotiazine • Thioridazine • Trifluoperazine

A group of drugs that are used in the treatment of psychotic illnesses (see *antipsychotic drugs*) some of which are also used to relieve severe nausea and vomiting (see *antiemetic drugs*).

phenotype

The physical appearance, form, and biochemical make-up of an individual. (In contrast, the *genotype* is an individual's genetic make-up.) The phenotype is influenced by the *genes* that a person possesses and by environmental factors (such as diet).

phenoxymethylpenicillin

A synthetic *penicillin drug* used to treat bacterial infections, such as pharyngitis, tonsillitis, and dental abscesses.

Possible adverse effects include rash and nausea. A few people may develop a serious allergic reaction, as can occur with other penicillin drugs.

phenylbutazone

A *nonsteroidal anti-inflammatory drug* (NSAID) used to relieve the symptoms of the inflammatory condition *ankylosing spondylitis*. Phenylbutazone may cause nausea, fluid retention, rash, and *peptic ulcer*. It may also increase the risk of certain *blood disorders*, such as agranulocytosis (a deficiency in granulocytes, a type of white *blood cell*). The drug is prescribed only under hospital supervision, and only if other drugs are ineffective.

phenylephrine

A *decongestant drug* used to relieve the symptoms of seasonal allergic rhinitis (hay fever; see *rhinitis, allergic*) and the common cold. As eye-drops, it is used to dilate the pupils for eye examinations. High doses or prolonged use of the nasal preparations may cause headache and blurred vision; if a person stops taking the drug suddenly, this may make nasal congestion worse. Use of phenylephrine for longer than a week is not, therefore, recommended.

phenylketonuria

An inherited disorder in which the *enzyme* that converts the *amino acid* phenylalanine into tyrosine (another amino acid) is defective. Unless phenylalanine is excluded from the diet, it builds up in the body and causes severe *learning difficulties*. All newborn babies are given the *Guthrie test*, in which a blood sample is taken to screen for phenylketonuria.

SYMPTOMS

Affected babies show few signs of abnormality, but, if phenylalanine is not excluded from the diet, they develop neurological disturbances including

epilepsy. The babies tend to have blonde hair and blue eyes, and their urine may have a musty odour. Many have the skin condition *eczema*.

TREATMENT AND PREVENTION

Phenylalanine is found in most foods that contain protein, and also in artificial sweeteners. A specially modified diet is generally recommended throughout life, and sticking to this diet is especially important during pregnancy, because high levels of phenylalanine in the mother can damage the fetus.

phenytoin

An *anticonvulsant drug* used in the treatment of *epilepsy*. Side effects may include nausea, dizziness, tremor, and overgrown and tender gums.

pheromone

A substance with a particular odour that, when released in minute quantities by an animal, affects the behaviour or development of other individuals of the same species.

Philadelphia chromosome

A *chromosomal abnormality* that is associated with one form of leukaemia (see *leukaemia, chronic myeloid*). In this abnormality, one copy of chromosome 22 has a missing section; this portion has become detached and then reattached to a copy of chromosome 9. (See also *chromosome; karyotype*.)

P

phimosis

Tightness of the foreskin, preventing it from being drawn back over the *glans* (head) of the penis. In uncircumcised babies, some degree of phimosis is normal, but it usually improves by age three or four. In some boys, the condition persists and may cause the foreskin to balloon out on urination. Attempts to retract a tight foreskin may make the condition worse.

Phimosis may also develop in adult men, causing painful erection and it may lead to *paraphimosis* (constriction of the penis behind the glans). Proper cleaning of the glans may not be possible, so *balanitis* (*infection of the glans*) may develop.

The treatment for both adults and children is *circumcision*.

phlebitis

Inflammation of a vein. A clot often develops, in which case the condition is termed *thrombophlebitis*.

phlebography

The obtaining of *X-ray* images of veins that have been injected with a *radiopaque* substance. An alternative name is *venography*.

phlebotomy

Puncture of a vein to remove blood (see *venepuncture; venesection*).

phlegm

See *sputum*.

phobia

A persistent, irrational fear of a certain object or situation. Many people have minor phobias, which may cause distress but do not affect everyday life. A phobia is considered a psychiatric disorder when it interferes with normal social functioning.

TYPES

Simple phobias (specific phobias) are the most common. These problems may involve fear of particular animals or situations, such as enclosed spaces (*claustrophobia*). Animal phobias usually start in childhood, but other types of phobia can develop at any time.

More severe, pervasive fears are called complex phobias. One form is *agoraphobia*, which often causes severe impairment. The disorder usually starts in the late teens or early 20s. Another complex phobia is social phobia – fear of being exposed to scrutiny, such as a fear of eating or speaking in public. The onset of this disorder usually occurs in late childhood or early adolescence.

CAUSES

The causes of phobias are unknown. Simple phobias are thought by some to be a form of *conditioning*. For example, a person with a fear of dogs may have been frightened by a dog in childhood.

SYMPTOMS AND COMPLICATIONS

Exposure to the feared object or situation causes intense *anxiety* and, in some cases, may lead to a *panic attack*. The person may start to avoid any situation that might involve contact with the trigger for the fear, and this may adversely affect his or her lifestyle. Phobias may also be associated with *depression* or with *obsessive-compulsive behaviour*. In addition, the person may attempt to relieve the fear by using drugs or drinking alcohol to excess.

TREATMENT

Treatment depends on the severity of the condition and the wishes of the individual. For simple phobias, no treatment may be necessary unless the feared object is so common that it cannot easily be avoided

(for example, if a person lives in the city but has a fear of lifts). Treatment is more commonly sought for complex phobias. It may involve *cognitive-behavioural therapy* and sometimes *antidepressant drugs*.

phocomelia

A limb defect in which the feet and/or the hands are joined to the trunk by short stumps. The condition is extremely rare, but used to occur as a side effect of women taking the drug *thalidomide* in early pregnancy.

pholcodine

A *cough suppressant*.

phosphates

Salts containing *phosphorus* and *oxygen*. Phosphates are an essential part of the diet and are present in many foods, including cereals, dairy products, eggs, and meat.

FUNCTION

Most of the phosphorus in the body is combined with *calcium* to form the structure of bones and teeth. The remainder is present in small amounts in most of the body's tissues, and plays a part in maintaining the *acid-base balance* of the blood, urine, saliva, and other body fluids. *ATP* (adenosine triphosphate) is a phosphate compound that stores the energy for chemical reactions in cells.

DISORDERS

In most people, the kidneys maintain a constant level of phosphates in the body by regulating the amount that is excreted in the urine. They can compensate for a slight deficiency of phosphates in the diet by reducing the amount lost in the urine.

Hypophosphataemia (an abnormally low level of phosphates in the blood) may occur in some forms of kidney disease, *hyperparathyroidism*, long-term treatment with *diuretic drugs*, *malabsorption*, or prolonged starvation. It causes bone pain, weakness, *seizures*, and, in severe cases, *coma* and death.

DRUG THERAPY

Phosphates may be taken by mouth in the form of drug preparations or milk to treat hypophosphataemia. They are also used to treat *hypercalcaemia* (abnormally high levels of calcium in the blood). Diarrhoea is a possible side effect of phosphate drugs.

phospholipid

A compound formed from one or more lipids (fats), phosphate, and, usually, glycerol. They are manufactured in the liver and small intestine. Examples of phospholipids include *lecithins*.

Phospholipids are important constituents of cell membranes and nerve tissues, particularly in the brain. In addition, those existing on the surfaces of blood platelets play a part in *blood clotting*. In an *autoimmune disorder* called *Hughes' syndrome*, the immune system may form antibodies to phospholipids and thus disrupt the clotting process, causing abnormal clot formation.

phosphorus

An essential *mineral* present in many foods, including cereals, dairy products, and meat. In the body, phosphorus is combined with *calcium* to form the bones and teeth. (See also *phosphates*.)

photocoagulation

The destructive heating of tissue by intense light focused to a fine point, as in *laser treatment*.

photophobia

An uncomfortable sensitivity or intolerance to light. It occurs with certain eye disorders, such as *corneal abrasion*, and is a feature of *meningitis* (inflammation of the membranes that surround the brain and spinal cord).

photorefractive keratectomy

A surgical treatment for *astigmatism* (a vision disorder resulting from uneven curvature of the front of the eye), *myopia* (shortsightedness), and *hypermetropia* (longsightedness) in which areas of the *cornea* are shaved away by *laser*.

photosensitivity

An abnormal reaction to light. Photosensitivity usually causes a rash on skin exposed to sunlight or artificial *ultraviolet light*. This often occurs because a photosensitizer (a substance such as a particular drug, dye, chemical in perfume or soap, or a plant such as mustard) has been ingested or applied to the skin. Photosensitivity is also a feature of disorders such as *systemic lupus erythematosus*.

People who are susceptible to photosensitivity reactions should avoid being exposed to sunlight and known photosensitizers and should use *sunscreens*.

phototherapy

Treatment that uses light, including sunlight, *ultraviolet light*, and blue light. Moderate exposure to sunlight is the most basic form and is often helpful in treating the skin disorder *psoriasis*. *PUVA*

is another form of phototherapy. Phototherapy may also be used to treat *seasonal affective disorder*.

PUVA

This therapy combines the use of long-wave ultraviolet light with a *psoralen drug*, which sensitizes the skin to light. The procedure is used to treat psoriasis and certain other skin diseases, such as *vitiligo*. Psoriasis may also be treated using short-wave ultraviolet light, sometimes combined with the application of coal tar.

BLUE LIGHT

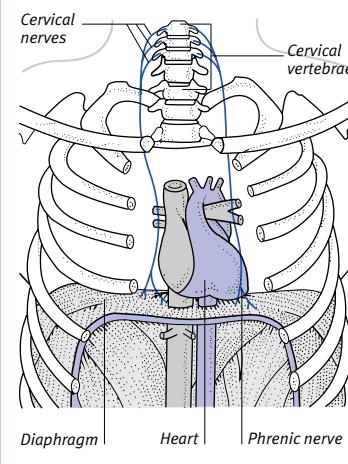

Visible blue light is used to treat neonatal jaundice (see *jaundice, neonatal*), which is due to high levels of the pigment *bilirubin* in the blood. The light is thought to cause the conversion of bilirubin into a harmless substance that can be excreted. To maximize exposure, the baby is undressed and placed under the lights in an incubator (with his or her eyes shielded).

phrenic nerve

One of the pair of main nerves that supply the *diaphragm*. The phrenic nerves branch from the third, fourth, and fifth cervical nerves in the neck (see *spinal nerves*) and then pass down through the chest to each side of the diaphragm. Each of the phrenic nerves carries motor impulses to one half of the diaphragm and plays a part in the control of breathing. Damage that occurs to either one of the nerves,

LOCATION OF PHRENIC NERVES

There are two phrenic nerves, one on each side of the body. Each follows a tortuous course from its origin in the neck, through the chest, to the diaphragm.

including invasion by a tumour (such as in *lung cancer*), results in *paralysis* of that half of the diaphragm.

physical examination

See *examination, physical*.

physiological saline

An *isotonic* solution of 0.9% sodium chloride in water, also called normal saline, used to replace body fluids and rehydrate tissues. Physiological saline is given by intravenous infusion.

physiology

The study of body functions, including physical and chemical processes of cells, tissues, organs, and systems, and their various interactions.

physiotherapy

Treatment with physical methods, such as exercise or physical agents. Physiotherapy can prevent or reduce joint stiffness and restore muscle strength in arthritis, or after a fracture has healed. It is also used to reduce pain, inflammation, and muscle spasm, and retrain joints and muscles, after *stroke* or nerve injury. Methods include active exercises and *passive movement, heat treatment, massage, ice-packs, hydrotherapy, and TENS* (therapeutic use of electrical currents).

Physiotherapy is also used to maintain breathing in people with impaired lung function, and to prevent and treat pulmonary complications after surgery. Techniques for doing this include *postural drainage, breathing exercises, and administration of oxygen, drugs, or moisture through a nebulizer*.

phyto-

A prefix meaning of plant origin.

phytomenadione

A form of *vitamin K*.

phyto-oestrogens

Oestrogens that occur naturally in plants.

pia mater

The innermost of the three membranes of the *meninges*, lying next to the brain.

pica

A craving to eat non-food substances such as earth or coal. Pica is common in early childhood and may occur during pregnancy. It may also occur in nutritional or iron-deficiency disorders, and in severe psychiatric disorders.

Pickwickian syndrome

An uncommon disorder characterized by extreme *obesity*, shallow breathing, excessive sleepiness, and *obstructive sleep apnoea*. Pickwickian syndrome is of unknown cause. The symptoms usually improve with weight loss; specific treatment for sleep apnoea may be required.

PID

The abbreviation for *pelvic inflammatory disease*.

piebaldism

A rare *genetic disorder* in which a patchy absence of the dark pigment *melanin* results in areas of skin and sometimes hair that lack pigmentation. In many cases, there is a white panel in the centre of the face, which may include the hair and eyebrows as well as the skin. Piebaldism shows an autosomal dominant pattern of inheritance.

piercing

See *ear piercing*.

Pierre Robin's syndrome

A disorder causing abnormalities of the lower jaw and throat. The condition may occur by itself, or may be associated with other problems. It is *congenital* (present at birth).

The main structural malformations are micrognathia (an abnormally small lower jaw) and cleft palate (or an unusually arched palate). Functional defects include a tendency for the tongue to fall backwards into the throat, causing breathing difficulty and a tendency to choke.

Affected babies may have difficulty in feeding. Micrognathia may disappear as the child grows, but cleft palate and airway obstruction may require surgery.

pigeon toes

A minor abnormality in which the leg or foot is rotated, forcing the foot and toes to point inwards. Although the condition occurs commonly in toddlers, it has usually corrected itself by the time the child is seven years old.

pigmentation

Coloration of the skin, hair, and *iris* of the eyes by *melanin*, a brown or black pigment produced by cells called melanocytes. The more melanin, the darker the coloration (the amount produced is determined by heredity and exposure to sunlight). Blood pigments can also colour skin (as in a bruise).

There are many defects of pigmentation, which may cause abnormally pale or dark skin, or may produce areas of discoloured skin.

REDUCED PIGMENTATION

Patches of pale skin occur in the skin disorders *psoriasis*, *pityriasis alba*, and *pityriasis versicolor*; these disorders cause skin scales to flake off, resulting in a loss of melanin. In *vitiligo*, areas of skin stop producing melanin.

The rare genetic disorder *albinism* is caused by a generalized deficiency of melanin, and results in very pale skin and white hair. Another genetic condition, *phenylketonuria*, results in a reduced level of melanin, making sufferers of the condition more pale-skinned and fair-haired than all the other members of their family.

INCREASED PIGMENTATION

Areas of dark skin may appear temporarily following disorders such as *eczema* or *psoriasis*, *pityriasis versicolor*, or *chloasma* (development of dark patches on the face due to hormonal changes). Such areas of dark pigmentation may also appear after the use of perfumes and cosmetics containing chemicals that cause *photosensitivity*.

Permanent areas of deep pigmentation, such as freckles, moles, or some types of naevi (see *naevus*), are usually due to an abnormality in some of the melanocytes. *Acanthosis nigricans*, a condition that may be either inherited or acquired, is characterized by dark patches of velvetlike, thickened skin. Darkening of the skin that is unrelated to sun exposure may occur in certain hormonal disorders, such as *Addison's disease* and *Cushing's syndrome*.

ABNORMAL COLORATION

Some forms of abnormal colouring result from excessive levels of certain pigments or other substances in the blood. An excess of the bile pigment bilirubin in *jaundice* turns the skin yellow, and an excessive blood level of iron in *haemochromatosis* turns the skin bronze. Discoloration may also be caused by an abnormal collection of blood vessels, as in a *haemangioma*, or may occur temporarily in a bruise, when blood leaks from ruptured vessels and collects under the skin.

piles

A common name for *haemorrhoids*.

pill, contraceptive

See *oral contraceptives*.

pilocarpine

A drug used in the form of eye-drops to treat *glaucoma* (raised pressure in the eyeball). Pilocarpine may initially cause blurred vision, headache, and eye irritation. In tablet form, the drug is used to treat *dry mouth* due to *Sjogren's syndrome* or *radiotherapy* to the head and neck.

 pilonidal sinus

A pit in the skin, often containing hairs, in the upper part of the buttock cleft. The cause is probably hair fragments growing inwards. Although the condition is usually harmless, infection may occur causing recurrent, painful abscesses.

If a pilonidal sinus is infected, the sinus and a wide area around it will be surgically removed. The resulting wound will usually be left open to allow slow healing from the skin layers below. Recurrence of infection is common, and plastic surgery is sometimes required.

pimozide

An *antipsychotic drug* also used to treat *Gilles de la Tourette's syndrome*. Pimozide may cause sedation, dry mouth, constipation, and blurred vision.

pimple

A small *pustule* or *papule*.

pindolol

A *beta-blocker drug* used to treat *angina pectoris* (chest pain due to inadequate blood supply to the heart) and *hypertension* (high blood pressure). Possible side effects are typical of other beta-blocker drugs, except that pindolol is less likely than some others to cause *bradycardia* (abnormally slow heartbeat).

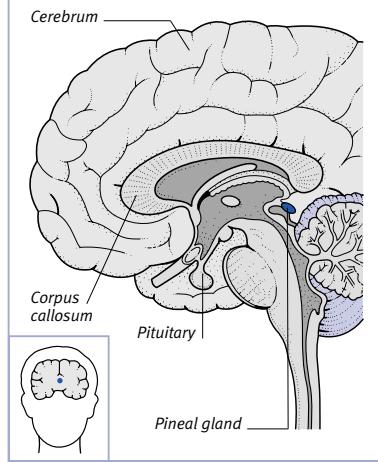

pineal gland

A tiny, cone-shaped structure deep within the *brain*. The pineal gland is situated just below the back of the *corpus callosum*, the band of nerve fibres that connects the two halves of the cerebrum (the topmost, and largest, area of the brain).

The sole function of the gland appears to be the secretion of the hormone *melatonin* in response to changes in light. The amount of melatonin secreted varies over a 24-hour cycle, being greatest at night. Hormone secretion is thought to be controlled through nerve pathways from the retina in the eye; a high light level seems to inhibit secretion. The exact function of melatonin is not understood, but it may help to synchronize circadian (24-hour) and other *biorhythms*.

LOCATION OF PINEAL GLAND

The pineal gland is situated in the brain, below the rear part of the corpus callosum.

pinguecula

A small, noncancerous, yellowish spot that occurs on the *conjunctiva* over the white of the eye. These spots are common in elderly people and may be removed purely for cosmetic reasons. If a pinguecula encroaches on the cornea, it may lead to *pterygium*.

pink-eye

A common name for *conjunctivitis*.

pinna

The fleshy part of the outer ear, consisting of a flap of cartilage and skin. It is also called the auricle.

pins-and-needles

A tingling or prickly feeling in an area of skin that is usually associated with *numbness* and, sometimes, a burning feeling. The medical term for this phenomenon is *paraesthesia*. Transient pins-and-needles is due to a temporary disturbance in the conduction of nerve signals from the skin to the brain. Persistent pins-and-needles may be caused by a nerve disorder, or *neuropathy*.

pinta

A bacterial skin infection, caused by *TREPONEMA CARATEUM*, occurring in remote tropical America. A large spot surrounded by smaller ones appears on the face, neck, buttocks, hands, or feet. After one to twelve months, it is followed by red skin patches that turn blue, then brown,

and finally white. A *penicillin drug* or *tetracycline* clears up the infection, but the skin may be permanently disfigured.

pinworm infestation

An alternative name for *threadworm infestation*.

pioglitazone

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) that is used in combination with other oral hypoglycaemics (either *metformin* or a sulphonylurea) in the treatment of type 2 *diabetes mellitus*. Pioglitazone acts by reducing resistance to insulin in the body tissues. Side effects may include gastrointestinal disturbances, weight gain, and anaemia.

piperazine

An *anthelmintic drug* used to treat *infestation* by *roundworms* and *threadworms*. Possible side effects include abdominal pain, nausea, vomiting, and diarrhoea.

Piriton

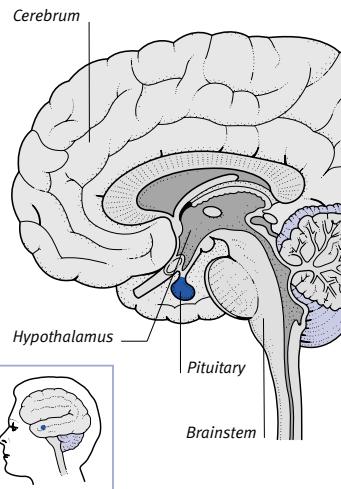

A brand name for the antihistamine drug *chlorphenamine*.

piroxicam

A type of *nonsteroidal anti-inflammatory drug* (NSAID) that is used to relieve the symptoms of types of *arthritis*, and to relieve pain in *bursitis*, *tendinitis*, and after minor surgery. Possible adverse

LOCATION OF PITUITARY GLAND

This master gland is itself controlled by the hypothalamus, located immediately above it.

effects of the drug include nausea, indigestion, abdominal pain, swollen ankles, *peptic ulcer*, and liver problems.

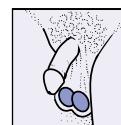

pituitary gland

Sometimes referred to as the master gland, the pituitary is the most important of the *endocrine glands* (glands that release hormones directly into the bloodstream).

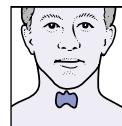

HORMONES SECRETED BY THE PITUITARY GLAND

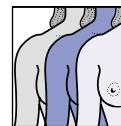

Growth hormone stimulates cell division and protein synthesis in tissues such as bone and cartilage, leading to growth.

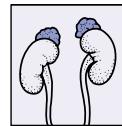

Luteinizing and follicle-stimulating hormones (LH and FSH) help control the function of male and female sex organs.

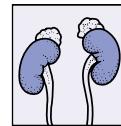

Thyroid-stimulating hormone (TSH) stimulates the thyroid gland to secrete various hormones vital to body metabolism.

Melanocyte-stimulating hormone (MSH) controls skin darkening by stimulating pigment cells (melanocytes).

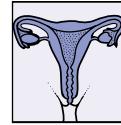

Adrenocorticotrophic hormone (ACTH) stimulates the adrenal glands to secrete hormones, with multiple effects on metabolism.

Antidiuretic hormone (ADH) acts on the kidneys to decrease water loss in the urine and thus reduces urine volume.

Prolactin stimulates milk production, particularly in response to the infants' sucking.

Oxytocin stimulates contraction of the uterus during childbirth and milk release from the breasts.

DISORDERS OF THE PITUITARY GLAND

Any abnormality of the pituitary gland usually means that it produces either too much or too little of one or more hormones, causing changes elsewhere in the body. Locally, serious effects may be caused by enlargement of the gland; for example, it may press on the nearby optic nerves and cause visual defects.

Congenital and genetic disorders

Deficiency of *growth hormone* may be a genetic disorder, or it may be due to congenital absence or undergrowth of the pituitary or to damage to the gland sustained during birth. Whatever the cause, deficiency of growth hormone leads to *short stature*.

Congenital growth hormone deficiency may also be associated with deficiency of other pituitary hormones, notably *ACTH* (adrenocorticotrophic hormone), *gonadotrophin hormones*, and thyroid-stimulating hormone (TSH).

P It regulates the activities of other endocrine glands and many body processes (see *endocrine system*).

For information on disorders that can affect the pituitary gland, see the pituitary gland disorders box.

STRUCTURE

The pituitary gland is a pea-sized structure attached by a stalk of nerve fibres to the *hypothalamus*, a region of the brain just above the gland. The hypothalamus controls pituitary function by nervous stimulation and by secreting substances called hormone-releasing factors.

The pituitary gland consists of three lobes: the anterior, the intermediate, and the posterior.

FUNCTIONS

The three lobes of the pituitary produce a range of hormones. For further information on the individual pituitary hormones and their effects, see the illustrated box, overleaf.

The anterior lobe produces most of the pituitary hormones including *growth hormone*, *prolactin*, *ACTH* (adrenocorticotrophic hormone), *TSH* (thyroid-stimulating hormone), and the *gonadotrophins* *FSH* (follicle-stimulating hormone) and *LH* (luteinizing hormone). The intermediate lobe secretes melanocyte-stimulating hormone (MSH). The secretion of these hormones is triggered by hormone-releasing factors from the hypothalamus.

Tumours

Pituitary tumours are usually noncancerous but may cause either overproduction of pituitary hormones (hyperpituitarism) or underproduction (hypopituitarism), as well as headaches and loss of the visual field.

Injury

Birth injury may cause loss of pituitary function, as may head injuries at any age.

Impaired blood supply

Rarely, the pituitary may suffer deprivation of its blood supply as a result of pressure exerted on its blood vessels from a growing tumour. This may cause a sudden loss of pituitary function, which may be fatal, or a more gradual loss, which produces signs of general underactivity of the gland.

A similar deprivation of blood supply may occur as a complication of massive blood loss associated with childbirth (Sheehan's syndrome). This may lead to

failure of milk production, and a wide range of secondary effects due to the resultant underactivity of other endocrine glands. Impaired blood supply may also occur due to *vasculitis* or pressure on the gland from an *aneurysm* of a nearby artery.

Radiation

Radiotherapy for a pituitary tumour may cause general underactivity of the gland.

INVESTIGATION

Techniques include analysis of pituitary hormones in the blood or urine, and of hormones from other endocrine glands under pituitary control; pituitary *X-rays*, *CT scanning*, or *MRI*; *angiography*, to show blood-vessel displacement by a pituitary tumour; and, possibly, a visual field test (see *vision tests*).

The posterior pituitary lobe secretes *ADH* and *oxytocin*. These hormones are actually produced in the hypothalamus, and pass down nerve fibres to be stored in the posterior lobe until they are needed.

pituitary tumours

Growths in the *pituitary gland*. Pituitary tumours are rare, and usually noncancerous, but they can put pressure on the *optic nerves*, causing visual defects.

CAUSES AND SYMPTOMS

The causes of pituitary tumours are unknown. One type, called an endocrine inactive tumour, causes the destruction of some of the hormone-secreting cells in the pituitary gland. This leads to inadequate hormone production, causing problems such as tiredness, loss of appetite, symptoms of *hypothyroidism* (underactivity of the thyroid gland), and cessation of menstrual periods or reduced sperm production.

Tumours may also cause the gland to produce excessive amounts of certain hormones. Tumours of the anterior lobe can cause various disorders. Overproduction of growth hormone causes *gigantism* or *acromegaly*. Excess thyroid-stimulating hormone (TSH) can lead to *hyperthyroidism*. Excess adrenocorticotrophic hormone (ACTH) can cause Cushing's disease (see *Cushing's syndrome*). An increase in prolactin can

cause *galactorrhoea* (abnormal milk production), *amenorrhoea* (absence of menstrual periods), and *infertility* in women.

In men, it can cause *impotence*, infertility, *feminization*, and galactorrhoea.

Tumours that affect the posterior pituitary may disrupt the production of anti-diuretic hormone (ADH) and lead to *diabetes insipidus*.

Pressure from tumour enlargement may cause headaches, cranial nerve *paralysis*, and defects of vision.

DIAGNOSIS AND TREATMENT

Diagnosis is made using *blood tests* to measure hormone levels; *X-rays*; *MRI* of the pituitary; and, often, *vision tests*.

Treatment may consist of surgical removal of the tumour, *radiotherapy*, hormone replacement, or a combination of these techniques. The drug *bromocriptine* may be used; it can reduce production of certain hormones and shrink some tumours.

pityriasis alba

A common skin condition occurring in childhood and adolescence, particularly in dark-skinned children, that is caused by mild *eczema*. Irregular, fine, scaly, pale patches appear on the face; the patches may be more noticeable after exposure to the sun, because they tan poorly. The condition can usually be cleared up with *emollients*.

pityriasis rosea

A common, mild skin disorder in which a rash of flat, scaly-edged, pink spots or patches appears on the trunk and upper arms. It is not contagious and mainly affects children and young adults. Its cause is unknown, but may be associated with a viral infection.

The first sign is a large, round spot, called a herald patch, on the trunk. The rash appears about a week later. It lasts for four to eight weeks, may cause itching, and usually clears up without treatment. Calamine lotion or *antihistamine drugs* may relieve any itching.

pityriasis versicolor

A common skin condition, also known as tinea versicolor, in which patches of white, brown, or salmon-coloured flaking skin appear on the trunk and neck. The patches are more noticeable on sun-tanned skin; they may be either paler or darker than the surrounding skin. Pityriasis versicolor mainly affects young and middle-aged adults. It is caused by *PITYROSPORUM*, a fungus that exists on most people's skin and normally produces no symptoms. The condition is not contagious.

Treatment is with *selenium sulphate* shampoo, used as a lotion, or with *antifungal drugs* in the form of a cream or lotion. The whole of the affected area must be treated thoroughly, to prevent the infection from recurring. With careful treatment, the infection will clear up in two to three weeks, but the spots may take months to disappear. Antifungal tablets may be needed if the rash does not improve or is very widespread.

pityrosporum

A group of fungi that normally live on the skin or the scalp, but which may sometimes cause *pityriasis versicolor* or may multiply excessively resulting in a condition called *folliculitis* (inflammation of the hair follicles). This overgrowth of fungi may occur in people with lowered resistance to infection; people taking *antibiotic drugs*, *corticosteroids*, or *oral contraceptives*; those with *diabetes mellitus*; and those under emotional stress. It may also be associated with a predisposition to severe dandruff or *seborrhoeic dermatitis*.

Treatment includes addressing any underlying cause and using solutions or creams containing *antifungal drugs*.

pivmecillinam

A type of *penicillin drug*.

pivot joint

A form of *joint* that allows only rotation, such as the joint between the top of the spine and the skull.

pizotifen

An *antihistamine drug* used to prevent migraine in people with frequent, disabling attacks. Adverse effects of taking the drug can include nausea, dizziness, drowsiness, dry mouth, and muscle pains. Prolonged use can in some cases cause weight gain.

PKU test

See *Guthrie test*.

placebo

A chemically inert substance given instead of a drug. Benefit may be gained from a placebo because the person taking it believes it will have a positive effect. As the effectiveness of any drug may be partly due to this "placebo effect", many new drugs are tested against a placebo preparation.

placenta

The organ that develops inside the uterus during pregnancy and that is the link between the blood supplies of the mother and the baby.

STRUCTURE

The placenta develops from the *chorion* (the outermost layer of cells that develops from the fertilized egg). It is attached to the uterus lining and connected to the baby by the *umbilical cord*. The placenta, and the other uterine tissues, which are all expelled at birth, are collectively known as the afterbirth.

FUNCTION

The placenta transfers oxygen, nutrients, and protective *antibodies* from the mother's circulation to the fetus's circulation and removes waste products from the fetal blood into the mother's blood for excretion by her lungs and kidneys.

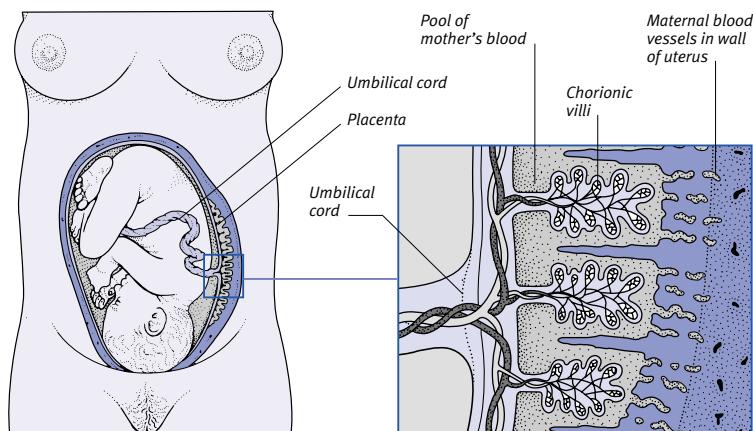

The organ also produces hormones such as *oestrogen*, *progesterone*, and *human chorionic gonadotrophin* (HCG). These hormones enter the mother's blood to help her body adapt to the conditions of pregnancy; they also prepare the breasts for *breast-feeding*. High levels of HCG appear in the woman's urine during early pregnancy, and detection of them in the urine forms the basis of *pregnancy tests*.

placental abruption

Separation of all or part of the placenta from the wall of the uterus before the baby is delivered.

FUNCTION OF THE PLACENTA

The mother's and baby's blood do not mix in the placenta, but are separated from each other by such a thin layer of cells that exchange of nutrients and oxygen (from mother to baby) and waste products (from baby to mother) can occur between the two blood circulations.

How the mother's and baby's blood are brought together

The baby's blood flows via the umbilical cord to the placenta, where it enters numerous tiny blood vessels arranged in "fingers" (chorionic

villi). These are surrounded by a pool of maternal blood brought to the placenta by a major artery.

CAUSES

The exact cause of placental abruption is not known, but it is more common in women who have long-term *hypertension* (high blood pressure) and in those who have previously had the condition or who have had several pregnancies. Smoking and high alcohol intake may also contribute to the risk of placental abruption.

SYMPOTMS

Symptoms usually occur suddenly and depend on how much of the placenta has separated from the wall of the uterus. They include vaginal bleeding, which can be severe haemorrhaging in complete separation; abdominal cramps or backache; severe, constant abdominal pain; and reduced fetal movements.

TREATMENT

If the bleeding does not stop, or if it starts again, it may be necessary to induce labour (see *induction of labour*). A small placental abruption is usually treated with bed-rest in hospital. In more severe cases of placental abruption, an emergency *caesarean section* is often necessary to save the life of the fetus. A *blood transfusion* is also sometimes required.

placenta praevia

Implantation of the *placenta* in the lower part of the uterus, near or over the cervix. The condition varies in severity from marginal placenta praevia, when the placenta reaches the edge of the cervical opening, to complete placental praevia, when the entire opening of the cervix is covered.

SYMPOTMS

Marginal placenta praevia may have no adverse effect. More severe cases often cause painless vaginal bleeding in late pregnancy, as placental tissue separates from the wall of the uterus.

TREATMENT

If the bleeding is slight and the pregnancy still has several weeks to run, bed rest in hospital may be all that is necessary. The baby will probably be delivered by *caesarean section* at the 38th week. If the bleeding is heavy or if the pregnancy is near term, an immediate delivery is carried out.

placenta, tumours of

See *choriocarcinoma*; *hydatidiform mole*.

plagiocephaly

Any asymmetry or distortion in the shape of the head. Plagiocephaly is usually due to irregularity in the closure of the *sutures* (fixed joints) between the skull bones.

SPREAD OF PLAGUE**Stage 1**

The bacterium that causes plague (*Yersinia pestis*) circulates mainly among wild rodents; the bacterium is spread from one rodent to another by rodent fleas.

Stage 2

Sometimes so many wild rodents die that the fleas transfer to and infest new wild hosts, such as rats, or even humans who enter plague-affected areas.

Stage 3

The real danger is of plague spreading to, and killing, large numbers of urban rats; rat fleas might then transfer from dead rats to humans en masse, causing an epidemic.

DIAGNOSIS AND TREATMENT

A sample of fluid from a bubo, or a sputum sample, is taken to establish the presence of plague bacteria and confirm the diagnosis. Possible treatments are *streptomycin* and *tetracycline drugs*.

plantar fasciitis

Fasciitis (inflammation of a layer of connective tissue) affecting the sole of the foot, especially the heel.

plantar wart

See *wart*, *plantar*.

plants, poisonous

Several species of plant, including foxglove, holly, deadly nightshade, and laburnum, are poisonous or can cause severe allergic reactions.

Paradoxically, many poisonous plants are also sources of useful drugs. Examples include deadly nightshade, from which *atropine* is made, and foxglove, from which *digitalis drugs* are created.

CAUSES AND SYMPTOMS OF POISONING

Toxins from plants can cause poisoning either through contact with the skin, if a person touches or handles the plants, or internally, if a person (usually a child) ingests them.

Skin contact Nettles, hogweed, poison ivy, and primula cause skin reactions, including rash, itching, and blistering, on contact. In some people, these reactions can be extremely severe.

Internal poisoning Plants that are poisonous to eat include foxglove, aconite, hemlock, laburnum seeds, and holly and deadly nightshade berries. Internal poisoning most commonly affects young children who have consumed colourful berries. Symptoms of poisoning vary according to the plant but may include abdominal pain, vomiting, flushing, breathing difficulty, *delirium*, and *coma*. Urgent medical attention is required.

TREATMENT

Skin reactions can be treated by washing the area affected (and any clothes that have come into contact with the plant), and applications of alcohol or *calamine lotion*. *Corticosteroid drugs* may be prescribed for severe reactions.

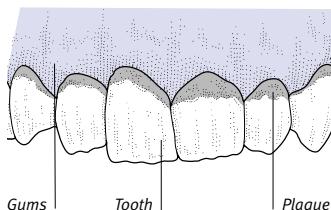

Internal poisoning usually requires *gastric lavage*. Fatal poisoning is rare. (See also *mushroom poisoning*.)

plaque

The term given to an area of *atherosclerosis* (fatty deposits within arteries). The plaques are symptomless until they

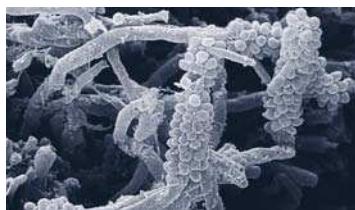

DEVELOPMENT OF PLAQUE

Plaque starts with a deposit of salivary mucus on the teeth. The mucus is colonized by various types of bacteria. Initially, the predominant bacteria are spherical cocci. After a day or two, long filamentous colonies of bacteria spread over the surface of the teeth.

Areas of plaque build-up

Plaque develops predominantly at the margin of teeth and gums. If the gums are inflamed or otherwise unhealthy, the plaque tends to develop more rapidly.

Mature plaque

This picture, taken with a scanning electron microscope (SEM), shows a mass of filamentous bacterial colonies in plaque, magnified about 3,000 times.

are large enough to reduce blood flow or until the surface of a plaque is disturbed, causing *thrombosis* (clotting of blood). Plaques in coronary arteries, which supply blood to the heart, cause *coronary artery disease*.

plaque, dental

A rough, sticky coating on the teeth consisting of saliva, bacteria, and food debris. It is the chief cause of tooth decay (see *caries, dental*) and *gingivitis* (gum disease), and forms the basis of a hard deposit (see *calculus, dental*).

Some of the *microorganisms* found in plaque, particularly the bacterium *STREPTOCOCCUS MUTANS*, break down sugar in the remains of *carbohydrate* food that sticks to the mucus, creating an acid that can erode tooth enamel.

plasma

The fluid part of *blood* that remains if the blood cells are removed. Plasma is a solution that contains many nutrients, salts, and proteins.

plasma D-dimers

Substances formed in the body by the breakdown of blood clots (see *blood clotting*); for example, when the body clears blocked blood vessels. Tests that can detect plasma D-dimers can be helpful in monitoring conditions such as *disseminated intravascular coagulation* or in deciding whether someone may have had a pulmonary embolism or deep vein thrombosis (see *thrombosis, deep vein*). These tests are not used to make or confirm a diagnosis, but the

possibility of pulmonary embolism or deep vein thrombosis may be ruled out if plasma D-dimers are not present.

plasmapheresis

A procedure for removing, or reducing the concentration of, unwanted substances in the blood; it is also known as plasma exchange.

Blood is withdrawn from the body in the same way as for a *blood donation* and the plasma portion of the blood is removed by machines known as cell separators. The blood cells are mixed with a plasma substitute and re-turned to the circulation in the same way as for a *blood transfusion*.

Plasmapheresis is used to remove damaging *antibodies* or *immune complexes* (antibody–antigen particles) from the circulation in various *autoimmune disorders* such as *myasthenia gravis* and *Goodpasture's syndrome*.

plasma proteins

Proteins that are present in blood *plasma*. These proteins include *albumin*, *blood clotting* proteins, and *immuno-globulins* (which are active in the immune system). In addition to their specific roles, the plasma proteins help to maintain blood volume by preventing the loss of water from the blood into the tissues. The proteins keep the water in the blood by a phenomenon called osmotic pressure (see *osmosis*). If proteins are lost from the plasma, excessive amounts of fluid may build up in the tissues; this fluid build-up is a condition called *oedema*.

plasminogen activator

See *tissue plasminogen activator*.

Plasmodium

A group of protozoa (single-celled organisms) including the microorganisms that are responsible for *malaria*. Once they are introduced into the body, usually via a mosquito bite, plasmodia live in liver cells, *red blood cells*, and in the bloodstream.

plaster cast

See *cast*.

plaster of Paris

A white powder that is made of a calcium compound that, when mixed with water, produces a paste that can be shaped before it sets. Plaster of Paris is used for constructing *casts* and making dental models (see *impression, dental*).

plastic surgery

Any operation carried out to repair or reconstruct skin and tissue that has been damaged or lost, is malformed, or has changed with aging. (Any procedures that are performed mainly to improve the appearance of a healthy person are described as *cosmetic surgery*.)

Plastic surgery is often performed to repair damage caused by severe burns or injuries, cancer, or some operations, such as *mastectomy* (removal of breast tissue). Some congenital conditions may also require plastic surgery; these include *cleft lip and palate*, *hypospadias* (a defect in the penis), and imperforate anus (see *anus, imperforate*).

Techniques that are used in plastic surgery include *skin grafts*, *skin flaps*, and *Z-plasty*; these may be combined with *implants* or a *bone graft*.

-plasty

A suffix meaning “shaping by surgery”. The term is usually used to describe various procedures in *plastic surgery*, such as *rhinoplasty* (surgery on the nose) and *mammoplasty* (reshaping or reconstruction of the breast).

platelet

The smallest type of *blood cell*; also called a *thrombocyte*. Platelets play a major role in *blood clotting*. When they are activated, for example by contact with damaged blood-vessel walls, they clump together at injury sites, releasing chemicals that constrict the damaged blood vessels and trigger the process of

Scanning electron micrograph of platelets

This SEM shows activated platelets (also called thrombocytes) magnified 13,000 times. Platelets play an important role in blood clotting.

clot formation. A deficiency of platelets (a condition called *thrombocytopenia*) can cause certain *bleeding disorders*.

platyhelminth

A flat or ribbon-shaped parasitic worm (see *liver fluke*; *schistosomiasis*; *tapeworm*).

play therapy

A method used in the *psychoanalysis* of young children, based on the principle that all play has some symbolic significance. Watching a child at play helps a therapist diagnose the source of the child's problems; the child can then be helped to "act out" thoughts and feelings that are causing anxiety.

plethora

A florid, bright-red, flushed complexion. It may be caused by dilation of blood vessels, or, less commonly, by *polycythaemia* (excessive numbers of red blood cells).

plethysmography

A way of estimating the blood flow in vessels by measuring changes in the size of a body part. Plethysmography of the penis is sometimes used to investigate *impotence* in men by establishing whether or not a man has erections while sleeping.

pleura

A thin, two-layered membrane, one layer covering the outside of the lungs and the other lining the inside of the chest cavity. Fluid in the pleural cavity (the space between the two layers) provides lubrication, allowing for the smooth expansion and contraction of the lungs during breathing.

DISORDERS

Pleurisy (inflammation of the pleura) is usually due to a lung infection, such as *pneumonia* or *tuberculosis*, and may lead to **pleural effusion** (a buildup of excess fluid between the layers of the pleura).

Pneumothorax (air in the pleural cavity) may result in collapse of a lung; the condition may occur spontaneously or may result from a penetrating injury. Cancerous tumours (see *mesothelioma*) may also develop in the pleura.

pleural effusion

An accumulation of fluid between the layers of the *pleura* (the membrane lining the lungs and chest cavity). Pleural effusion may be caused by lung infections such as *pneumonia* or *tuberculosis*, or other lung disorders such as *pulmonary embolism*, or *mesothelioma* (a tumour of the pleura). It may also result from *heart failure* or *cancer*. Pleural effusion may affect one or both sides of the chest. The excess fluid puts pressure on the lung beneath, gradually making breathing difficult.

Diagnosis is confirmed by *chest X-ray*. Some fluid may be removed with a needle and syringe and examined to find the cause of the condition. A *biopsy* (tissue sample) of the pleura may also be needed. The underlying cause is treated; fluid may also be drained off to relieve breathing problems.

pleurisy

Inflammation of the *pleura* (the membrane lining the lungs and chest cavity). Causes include lung infections, such as *pneumonia*, or, more rarely, *pulmonary embolism*, *lung cancer*, or *rheumatoid arthritis*. Pleurisy causes a sharp chest pain, which is worse when breathing in; this pain is due to the inflamed layers of the membrane rubbing together. Treatment of the condition is aimed at the underlying cause, and *analgesic drugs* (painkillers) are also given.

pleurodynia

Pain in the chest, also known as Bornholm disease. Pleurodynia is caused by *coxsackievirus B* infection. It often occurs in epidemics and usually affects children.

There is sudden severe pain in the lower chest or upper abdomen, with fever, sore throat, headache, and malaise. The disease usually settles in three to four days without treatment.

plexus

A network of interwoven nerves or blood vessels. Examples include the *solar plexus* (the large network of nerves just behind the stomach) and the *brachial plexus* (a network of nerves in the neck and upper arm).

plication

A surgical procedure in which tucks are made in the walls of a hollow organ and then stitched in order to decrease the size of the organ.

Plummer–Vinson syndrome

Difficulty in swallowing due to webs of tissue forming across the upper *oesophagus*. The syndrome often occurs along with severe iron-deficiency *anaemia* and affects middle-aged women.

plutonium

A radioactive metallic element which occurs naturally only in *uranium* ores; it is produced artificially in breeder reactors. It is used as a fuel in nuclear reactors and nuclear weapons. The element is highly toxic if it enters the body, because it emits high levels of radiation and is absorbed into the bone marrow, where it may remain for many years.

PMS

The abbreviation often used for *premenstrual syndrome*.

PMT

The abbreviation for premenstrual tension, an alternative name for *premenstrual syndrome*.

pneumaturia

The presence of gas, including air, in the *urine*. Pneumaturia usually indicates that a *fistula* (abnormal channel) has developed between the bladder and the intestine.

pneumo-

A prefix meaning related to the lungs, to air, or to the breath.

pneumococcus

A common name for the bacterium *STREPTOCOCCUS PNEUMONIAE* (see *Streptococcal infections*).

pneumoconiosis

Any of a group of lung diseases that are caused by the inhalation of certain mineral dusts. Dust particles of less than 0.005 mm across can reach the air sacs in the lungs (see *alveolus*, *pulmonary*); they may accumulate and cause thickening and scarring. As a result, the lungs may become less efficient at supplying oxygen to the blood.

TYPES AND CAUSES

The main types of pneumoconiosis are *asbestosis* (see *asbestos-related diseases*), coal workers' pneumoconiosis,

and silicosis, caused by silica dust. These diseases primarily affect workers over 50 years of age. However, the incidence is falling due to better preventive measures.

SYMPOTMS AND COMPLICATIONS

The main symptom of pneumoconiosis is shortness of breath. In severe cases, *cor pulmonale* (right-sided heart failure due to lung damage) or *emphysema* (destruction of the air sacs in the lungs) may develop. The risk of *tuberculosis* is increased in coal workers' pneumoconiosis and silicosis; the risk of *lung cancer* is increased in asbestos. Smoking further increases the risk.

DIAGNOSIS AND TREATMENT

Pneumoconiosis is often detected by a *chest X-ray* before symptoms develop. Diagnosis is also based on a history of exposure to dusts, medical examination, and *pulmonary function tests*.

There is no treatment for the condition apart from treating any complications. Further exposure to any dust must be avoided.

pneumocystis pneumonia

A lung infection caused by *PNEUMOCYSTIS CARINII*, a type of *protozoa*. Pneumocystis pneumonia is an *opportunistic infection*, which is dangerous only to people with impaired resistance to infection. It is particularly common in those with *AIDS*. Symptoms include fever, dry cough, and shortness of breath, and may last for several weeks or months.

Diagnosis is made by examination of sputum or a lung *biopsy* (tissue sample). High doses of *antibiotic drugs* (commonly co-trimoxazole) may eradi-

cate the infection; lower doses are used in the long term to prevent infection in people at increased risk.

pneumonectomy

Surgery carried out to remove a *lung*.

pneumonia

Inflammation of the lungs usually due to infection. There are two main types: lobar pneumonia and bronchopneumonia. Lobar pneumonia first affects one lobe of a lung. In the condition bronchopneumonia, inflammation initially starts in the bronchi and bronchioles (airways), then spreads to affect patches of tissue in one or both lungs.

CAUSES

Pneumonia is usually caused by various types of infection. Most cases are due either to viruses, such as adenovirus or respiratory syncytial virus, or to bacteria, such as *STREPTOCOCCUS PNEUMONIAE*, *HAEMOPHILUS INFLUENZAE*, *STAPHYLOCOCCUS AUREUS*, and *MYCOPLASMA PNEUMONIAE*.

Another form is aspiration pneumonia, due to accidental inhalation of vomit. Aspiration pneumonia usually occurs in people whose cough reflex is not functioning, such as those who have drunk excessive amounts of alcohol or taken certain illegal drugs, or people who have suffered a head injury.

SYMPOTMS AND COMPLICATIONS

Symptoms usually include fever, chills, shortness of breath, a sharp chest pain, and a cough that produces yellow-green *sputum* and occasionally blood.

Potential complications include *pleural effusion* (fluid around the lung), *pleurisy* (inflammation of the membrane lining

the lungs and chest cavity), a lung *abscess* (collection of pus), and *septicaemia* (blood poisoning).

DIAGNOSIS AND TREATMENT

Diagnosis is made by physical examination, *chest X-ray*, and examining sputum and blood for microorganisms. Treatment depends on the cause, and usually includes *antibiotic drugs*. *Aspirin* or *paracetamol* may be given to reduce fever, and, in severe cases, *oxygen therapy* and artificial *ventilation* may be needed.

In most cases, recovery usually occurs within two weeks.

pneumonitis

Inflammation of the lungs that may cause coughing, breathing difficulty, and wheezing. Causes include an allergic reaction to dust containing animal or plant material (see *alveolitis*) and exposure to radiation (see *radiation hazards*). Pneumonitis may also occur as a side effect of drugs, such as *amiodarone* and *azathioprine*.

pneumothorax

A condition in which air enters the pleural cavity (the space between the layers of membrane lining the lung), causing partial or total collapse of the lung. The air may enter the lungs from the airways or from outside the body.

CAUSES

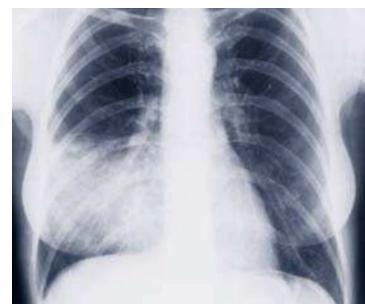

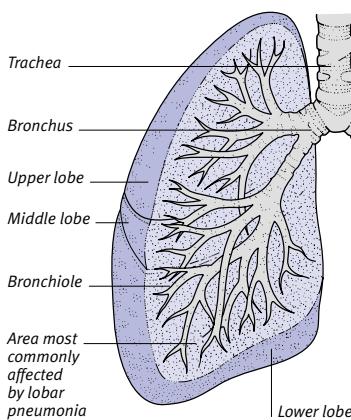

The most common cause is the spontaneous rupture of an enlarged alveolus (air sac). This occurrence is much more common in men than in women; it usually affects tall, thin young men who have no underlying lung disease. Other possible causes include a penetrating

PNEUMONIA

Pneumonia is not a single disease, but the name for several types of lung inflammation usually caused by infectious organisms. In some cases, accidental inhalation of vomit or a liquid may start an infection. The symptoms, treatment, and outcome vary greatly, depending on the cause and on the general health of the patient.

Lobar pneumonia

In this type of pneumonia, the inflammation is usually confined to just one lobe of one lung, often a lower lobe.

Chest X-ray in lobar pneumonia

The X-ray clearly shows lobar pneumonia in the patient's right lung (on the left in the image). The blotchy white areas within the darker areas correspond to patches of inflamed lung.

chest wound that allows air into the pleural cavity, or a fractured rib that tears the lung beneath it.

SYMPOTMS

The main symptoms of pneumothorax are chest pain or shortness of breath, which varies depending on the size of the pneumothorax. If air continues to leak, the pneumothorax may grow to produce a tension pneumothorax. This condition may be life-threatening. It causes an area of high pressure that compresses the lung and heart tissues, preventing the passage of oxygen-rich blood from the lungs to the heart.

DIAGNOSIS AND TREATMENT

Diagnosis is confirmed by *chest X-ray*. A small pneumothorax may disappear in a few days without treatment. A larger one, or one associated with underlying lung disease, may need hospital treatment. This involves removing the air through a tube with a one-way valve, known as a chest drain, to allow the lung to reinflate fully.

pocket, gingival

A feature of marginal *periodontitis*.

podiatry

Another name for *chiropody*, a paramedical speciality concerned with the feet.

podophyllin

A drug used to treat genital warts (see *warts, genital*). Podophyllin may cause irritation of the treated area and severe toxicity on excessive application.

poison

A substance that, in small amounts, disrupts the structure and/or function of cells. (See also *drug poisoning; poisoning*.)

poisoning

Poisons may be swallowed, inhaled, absorbed through the skin, or injected under the skin (as with an insect sting). They may also originate within the body, for example when bacteria produce *endotoxins*, or when *metabolic disorders* produce poisonous substances or allow them to accumulate. Poisoning may be acute, if a large amount of poison enters the body in a short time, or chronic, resulting from a gradual accumulation of poison that is not quickly eliminated from the body.

Unintentional poisoning occurs most commonly in young children. Adults may be poisoned by mistaking the dosage of a prescribed drug (see *drug poisoning*), by taking very high doses of vitamin or mineral supplements, by ex-

posure to poisonous substances in industry, or by *drug abuse*. Poisoning may also be a deliberate attempt to commit *suicide*.

Antidotes may be available to counteract the effects of the poison.

polio

An abbreviation for *poliomyelitis*.

poliomyelitis

Also called polio, a highly infectious disease caused by the polio virus. It is usually mild, but in serious cases, it attacks the brain and spinal cord, sometimes causing paralysis or death.

CAUSE AND INCIDENCE

The virus is spread from the faeces of infected people to food. Airborne transmission also occurs. In countries with poor hygiene and sanitation, most children develop immunity through being infected early in life, when the infection rarely causes serious illness. In countries with better sanitation, this does not occur and, if children are not vaccinated, epidemics can occur. In the UK, however, polio is now very rare due to a vaccination programme.

SYMPOTMS

Most infected children have no symptoms at all. In others, however, there is usually an *incubation period* of seven to 14 days, after which a slight fever, sore throat, headache, and vomiting occur.

Most children recover completely after a few days. In some, however, inflammation of the *meninges* (membranes surrounding the brain and spinal cord) may develop. This condition causes fever, severe headache, stiff neck and back, and aching muscles, sometimes with widespread twitching. In a few cases, extensive paralysis, usually of the legs and lower trunk, then develops within a few days. If the infection spreads to the *brainstem*, the affected person may find it difficult or impossible to breathe and swallow.

DIAGNOSIS

Diagnosis is made from a sample of cerebrospinal fluid (see *lumbar puncture*), a throat *swab*, a faeces sample, or *blood tests* for antibodies to the virus. Paralysis occurring with an acute feverish illness is characteristic of severe polio, and an immediate diagnosis can often be made.

TREATMENT

There is no effective drug treatment for polio. Nonparalytic patients usually need bed rest and *analgesic drugs* (painkillers). If the person is paralysed, *physiotherapy* and, in some cases, *catheterization, trache-*

ostomy (surgical creation of an opening in the windpipe for a breathing tube), and *artificial ventilation* are needed.

OUTLOOK

Recovery from nonparalytic polio is complete. More than half of those with paralysis make a full recovery, fewer than a quarter are left with severe disability, and fewer than 1 in 10 dies.

PREVENTION

In the UK, vaccination against polio is given at approximately two, three, and four months, with a booster dose given between the ages of three and five, and again on leaving school (see *immunization*). Parents and carers should also keep their immunization up-to-date.

pollen

Dustlike grains produced by the male sexual organs of plants for fertilizing the female organs. Pollens from flowers, grasses, and some other plants may produce allergic reactions (see *allergy*) in humans and cause disorders such as hay fever (see *rhinitis, allergic*).

pollution

Contamination of the environment by *poisons*, radioactive substances, *microorganisms*, or other wastes.

poly-

A prefix meaning "many" or "much".

polyarteritis nodosa

Also called periarteritis nodosa, an uncommon form of *vasculitis* (inflammation of blood vessels), affecting medium-sized arteries. Areas of arterial wall become inflamed, weakened, and liable to *aneurysms* (ballooned-out segments). The severity of the condition depends on the arteries that are affected and how much they are weakened.

CAUSE AND INCIDENCE

The cause seems to be an *immune system* disturbance, sometimes triggered by exposure to the *hepatitis B* virus. It is most common in adults and affects men more than women.

SYMPOTMS

Early symptoms of polyarteritis nodosa include fever, aching muscles and joints, general malaise, loss of appetite and weight, and, sometimes, nerve pain. There may also be *hypertension* (high blood pressure), skin ulceration, and *gangrene* (localized tissue death). If the coronary arteries are affected, *myocardial infarction* (heart attack) may occur. Many patients suffer abdominal

pain, nausea, vomiting, diarrhoea, and blood in the faeces. The condition may occasionally lead to *kidney failure*.

DIAGNOSIS, TREATMENT, AND OUTLOOK

Diagnosis is made by *biopsy* (tissue sampling) and *angiography*. Large doses of *corticosteroids*, and in some cases *immunosuppressants*, may allow survival for at least five years. Without treatment, few patients survive for this length of time.

polyarthritis

Any form of *arthritis* (joint inflammation) that affects several joints at once. It may be a complication of infections such as *rubella*, *gastroenteritis*, or sexually transmitted infections (see *reactive arthritis*). Other arthritic conditions that can cause polyarthritis include *rheumatoid arthritis*, *osteoarthritis*, and *juvenile chronic arthritis*.

polycystic kidney

See *kidney, polycystic*.

polycystic ovary syndrome

A condition, previously known as Stein–Leventhal syndrome, that is characterized by multiple *ovarian cysts* together with oligomenorrhoea (scanty periods) or *amenorrhoea* (absence of periods), reduced fertility, *hirsutism* (excessive hairiness), and *obesity*. Most women with the syndrome begin menstruation at a normal age, but between the ages of 15 and 30 periods become irregular and then cease. Hirsutism and obesity occur in about half of all cases.

CAUSES

The condition is now thought to result from *insulin* resistance, which leads to the overproduction of insulin. This situation is associated with increased levels of *androgen hormones*, giving rise to symptoms. Polycystic ovary syndrome may also have a genetic element.

DIAGNOSIS AND TREATMENT

A diagnosis of polycystic ovary syndrome is based on the patient's history, measurement of hormone levels, and *ultrasound scanning* of the ovaries. Treatment depends on which aspect of the condition most concerns the patient. Weight reduction often brings about an improvement in all other symptoms and the return of regular periods. *Metformin*, an *oral hypoglycaemic* drug, may be used to reduce insulin resistance and as an aid to weight loss; hirsutism may respond to treatment with an anti-androgen drug, such as *cypertroponerone*; fertility treatment with the anti-oestrogen drug *clomifene* is often successful.

OUTLOOK

In the long term, women with polycystic ovary syndrome are at an increased risk of developing *diabetes mellitus* during pregnancy and in later life. Obesity leads to a greater risk of *atherosclerosis* and *hypertension* (high blood pressure). High levels of oestrogen may also increase the risk of developing endometrial cancer (see *uterus, cancer of*).

polycythaemia

A condition in which an increased production of red *blood cells* leads to an unusually large number of them in the blood. This disorder is usually caused by another disorder or by *hypoxia* (reduced oxygen in the blood and body tissues), in which cases it is called secondary polycythaemia. If the increase in red blood cells occurs for no apparent reason, it is called polycythaemia vera or primary polycythaemia.

SECONDARY POLCYTHAEMIA

Secondary polycythaemia occurs naturally at high altitudes due to the reduced oxygen level. It can also result from a disorder that impairs the oxygen supply to the blood, such as chronic bronchitis (see *pulmonary disease, chronic obstructive*). In these cases, the low level of oxygen in the blood stimulates the kidneys to produce a hormone called erythropoietin, which in turn stimulates the bone marrow to produce more red cells and thus compensate for the lack of oxygen. Secondary polycythaemia may also be secondary to *liver cancer*, some kidney disorders, or heavy smoking.

Descending to sea level, or effective treatment of an underlying disorder, returns the blood to normal.

POLCYTHAEMIA VERA

Polycythaemia vera is a rare disorder that mainly affects people over the age of 40. The large number of red blood cells causes increased volume and thickening of the blood, which may lead to headaches, blurred vision, and *hypertension* (high blood pressure). There may also be flushed skin, dizziness, night sweats, and widespread itching. The *spleen* is often enlarged.

Possible complications include a tendency to bleed easily or for the blood to clot; *stroke*; and disorders affecting the bone marrow, such as *myelofibrosis* or acute leukaemia (see *leukaemia, acute*).

Diagnosis is made from a physical examination and *blood tests* and by ruling out other possible causes of poly-

cythaemia. Treatment is by *venesection* (bloodletting) sometimes in combination with *anticancer drugs* or with radioactive phosphorus. This enables most patients to survive for 10 to 15 years.

polydactyly

A birth defect in which there is an excessive number of fingers or toes. The extra digits may be fully formed or they may be fleshy stumps. Polydactyly often runs in otherwise normal families; however, it may also occur as part of *Laurence–Biedl–Moon syndrome* or some other congenital syndromes.

Polydactyly

Polydactyl digits are sometimes fully formed but are most often rudimentary (undersized). They are usually removed surgically during childhood.

polydipsia

Persistent excessive thirst (see *thirst, excessive*). Examples of conditions that can cause polydipsia include *diabetes mellitus* and *diabetes insipidus*.

polyhydramnios

Excess *amniotic fluid* surrounding the fetus during pregnancy.

CAUSES

The condition often has no known cause. It sometimes occurs if the fetus has a malformation that makes normal swallowing impossible, or if the pregnant woman has *diabetes mellitus*.

SYMPTOMS

The excess amniotic fluid usually accumulates during the second half of pregnancy, producing symptoms from about week 32. The main symptom is abdominal discomfort. Other possible symptoms are breathlessness and swelling of the legs (see *oedema*). The uterus is larger than expected.

Occasionally, acute polyhydramnios occurs. Fluid collects rapidly, causing abdominal pain, breathlessness, nausea, vomiting, and leg swelling. The abdomen becomes tense, and the skin is shiny. Premature labour may occur.

DIAGNOSIS AND TREATMENT

The condition is usually evident from a physical examination, but *ultrasound scanning* may be needed. In mild cases, only rest is needed. In more severe cases, amniotic fluid may be withdrawn using a needle. In late pregnancy, *induction of labour* may be performed.

polymerase chain reaction (PCR)

A method of rapidly copying *DNA* sequences so that they can be analysed.

polymorphic light eruption (PLE)

A common skin condition that occurs in people who are sensitive to light (see *photosensitivity*) and results from exposure to *ultraviolet light* rays in sunlight. PLE is thought to be a form of delayed *allergy*, but the cause is unknown.

Light causes an itchy rash of papules (raised bumps) to develop on exposed areas of skin. The rash may last for several days. Sunblock should be used as a preventative measure. A mild case of PLE may be treated by applying a topical *steroid*. In severe cases, a short course of oral steroids can be used to prevent or treat an attack. Controlled exposure to ultraviolet light (see *phototherapy*) may reduce the symptoms in resistant cases.

polymyalgia rheumatica

An uncommon disease that occurs in elderly people, which is marked by pain and stiffness in the muscles of the hips, thighs, shoulders, and neck. Symptoms are worse in the mornings. The cause is unknown, but the condition may be associated with *temporal arteritis*. It is unusual before the age of 50.

The diagnosis is often difficult to confirm; it is based on the patient's history, a physical examination, and *blood tests* (including an *ESR*). If temporal arteritis is suspected, a *biopsy* (removal of a tissue sample for analysis) may be performed on an artery at the side of the scalp. *Corticosteroid drugs* usually improve the condition within a few days.

polymyositis

A rare disease in which the muscles are inflamed and weak.

polymyxins

A group of *antibiotic drugs* derived from the bacterium *BACILLUS POLYMYXA*. Polymyxins, which include the drug *colistin*, are given to treat eye and skin infections.

polyp

A growth that projects, usually at the end of a stalk, from the lining of the nose, the cervix, the intestine, the larynx, or from any other *mucous membrane*. Some types of polyp are liable to develop into cancer, and these types are surgically removed.

polypeptide

A compound made up of many *peptides*.

polypharmacy

The practice of prescribing several drugs to one person at the same time. Combinations of drugs may be more effective than single drugs and may reduce the risk of drug resistance. However, polypharmacy increases the risk of drug interactions and, as a result, the risk of adverse effects.

polyposis, familial adenomatous

A rare, inherited disorder, also known as *polyposis coli*, in which many *polyps* are present throughout the large intestine, but mainly in the colon. If familial adenomatous polyposis (FAP) is not treated, cancer of the colon (see *colon, cancer of*) is almost certain to develop.

The polyps may appear from the age of ten. They may cause bleeding and diarrhoea; however, there are often no symptoms until cancer has developed. The polyps are detected by *colonoscopy* (examining the interior of the colon with a viewing instrument).

There is a 50 per cent chance that a child of an affected person will inherit the disease, so medical surveillance is necessary from about the age of 12. Individual polyps may be heat-treated (see *cauterization*). Since there is a high risk of developing cancer; a *colectomy* and *ileostomy* are often performed.

polysaccharide

A *carbohydrate* that is formed from many *monosaccharides* (simple sugar molecules) joined together. Examples of polysaccharides include *glycogen* (the main form in which carbohydrates are stored in the body); *starch*, a form of carbohydrate obtained from fruits, vegetables, and cereals; and *cellulose*, an indigestible material found in plant-based foods (see *fibre, dietary*).

Polytar

A brand name for liquid preparations containing coal tar, used in treatments for *dandruff*, *eczema*, and *psoriasis*.

polyunsaturated fats

Fats (see *fats and oils*) with relatively few hydrogen atoms in their chemical structure. Polyunsaturated fats tend to protect against cardiovascular disease.

polyuria

See *urination, excessive*.

PoM

The abbreviation for *prescription-only medicine*.

gompholyx

An acute form of *eczema* in which itchy blisters form on the palms and/or soles. The condition, also called dyshydrotic eczema, is sometimes due to an allergic response. Rarely, it is associated with *fungal infections* of the skin. Treatment is with an *emollient* and topical application of a *corticosteroid drug*.

pons

The middle part of the *brainstem*.

Ponstan

A brand name for the nonsteroidal anti-inflammatory drug *mefenamic acid*.

POP

An abbreviation for "progesterone-only pill" (see *oral contraceptives*) and for "plaster of Paris" cast.

popliteal cyst

A fluid-filled sac that develops at the back of the knee. The cysts may occur in both adults and children, but for different reasons.

In children, the condition may be due to a swollen *bursa* (fluid-filled pad) behind the knee; the cause is unknown, but not related to any knee problem. These cysts usually cause no symptoms and disappear spontaneously.

In adults, the cysts usually result from conditions that cause chronic swelling or an accumulation of fluid in the knee joint. One possible cause is *osteoarthritis*; others include injuries to the *meniscus* (cartilage inside the knee) or to the ligaments, which allow *synovial fluid* (which lubricates joints) to escape from the joint capsule.

Most popliteal cysts disappear without treatment, although some may rupture, resembling a *deep vein thrombosis* (DVT). A diagnosis of DVT must be excluded before treatment with rest and *analgesic drugs*. In some cases, the cyst may need to be removed surgically.

pore

A tiny opening, usually in the skin.

porphyria

Any of a group of rare, often inherited disorders caused by the accumulation of substances called porphyrins.

CAUSES

Porphyrins are chemicals formed in the body during the manufacture of haem (a component of *haemoglobin*, the oxygen-carrying pigment in red blood cells). A block in this process causes a buildup of porphyrins, which can act as a poison. Such blocks may result from various genetic *enzyme* deficiencies. Porphyria may also be due to poisoning.

TYPES AND SYMPTOMS

There are six types of porphyria, each of which has different symptoms. Sufferers often have a rash or blistering brought on by sunlight, and may have abdominal pain and nervous system disturbances due to the effects of certain drugs or alcohol.

Acute intermittent porphyria This form usually appears in early adulthood, causing abdominal pain, and often limb cramps, muscle weakness, and psychiatric disturbances. The patient's urine turns red when left to stand. *Barbiturate drugs, phenytoin, oral contraceptives*, and certain other drugs precipitate attacks.

Variegate porphyria This condition has similar effects to acute intermittent porphyria, and may be caused by the same drugs. An additional symptom is blistering on skin that is exposed to sunlight.

Hereditary coproporphyria This form also has similar effects to acute intermittent porphyria, and may cause additional skin symptoms.

Protoporphyria In this form of porphyria, mild skin symptoms appear after exposure to sunlight.

Porphyria cutanea tarda This condition causes blistering of skin that is exposed to the sun, but with no disturbances of the digestive or nervous systems. Wounds are slow to heal, and urine is sometimes pink or brown. Many cases are precipitated by liver disease.

Congenital erythropoietic porphyria This is the rarest and most serious form of porphyria. It causes red discolouration of urine and teeth, excessive hair growth, severe skin blistering and ulceration, and haemolytic *anaemia*. Death may occur in childhood.

DIAGNOSIS AND TREATMENT

Diagnosis is made from abnormal levels of porphyrins in the urine and faeces. Treatment of porphyria is difficult.

Avoiding sunlight and/or precipitating drugs is the most important measure. Acute intermittent porphyria, hereditary coproporphyria and variegate porphyria may be helped by the administration of *glucose* or hemin (a substance that is chemically related to haem). Cases of porphyria cutanea tarda may sometimes be helped by *venesection* (withdrawing blood from a vein).

portal hypertension

Increased blood pressure in the portal vein, which carries blood from the stomach, intestines, and spleen to the liver. The pressure causes *oesophageal varices* (widened veins in the oesophagus), which may rupture and cause internal bleeding. In addition, fluid is forced out of the overloaded portal vein, resulting in *ascites* (accumulation of fluid in the abdomen).

CAUSES

The most common cause of portal hypertension is *cirrhosis* of the liver, in which areas of scar tissue in the liver obstruct the portal vein. Another possible cause is *thrombosis* (abnormal blood clotting) due to narrowing of the portal vein. The narrowing may be *congenital* (present from birth), appear shortly after birth, or develop later in life (due to compression of the vein by enlarged

lymph nodes, or to inflammation resulting from an infection). In tropical areas, a common cause is disease that causes the spleen to enlarge and results in an increased blood flow from the spleen through the portal vein.

A rare cause of portal hypertension is an abnormal connection that occurs between the portal vein and an artery (see *arteriovenous fistula*); this type is usually the result of injury.

SYMPTOMS

Symptoms may only appear once complications have developed. Ruptured oesophageal varices lead to massive, recurrent vomiting of blood and produce black faeces (*melaena*). Ascites results in abdominal swelling and discomfort, and sometimes difficulty in breathing. In addition, the veins that are situated just under the skin of the abdomen may be visibly swollen.

DIAGNOSIS

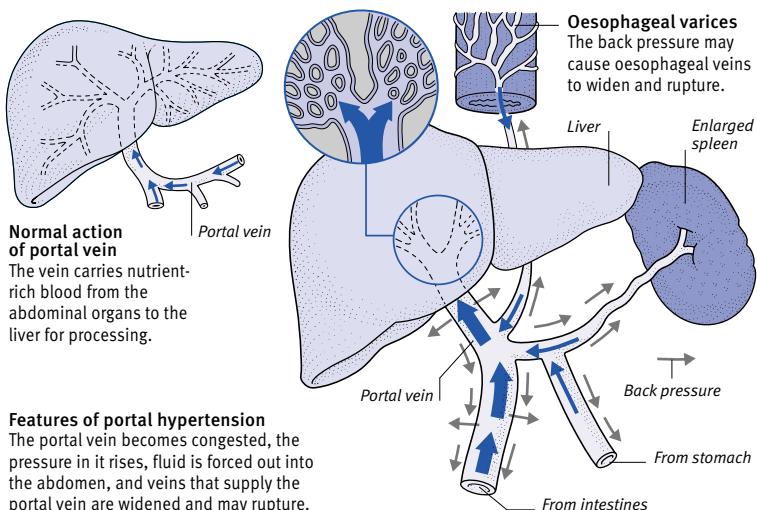

Diagnosis is usually made from the symptoms and signs. *Doppler ultrasound scanning* may be used to assess the pressure in the portal vein.

TREATMENT

Various treatments may be used to reduce blood pressure and to stop bleeding or prevent further bleeding. For example, ruptured blood vessels may be treated by sclerotherapy, in which a chemical is

PORTAL HYPERTENSION

The most common cause of portal hypertension is cirrhosis of the liver or some other obstruction to the blood flow through the liver. The portal vein becomes congested with blood, with the result that back pressure develops through the system of veins that join the portal vein.

injected into the veins to block them. A *shunt* is sometimes carried out to prevent further bleeding. Ascites is controlled by restriction of salt and with *diuretic drugs*.

port-wine stain

A purple-red birthmark that is a permanent, non-raised type of *haemangioma*. Port-wine stains are a feature of *Sturge–Weber syndrome*.

positron emission tomography

See *PET scanning*.

posseting

A term for the regurgitation of small quantities of milk by infants after they have been fed. Posseting is common and harmless.

postcoital contraception

See *contraception, emergency*.

posterior

Relating to the back of the body, or referring to the rear part.

postherpetic neuralgia

Burning pain due to nerve irritation (see *neuralgia*) occurring at the site of a previous attack of *herpes zoster* (shingles).

postmaturity

A condition in which a pregnancy persists for longer than 42 weeks; the average length of a normal pregnancy is 40 weeks (see *gestation*). Postmaturity may be associated with a family tendency to prolonged pregnancy.

Postmaturity is associated with a prolonged labour and an increased risk of a difficult delivery; this is because a postmature fetus is larger than average, and the skull bones are harder and mould less readily to fit through the birth canal. The risk of fetal death increases after 42 weeks because the *placenta* becomes less efficient, causing the fetus to be starved of oxygen and nutrients. Postmature infants tend to have dry skin and may be more susceptible to infection.

Many obstetricians attempt to prevent postmaturity by *induction of labour* as the pregnancy nears 42 weeks.

postmenopausal bleeding

Abnormal vaginal bleeding in women who have already gone through the *menopause* (the time when *ovulation* and *menstruation* cease). The bleeding may be a symptom of various disorders of the reproductive organs. The most

common, and least serious, is irritation of the genital tissues (see *vulvovaginitis*). Other causes include *cervical erosion*; cervical cancer (see *cervix, cancer of*); growths in the uterus (see *uterus, cancer of; polyp*); or, rarely, cancer of the vulva or the vagina. All postmenopausal bleeding must be investigated in order to exclude the possibility of cancer.

postmenopausal osteoporosis

Osteoporosis (loss of bone density) in women who have gone through the *menopause* (the time when *ovulation* and *menstruation* cease). In postmenopausal women, thinning of the bones is due to the sharp decrease in levels of *oestrogen hormones*, which normally help to maintain bone mass.

postmenopause

The period of a woman's life following the *menopause* (the time when *ovulation* and *menstruation* cease).

postmortem examination

An alternative term for an *autopsy*.

postmyocardial infarction syndrome

Another name for *Dressler's syndrome*.

postnasal drip

A watery or sticky discharge from the back of the nose into the *nasopharynx* (the uppermost part of the throat, behind the nose), particularly at night when a person is lying down. The fluid may cause a cough, hoarseness, or the feeling of a foreign body. The usual causes are allergic *rhinitis* (inflammation of the mucous membrane in the nose) and the common cold. Another cause, in young children, is enlarged *adenoids*.

postnatal care

Care of the mother after *childbirth* until about six weeks later.

After delivery, the mother's temperature, pulse, and blood pressure are monitored, especially after a *caesarean section* or if there have been complications, such as *pre-eclampsia* or bleeding.

The length of the stay in hospital depends on whether or not there have been any complications. Women used to remain in hospital for up to a week after delivery, but nowadays the length of stay after a straightforward delivery may be only 48 hours or even less. During the hospital stay, a daily check is made for any signs of *puerperal sepsis*

(infection of the genital tract after childbirth), including inspection of the *lochia* (vaginal discharge after childbirth). If the woman has had an *episiotomy* or if she has torn tissue around the vagina, the wounds are checked daily.

The woman is encouraged to walk as soon as possible after the delivery to reduce the risk of *thrombosis* (abnormal blood clotting). If necessary, help is given with feeding techniques (see *bottle-feeding; breast-feeding*). There may also be instruction on various abdominal exercises and *pelvic floor exercises*, which can help to restore muscle tone.

A final postnatal check-up usually takes place about six weeks after delivery. The obstetrician or GP may check the woman's blood pressure, weight, breasts, haemoglobin levels, and emotional state; may examine the uterus and bladder to make sure they are in the correct positions; may check for urinary incontinence (see *incontinence, urinary*); may take a smear; and ensures that any wounds are healing properly. Advice on *contraception* may also be given.

postnatal depression

Depression in a woman after *childbirth*. The cause is probably a combination of sudden hormonal changes and psychological and environmental factors. The depression ranges from an extremely common and mild, shortlived episode ("baby blues") to a rare, severe depressive illness: *puerperal psychosis*.

MILD DEPRESSION

Most mothers first get the "blues" four to five days after childbirth and may feel miserable, irritable, and tearful. The feeling is caused by hormonal changes, perhaps coupled with a sense of anticlimax after the birth or an overwhelming sense of responsibility for the baby. With reassurance and support, the depression usually passes in two to three days.

MORE SEVERE DEPRESSION

In some women, postnatal depression lasts for several weeks and causes a constant feeling of tiredness, difficulty in sleeping, loss of appetite, and restlessness. The condition usually clears up of its own accord or is treated with *antidepressant drugs* and emotional support.

PUERPERAL PSYCHOSIS

This condition causes severe mental confusion, feelings of worthlessness, threats of suicide or harm to the baby, and sometimes *delusions*. Admission to hospital, ideally with the baby, and anti-depressant drugs are often needed.

postpartum depression

See *postnatal depression*.

postpartum haemorrhage

Excessive blood loss after *childbirth*. It is more common after a long labour or after a multiple birth.

CAUSES AND SYMPTOMS

Most cases of postpartum haemorrhage occur immediately after delivery (primary postpartum haemorrhage) and are due to excessive bleeding from the site where the *placenta* was attached to the uterus. Normally, once the placenta is delivered, contractions of the uterus constrict the blood vessels at the site, and stop the bleeding. Excessive bleeding may be caused by failure of the uterus to contract efficiently after delivery. It may also be due to the retention of placental tissue within the uterus.

Haemorrhaging immediately after delivery may also be caused by tears anywhere along the birth canal. Tearing is more likely to occur during a *forceps delivery* or a *breech delivery*. In some cases, however, postpartum haemorrhage occurs because the mother has a bleeding disorder.

Occasionally, haemorrhage occurs with pain and fever between five and 10 days after delivery (secondary postpartum haemorrhage). In these cases of haemorrhage, the cause is usually infection of a retained fragment of placenta.

TREATMENT

A blood transfusion may be given to replace lost blood, and emergency treatment may be needed for *shock* (a severe drop in blood pressure, which may be due to heavy blood loss). Other treatment depends on the cause of the haemorrhage. Any retained placental tissue may need to be removed; an injection of a drug such as *ergometrine* may be given to stimulate uterine contractions; and any lacerations that have been made in the vagina or on the cervix are sutured (stitched). *Antibiotic drugs* are used to treat infection and iron supplements may be needed to counteract iron deficiency due to blood loss.

post-traumatic stress disorder

A form of *anxiety* that develops after a stressful or frightening event. Common causes include natural disasters, violence, *rape*, torture, serious physical injury, and military combat.

Symptoms may develop immediately after the event or may not appear for many months or years afterwards. They

include flashbacks (recurring memories or dreams of the event), a sense of personal isolation, and disturbed sleep and concentration. There may be a deadening of feelings, or irritability and feelings of guilt, sometimes building up to *depression*. The symptoms may be worsened by any reminder of the trauma.

Most people recover, in time, with emotional support and counselling. However, prolonged physical and emotional trauma (such as that experienced in a concentration camp) may scar a person psychologically for life, altering his or her personality.

postural drainage

A technique that enables sputum (phlegm) or other secretions to drain from a person's lungs in order to clear the lungs and so ease breathing.

Postural drainage is used in the treatment of *cystic fibrosis* and *bronchiectasis*, a lung disorder. The person lies on his or her front or side, with the head lower than the chest. This position allows the secretions to drain by gravity, into the *trachea* (windpipe), from where they can be coughed up. Tapping the person's chest with cupped hands can help to loosen sticky secretions.

postural hypotension

See *hypotension*.

posture

The relative positions of different parts of the body when a person is at rest or during movement. Good posture consists of balancing the body weight around the body's centre of gravity, which is in the lower spine and pelvis. Maintaining good posture helps prevent neck pain and back pain.

post-viral fatigue syndrome

See *chronic fatigue syndrome*.

potassium

A metallic *mineral* needed to help maintain normal heart rhythm, regulate the body's water balance, conduct nerve impulses, and contract muscles.

Many foods contain potassium; particularly rich dietary sources include lean meat, whole grains, green leafy vegetables, beans, and various fruits, such as apricots, dates, and peaches.

POTASSIUM DEFICIENCY

When there is a low level of potassium in the blood, the condition is known as *hypokalaemia*. This condition usually

results from loss of fluids through diarrhoea and/or vomiting, and causes fatigue, drowsiness, dizziness, and muscle weakness. Children are particularly susceptible to this form of potassium loss. In more severe cases of hypokalaemia, there may be abnormal heart rhythms and muscle paralysis.

Other potential causes of hypokalaemia include any prolonged treatment that involves taking *diuretic drugs* or *corticosteroid drugs*; overuse of *laxative drugs*; *diabetes mellitus*; *Cushing's syndrome* (over-production of corticosteroid hormones by the adrenal glands); *aldosteronism* (overproduction of the hormone aldosterone by the adrenal glands); certain kidney diseases; excessively high intake of coffee or alcohol; and extremely profuse sweating.

POTASSIUM EXCESS

Excess potassium in the blood is known as *hyperkalaemia* and is much less common than hypokalaemia. It may be due to excessive intake of potassium supplements, severe *kidney failure*, *Addison's disease*, or prolonged treatment with potassium-sparing *diuretics*. The effects of high potassium levels in the blood can include numbness and tingling, disturbances of the heart rhythm, and muscle paralysis. In severe cases, there may be *heart failure*.

potassium channel activators

A class of drugs that are used in the prevention and long-term treatment of *angina* (chest pain due to inadequate blood supply to the heart). Nicorandil is a potassium channel activator that acts in a similar way to *nitrates*, and widens both arteries and veins. Possible side effects of taking potassium channel activators include flushing, nausea, vomiting, and dizziness.

potassium citrate

A substance used to relieve discomfort in mild *urinary tract infections* by making the urine less acid.

potassium permanganate

A drug that has an *antiseptic* and *astringent* effect and is used to treat *dermatitis*. Potassium permanganate can occasionally cause irritation and can also stain skin and clothing.

potency

The ability of a man to perform *sexual intercourse*; or the ability of a drug to cause desired effects.

Pott's fracture

A combined fracture and dislocation of the ankle caused by excessive or violent twisting. The *fibula* (the outer of the two bones of the lower leg) breaks just above the ankle; in addition, the *tibia* (shin) breaks or the *ligaments* tear, resulting in dislocation.

poultice

A warm pack consisting of a soft, moist substance (such as *kaolin*) that is spread between layers of soft fabric. Poultices are applied to the skin. They were once widely used for the reduction of localized pain or inflammation, bringing *boils* to a head, and improving circulation in a specific area.

pox

Any of various infectious diseases characterized by blistery skin eruptions (for example *chickenpox*). Pox is sometimes used as a slang word for *syphilis*.

Prader–Willi syndrome

A rare *genetic disorder* that is believed to result from a *chromosomal abnormality* affecting chromosome 15. The condition is congenital (present at birth).

The physical features of this condition include *short stature*; *hypogonadism* (underdeveloped testes or ovaries); a small penis, in males; very small hands and feet; almond-shaped eyes; and *squint*. Mental characteristics include specific *learning difficulties*.

Affected babies have *hypotonia* (floppy muscles), feeding difficulties, and are abnormally sleepy; these problems lessen after about six months. Young children may be slow learning to walk and talk (see *developmental delay*).

Affected children develop an uncontrollable hunger and an obsession with eating. If their food intake is not controlled, they will eat continually. This can lead to *obesity*, which may in turn cause other disorders, such as *diabetes mellitus* and *heart failure*. The desire for food may cause behavioural problems if a child is prevented from eating; in addition, he or she may suffer from *anxiety* and show harmful behaviour, such as picking at the skin. In most other aspects, children with Prader–Willi syndrome are generally good-natured, although their problems may cause them to be socially isolated.

Treatment is for the symptoms. Parents, teachers, and carers must ensure that the child does not eat too much.

Underdevelopment of sexual organs, especially in boys, may be corrected by treatment with *sex hormones*. *Growth hormone* may be given for short stature. Learning difficulties are treated with appropriate education or therapy.

pravastatin

A *lipid-lowering drug*.

praziquantel

An *anthelmintic drug* used to treat *tapeworm infestation* and *schistosomiasis*. Side effects may include dizziness, drowsiness, and abdominal pain.

prazosin

A *vasodilator drug* used to treat *hypertension* (high blood pressure), *heart failure*, *Raynaud's disease*, and urinary symptoms resulting from an enlarged prostate gland (see *prostate, enlarged*). Side effects include dizziness and fainting, nausea, headache, and dry mouth.

precancerous

A term applied to any condition in which there is a tendency for *cancer* to develop. Such conditions are characterized by abnormal changes in cells; the affected areas may need to be removed in order to prevent cancer.

Examples of precancerous conditions are *cervical intraepithelial neoplasia*, the pre-invasive stage of cervical cancer (see *cervix, cancer of*); *leukoplakia* of the mouth, vulva, or penis, which can develop into *squamous cell carcinoma*; and familial adenomatous polyposis (growth of multiple polyps within the intestine; see *polyposis, familial adenomatous*), which may also become cancerous.

Certain other disorders carry a risk of cancerous changes, but such changes are less inevitable than with precancerous conditions. These disorders may require monitoring, but do not always need treatment. Examples are *ulcerative colitis* (chronic inflammation and ulceration of the lining of the colon and rectum), carrying an increased risk of tumours in the colon and rectum, and atrophic *gastritis* (inflammation of the stomach lining).

precocious puberty

The development of *secondary sexual characteristics* that occurs before age eight in girls and nine in boys.

CAUSES

Precocious puberty is uncommon. It may be due to various disorders that

can cause the production of *sex hormones* at an abnormally early age. Some possible underlying causes include a *brain tumour* or other brain abnormalities; abnormality of the adrenal glands (for example, *congenital adrenal hyperplasia*); *ovarian cysts*, and *tumours*, or a tumour in the testes. In some cases, no underlying cause can be identified.

SYMPTOMS

The hormones may cause a premature growth spurt followed by early fusion of the bones. As a result, affected children may initially be tall but, if untreated, final height is often greatly reduced.

INVESTIGATION AND TREATMENT

The child's pattern of pubertal development is assessed by a doctor. *Blood tests* are performed in order to measure hormone levels. *Ultrasound scanning* of the ovaries and testes, and *CT scanning* of the adrenal glands or brain, may also be carried out, depending on the underlying cause that is suspected.

Treatment is of the underlying cause, and hormone drugs may be given to delay puberty and increase final height.

predisposing factors

Factors that lead to increased susceptibility to a disease.

prednisolone

A *corticosteroid drug* used in the treatment of a wide variety of disorders.

pre-eclampsia

A serious condition that can arise from 20 weeks of pregnancy. Features of pre-eclampsia include *hypertension* (high blood pressure), *oedema* (accumulation of fluid in tissues), and *proteinuria* (protein in the urine). If severe, symptoms may include headache, nausea and vomiting, abdominal pain, and visual disturbances. The cause is not fully understood.

The condition, which is sometimes called pre-eclamptic toxæmia or PET, is more common in first pregnancies and if the mother suffers from *diabetes mellitus*, hypertension, or kidney disease. Pre-eclampsia may cause liver, kidney, or *blood clotting* problems. Untreated pre-eclampsia may lead to *eclampsia*, which can cause *seizures* in the mother and even death of the mother and/or fetus.

For some cases, treatment is with bedrest and *antihypertensive drugs*. The health of the fetus and functioning of the placenta must be carefully monitored. In late pregnancy, or if severe, *induction of labour* or *caesarean section*

may be necessary. The condition can be prevented by frequent blood pressure checks and *urinalysis* (to look for protein in the urine) as part of *antenatal care*.

pregnancy

The period from *conception* to birth. Pregnancy begins with *fertilization* of an ovum (egg) and its implantation. The egg develops into the *embryo*, which becomes the *fetus*, and the *placenta*, the organ that nourishes the embryo and then the fetus.

Most eggs implant into the uterus. Very occasionally, an egg implants into an abnormal site, such as a fallopian tube, resulting in an *ectopic pregnancy*.

STAGES AND FEATURES OF PREGNANCY

Pregnancy is traditionally dated from the first day of a woman's last menstrual period (LMP), although conception would not have taken place until two weeks after this. A normal pregnancy is considered to last between 37 and 42 weeks; it is divided into three stages (trimesters) of three months each. For the first eight weeks of pregnancy, the developing baby is called an embryo; thereafter it is called a fetus.

In the first trimester the breasts start to swell and may become tender. *Morning sickness* is common. The baby's major organs have developed by the end of this

stage. During the second trimester, the mother's nipples enlarge and darken and weight rises rapidly. The baby is usually felt moving by 16–22 weeks. During the third trimester, stretch marks and *colostrum* (nipple secretions) may appear, and *Braxton Hicks' contractions* may be felt. The baby's head engages at about 36 weeks.

For details on the physical features and changes of pregnancy, see the illustrated box below. For information on the hormones involved in sustaining pregnancy, see the box overleaf.

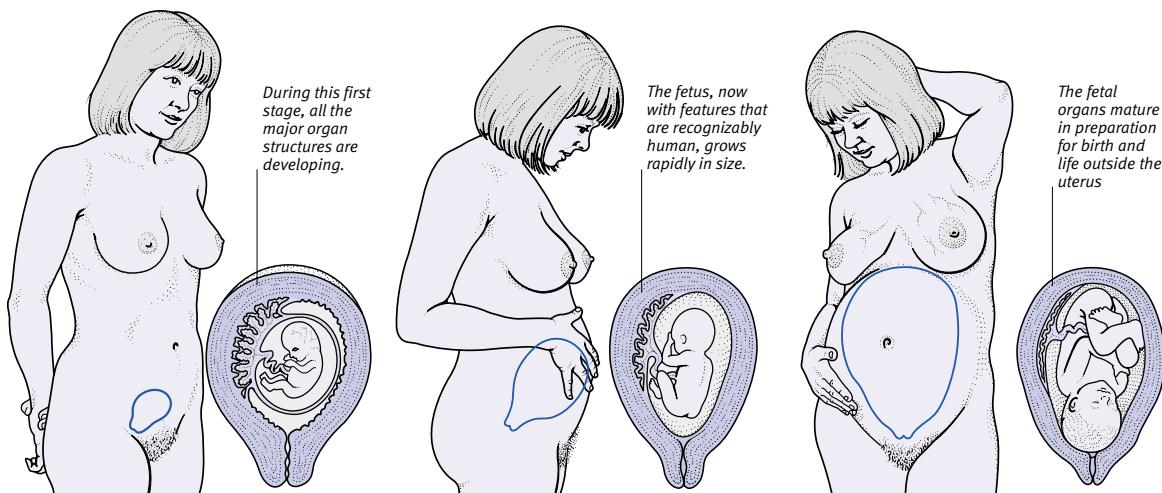

PROBLEMS IN PREGNANCY

In addition to the expected features of pregnancy, such as experiencing nausea

STAGES AND FEATURES OF PREGNANCY

Pregnancy typically lasts 40 weeks, counted from the first day of the pregnant woman's last menstrual period, and is conventionally divided into three trimesters, each lasting three months. For the first eight weeks following conception,

the developing baby is referred to as an embryo; thereafter, it is known as a fetus. It is during the early part of pregnancy (first trimester), while the growing baby is still an embryo, that it is at its most vulnerable to damage.

First trimester (0 to 12 weeks)

The first sign of pregnancy is usually the absence of a menstrual period, although some women have breakthrough bleeding. The breasts start to swell and may become tender as the mammary glands develop to prepare for *breast-feeding*. The nipples start to enlarge and the veins over the surface of the breasts become more prominent. A supportive bra should be worn.

Nausea and vomiting are common, and are often worse in the morning; these problems usually persist for six to eight weeks (see *Vomiting in pregnancy*). There is a need to pass urine more frequently and there is often a creamy white discharge from the vagina. Many women feel unusually tired during the early weeks of pregnancy. Some notice a metallic taste in the mouth or a craving for certain foods or non-edible products. Weight begins to increase towards the end of this stage.

Second trimester (13 to 28 weeks)

From 16 weeks, the enlarging uterus is easily felt from the outside and the woman begins to look noticeably pregnant. The nipples enlarge and darken, and skin pigmentation may deepen. Some women may feel warm and flushed. Appetite tends to increase and weight rises rapidly. The woman's facial features tend to become heavier. By 22 weeks (and usually between the 16th and 20th weeks), most pregnant women have felt the baby moving around (a sensation that is sometimes known as "quickenings").

During the second trimester, nausea, vomiting, and frequency of urination diminish, and the woman may feel generally better and more energetic than she did during the early weeks. The heart-rate increases, as does the volume of blood pumped by the heart; these changes allow the fetus to develop properly. However, they put an extra strain on the heart of women who have pre-existing heart disease.

Third trimester (29 to 40 weeks)

In some women, stretch marks develop on the abdomen, breasts, and thighs. Also, a dark line may appear that runs from the umbilicus to the pubic hair. *Colostrum* (secretions from the nipples) can be expressed from the nipples.

Minor problems are common. Many women become hot and sweat easily because body temperature rises slightly. More rest may be needed at this stage, although for many women it is difficult to find a comfortable position. *Braxton Hicks' contractions* may start to get stronger.

The baby's head engages (drops down low into the pelvis) around the 36th week in a first pregnancy, but not until a few weeks later in subsequent pregnancies. This so-called "lightening" may relieve pressure on the upper abdomen and on breathing, but it increases pressure on the bladder and may result in a more copious vaginal discharge.

and tiredness, some women experience certain common, minor health problems. Although these conditions may be uncomfortable or troublesome, they usually disappear after delivery.

During pregnancy, food passes through the intestine more slowly than normal. This enables more nutrients to be absorbed for the baby, but also tends to cause constipation. *Pica* (craving to eat substances other than foods) is another common condition. In late

pregnancy, the growing fetus puts pressure on the internal organs; this pressure may result in *haemorrhoids*, *heartburn* (due to acid reflux), swollen ankles, and *varicose veins*. Other common disorders during pregnancy include *urinary tract infections*, stress incontinence (see *incontinence, urinary*), and *vaginal candidiasis*.

Complications of pregnancy and disorders that affect it include *antepartum haemorrhage*; *diabetic pregnancy*; *miscarriage*; *polyhydramnios*; *pre-eclampsia*; *pre-*

maturity; and *Rhesus incompatibility*. (See also *childbirth*; *fetal heart monitoring*; *pregnancy, multiple*.)

pregnancy, drugs in

Certain drugs taken during *pregnancy*, such as *thalidomide* and *isotretinoin*, may pass from the mother to the fetus through the *placenta*. They may interfere with fetal development, leading to *birth defects*. Relatively few drugs have been proved to cause harm to a developing baby, but no drug should be considered completely safe, especially in early pregnancy. Pregnant women should seek medical advice before taking any drug, including over-the-counter preparations. However, if the benefits of a drug to the mother outweigh the risks to the fetus, the drug may be recommended.

Problems may also be caused in a developing baby if a pregnant woman drinks *alcohol*, smokes tobacco (see *smoking*), or takes drugs of abuse. The babies of women who use *heroin* during pregnancy tend to have a low birth-weight and a higher death rate than normally expected during the first few weeks of life. Babies of women who abuse drugs intravenously are at high risk of *HIV* infection.

pregnancy, false

An uncommon psychological disorder, which is also known as *pseudocyesis*. In false pregnancy, a woman has many of the physical signs of pregnancy, including *morning sickness*, *amenorrhoea* (absence of periods), enlarged breasts, and abdominal swelling, but is not pregnant. The woman is convinced that she is pregnant. Treatment for false pregnancy may involve *counselling* or *psychotherapy*. (See also *conversion disorder*.)

pregnancy, multiple

More than one *fetus* in the uterus. Multiple *pregnancy* can occur if two or more ova (eggs; see *ovum*) are fertilized at the same time or if a single egg divides early in development.

CAUSES AND INCIDENCE

Twins are the most common type of multiple pregnancy and occur in about 1 in 80 pregnancies; triplets occur in about 1 in 8,000, and quadruplets in about 1 in 500,000. Multiple pregnancies are more common in women who are treated with *fertility drugs*, or if a number of fertilized ova are implanted in the uterus during *in vitro fertilization*.

EFFECTS OF HORMONES DURING PREGNANCY

A pregnant woman undergoes many changes that enable her to maintain the pregnancy, nourish the baby, and prepare for breast-feeding. These adaptations are brought about by increased levels of the female sex hormones oestrogen and progesterone, and by the action of two other hormones, human chorionic gonadotrophin (HCG) and human placental lactogen (HPL), produced only by the placenta.

Hormone	Effect
Progesterone	<p>Decreases the excitability of smooth muscle, thereby helping to prevent uterine contractions and premature labour.</p> <p>Causes constipation and oesophageal acid reflux as a result of its effects on smooth muscle.</p> <p>Increases body temperature.</p> <p>Affects mood.</p> <p>Increases breathing rate.</p>
Human placental lactogen (HPL)	<p>Increases energy production necessary for fetal development.</p> <p>Causes enlargement of breasts and development of milk glands.</p> <p>Induces temporary diabetes mellitus (gestational diabetes) in susceptible women as a result of its effects on metabolism.</p>
Human chorionic gonadotrophin (HCG)	<p>Increases energy production necessary for fetal development.</p> <p>Induces gestational diabetes in susceptible women.</p>
Oestrogens	<p>Are important for the development of the reproductive system and breasts.</p> <p>Stimulate growth of the uterine muscle to enable the powerful contractions of labour.</p> <p>Increase vaginal secretions.</p> <p>Increase the size of the nipples and help the development of milk glands in the breasts.</p> <p>Increase the production of protein, which is essential for healthy growth of the woman and fetus.</p> <p>Alter collagen and other substances to allow body tissues to soften and stretch in preparation for labour.</p> <p>Relax ligaments and joints.</p> <p>May cause sciatica and backache, and may also contribute to the formation of varicose veins as a result of their effects on body tissue.</p>
Melanocyte-stimulating hormone	Stimulates pigmentation (in combination with oestrogens), particularly of the nipples. May also produce chloasma (darkening of the facial skin).

SYMPOTMS AND COMPLICATIONS

The common problems that are associated with normal pregnancy may be more severe in a multiple pregnancy. There is also an increased risk of severe morning sickness, *anaemia*, and *antepartum haemorrhage*. *Hypertension* (high blood pressure), *polyhydramnios* (an excess of amniotic fluid), *postpartum haemorrhage*, and *malpresentation* (abnormal positioning of a fetus just before birth) all occur more frequently in a multiple pregnancy. *Prematurity* is a common complication, and the weight of each baby is usually less than the weight of a single baby. *Caesarean section* is required more frequently than for single pregnancies.

DIAGNOSIS AND TREATMENT

During the woman's antenatal examination, the doctor or midwife may be able to feel more than one fetus, and may find that the abdomen is larger than expected for the stage of gestation. The doctor or midwife may also be able to hear more than one fetal heartbeat when listening through a stethoscope. Ultrasound scanning may be used to confirm the diagnosis.

The woman is advised to take more rest during pregnancy and to increase her intake of protein. Supplements of *iron* and *folic acid* are also recommended in order to prevent iron-deficiency anaemia in the mother and *neural tube defects* in the fetuses, respectively.

MULTIPLE PREGNANCY

About one pregnancy in 80 is multiple (e.g. twins or triplets). The rate is highest among women in their 30s. Problems arise more often in multiple pregnancies than in single pregnancies. For example, twins are much more likely than single babies to be born prematurely.

Amniotic sacs

Fetal heads

Ultrasound scan revealing twins

Ultrasound scanning of the woman's uterus can reveal the presence of twins within the first several weeks of pregnancy. Here, two fetal heads and a limb that belongs to the fetus on the right can be seen.

pregnancy tests

Tests on urine or blood performed to determine whether a woman is pregnant. Pregnancy testing kits are available over the counter from pharmacies.

All kits are designed to test for the presence of *human chorionic gonadotrophin* (HCG) in a sample of urine. This hormone is normally produced only by a developing placenta; the tests are extremely accurate (about 97 per cent accurate for a positive result and 80 per cent accurate for a negative result) and can be reliably used from the first day of a missed period. The test can, however, misdiagnose pregnancy in cases of *hydatidiform mole*, due to very high HCG levels.

Different brands of test vary, but all involve introducing a sample of urine to a test stick that has been treated with a chemical that reacts with HCG. *Blood tests* for detecting pregnancy can be used from 9 to 12 days after conception (even before a period is missed).

premature aging syndrome

See *progeria*.

premature ejaculation

See *ejaculation, disorders of*.

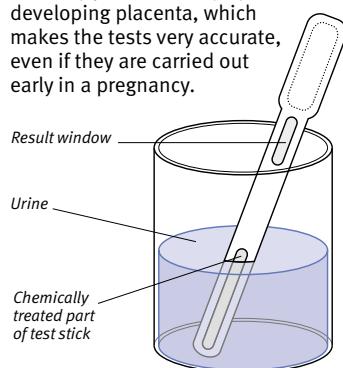

premature menopause

Menopause (cessation of ovulation and menstruation) that occurs before the age of 40. Premature menopause can be caused by any disorder or treatment in

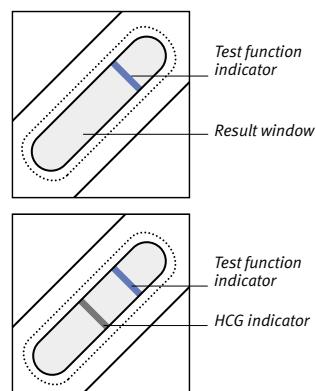

which the ovaries are destroyed or removed or ovarian functions are permanently disrupted (*radiotherapy* of the pelvic region, for example). *Hormone replacement therapy* can relieve symptoms and reduce the risk of *osteoporosis* (loss of bone tissue). For women who want to conceive, *in vitro fertilization* (IVF) is possible, using donor eggs.

PREGNANCY TEST KIT

The pregnancy test shown here is one of a variety that are available over the counter at chemist's shops, allowing pregnancy testing to be carried out at home. All of the kits test for the presence of the hormone *human chorionic gonadotropin* (HCG) in a sample of urine. HCG is normally produced only by a developing placenta, which makes the tests very accurate, even if they are carried out early in a pregnancy.

1 The indicator stick is dipped into a container of urine (as shown here). Alternatively, the user can place it directly into the urine flow while passing urine normally.

2 The first line that becomes visible in the result window shows that the test is working. If HCG is present, this line is quickly followed by a second, different coloured line, which signifies pregnancy. A result can be obtained within a few minutes.

premature sexual maturation

See *precocious puberty*.

prematurity

The birth of a baby that occurs before 37 weeks' *gestation*. The premature infant may not be sufficiently developed to cope with independent life and needs special care.

CAUSES

Nearly 50 per cent of premature deliveries occur for no known reason. The remainder are due to conditions such as *pre-eclampsia*, *hypertension*, *diabetes mellitus*, long-standing kidney disease, and heart disease. Other causes are *antepartum haemorrhage*, intrauterine infection, or premature rupture of the membranes. A common cause of premature birth is multiple pregnancy (see *pregnancy, multiple*).

FEATURES AND COMPLICATIONS

A premature infant is smaller than a full-term baby. He or she lacks subcutaneous fat, is covered with downy hair (*lanugo*), and has very thin skin.

The baby's internal organs are also immature. The major complication is *respiratory distress syndrome*, which may occur because the lungs are insufficiently developed. There are also increased risks of brain haemorrhage, *jaundice*, and *hypoglycaemia* (low blood sugar). The baby has a limited ability to suck and to maintain a normal body temperature, and he or she is also prone to infection due to a poorly developed immune system. The earlier a baby is born, the more likely it is that he or she will have such problems.

TREATMENT AND OUTLOOK

Premature infants are usually nursed in a special baby unit that provides intensive care. The baby is placed in an *incubator*. He or she may have artificial ventilation to assist breathing, artificial feeding through a stomach tube or into a vein, and treatment with *antibiotic drugs* and *iron and vitamin supplements*. The baby is usually kept in hospital until he or she has reached a weight of at least 2.25 kg, is growing sufficiently, and is feeding well.

With the modern techniques that are now generally available, some infants survive even if they are born as early as 24 weeks' gestation. Most babies that are born after 28 weeks, and given specialist care, survive. The majority of premature babies catch up with full-term babies, in terms of their development, before the end of their first year.

PREMATURITY

A premature baby may need to be nursed in an incubator where the temperature and humidity are carefully controlled and the baby can be closely observed. If breathing difficulties develop, they may be treated by artificial ventilation. Very small babies cannot suck so they must be fed intravenously or via a tube passed into the stomach. If jaundice develops, they may be treated by phototherapy (light therapy), which breaks up the bilirubin that causes the yellow discolouration of the skin.

Premature infant

This baby was born several weeks prematurely and is being fed via a flexible tube that passes through the nose and oesophagus into the stomach.

FEATURES AND COMPLICATIONS OF PREMATURITY**Physical features**

- Low birthweight (often less than 2.5kg)
- Small size
- Relatively large head and hands
- Thin, smooth, shiny skin
- Veins visible under the skin
- Little fat under the skin
- Wizened, wrinkled features
- Soft, flexible ear cartilage
- Short toenails (but normal length fingernails)
- Downy (lanugo) hair
- Reduced vernix (greasy substance that covers the newborn)
- Protuberant abdomen
- Enlarged clitoris (girls)
- Small scrotum (boys)
- Feeble, whining cry
- Irregular breathing
- Poor sucking and swallowing ability
- Tendency to regurgitate

Complications

- Increased risk of birth injury
- Respiratory distress syndrome
- Recurrent episodes of breathing stoppage
- Jaundice
- Infection
- Poor temperature control
- Anaemia
- Hypoglycaemia (low blood sugar level) and other disturbances of body chemicals
- Rickets
- Increased bleeding tendency
- Brain haemorrhage
- Necrotizing enterocolitis (severe intestinal inflammation that may lead to death of intestinal tissue)

premedication

The term applied to drugs that are given, usually by injection, one to two hours before an operation in order to prepare a person for surgery. The pre-medication injection usually contains an opioid *analgesic drug* (painkiller), and often an *anticholinergic drug* (which reduces the secretions in the airways and protects the heart).

premenstrual syndrome

The combination of physical and emotional symptoms that occurs in many women in the week or so running up to *menstruation*. Premenstrual syndrome (commonly known as PMS) begins at or after *ovulation* (the mid-point of the menstrual cycle, when an egg is released from an ovary) and continues up until the onset of menstruation. In

some women, the condition may be so severe that work and social relationships are seriously disrupted.

CAUSES

Theories for the cause of PMS include hormonal changes and vitamin or mineral deficiencies, but none of these has been confirmed.

SYMPOTMS

The most common emotional symptoms are fatigue, irritability, tension, aggression, tearfulness, and depression. Physical symptoms include breast tenderness, fluid retention, headache, backache, and lower abdominal pain.

TREATMENT

No single treatment has proved completely successful. Remedies for specific symptoms include dietary changes, relaxation techniques, and regular physical exercise. Pyridoxine (vitamin B₆) may help to relieve some symptoms in some women. *Oral contraceptives* can relieve symptoms by suppressing the normal menstrual cycle. Progesterone supplements may sometimes be used but are not always effective. The *antidepressant drug* fluoxetine is now licensed to treat PMS.

premenstrual tension

See *premenstrual syndrome*.

premolar

One of eight permanent grinding teeth, two in the upper and two in the lower jaw on each side of the mouth, located between the canines and molars. (See also *permanent teeth; eruption of teeth*.)

Prempak-C

A brand-name drug used in *hormone replacement therapy* to relieve symptoms of the *menopause* and to prevent *osteoporosis*. Prempak-C contains conjugated oestrogens (see *oestrogen drugs*) and norgestrel (a *progestogen drug*).

prenatal

A term referring to the period of pregnancy; often a synonym for antenatal.

prepuce

See *foreskin*.

presbyacusis

The progressive loss of hearing that occurs with age. Presbyacusis is a form of sensorineural *deafness* (degeneration of the hair cells and nerve fibres in the inner ear), which makes sounds less clear and tones less audible.

SYMPOTMS AND CAUSES

The symptoms of presbyacusis develop gradually. People with the condition often find it difficult to understand speech and cannot hear well when there is background noise. The severity and progression of the disorder vary considerably from person to person.

Presbyacusis may be exacerbated by exposure to high *noise* levels, diminished blood supply to the inner ear due to *atherosclerosis* (the buildup of fatty deposits on artery walls), and damage to the inner ear from drugs such as *aminoglycoside drugs*.

DIAGNOSIS AND TREATMENT

Diagnosis is by physical examination using an otoscope, and by various *hearing tests* to determine the type and degree of hearing loss. *Hearing-aids* help most affected people.

presbyopia

The progressive loss of the power of adjusting the eye (see *accommodation*) for near vision. The focusing power of the eyes weakens with age. Presbyopia is usually noticed around the age of 45 when the eyes cannot accommodate to read small print at a normal distance. Reading *glasses* with convex lenses are used to correct presbyopia.

prescribed diseases

A group of industrial diseases that give sufferers legal entitlement to financial benefit. To be eligible, a claimant has to have worked in an occupation that is recognized to increase the risk of developing a particular disease.

Examples include conditions due to physical agents (such as occupational *deafness*), biological agents (for example, *anthrax*), or chemical agents (such as *lead poisoning*); *pneumoconiosis*; and *byssinosis*. (See also *notifiable diseases; occupational disease and injury*.)

prescription

An instruction written by a doctor that directs a pharmacist to dispense a particular drug in a specific dose. A prescription details how often the drug must be taken, how much is to be dispensed, and other relevant facts.

prescription-only medicine (PoM)

Drugs and medicines that are not available over the counter and can only be obtained by *prescription*. PoMs are those whose safe use is hard to ensure without medical supervision. Some are

subsequently reclassified to *over-the-counter (OTC) drugs* once their efficacy and safety have been established.

presenile dementia

A type of *dementia* (a deterioration in brain function) that occurs in a person under 65. (Most dementia affects those over 65.) Possible causes of presenile dementia include damage to brain tissue resulting from *AIDS* or *alcohol dependence*; severe vitamin deficiencies, as in *Wernicke-Korsakoff syndrome* or *pernicious anaemia*; a serious *head injury*; or *Alzheimer's disease*.

The underlying cause of presenile dementia is treated, if possible. Damage to brain tissue is irreversible, however, but drug treatment may help to relieve any associated symptoms such as *depression*.

presentation

A term describing the position of the fetus before *childbirth*. The presentation is classified by the part of the fetus that is closest to the cervix and will emerge first. The cephalic (head) presentation is normal. Forms such as the breech presentation (in which the buttocks lie over the cervix) and the shoulder presentation may cause problems during delivery (see also *breech delivery*). The term presentation is also used to describe how an illness or condition manifests itself.

preservative

A substance that inhibits the growth of bacteria, yeasts, and moulds and therefore protects foods from putrefying and fermenting. Examples include sulphur dioxide, benzoic acid, salt, sugar, and nitrites. (See also *food additives*.)

pressure points

Places on the body where pressure can be applied by hand to limit severe arterial bleeding (in which bright red blood is pumped out in regular spurts with the heartbeat). At these points, arteries lie near the surface of the body and can easily be compressed against a bone to stop the blood flow.

Major pressure points of the body include the brachial pressure point in the middle part of the upper arm and the carotid pressure point at the side of the neck, below the jaw.

pressure sore

See *bedsore*.

prevalence

The total number of cases of a disease in existence at any one time in a defined population. Prevalence is often expressed as the number of cases per 100,000 people. (See also *incidence*.)

preventive dentistry

An aspect of dentistry concerned with the prevention of tooth decay and gum disease. It consists of the encouragement of good *oral hygiene*, *fluoride treatment*, and *scaling*.

preventive medicine

The branch of medicine that deals with disease prevention. It involves public health measures, such as the provision of pure water supplies and sanitation; health education and promotion; specific preventive measures, such as *immunization* against infectious diseases; and *screening* programmes to detect diseases before they cause symptoms.

In affluent countries, the main objective of preventive medicine is to educate the adult population to adopt a healthier lifestyle. In the UK, many of the deaths that occur in adults before the age of 65 are preventable, being due to accidents and/or linked to such factors as *smoking*, an unhealthy diet, excessive *alcohol* consumption, and insufficient exercise. Adoption of a healthier lifestyle, the wider use of screening for various cancers, and measures to reduce accidents could all lead to substantial improvements in health.

priapism

Persistent, painful *erection* of the *penis* that occurs without sexual arousal. This is a dangerous condition that requires emergency treatment.

Priapism occurs when the penis has become erect but blood cannot drain from the spongy tissue, and as a result the erection cannot subside. Possible causes include a blockage in the penile blood vessels due to a blood disorder such as *sickle cell anaemia*; damage to nerves supplying the penis; or, rarely, the effects of treatment for *impotence*.

Urgent treatment is needed to avoid permanent damage to the tissues of the penis. Blood may be withdrawn from the penis with a needle.

prickly heat

An irritating skin rash that is associated with profuse sweating. The medical name is *miliaria rubra*. Multiple tiny,

red, itchy spots cover the affected areas of skin and are accompanied by prickling sensations. The irritation tends to affect areas where sweat collects, such as the armpits.

The cause is not fully known, but unevaporated sweat is an important contributory factor; the ducts from sweat glands become blocked with debris and leak sweat into the skin. Frequent cool showers and sponging of the affected areas relieve the itching.

primaquine

A drug used to treat *vivax* and *ovale malaria*. It is given after treatment with *chloroquine*. Side effects include nausea, vomiting, and abdominal pain. In people with *G6PD deficiency*, primaquine may cause *haemolytic anaemia* (see *anaemia, haemolytic*).

primary

A term that is used to describe a disease that has originated within the affected organ or tissue and is not derived from any other cause or source; an example is primary *cancer*. The term "primary" is also applied to the first of several diseases that may affect a tissue or organ. The preventive measures that are taken before an illness has manifested itself are known as primary prevention; secondary prevention is used to prevent a recurrence of the disease.

primary biliary cirrhosis

See *biliary cirrhosis*.

primary care

Health care that is provided by a general practitioner (GP) or other healthcare professional who is the first point of contact for a patient who is seeking medical treatment.

primary central nervous system lymphoma (PCNSL)

A form of non-Hodgkin's lymphoma (see *lymphoma, non-Hodgkin's*) affecting the brain or spinal cord. The cancer occurs most commonly in *immunocompromised* people (those with lowered resistance to infection), such as people with *AIDS* and those who are taking *immunosuppressant drugs*.

primary teeth

The first teeth to erupt (also known as milk teeth), which usually start to appear around the age of six months. The primary teeth are replaced by the

permanent teeth from about the age of six years. There are 20 primary teeth in total, ten of which are in the upper jaw and ten in the lower jaw. (See also *teeth; eruption of teeth; teething*.)

primidone

An *anticonvulsant drug* that is used to treat *epilepsy* and, occasionally, *tremor*. It is usually prescribed with another anticonvulsant. Adverse effects of the drug may include drowsiness, clumsiness, and dizziness.

primitive reflex

See *reflex, primitive*.

Prinzmetal's angina

See *variant angina*.

prion

A tiny, protein-based infectious particle. Prions transmit diseases that cause degeneration of the central nervous system, including *Creutzfeld-Jakob disease* in humans and *bovine spongiform encephalopathy (BSE)* in cattle.

Prions do not contain *nucleic acids*, unlike viruses, and are difficult to destroy because they are highly resistant to heat and disinfectants. There is currently no treatment available for prion diseases. (See also *slow virus diseases; spongiform encephalopathy*.)

Pripsen

A brand name for the anthelmintic (worm-killing) drug *piperazine*.

PRK

The abbreviation for *photorefractive keratotomy*.

probenecid

A drug that was formerly used in the long-term treatment of *gout*. Probenecid is used to prevent kidney damage in AIDS patients who are taking the drug *cidofovir* for the treatment of *cytomegalovirus retinitis*. Probenecid may cause nausea and vomiting. Other possible side effects of probenecid include flushing and dizziness.

probiotic bacteria

Species of microorganisms that inhabit the digestive tract, guarding it against harmful microorganisms such as *bacteria, yeasts*, and *viruses*. Some drinks are manufactured using probiotic bacteria; they are thought to protect the health of the *digestive system*.

procainamide

An *antiarrhythmic drug* that is used to treat certain types of *tachycardia* (abnormally rapid heartbeat). Procainamide may cause nausea, vomiting, loss of appetite, and, rarely, confusion. Prolonged treatment with this drug may induce *lupus erythematosus*.

procaine

A local anaesthetic (see *anaesthesia, local*).

procarbazine

An *anticancer drug* used most often in *Hodgkin's disease*. Side effects are typical of anticancer drugs.

prochlorperazine

A *phenothiazine-type antipsychotic drug* used to relieve symptoms of certain psychiatric disorders, such as *schizophrenia* and *mania*. Prochlorperazine is also used in small doses as an *antiemetic drug*. It may in some cases cause involuntary movements of the face and limbs, lethargy, dry mouth, blurred vision, and dizziness.

procidentia

A medical term for severe *prolapse*, usually of the uterus.

proctalgia fugax

A severe cramping pain in the *rectum* unconnected with any disease. It may be due to muscle spasm. The pain is usually of short duration and subsides without any treatment.

proctitis

Inflammation of the *rectum*, causing soreness and bleeding, sometimes with a mucus and pus discharge. Proctitis commonly occurs as a feature of certain diseases including *ulcerative colitis*, *Crohn's disease*, or *dysentery*. In cases where inflammation is confined to the rectum, the cause is often unknown. Proctitis is sometimes due to *gonorrhoea* or another sexually transmitted infection, especially in male homosexuals. Rare causes of proctitis include *tuberculosis*, *amoebiasis*, and *schistosomiasis*.

Diagnosis is made by *proctoscopy* (examination of the rectum with a viewing instrument). A *biopsy* (collection of a tissue sample) is sometimes carried out at the same time. Treatment of the underlying condition usually clears the problem. *Corticosteroid drugs* may relieve symptoms.

proctoscopy

Examination of the *anus* and *rectum* using a proctoscope (a rigid viewing instrument).

procyclidine

An *anticholinergic drug* that is used to treat *Parkinson's disease*. It is also used to minimize the side effects of some *antipsychotic drugs*. The possible adverse effects of procyclidine include a dry mouth and blurred vision.

prodrome

An early warning symptom of illness. One example of a prodrome is an aura, which is a particular set of physical and mental symptoms that may occur immediately before an attack of *migraine* or *epilepsy*.

progeria

Premature aging. There are two forms of progeria, and both are very rare.

In Hutchinson-Gilford syndrome, premature aging starts at about four years old, and many features of old age, including grey hair, balding, sagging skin, and *atherosclerosis* (buildup of fatty deposits on artery walls), have developed by the age of ten to twelve. Death usually occurs at puberty. Werner's syndrome (adult progeria) starts in adolescence or early adulthood and follows the same course.

The cause of Hutchinson-Gilford syndrome is a gene mutation. The cause of progeria is unknown.

progesterone hormone

A female sex hormone essential for the functioning of the female reproductive system. Progesterone is made in the *ovaries* during the second half of the menstrual cycle (see *menstruation*), and by the *placenta* during *pregnancy*. Small amounts are also produced by the *adrenal glands* and, in men, by the *testes*.

During the menstrual cycle, increasing progesterone levels after *ovulation* (the release of an egg from an ovary) cause the endometrium (uterine lining) to thicken in preparation for receiving a fertilized egg. If fertilization does not occur, the production of progesterone and *oestrogen hormones* falls to a level that results in a *menstrual period*, during which the uterine lining is expelled from the body.

If pregnancy occurs, progesterone is produced by the *placenta*. It causes a number of changes in the mother's

body, one of which is enlargement of the breasts. A fall in the mother's progesterone level in late pregnancy helps to initiate labour (see *childbirth*).

Other effects of progesterone in women include increased fat deposition and increased *sebum* production by glands in the skin.

progestogen drugs**COMMON DRUGS**

- Desogestrel • Dydrogesterone
- Levonorgestrel • Medroxyprogesterone
- Norethisterone • Norgestimate • Norgestrel
- Progesterone

A group of drugs that are similar to *progesterone hormone*. They include both natural progesterone and synthetic progesterone derivatives.

Progestogen drugs are used in *oral contraceptives*. They may be used on their own in, for example, the progestogen-only pill, as *contraceptive implants*, or as contraceptive injections (see *contraceptives, injectable*), or in combination with *oestrogen drugs* in the combined pill. Progestogens work by making the cervical mucus impenetrable to sperm; reducing the production of *gonadotrophin hormones*, which may prevent eggs from ripening in the ovaries; and altering the lining of the uterus in order to prevent the implantation of fertilized eggs. They also reduce the movement of an egg along the fallopian tube, which may lead to an increased risk of an *ectopic pregnancy*.

Another use for progestogens is in *hormone replacement therapy (HRT)*. A progestogen drug is used in combination with an oestrogen drug to reduce the risk of uterine cancer (see *uterus, cancer of*), which may occur if oestrogens alone are taken over a long period of time. The progestogens induce a monthly shedding of the uterine lining, if taken cyclically (for the last 10–13 days of the cycle).

Progestogen drugs are also prescribed as a treatment for various menstrual problems (see *menstruation, disorders of*). In addition, they are used to treat *premenstrual syndrome*, *endometriosis* (a condition in which fragments of uterine lining are found elsewhere in the pelvic cavity), and are sometimes used as *anticancer drugs*.

Adverse effects of taking progestogen drugs are weight gain, *oedema* (accumulation of fluid in body tissues), headache, dizziness, rash, irregular

periods, breast tenderness, and, less commonly, *ovarian cysts*. (See also *contraception, hormonal methods of*.)

progestogen-only pill

See *oral contraceptives*.

prognathism

Abnormal protrusion of the lower jaw or both jaws.

prognosis

An assessment of the probable course and outcome of a disease.

progressive

A term that is used to describe a condition that becomes more severe and/or extensive over time.

progressive muscular atrophy

A type of *motor neuron disease* in which the muscles of the hands, arms, and legs become weak and wasted and twitch involuntarily. As the muscular atrophy advances, it eventually spreads to other muscles.

proguanil

An antimalarial drug that is used in the prevention of *malaria*. Side effects of the drug are rare. Indigestion, nausea, or vomiting may occur but usually disappear as treatment continues.

prolactin

A *hormone* produced by the *pituitary gland*. Prolactin helps to stimulate the development of the mammary glands (see *breast*), and to initiate and maintain milk production for *breast-feeding*. (See also *prolactinoma*.)

prolactinoma

A noncancerous tumour of the *pituitary gland* that causes overproduction of the hormone *prolactin*. In women, this may result in *galactorrhoea* (breast secretion at any time other than during breast-feeding), *amenorrhoea* (absence of menstrual periods), or *infertility*. In men, it may lead to *impotence* and *gynaecomastia* (development of breasts). In either sex, it may cause headaches, *diabetes insipidus*, and, if the tumour presses on the optic nerves, loss of the outer *visual field*.

Diagnosis of the condition is made from *blood tests* and *CT scanning* or from *MRI* of the brain. Treatment of prolactinoma may involve removal of the tumour, *radiotherapy*, or prescribing the drug *bromocriptine*.

prolapse

The displacement of part or all of an organ or tissue from its normal position in the body (see *disc prolapse*; *mitral valve prolapse*; *rectal prolapse*; *uterovaginal prolapse*; *uterus, prolapse of*).

promazine

A *phenothiazine-type antipsychotic drug* that is used as a sedative drug. Possible adverse effects include abnormal movements of the face and limbs, drowsiness, lethargy, constipation, dry mouth, and blurred vision. Long-term treatment may cause *parkinsonism*.

promethazine

An *antihistamine drug* used to relieve itching in a variety of skin conditions, such as *eczema*. It is also used as an *antiemetic drug*, and sometimes as a *pre-medication*. Possible adverse effects of promethazine include a dry mouth, blurred vision, and drowsiness.

pronation

The act of turning the body to a prone (face-down) position, or the hand to a palm-backwards position.

propantheline

An *antispasmodic drug* used to treat *irritable bowel syndrome* and forms of *urinary incontinence*. Possible adverse effects of propantheline include a dry mouth, blurred vision, and retention of urine.

Propecia

A brand name for *finasteride*, an anti-androgen drug (one that blocks the effects of male sex hormones). This preparation is used to treat male-pattern baldness (see *alopecia*).

prophylactic

A drug, procedure, or piece of equipment that is used to prevent disease. The term is also used to describe a *condom*.

prophylactic antibiotics

Antibiotic drugs that are used to prevent the development of bacterial infections. They are used, for example, in people who are undergoing surgery or in those with recent, serious injuries. They are given, for example, to prevent *endocarditis* in patients who have replacement *heart valves* or heart-valve lesions who are undergoing dental procedures. They may also be given to people who are in close contact with a source of meningococcal *meningitis* to prevent

contraction of the disease, as well as to prevent infection following a bite (see *bites, animal; bites, human*).

Pro Plus

A brand name for *caffeine* in the form of over-the-counter tablets.

propranolol

A *beta-blocker drug* used to treat *hypertension* (high blood pressure), *angina pectoris* (chest pain due to inadequate blood supply to the heart), and cardiac *arrhythmias* (irregular heartbeats). It may also be used to reduce the risk of further heart damage after *myocardial infarction* (heart attack). In addition, it relieves symptoms of *hyperthyroidism* (overactivity of the thyroid gland) and *anxiety*, and can prevent *migraine* attacks.

Possible adverse effects of propranolol are typical of most beta-blocker drugs; they include fatigue, nausea, and cold hands and feet.

proprietary

A term for a drug patented for production by one company.

proprioception

The body's internal system for collecting information about its position and the state of contraction of its muscles.

Information originating from proprioceptors (sensory nerve endings in the muscles, tendons, joints, and inner ear) passes to the brain and spinal cord. The information is used to make adjustments to maintain posture and balance. During movement, there is a constant feedback of information from the proprioceptors and the eyes to the brain. This helps the brain to ensure that actions are smooth and coordinated.

proptosis

A term meaning protrusion, especially of the eyeballs (see *exophthalmus*).

propylthiouracil

A drug used to treat *hyperthyroidism* (overactivity of the thyroid gland) or to control its symptoms before a *thyroidectomy* (surgical removal of thyroid tissue). Possible side effects are itching, headache, rash, joint pain, and decreased production of *white blood cells*.

prostaglandin

One of a group of *fatty acids* that is made naturally in the body and acts in a similar way to *hormones*. Prostaglandins

were first discovered in semen but are now known to occur in many different body tissues, including the uterus, brain, and kidneys. Prostaglandins are divided into broad groups according to their chemical structure.

Prostaglandins produce a wide range of effects on the body. These actions include causing pain and inflammation in damaged tissue; protecting the lining of the stomach and duodenum against ulceration; lowering blood pressure; and stimulating contractions in labour. (These effects may also be achieved by the use of *prostaglandin drugs*.) For further information describing the effects of various prostaglandins, see the box below.

Certain drugs counteract the effects of prostaglandin in the body. Examples of these drugs are *aspirin*, *nonsteroidal anti-inflammatory drugs* (NSAIDs), and *corticosteroids*, which relieve pain and

inflammation by reducing prostaglandin production in the tissues. If taken for a long period, however, NSAIDs and aspirin may increase the risk of a peptic ulcer, in part by reducing the production of the prostaglandins that protect the stomach lining.

prostaglandin drugs

Synthetically produced *prostaglandins*. Dinoprostone is used with synthetic *oxytocin* for *induction of labour*. *Mifepristone* may be taken orally to induce an *abortion*; this is followed by insertion of a gemeprost suppository, which softens and helps to dilate the cervix. Alprostadil is used to treat newborn infants who are awaiting surgery for certain congenital heart diseases.

prostate, cancer of

A cancerous growth in the *prostate gland* that is one of the most common types of cancer in men. The cause of the cancer is unknown, but the male sex hormone *testosterone* has been found to influence the growth rate and spread of the tumour. Men who have a family history of prostate cancer are at an increased risk of developing cancer of the prostate and the condition most commonly affects elderly men.

SYMPOTMS

An enlarged prostate (see *prostate, enlarged*) may cause symptoms that include difficulty in starting to pass urine, poor urine flow, and increased frequency of urination. If a tumour blocks the *urethra* (the passage from the bladder to the outside of the body) or the cancer spreads to the *ureters* (the tubes linking each kidney to the bladder), urine flow may eventually cease altogether (see *urinary retention*).

In some cases, there are no urinary symptoms and the first signs may only appear once secondary cancers have arisen. Such signs may include pain in the bones, enlarged *lymph nodes*, shortness of breath (due to tumours in the lungs), and weight loss.

SCREENING AND DIAGNOSIS

Some older men and men suspected of having prostate cancer may be screened for the disorder. This procedure involves tests to detect blood levels of a protein called *prostate-specific antigen (PSA)*, as well as a *rectal examination*. If blood levels of PSA are above a certain level, this may be an early sign of prostate cancer; rectal examination allows a doctor to assess the size and hardness of the gland.

Transrectal *ultrasound* (a procedure in which an ultrasound probe is inserted into the rectum) and a *biopsy* (removal of a tissue sample for analysis) are used to confirm a diagnosis. *Blood tests* and a bone scan (see *radionuclide scanning*) may also be carried out.

TREATMENT

Medical opinions vary regarding the appropriate treatment for localized prostate cancer. If the man is elderly and has a small prostate cancer that has not spread, no treatment may be recommended; the man's condition will be monitored. For younger men, *prostatectomy* (removal of the prostate gland) or *radiotherapy* may be performed.

In many cases, widespread disease is controllable for some years with the use of drugs or with *orchidectomy* (removal of part or all of the testes).

prostatectomy

The surgical removal of part or all of the *prostate gland*. Prostatectomy is performed to treat enlargement of the prostate (see *prostate, enlarged*), in cases where the enlarged prostate is obstructing the flow of urine, and cancer (see *prostate, cancer of*).

The most common method is transurethral prostatectomy, in which the prostate is accessed via the urethra (the channel in the penis through which urine is excreted), thereby avoiding open surgery. If the prostate gland is very enlarged, retropubic prostatectomy may be performed: an incision is made to expose the prostate and the tissue is removed. These techniques are shown in the illustrated box overleaf.

Prostatectomy may affect potency or sexual sensation, though this is not common. The operation usually causes sterility due to a condition called retrograde *ejaculation*, in which semen is expelled backwards into the bladder rather than out of the penis. This condition, though abnormal, is not harmful.

prostate, enlarged

Increased size of the inner zone of the *prostate gland*, caused by benign prostatic hypertrophy (see *prostatic hypertrophy, benign*), *prostate cancer*, or *prostatitis* (inflammation of the prostate gland). Enlargement of the prostate can cause obstruction to the flow of urine from the bladder to the urethra, leading to *prostatism* and *urinary retention* (the inability to pass urine). The size of the gland can be assessed by a *rectal examination*.

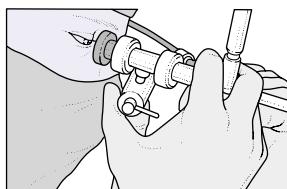

EFFECTS OF SOME PROSTAGLADINS	
Type	Effect
PGA ₁	<ul style="list-style-type: none"> ● Lowers blood pressure. ● May protect against peptic ulcer.
PGD ₂	<ul style="list-style-type: none"> ● Causes inflammation. ● Involved in asthma.
PGE ₁	<ul style="list-style-type: none"> ● Stimulates contractions of the uterus. ● Lowers blood pressure. ● Reduces stickiness of platelets in blood.
PGE ₂	<ul style="list-style-type: none"> ● Causes inflammation. ● Widens airways. ● Increases stickiness of platelets in blood. ● Stimulates contractions of the uterus. ● Protects against peptic ulcer.
PGF ₂ alpha	<ul style="list-style-type: none"> ● Stimulates contractions of the uterus. ● Narrows airways.
PGG ₂	<ul style="list-style-type: none"> ● Causes inflammation.
PGI ₂	<ul style="list-style-type: none"> ● Reduces stickiness of platelets in blood.

PROSTATECTOMY: REMOVAL OF THE PROSTATE GLAND

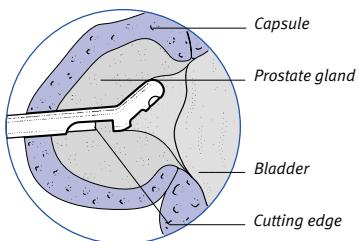

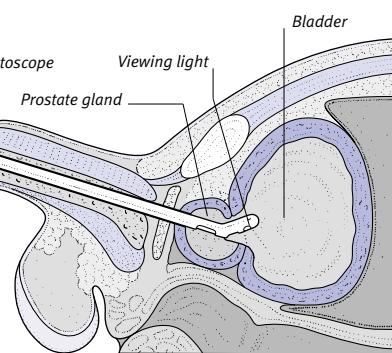

Two of the possible methods of removal are shown. The transurethral method (TURP) is the most commonly used. It avoids the disadvantages of an abdominal incision and

usually permits a shorter stay in hospital. The retropubic method may be necessary if the prostate is very enlarged or if surgery is a treatment for prostate cancer.

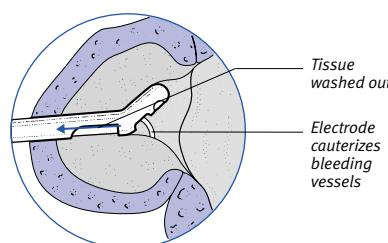

TRANSURETHRAL PROSTATECTOMY

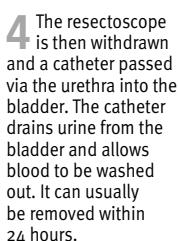

1 Under general or spinal anaesthesia, a special type of cystoscope (bladder viewing tube) called a resectoscope is passed up the urethra so that the prostate can be seen.

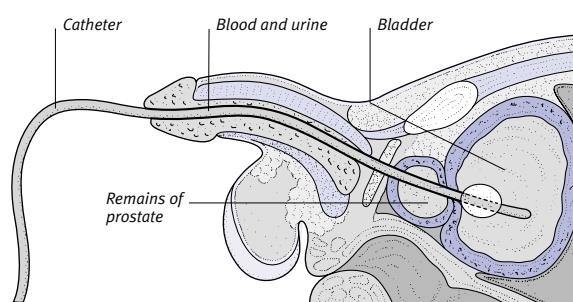

2 A heated wire loop, or sometimes a cutting edge, is inserted through the resectoscope and used to cut away as much of the prostatic tissue as possible.

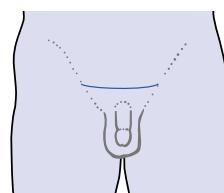

3 The pieces of tissue are washed out through the resectoscope and any bleeding vessels are cauterized by means of an electrode passed up the tube.

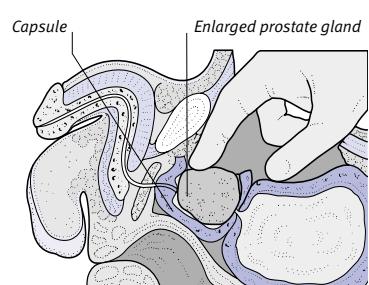

4 The resectoscope is then withdrawn and a catheter passed via the urethra into the bladder. The catheter drains urine from the bladder and allows blood to be washed out. It can usually be removed within 24 hours.

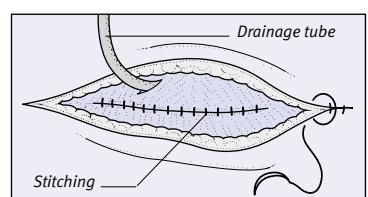

RETROPUBLIC PROSTATECTOMY

1 Under general anaesthesia, an incision is made in the abdomen to expose the bladder and prostate. The surgeon cuts open the capsule containing the gland.

2 The surgeon then removes the prostatic tissue. Once it is removed, bleeding vessels are cauterized and a catheter is then passed up the urethra in order to drain urine from the bladder.

3 A tube is inserted beside the empty capsule to drain any fluid and blood that may collect; the abdomen is sewn up. The tube and catheter are left in for a few days.

prostate gland

A solid, chestnut-shaped organ that surrounds the first part of the male *urethra*. The prostate gland is situated just underneath the *bladder*. It produces secretions that form part of the seminal fluid during *ejaculation*.

The prostate gland consists of two distinct zones: an inner zone, which produces secretions that keep the lining of the urethra moist, and an outer zone, which produces seminal secretions. Two ejaculatory ducts pass from

the seminal vesicles through the prostate gland to enter the urethra; the ducts carry fluid and nutrients from the vesicles to be added to the semen. The prostate gland weighs only a few grams at birth. At puberty, *androgen hormones* cause the gland to enlarge, and it reaches adult size at around age 20. In most men, the prostate begins to enlarge further after the age of 50.

There are a number of disorders that affect the prostate gland. These include benign prostatic hypertrophy (see *pro-*

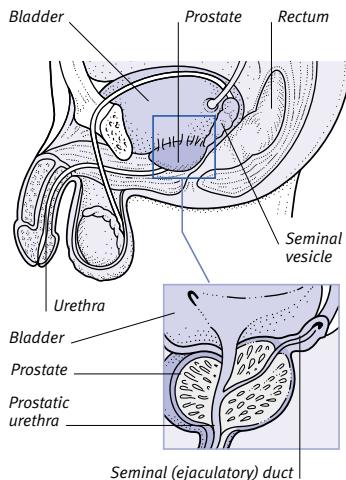

static hypertrophy, benign), cancer (see *prostate, cancer of*), and *prostatitis* (inflammation of the prostate gland).

prostate-specific antigen (PSA)

An *enzyme* that is normally produced by the prostate gland. If the enzyme is produced in excess, it may indicate the presence of *prostate cancer*; tests to detect blood levels of PSA are therefore used as a screening test for prostate cancer. However, PSA levels may also be raised in other conditions such as

LOCATION OF PROSTATE GLAND

Located under the bladder and in front of the rectum, the prostate gland secretes substances into the semen as the fluid passes through ducts leading from the seminal vesicles into the urethra.

benign prostatic hypertrophy (see *prostatic hypertrophy, benign*) and *prostatitis* (inflammation of the prostate).

prostatic hypertrophy, benign

An increase in size of the *prostate gland*, which is most common in men over the age of 50. The cause is unknown.

SYMPOTMS

The enlarging prostate compresses and distorts the *urethra*, impeding the flow of urine from the bladder (known as outflow obstruction). This causes symptoms of *prostatism*, such as frequent urination and dribbling at the end of the urine stream. There may also be incontinence (see *incontinence, urinary*). Eventually the bladder is unable to expel all the urine (see *urinary retention*) and becomes distended, causing swelling, which may be painful. The bladder's inability to empty completely each time urine is passed may lead to *urinary tract infections*. *Kidney failure* may occur as a complication of outflow obstruction.

DIAGNOSIS AND TREATMENT

Prostate enlargement is detected by a *rectal examination*. Tests may include *blood tests*, *ultrasound scanning*, and recording the strength of urine flow. Tests to exclude *prostate cancer* as a cause of enlargement may be needed.

Mild cases do not require treatment, but severe abdominal pain due to blockage of the urine flow needs immediate treatment. Men with a severely enlarged prostate usually require *prostatectomy* (surgical removal of the prostate gland). Alternatively, *alpha-blocker drugs* may be given to improve the flow of urine or *antiandrogen drugs* may be used to counteract the effects of testosterone.

prostatism

Symptoms that arise from the enlargement of the prostate gland (see *prostate, enlarged*) due to its compression and distortion of the *urethra*, which impedes the flow of urine from the bladder (outflow obstruction). Symptoms of prostatism often include frequent urination (see *urination, frequent*), getting up at night to urinate, delay before the urine stream starts, dribbling at the end of the stream, and incontinence (see *incontinence, urinary*).

prostatitis

Inflammation of the *prostate gland*, usually affecting men aged between 30 and 50. It is often caused by a bacterial infection that has spread from the *urethra*. The presence of a urinary *catheter* increases the risk of prostatitis.

The main symptoms of prostatitis are fever, flu-like symptoms, and pain in the lower back. There may also be pain around the rectum, which is particularly troublesome on passing faeces. Diagnosis is made by *rectal examination* and tests on urine samples. Treatment is with *antibiotic drugs*. The condition may be slow to clear up and tends to recur.

prosthesis

An artificial replacement for a missing or diseased part of the body; for example, artificial limbs (see *limb, artificial*), heart valves (see *heart-valve surgery*), or glass eyes (see *eye, artificial*).

prosthetics, dental

The branch of *dentistry* concerned with the replacement of missing teeth and their supporting structures. It includes *dentures*, overdentures (semipermanent fittings over existing teeth), crowns (see *crown, dental*), and bridges (see *bridge, dental*).

protease inhibitors

A type of *antiretroviral drug* that is used to delay the progression of *HIV* infection. (See also *AIDS*.)

proteins

Large molecules consisting of hundreds or thousands of *amino acids* linked into long chains. Proteins may be combined with sugars (glycoproteins) and *lipids* (lipoproteins).

There are two main types of proteins. The first type, fibrous proteins, are insoluble and form the structural basis of many body tissues. The second type, lobular proteins, are soluble and include all *enzymes*, many *hormones*, and some blood proteins, such as *haemoglobin*. In addition, the *chromosomes* in cell nuclei are formed from proteins linked with *nucleic acids*, and cell walls are formed in part from proteins linked with lipids (see *cell*).

Dietary proteins are needed mainly in order to supply the body with amino acids. Ingested proteins are broken down in the digestive system to form amino acids, which are then absorbed and rebuilt into new body proteins (see *protein synthesis*).

protein synthesis

The formation of protein molecules through the joining of *amino acids*. Proteins provide many of the structural components and the enzymes that promote biochemical reactions in the body, so their manufacture is essential for development and growth.

Different cells manufacture various ranges of proteins. The instructions for these processes are held by the *DNA* (deoxyribonucleic acid) in the nucleus of the cell. Protein synthesis starts when a *gene* (a particular length of DNA) acts as a template to form a strand of a substance called messenger *RNA*. Like DNA, RNA consists of a string of building blocks, which are called nucleotide bases; the sequence of bases provides the genetic code for making whichever protein is required.

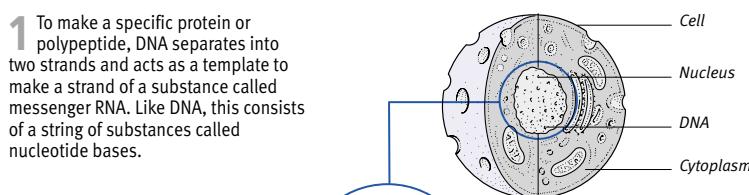

The strand of messenger RNA passes out of the cell nucleus, where it is then decoded (see the illustrated box overleaf) to form a polypeptide chain (a string of amino acids). Several polypeptide chains may be combined to form one protein molecule.

The rate of protein synthesis is regulated by adjustments in the amount of messenger RNA formed in the nucleus of the cell. Highly complex mechanisms operate in order to ensure that the cell manufactures the correct type of proteins, in the required quantities, and at exactly the right time.

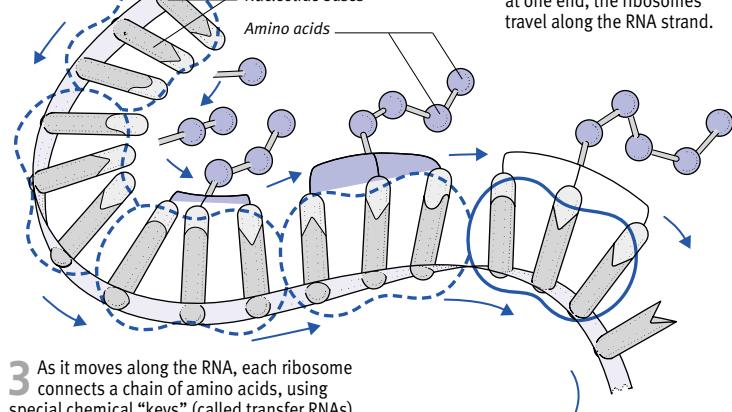

STEPS IN PROTEIN SYNTHESIS

Proteins consist of one or more subunits, which are called polypeptides. These are formed, within cells, from building blocks called amino acids, which are provided to each cell as raw materials. The instructions for making polypeptides are encoded in the DNA that is present within the cell nucleus.

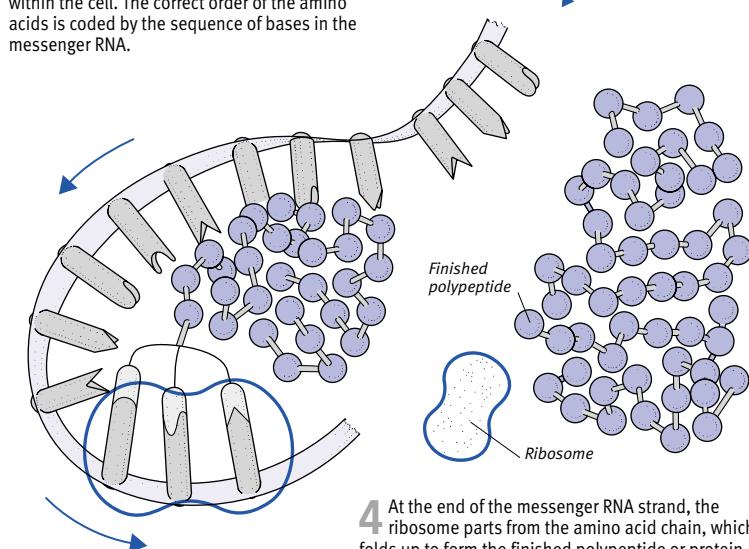

1 To make a specific protein or polypeptide, DNA separates into two strands and acts as a template to make a strand of a substance called messenger RNA. Like DNA, this consists of a string of substances called nucleotide bases.

2 The messenger RNA passes out of the cell nucleus into the cytoplasm, where it is latched on to by several decoding particles called ribosomes. Starting at one end, the ribosomes travel along the RNA strand.

P **3** As it moves along the RNA, each ribosome connects a chain of amino acids, using special chemical "keys" (called transfer RNAs) within the cell. The correct order of the amino acids is coded by the sequence of bases in the messenger RNA.

4 At the end of the messenger RNA strand, the ribosome parts from the amino acid chain, which folds up to form the finished polypeptide or protein.

proteinuria

The presence of *protein* in the *urine*. It may result from kidney disorders, such as *glomerulonephritis* and *urinary tract infection*. Proteinuria may also occur because of a generalized disorder that causes increased protein in the blood. It is diagnosed by *urinalysis*.

Prothiaden

A brand name for the antidepressant drug *dosulepin*.

prothrombin time

A form of *blood-clotting test*. The conversion of prothrombin to thrombin is one of the chemical reactions that takes place during the process of *blood clotting*. This reaction depends on the presence of clotting factors together with calcium and a substance called thromboplastin. If calcium and thromboplastin are added to a sample of blood, it should clot within a certain time. A clotting time that is abnormally slow indicates a deficiency of clotting factors, as occurs in some liver diseases and in vitamin K deficiency. Tests to measure prothrombin time are used to monitor people undergoing treatment with *warfarin* (an *anticoagulant drug*). (See also *International Normalized Ratio*.)

proton pump inhibitors

A type of *ulcer-healing drug*, for example *omeprazole*, that is used in the treatment of *peptic ulcers*.

protoplasm

A term for the entire contents of a *cell*.

protozoa

The simplest, most primitive type of animal, consisting of a single cell. Protozoa are bigger than *bacteria* but still microscopic. About 30 types are human parasites, including those responsible for *malaria*, *amoebiasis*, *giardiasis*, *sleeping sickness*, *trichomoniasis*, *toxoplasmosis*, and *leishmaniasis*.

proximal

A term describing a part of the body nearer to a central point of reference, such as the trunk. (See also *distal*.)

Prozac

A brand name for the antidepressant drug *fluoxetine*.

prurigo

Thickening and *itching* of the *skin* due to repeated scratching.

pruritus

The medical term for *itching*.

pruritus ani

Itching of the *anus*. Causes of pruritus ani may include an *anal fissure*, *haemorrhoids*, or *threadworm infestation*.

PSA

The abbreviation for *prostate specific antigen*.

pseud-/pseudo-

Prefixes meaning false.

pseudarthrosis

A term meaning "false joint", which is used to describe an operation in which the ends of the two opposing bones in a joint are removed and a piece of tissue is fixed in the gap as a cushion. The term also describes a rare childhood condition in which congenital abnormality of the lower half of the *tibia* leads to spontaneous fracture.

pseudoacanthosis nigricans

The most common form of *acanthosis nigricans*, a condition in which dark patches of thickened skin appear in the body's various skin folds.

pseudocyesis

See *pregnancy, false*.

pseudodementia

Severe *depression* in elderly people that mimics *dementia*. Symptoms of pseudodementia include intellectual impairment and loss of memory.

pseudoephedrine

A *decongestant drug* used to relieve *nasal congestion*. High doses may cause anxiety, nausea, and dizziness. Occasionally, *hypertension*, headache, and *palpitations* occur. Pseudoephedrine nasal drops should not be taken for longer than a week because this may cause a sudden increase in congestion on stopping the drug.

pseudoepidemic

An outbreak of an illness in a community or in an institution that is thought to be due to a form of *hysteria*. Typical symptoms are headache and a general feeling of sickness.

pseudogout

A form of *arthritis* that results from the deposition of calcium pyrophosphate crystals in a joint. The underlying

cause is unknown; in rare cases, it is a complication of *diabetes mellitus*, *hyperparathyroidism*, and *haemochromatosis*. Symptoms are similar to *gout*. Diagnosis is from a sample of joint fluid. Treatment is with *nonsteroidal anti-inflammatory drugs* (NSAIDs).

pseudohermaphroditism

A *congenital* abnormality in which the external genitalia resemble those of the opposite sex, but ovarian or testicular tissue is present as normal. A female with pseudohermaphroditism may have an enlarged *clitoris* that resembles a *penis* and enlarged *labia* resembling a *scrotum*. A male may have a very small penis that may resemble a clitoris and a divided scrotum resembling labia. (See also *hermaphroditism*, *sex determination*.)

pseudomonas

Species of rodlike *bacteria* that are inhabitants of soil and some decomposing matter. *PSEUDOMONA AERUGINOSA* is capable of causing disease in humans and is present in pus from wounds.

psilocybin

An *alkaloid* that is present in certain types of mushrooms. It is a *hallucinogenic drug* possessing properties that are similar to those of *LSD*.

psittacosis

A rare illness resembling *influenza* that is caused by the microorganism *CHLAMYDIA PSITTACI*. The disease is contracted by inhaling dust containing the droppings of infected birds, such as pigeons or poultry. Most cases occur among poultry farmers, pigeon owners, and people working in pet shops. Common symptoms are severe headache, fever, and cough, developing a week or more after infection. Other symptoms may include muscle pains, sore throat, nosebleed, lethargy, depression. In some cases, breathing difficulty may also occur.

A diagnosis of psittacosis is made by confirmation of the presence of *antibodies* against *CHLAMYDIA PSITTACI* in the blood. Treatment of the disease is with *tetracycline* antibiotic drugs. If no treatment is given, death may result.

psoas muscle

A muscle that bends the hip upwards towards the chest. There are two parts: psoas major and psoas minor. The psoas major acts to flex the hip. The psoas minor bends the spine down to the pelvis.

psoralen drugs

Drugs containing chemicals called psoralens, which occur in some plants and are present in some perfumes. When absorbed into the skin, psoralens react with *ultraviolet light* to cause skin darkening or inflammation. Psoralen drugs may be used in conjunction with ultraviolet light (a combination called *PUVA*) to treat *psoriasis* and *vitiligo*.

Overexposure to ultraviolet light during treatment, or to too high a dose of a psoralen drug, may cause redness and blistering of the skin. Psoralens in perfumes may cause *photosensitivity*.

psoriasis

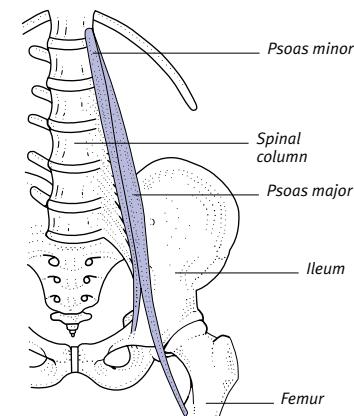

A common skin disease characterized by thickened patches of red, inflamed skin, often covered by silvery scales. The disease usually appears between the ages of 10 and 30, tends to run in families, and affects both men and women. The exact cause of the disease is unknown, although one form (guttate psoriasis) may be caused by a *streptococcal infection*, such as *tonsillitis*.

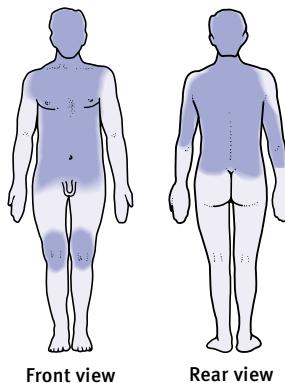

SYMPTOMS AND TYPES

In psoriasis, new skin cells are made about ten times faster than normal. The excess cells accumulate, forming thickened patches covered with dead, flaking skin. Sometimes, there is also a painful swelling and stiffness of the joints (see *arthritis*). Psoriasis tends to recur in

LOCATION OF PSOAS MUSCLE

The muscle has two parts – major and minor. The psoas major acts to flex the hip (bend it up towards the trunk) and rotates the thigh inwards. The psoas minor acts to bend the spine down towards the pelvis.

Psoriasis on the knees

Distribution and appearance of psoriasis
The knees, elbows, scalp, trunk, and back are common sites for psoriasis. The usual appearance is of patches of thickened skin covered by dry, silvery, adherent scales.

P

attacks, which may be triggered by factors such as emotional stress, skin damage, and physical illness.

There are different forms of the disease, and the most common of which is discoid, or plaque, psoriasis, in which patches appear on the trunk, limbs, and scalp. Another type, guttate psoriasis, occurs most often in children, and consists of many small patches that develop over a wide area of skin. Pustular psoriasis is characterized by small *pustules* over part or all of the body.

TREATMENT

In most cases of psoriasis, the condition can be improved with topical treatments, such as those containing *corticosteroid drugs*, coal tar, *calcipotriol* and other *vitamin D* analogues. Other treatments include dithranol ointment, *PUVA*, and drugs such as *methotrexate*. Psoriasis is usually a long-term condition.

psych-

A prefix meaning mental processes or activities, as in psychology.

psyche

A term meaning mind. (See also *psychoanalytic theory*.)

psychiatry

The branch of medicine concerned with the study, prevention, and treatment of mental illness and emotional and behavioural problems. Psychiatrists conduct examinations of physical and mental state and trace the patient's personal and family history. Treatment may include medication, *counselling*, *psychotherapy*, *psychoanalysis*, *cognitive-behavioural therapy*, or *ECT*.

psychoanalysis

A treatment that is based on *psychoanalytic theory* that is used to help people who have *neuroses* and *personality disorders*. A modified approach may also be used in the treatment of *psychosis*. Psychoanalysis aims to help the patient to understand his or her emotional development and to make adjustments in particular situations. Interpretation of the patient's dreams is another aspect of the treatment (see *dream analysis*).

psychoanalytic theory

A system of ideas developed by Sigmund Freud that explains personality and behaviour in terms of unconscious wishes and conflicts. The main emphasis was on sexuality. Freud believed that a child passes through three stages in the first few years of life: oral, anal, and genital. After this, the child develops a sexual attraction to the parent of the opposite sex and wants to eliminate the other parent (*Oedipus complex*). Sexual feelings become latent around the age of five but re-emerge at puberty. Psychological problems may develop if *fixation* occurs at a primitive stage.

MODERN DEVELOPMENTS

Modern psychoanalysis has progressed from these early ideas and is generally based on the observation that the majority of emotional problems are caused by childhood experiences. The aim of psychoanalysis is to free the individual from the past, thereby helping him or her to adjust to the present.

psychodrama

An aid to treatment with *psychotherapy* in which the patient acts out certain roles or incidents. Psychodrama is often carried out with a partner or in a group; music, dance, and mime are often used as part of psychodrama.

psychogenic

A term used to describe a symptom or disorder that is caused by psychological or emotional problems.

psychology

The scientific study of mental processes. Psychology deals with all internal aspects of the mind, such as *memory*, feelings, *thought*, and *perception*, as well as external manifestations, such as *speech* and behaviour. In addition, psychology is concerned with *intelligence*, *learning*, and *personality* development.

psychometry

The measurement of psychological functions with the use of *intelligence tests*, *personality tests*, and tests for specific aptitudes, such as *memory*, logic, concentration, and speed of response.

psychoneurosis

A term that can be used interchangeably with *neurosis*.

psychopathology

The study of abnormal mental processes. There are two main approaches: the descriptive, which aims to record symptoms that make up a diagnosis of mental illness; and the psychoanalytic, which is concerned with a person's unconscious feelings and motives.

psychopathy

An outdated term for an *antisocial personality disorder*.

psychopharmacology

The study of drugs that affect mental states, such as *antipsychotic drugs*, *anti-depressant drugs*, and *anti-anxiety drugs*.

psychosexual disorders

A range of disorders related to sexual function. Psychosexual disorders include *transsexualism*, *psychosexual dysfunction*, and sexual *deviation*.

psychosexual dysfunction

A disorder in which there is interference with the sexual response for no physical cause. (See also *sex therapy*.)

psychosis

A severe mental disorder in which the individual loses contact with reality and develops a distorted view of life. Unlike *neurotic* people, who know they have a problem, those with psychoses may be unaware they are ill. The cause is most

likely to be a disorder of brain function. *Drug abuse* may also precipitate psychosis, which can be acute or chronic.

Psychosis is divided into three main categories, namely *schizophrenia*, *manic-depressive illness*, and organic brain syndrome (see *brain syndrome, organic*). *Paranoia* may be considered to constitute a fourth category. Symptoms of psychosis include *delusions*, *hallucinations*, and change in affect (mood), including *mania* and *depression*.

Episodes of acute psychosis may improve with or without drug treatment. *Antipsychotic drugs* are usually effective in controlling the symptoms. Long-term treatment, *rehabilitation*, and support are often needed. (See also *puerperal psychosis*.)

psychosomatic

A term that describes physical disorders that seem to be caused, or made worse, by psychological factors. Common examples of conditions that may be psychosomatic are headache, breathlessness, nausea, *asthma*, *irritable bowel syndrome*, *dyspepsia*, and some types of *eczema*. (See also *somatization disorder*.)

psychosurgery

Any operation on the brain that is carried out as a treatment for serious mental illness. It is performed only as a last resort when other treatments have failed. Prefrontal *lobotomy* has now been largely replaced by types of *stereotaxic surgery*.

psychotherapy

Treatment of mental and emotional problems by the use of psychological methods. Patients talk to a therapist about their symptoms and problems, with the aim of learning about themselves, developing insights into their relationships, and, ultimately, changing their behaviour patterns.

psychotropic drugs

Drugs that have an effect on the mind, including *hallucinogenic drugs*, *sedative drugs*, *sleeping drugs*, *tranquillizer drugs*, and *antipsychotic drugs*.

pterygium

A wing-shaped thickening of the *conjunctiva* that extends from either side of the eye towards the centre. Pterygium is attributed to prolonged exposure to bright sunlight and is common in tropical areas. It is surgically removed if it threatens vision or causes discomfort.

Appearance of pterygium

The conjunctiva has extended beyond the white of the eye to encroach on the cornea (the transparent front part of the eye).

Congenital ptosis in a child

This condition, which is present from birth, should be corrected surgically in order to prevent any disturbance of visual development.

ptosis

Drooping of the upper eyelid. It may be *congenital*, occur spontaneously, or be due to injury or disease, such as *myasthenia gravis*. It may be due to weakness of the levator muscle of the eyelid or interference with nerve supply. Severe congenital ptosis is corrected surgically.

ptyalism

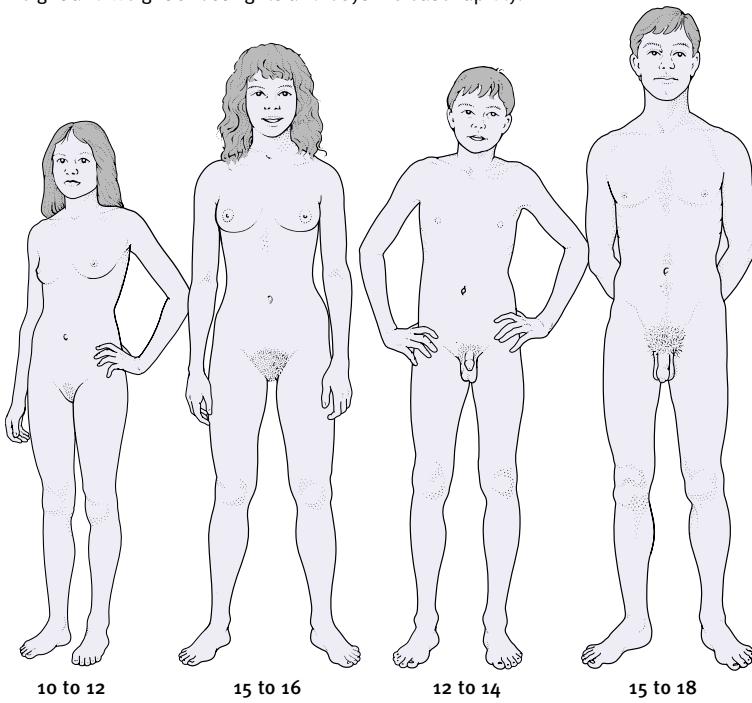

See *salivation, excessive*.

puberty

The period during which adult body features (see *sexual characteristics, secondary*) develop and sexual organs mature, making reproduction possible.

CHANGES OF PUBERTY

There is considerable variation in the age of onset of puberty, but girls, on average, undergo puberty at an earlier age than boys. The entire process takes about three to four years to reach completion. In addition to the changes specific to each sex, height and weight of both girls and boys increase rapidly.

Girls

Puberty most often starts between the ages of 10 and 12 in girls. Major changes include growth of breasts and pubic hair, widening of the hips, enlargement of the uterus, and the onset of menstruation.

Boys

The main changes are enlargement of the sex organs, widening of the shoulders, deepening of the voice, and the growth of facial and pubic hair. The onset is usually between the ages of 12 and 14.

Puberty usually occurs between the ages of 10 and 15. It is initiated by the pituitary gland producing *gonadotrophin hormones*, which in girls stimulate the ovaries to increase secretion of oestrogen hormones and in boys the testes to increase secretion of testosterone.

Puberty is accompanied by a significant growth spurt. Body weight may double during this period, primarily due to muscle growth in boys and increased fat in girls. The growth spurt occurs later in boys.

PUBERTY IN GIRLS

The first sign of puberty in girls is usually breast budding, which occurs around the age of 11; in about one third of girls, pubic hair appears first. The breasts may grow at unequal rates, but any difference usually disappears by the time full maturity is reached. Other secondary sexual characteristics, such as the wider pelvis, the female distribution of fat, and the growth of pubic and underarm hair, develop progressively during this period.

The first menstrual period (see *menstruation*) usually occurs a year or more after the start of puberty. The process of puberty is considered complete when periods occur at regular, predictable intervals. The age at which menstruation starts has decreased during the past century, probably because of an improvement generally in nutrition and living standards, but is now stable. Strenuous sports or other hard physical activity (such as ballet), and debilitating disease, can also delay the onset of menstrual periods.

PUBERTY IN BOYS

In boys, puberty is heralded by a sudden increase in the growth of the testes and scrotum, followed by the appearance of pubic and facial hair. The penis begins to grow around the age of 13 and reaches its adult size about two years later; however, there is a wide variation, so that, at the age of 14, some boys may be fully grown while others still have immature genitals.

Secretion of the male sex hormone *testosterone* increases; this stimulates sperm production and causes the *prostate gland* and *seminal vesicles* to mature. It leads to the development of the typical male distribution of hair on the face, chest, and abdomen. The larynx enlarges and the vocal cords become longer and thicker, causing the pitch of the voice to drop. (See also *delayed puberty*; *precocious puberty*.)

pubic bone

The front part of each of the two hip bones (see *pelvis*). The two pubic bones meet at the pubic *symphysis*, which is situated at the front of the pelvis.

pubic lice

Small, wingless insects (*PHTHIRUS PUBIS*), also called crab lice or crabs, that live in the pubic hair and feed on blood. A louse has a flattened body, up to 2 mm across. Female lice lay eggs (nits) on the hair, where they hatch about eight days later. On men, the lice may also be found in hair around the anus, on the legs, on the trunk, and on the face. The bites sometimes cause itching.

The lice are usually spread from person to person by sexual contact. Children can become infested by transmission from parents, and the lice may live on the eyelids. An insecticide lotion will kill the lice and eggs. In addition, anyone in contact with the infested person should be treated, and clothes and bedding should be washed in water hotter than 60°C before use.

public health

The branch of medicine that is concerned with prevention of disease through measures such as health education, provision of clean water supplies, sewage disposal, safer working conditions, methods of infection control, immunizations, and care of pregnant women and young children. Public health functions are covered by many people and agencies, such as Environmental Health Officers, Medical Officers of Environmental Health, and the Public Health Laboratory Service.

pudenda

The external *genitalia*.

pudendal block

A type of *nerve block* used to provide pain relief for a *forceps delivery*. A local anaesthetic (see *anaesthesia, local*) is injected into either side of the *vagina* near the pudendal nerve.

puerperal psychosis

A severe mental illness that follows *childbirth*. Symptoms of *psychosis* usually develop within two weeks of delivery of the baby and include confusion and mood swings, together with disordered thinking and behaviour, for example believing that the baby is abnormal. *Hallucinations* and *delusions* also occur.

There may be very severe *depression*, including thoughts of suicide and/or of harming the baby. Many women who suffer from puerperal psychosis have a family history of psychotic illness or have had such an illness themselves.

Puerperal psychosis requires urgent psychiatric assessment and hospitalization, ideally in a mother and baby psychiatric unit. Treatment of the condition is with *antipsychotic drugs* and *antidepressant drugs*.

puerperal sepsis

An infection that originates in the genital tract within the first ten days after *childbirth*, *miscarriage*, or *abortion*. Formerly a common cause of death, puerperal sepsis is now easily treated with *antibiotic drugs*.

puerperium

The period of time after *childbirth* during which the *uterus* and genitals return to their pre-pregnancy state.

pulmonary

Relating to the *lungs*.

pulmonary disease, chronic obstructive

A combination of the two lung conditions *chronic bronchitis* and *emphysema*. Chronic obstructive pulmonary disease (COPD) severely restricts air flow into or out of the lungs. Bronchitis causes inflammation and narrowing of the airways, while emphysema results in damage to the alveoli (tiny air sacs) in the lungs, making them much less effective at transferring oxygen from the lungs to the bloodstream.

The major cause of COPD is *smoking*. Atmospheric pollution is a contributory factor, and occupational exposure to dusts and certain other irritants can worsen pre-existing COPD.

SYMPTOMS

Some affected people (so-called "pink puffers") maintain adequate oxygen in their bloodstream through an increase in their breathing rate; however, they suffer from almost constant shortness of breath. Others ("blue bloaters") have cyanosis (a bluish discoloration of the skin and mucous membranes), and sometimes *oedema* (accumulation of fluid in tissues), mainly due to *heart failure* resulting from the lung damage.

DIAGNOSIS AND TREATMENT

COPD may be diagnosed from the symptoms and a physical examination.

The diagnosis of COPD is confirmed by procedures such as *pulmonary function tests*, *chest X-rays* and *CT scans*.

Lung damage that is pre-existing is irreversible, but the affected person must stop smoking immediately in order to prevent further damage. Also, exposure to smoke, pollution, dust, damp, and cold should be minimized.

Drug treatment for COPD may include *bronchodilator drugs* to widen the airways, *diuretic drugs* to remove excess fluid, and *antibiotic drugs* for chest infections. Some people may need *oxygen therapy* for the relief of severe shortness of breath.

pulmonary embolism

Obstruction that affects the pulmonary artery or one of its branches in the lung by an *embolus*, usually a blood clot that has formed as a result of deep vein thrombosis (see *thrombosis*, *deep vein*). In cases in which the embolus is large enough to block the main pulmonary artery or if there are many clots, it may lead to *cardiac arrest* and require emergency resuscitation (see *cardiopulmonary resuscitation*).

CAUSES AND SYMPTOMS

Pulmonary embolism is more likely after recent surgery, pregnancy, oestrogen treatment – for example with the combined pill (see *contraceptives, oral*) or *hormone replacement therapy* (HRT) –

and immobility, including long-haul flights. It may also be linked to *thrombophilia* (a genetic tendency for blood to clot too readily). A massive embolus can cause sudden death. Smaller emboli may cause severe shortness of breath, rapid pulse, dizziness, chest pain that is made worse by breathing, and coughing up of blood. Tiny emboli may not produce any symptoms, but, if recurrent, they may eventually lead to *pulmonary hypertension* (high blood pressure in the arteries that supply the lungs). After having a first embolism, the risk of developing further emboli is significantly increased.

DIAGNOSIS

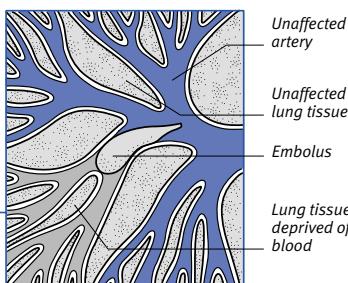

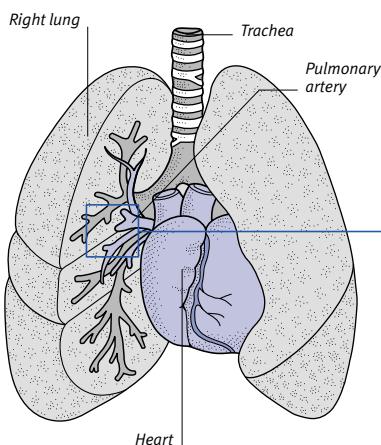

A diagnosis may be made using procedures including *chest X-rays*, *radionuclide scanning*, and *pulmonary angiography*. An *ECG* and analysis of arterial *blood gases* may also be performed.

TREATMENT

Treatment depends on the size and severity of the embolus. A small clot gradually dissolves; *thrombolytic drugs* may be given to speed up this process. Surgery may be needed to remove larger clots. *Anticoagulant drugs* reduce the chance of developing further clots. If the condition recurs, however, tests are needed to investigate the possibility of *blood clotting* disorders. Affected females should stop using combined oral contraceptives and HRT.

PULMONARY EMBOLISM

This condition results when one or more emboli (fragments of material) break off from a blood clot, usually in a vein, and are carried, via the heart, to the lungs. The effects mainly depend on the size and numbers of emboli but also on the general health of the person's lungs and heart.

Site of obstruction

Emboles are carried into the lungs by the pulmonary artery. They may lodge within one of the larger or medium-sized arteries and partially deprive a section of lung tissue of a blood supply.

pulmonary fibrosis

Scarring and thickening of lung tissue, usually as a result of previous lung inflammation. It may be confined to an area of the lung affected by a condition such as *pneumonia* or *tuberculosis*, or it may be widespread through the lungs (see *fibrosing alveolitis*). Shortness of breath is a common symptom.

Diagnosis is confirmed by *chest X-ray*. Treatment depends on the cause, but in most cases the fibrosis is irreversible and treatment aims to prevent the condition from progressing.

pulmonary function tests

A group of procedures that are used to evaluate lung function, to confirm the presence of lung disorders, or to ensure that surgery on the lungs will not disable the patient. Pulmonary function tests include an assessment of the degree of *bronchospasm* (narrowing of the airways due to muscle contraction) with a *peak-flow meter*, *spirometry*, measurement of lung volume, a test of *blood gases*, and measurement of the exchange of gases across the alveoli (the tiny air sacs in the lungs).

pulmonary hypertension

A disorder in which the blood pressure in the arteries supplying the lungs is abnormally high, which develops in response to increased resistance to blood flow through the lungs. In order to maintain an adequate blood flow, the right-hand side of the heart needs to contract more vigorously than previously. As a consequence of this extra work for the heart, right-sided *heart failure* may later develop.

CAUSES

Causes of pulmonary hypertension may include chronic obstructive pulmonary disease (COPD) (see *pulmonary disease*, *chronic obstructive*), a *pulmonary embolism*, *pulmonary fibrosis*, and some congenital heart diseases (see *heart disease*, *congenital*), but it can also develop without an obvious cause.

SYMPOTMS

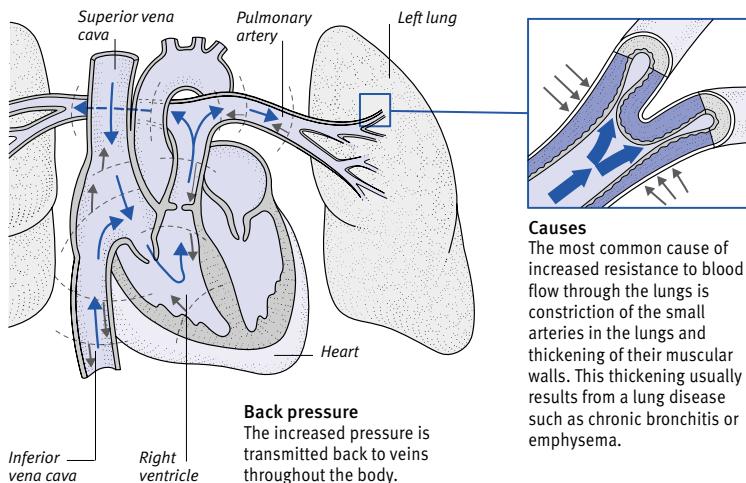

Symptoms, which include enlarged veins in the neck, enlargement of the liver, and generalized *oedema*, only develop when heart failure occurs.

TREATMENT

Treatment is aimed at the underlying disorder (if this is known) and the relief of the heart failure. *Diuretic drugs* or other drugs may be given, and *oxygen therapy* may also be necessary.

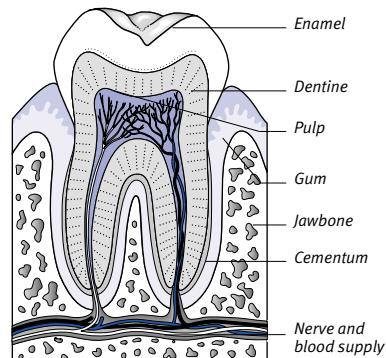

PULMONARY HYPERTENSION

In this condition, there is increased resistance to blood flow through the lungs (blue arrows), usually due to lung disease. The result is a rise in pressure in the pulmonary artery, the right side of the heart (black lines and arrows), and in the veins that bring blood to the heart.

Causes

The most common cause of increased resistance to blood flow through the lungs is constriction of the small arteries in the lungs and thickening of their muscular walls. This thickening usually results from a lung disease such as chronic bronchitis or emphysema.

Location of the dental pulp

The pulp is the soft core at the centre of a tooth. If tooth decay reaches as far as the pulp, the latter degenerates rapidly and must be removed in order to save the tooth.

pulpotomy

The removal of the tooth *pulp*. Pulpotomy is part of the procedure called *root-canal treatment*.

pulpitis

Inflammation of the dental *pulp*, which most commonly occurs as a result of *dental caries*. Pulpitis can lead to periapical *periodontitis* and a periapical abscess (see *abscess, dental*).

pulpotomy

Removal of the coronal part of the *pulp* of a tooth after it has become inflamed, usually by infection. Infection of the pulp is most often caused by extensive tooth decay (see *caries, dental*) or to dental fractures (see *fracture, dental*). Now, pulpotomy is performed only on primary teeth. The technique prevents further degeneration of the pulp.

pulse

The rhythmic expansion and contraction of an artery as blood is forced through it, pumped by the heart. The pulse can be felt at various points on the exterior of the body where arteries lie just below the skin's surface. Examples of such pulse points are the inside of the wrist, the side of the neck, and the top of the thigh.

pump, infusion

A machine that is used in order to administer a continuous and controlled amount of a drug or sometimes of another fluid (such as *insulin* or opioid *analgesic drugs*). The fluid is delivered through a needle that is inserted into a vein or under the skin.

P pulmonary incompetence

A rare defect of the pulmonary valve at the exit of the heart's right *ventricle* (lower chamber). The valve fails to close properly, allowing blood to leak back into the heart. The usual causes of pulmonary incompetence are *rheumatic fever*, *endocarditis* (inflammation of the inner lining of the heart), or severe *pulmonary hypertension*.

pulmonary oedema

Accumulation of fluid in the lungs, which is usually due to left-sided *heart failure*. The build-up of fluid may also be due to a chest infection, to inhalation of irritant gases, or to any of the problems that cause generalized *oedema* (fluid accumulation in tissues).

The main symptom of pulmonary oedema is breathlessness, which is usually worse when the person is lying flat and may disturb sleep (see *paroxysmal nocturnal dyspnoea*). There may also be a cough that produces frothy sputum, which is sometimes pink coloured. In some cases breathing may sound bubbly or possibly wheezy.

A diagnosis of pulmonary oedema is made by a *physical examination* and by a *chest X-ray*. Treatment of the condition may include *morphine*, *diuretic drugs*, *aminophylline*, and *oxygen therapy*; *artificial ventilation* may also be given.

pulmonary stenosis

A *heart* condition in which the outflow of blood from the right *ventricle* (lower heart chamber) is obstructed, causing the heart to work harder in order to pump blood to the lungs.

CAUSES

The obstruction may be caused by narrowing of the pulmonary valve at the exit of the ventricle; by narrowing of the pulmonary artery, which carries blood to the lungs; or by narrowing of the upper part of the ventricle.

SYMPOTMS

Pulmonary stenosis is usually *congenital*, and it may occur on its own or with a set of heart defects that collectively are called the *tetralogy of Fallot*. In rare cases, the stenosis develops later in life, after *rheumatic fever*, and it may cause symptoms of heart failure.

DIAGNOSIS AND TREATMENT

Diagnosis of pulmonary stenosis is made by a *chest X-ray*, *ECG*, *echocardiography*, and Doppler *ultrasound* scanning. A *balloon catheter* may relieve the narrowing. In more serious cases, *heart-valve surgery* or other types of *open heart surgery* are often very successful.

pulp, dental

The soft tissue containing blood vessels and nerves that is situated in the middle of each tooth (see *teeth*).

pump, insulin

A type of infusion pump (see *pump, infusion*) used to administer a continuous dose of insulin to some patients with *diabetes mellitus*. The rate of flow is adjusted so that the level of blood glucose (sugar) is constant.

punch-drunk

A condition that is characterized by slurred speech, impaired concentration, and slowed thought processes. It is caused by brain damage from several episodes of brief loss of consciousness due to head injury.

PUO

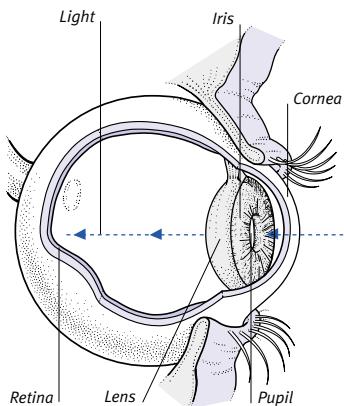

See *pyrexia of unknown origin*.

pupil

The circular opening in the centre of the *iris*. In bright conditions, the pupil constricts; in dim light, it dilates.

LOCATION OF THE PUPIL

The pupil is the circular opening in the centre of the iris. It can be widened or narrowed by muscles in the iris to adjust the amount of light entering the eye.

**purgative**

A term for a *laxative drug*.

purine

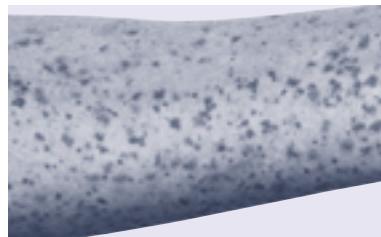

Any of a group of nitrogen-containing compounds synthesized in the body or produced by the digestion of certain proteins. Increased levels of purine can cause *hyperuricaemia*, which may lead to *gout*. Foods that have a high purine content include sardines, liver, kidneys, pulses, and poultry. Purine is also a

component of adenine and guanine, two *nucleotide* bases found in the *nucleic acids* DNA and RNA.

purpura

Any of a group of disorders that are characterized by purple to red-brown areas (or spots) on the skin, caused by bleeding within the skin or mucous membranes. The term purpura also refers to the discoloured areas themselves, which do not blanch (go pale) when pressure is applied to the skin (see *glass test*).

There are many different types and causes of purpura. Common purpura, which is also known as senile purpura, mostly affects women who are middle-aged or elderly. Large discoloured areas, which are caused by thinning of the tissues supporting blood vessels under the skin, appear on the thighs or the back of the hands and forearms. One type, *Henoch–Schönlein purpura*, is caused by inflammation of the blood vessels that lie just beneath the skin. Purpura can also occur as a result of *thrombocytopenia* (a bleeding disorder). Additionally, purpura can be associated with *septicaemia* (blood poisoning) and it can be seen with *meningitis* (inflammation of the membranes that cover the brain and the spinal cord).

Appearance of Henoch–Schönlein purpura
This condition can occur following an infection, or it may be caused by an allergic reaction. Here, a raised rash has appeared on the arm.

purulent

A term that means containing, producing, or consisting of *pus*.

pus

A pale yellow or green, creamy fluid that is found at the site of a bacterial infection. The creamy fluid is composed of many millions of dead white *blood cells*, as well as partly digested tissue, dead and living bacteria, and some other substances. When a collection of pus occurs within a solid area of tissue, this is called an *abscess*.

pustule

A small skin *blisters* that contains *pus*.

PUVA

A type of *phototherapy* that is used to treat a variety of skin conditions, in particular *psoriasis*. PUVA is a combination of a *psoralen drug* and a controlled dose of long-wavelength *ultraviolet light*.

pyelitis

See *pyelonephritis*.

pyelography

Another term for *urography* (see *intravenous urography*).

pyelolithotomy

An operation that is performed in order to remove a kidney stone (see *calculus, urinary tract*). Pyelolithotomy has been largely replaced by other procedures that are less invasive. One example is *lithotripsy*, which uses ultrasonic waves to break up the stones.

pyelonephritis

Inflammation of the *kidney*, which is usually the result of a bacterial infection. Pyelonephritis is more common in women and is most likely to occur during pregnancy. Symptoms include a high fever, chills, and back pain. *Septicaemia* (blood poisoning) may be a complication. Treatment is with *antibiotic drugs*. Recurrent pyelonephritis can lead to *kidney failure*. (See also *vesicoureteric reflux*.)

pyeloplasty

A surgical procedure that is used to relieve *hydronephrosis* (a buildup of fluid in the *kidney*) that results from structural defects in the renal pelvis (the part of the kidney involved in collecting urine) or in the *ureter* (the tube carrying urine from the kidney to the bladder). The operation involves reshaping the affected areas.

pyloric sphincter

The valve situated at the base of the *stomach*; its function is to control movement of food into the *duodenum*.

pyloric stenosis

A condition that is characterized by narrowing of the pylorus (the lower outlet from the stomach). Pyloric stenosis causes an obstruction to the passage of food into the *duodenum* (the first part of the small intestine).

PYLOROPLASTY

CAUSES

Pyloric stenosis occurs in babies as a result of thickening of the pyloric muscle. When it occurs in adults, however, the condition is due to scarring from a *peptic ulcer* or *stomach cancer*.

SYMPOTMS

Babies start projectile vomiting (profuse vomiting in which the stomach contents may be ejected several feet) two to five weeks after birth. Adults with the disorder vomit undigested food several hours after a meal.

DIAGNOSIS

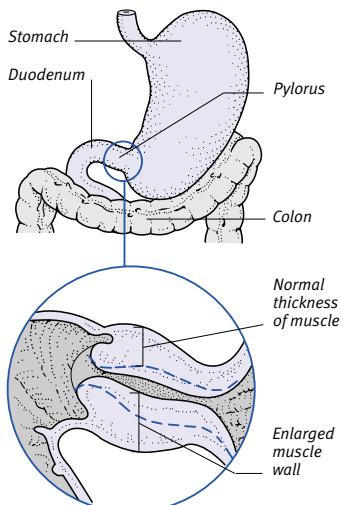

In infants, *ultrasound scanning* is the procedure used for confirmation of the diagnosis. In adults, however, diagnosis is likely to be made by means of a *barium X-ray examination* and a *gastroscopy* (examination of the stomach using a viewing instrument).

TREATMENT

In infants, surgical treatment involves making an incision along the thickened muscle. In adults, surgery is carried out to correct the underlying cause.

PYLORIC STENOSIS IN INFANTS

In infantile pyloric stenosis, the muscle surrounding the outlet from the stomach is abnormally thickened, as shown in the enlarged drawing (below). The condition occurs more often in male than female babies and tends to run in families – infants of a woman who was affected with pyloric stenosis as a baby may develop it.

pyloroplasty

An operation in which the pylorus (the outlet leading from the stomach) is widened in order to allow free passage of food into the intestine. Pyloroplasty may be performed as part of the surgery for a *peptic ulcer*, or may be performed in order to prevent tightening of the pyloric muscles after *vagotomy* (cutting of the vagus nerve to reduce stomach acid production).

pyo-

A prefix that is used to denote a relationship to *pus*. The prefix py- is also used in the same way.

pyoderma gangrenosum

A rare condition that is characterized by ulcers, usually on the legs, that turn into hard, painful areas surrounded by discoloured skin. Pyoderma gangrenosum occurs as a rare complication in *ulcerative colitis*.

pyogenic granuloma

A common, noncancerous skin tumour that develops on exposed areas after minor injury. The tumour can be removed surgically, by *electrocautery*, or by *cryosurgery*.

pyrazinamide

A drug sometimes used to treat *tuberculosis*. Possible adverse effects are nausea, joint pains, *gout*, and liver damage.

pyrexia

A medical term for *fever*.

pyrexia of unknown origin

Persistent fever, lasting ten days or more, with no apparent cause. It is usually due to an illness that is difficult to diagnose or a common disease that appears in an unusual way. Such illnesses include viral infections; *tuberculosis*; cancer, particularly *lymphoma*; and *collagen diseases*, such as systemic *lupus erythematosus* and *temporal arteritis*. Another possible cause of pyrexia of unknown origin is a reaction to a *drug*.

pyridoxine

Vitamin B₆ (see *vitamin B complex*). Dietary deficiency of this vitamin is very rare but can be induced by some drugs. Supplements of pyridoxine (50 to 100 mg per day) are sometimes used to treat *premenstrual syndrome*. There is a possible risk of toxicity if high doses of the supplement are taken long term.

pyrimethamine

A drug that is used in combination with other drugs to treat resistant *malaria*.

pyrogen

A substance that produces *fever*. The term is usually applied to proteins released by white *blood cells* in response to infections. The word is also sometimes used to refer to chemicals released by microorganisms.

pyromania

A persistent impulse to start fires. It is more often seen in males, and may be associated with a low IQ, alcohol abuse, and a *psychosexual disorder*.

pyruvate kinase deficiency

A disorder in which there are abnormally low levels of an *enzyme* called pyruvate kinase, which is carried in *red blood cells*. Normally, pyruvate kinase aids the breakdown of glucose to create energy in *anaerobic* (low-oxygen) conditions. If there is a deficiency of the enzyme, the red cells cannot generate enough energy for themselves; they also develop chemical imbalances that cause them to be destroyed prematurely by the spleen, thereby causing anaemia (see *anaemia, haemolytic*) and enlargement of the spleen. The disorder is usually the result of an autosomal recessive gene defect (see *genetic disorders*).

The severity of the disease varies. Most people require no treatment. *Blood transfusions* may be needed in some cases, particularly when the person is under physiological stress (such as acute illness or pregnancy), at which times the disease tends to be worse. *Splenectomy* (removal of the spleen) may be recommended in severe cases.

pyuria

The presence of *white blood cells* in the *urine*, which is often an indication of an infection of a *kidney* or *urinary tract infection* and inflammation.

Q

QALY

A quality-adjusted life year. QALY is used by health economists to compare the relative costs and outcomes of treatment for various diseases. Each year of life saved or prolonged is adjusted by a factor, Q, which takes account of how close to normal the individual's lifestyle is before and after treatment.

Q fever

An uncommon illness causing symptoms that are similar to those of *influenza*. Q fever occurs throughout the world.

CAUSES

Q fever is caused by the *rickettsia* (a type of small bacterium) *COXIELLI BURNETTI* and may be contracted by inhaling dust contaminated with faeces, urine, or birth products from infected farm animals. Rarely, it is spread by tick bites.

SYMPTOMS

Symptoms develop suddenly about 20 days after infection. They include high fever (lasting up to two weeks), severe headache, muscle and chest pains, and a cough. A form of *pneumonia* subsequently occurs. Most people recover, but the disease is sometimes prolonged: occasionally, *hepatitis* (liver inflammation) or *endocarditis* (inflammation of the inner lining of the heart) may develop.

DIAGNOSIS AND TREATMENT

After diagnosis is confirmed by a *blood test*, treatment is with *antibiotic drugs*. A vaccine is available for people at risk.

quackery

A false claim by someone to have the ability to diagnose and treat disease.

quadrantectomy

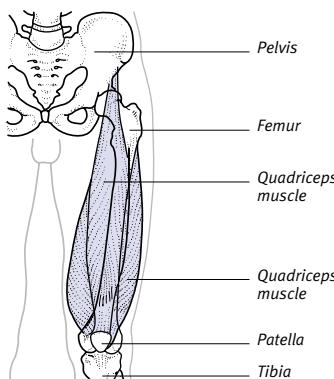

A surgical procedure that involves the removal of tissue in one quadrant of a breast in order to treat *breast cancer*. (See also *lumpectomy*; *mastectomy*.)

quadriceps muscle

A large muscle with four distinct parts, located at the front of the thigh. The quadriceps muscle straightens the knee.

LOCATION OF THE QUADRICEPS MUSCLE

One upper end attaches to the pelvis; the other two ends attach to the femur. The lower ends merge into a tendon that surrounds the patella and attaches to the tibia.

DISORDERS

The most common quadriceps disorder is a *haematoma* (collection of blood), due to a direct blow. Bruising may follow after a few days. Rarely, bone forms in the haematoma, restricting movement.

Sudden stretching of the leg may tear the muscle, especially in middle-aged or elderly people. Rupture of the quadriceps tendon can be caused by a direct blow to the leg or stumbling. Knee disorders that cause pain or swelling, limiting full extension of the leg, cause the muscle to begin to waste away within 48 hours, making the knee feel as if it is giving way when weight is placed on the affected leg. Exercises to strengthen the quadriceps are used to treat certain knee disorders.

quadriparalysis

Muscle weakness in all four limbs and the trunk. (See also *quadriplegia*.)

quadriplegia

Paralysis of all four limbs and the trunk, also known as tetraplegia. Quadriplegia may be caused by damage to the *spinal cord* in the neck region. The condition results in loss of feeling and power in the affected parts. (See also *paraplegia*.)

quarantine

The isolation of a person or animal recently exposed to a serious infectious disease in order to prevent the spread of the disease by symptomless individuals.

Quarantine procedures are now rarely used due to the reduced incidence of serious infectious diseases and the availability of *vaccinations* for many of them. The principal remaining quarantine regulations apply to animals imported into countries that are free from *rabies*.

quickening

The first fetal movements felt by a pregnant woman, which usually occur after about 18 weeks' gestation.

quinapril

An *ACE-inhibitor drug* used in the treatment of *hypertension* and *heart failure*.

quinine

The oldest drug treatment for *malaria*. Quinine is mainly used in large doses to treat strains that are resistant to other antimalarials. There is a high risk of side effects such as headache, nausea, ringing in the ears, hearing loss, and visual disturbance. It is also prescribed in low doses to help prevent leg cramps at night; side effects in this case are rare.

quinolone drugs

COMMON DRUGS

- Ciprofloxacin • Levofloxacin • Nalidixic acid
- Norfloxacin • Ofloxacin

A group of *antibiotic drugs* used to treat bacterial infections. Quinolones are derived from chemicals, rather than from living organisms. They are used to treat a range of conditions, including *prostatitis* (inflammation of the prostate), *urinary tract infections*, acute diarrhoeal diseases (such as those caused by *salmonella infections*), and *enteric fever*. Ciprofloxacin may also be used as an initial treatment for *anthrax*. The absorption of quinolones is reduced by *antacid drugs*.

POSSIBLE ADVERSE EFFECTS

Side effects include nausea, diarrhoea, headache, sleep disorders, rash, and blood disorders. Rarely, there is tendon damage (especially in the elderly and those taking corticosteroid drugs).

WARNING

Quinolones should be used with caution by people with *epilepsy*, during pregnancy and breast-feeding, and by children and adolescents. Swelling and pain in the tendons should be reported.

quinsy

Another name for a *peritonsillar abscess* (an abscess in the soft tissue around the tonsils), a complication of *tonsillitis*.

R

rabies

An acute viral infection of the nervous system, once known as hydrophobia, that affects mammals, including bats. The virus travels along nerve pathways to the brain; once symptoms develop, rabies is usually fatal.

CAUSES AND INCIDENCE

Rabies can be transmitted from a rabid animal to a human by a bite or a lick over broken skin; most human cases result from being bitten by a rabid dog. Rabies is an extremely rare disease in the UK.

SYMPOTMS

The average *incubation period* (the time between exposure to the infection and the appearance of symptoms) is one to two months, depending on the site of the bite. The first symptoms of rabies are slight fever and headache. These are followed by restlessness, hyperactivity, and, in some cases, strange behaviour, hallucinations, and paralysis. The victim develops *seizures*, *arrhythmias* (see *arrhythmia, cardiac*), and paralysis of the respiratory muscles. There is often intense thirst but drinking induces painful spasms of the throat. Death usually occurs ten to 14 days after the onset of symptoms.

TREATMENT AND PREVENTION

Following an animal bite, *immunization* with human rabies *immunoglobulin* and a course of rabies vaccine is necessary; this may prevent the onset of rabies. If symptoms appear, they are treated with sedative drugs and *analgesics* (painkillers).

Emphasis is placed on preventing the disease through *quarantine* regulations and human and animal immunization. Prophylactic immunization is recommended for certain people, for example wild animal handlers and travellers to countries where rabies is endemic. (See also *bites, animal*.)

rachitic

A term that is used to describe abnormalities associated with *rickets* (a bone disease caused by a deficiency of vitamin D) or to refer to people or populations particularly afflicted by rickets.

rad

A unit of absorbed dose of ionizing radiation (see *radiation unit*), which has been superseded by the gray (Gy). "Rad" stands for radiation absorbed dose.

radial keratotomy

See *keratotomy, radial*.

radial nerve

A branch of the *brachial plexus*. The radial nerve, one of the main nerves of the arm, runs from the shoulder to the hand. The radial nerve controls the muscles that straighten the wrist. It conveys sensation from the back of the forearm; the thumb, second, and third fingers; and the base of the thumb.

The radial nerve may be damaged by a fracture of the *humerus* (upper-arm bone) or by persistent pressure on the armpit, such as from the use of a crutch. Such damage may result in *wrist-drop* (an inability to straighten the wrist) and numbness in the areas of skin supplied by the radial nerve.

radiation

The emission of energy (as electromagnetic waves) or matter (as particles) from unstable atoms, which turns them into a more stable form. Some types of radiation are harmful to life; other types are essential, such as light and heat energy radiated from the sun. Even harmful radiation may be used for beneficial purposes. In treatment by *radiotherapy*, for example, the biologically damaging effects of radiation are used to destroy cancerous cells.

IONIZING RADIATION

Four significant types of harmful radiation are gamma radiation, *X-rays*, alpha particles, and beta particles. Gamma radiation and X-rays are types of electromagnetic waves and are similar to more energetic forms of light. The principal difference between the two is that gamma rays are produced by the spontaneous decay of radioactive materials whereas X-rays are produced by a machine. Particle radiation may be produced either during the decay of radioactive atoms or by machine.

All four types of harmful radiation cause damage by ionization: the waves or particles knock out electrons from atoms in the matter that they pass through, turning them into highly reactive *ions*. In the case of living tissue, the ions formed can cause biological damage. Radioactive substances that emit

any of these types of radiation constitute a health hazard. However, alpha particles cannot penetrate the skin, and therefore sources of alpha radiation are only dangerous if they are ingested or inhaled. Gamma radiation can travel large distances through many substances; even distant gamma sources can pose a risk to humans.

Most sources of radiation are natural. Natural sources of ionizing radiation include cosmic rays from space and radioactive minerals. In some areas, the gas *radon*, which is found in soil, rocks, or building materials, is a major source of ionizing radiation. Sources of ionizing radiation that are artificial include X-ray machines, radioactive isotopes used in diagnosis and treatment (see *radionuclide scanning*), and nuclear reactors.

NONIONIZING RADIATION

Less energetic types of radiation, such as *ultraviolet light*, may cause biological damage by mechanisms other than ionization. Ultraviolet radiation from the sun does not penetrate the body deeply, but can damage genetic material in cells and may lead to *skin cancer*.

Other types of nonionizing radiation to which people are subjected are *ultrasound*, used in medicine for diagnosis and treatment, and radio waves that are generated during *MRI* (magnetic resonance imaging). These techniques are not thought to have any adverse side effects. (See also *radiation hazards*; *radiation sickness*; *radiation unit*).

radiation dermatitis

A type of *dermatitis* (inflammation of the skin) that may be caused by single exposure to a high dose of *radiation*.

radiation enteritis

A potentially long-standing form of *enteritis* (inflammation of the small intestine) that is caused by exposure of the intestine to *radiation*, including the use of *radiotherapy*. The symptoms of radiation enteritis include nausea, vomiting, and diarrhoea.

radiation fibrosis

Scarring and thickening of the tissues around an area of the body that has been treated with *radiotherapy*.

radiation hazards

Hazards brought about by *radiation* (the emission of energy in the form of waves or particles) that may arise either from external sources of radiation, such

as X-rays or gamma rays, or from radioactive materials taken into the body. The effects of radiation depend on the dose, the duration of exposure, and the organs exposed.

With some forms of radiation, damage occurs only when the radiation dose exceeds a certain limit – this is usually 1 sievert (Sv) (see *radiation unit*). Examples of such damage are *radiation dermatitis*, *cataract*, organ failure (which may occur many years later), or *radiation sickness* (an early reaction to massive irradiation).

For other types of radiation damage, the risk that damage will occur increases with repeated doses of radiation. *Cancer* that is caused by radiation-induced *mutation* (a change in the genetic material of living cells) is a major example of this type of damage. Radioactive leaks from nuclear reactors can cause a rise in mutation rates, which may lead to an increase in the incidence of cancers, such as *leukaemias*; *birth defects* in succeeding generations; and hereditary diseases. Cancer usually develops years after exposure.

Damage can be controlled by limiting exposure to radiation. People exposed to radiation at work should have their exposure closely monitored to ensure that it does not exceed safe limits. People of reproductive age or younger should have their reproductive organs shielded when having X-rays or undergoing *radiotherapy*.

There is no evidence of radiation hazards arising from visual display units (VDUs) or the *irradiation of food*.

radiation sickness

The term applied to the acute effects of ionizing *radiation* on the whole, or a major part, of the body when the dose exceeds 1 gray (Gy) of X-rays or gamma rays or 1 sievert (Sv) of other types of radiation (see *radiation unit*).

The effects of radiation depend on the dose and the duration of exposure. Total-body doses of less than 2 Gy are unlikely to be fatal to a healthy adult. At doses of 1 to 10 Gy, transient nausea and occasional vomiting may occur, but these usually disappear rapidly and are often followed by a two- to three-week period of relative wellbeing. By the end of this period, the effects of radiation damage to the bone marrow and *immune system* begin to appear, with repeated infections (which may be fatal unless treated with *antibiotic drugs*) and petechiae

(pinpoint spots of bleeding under the skin). Some people are successfully treated with a *bone marrow transplant* or by isolation in a sterile environment until the bone marrow recovers.

With a dose of 10 to 30 Gy there is also an early onset of nausea and vomiting, but these symptoms tend to disappear a few hours later. However, damage to the gastrointestinal tract, which causes severe and frequently bloody *diarrhoea* (known as the gastrointestinal syndrome), and overwhelming infection due to damage to the immune system are likely to result in death between four and 14 days after exposure.

Acute exposures of 30 to 100 Gy cause the rapid onset of nausea, vomiting, anxiety, and disorientation. Within hours, the victim usually loses consciousness and dies due to damage to the *nervous system* and *oedema* (accumulation of fluid) of the brain; these combined effects are known as the central nervous system syndrome.

radiation unit

Several different internationally agreed units (called SI units) are used to measure ionizing *radiation*. For example, the becquerel (symbol Bq) is the SI unit of spontaneous activity of a radioactive source such as uranium. In medicine, the most commonly used units are the gray (symbol Gy) and sievert (symbol Sv).

The gray is the SI unit of radiation that is actually absorbed by any tissue or substance as a result of exposure to radiation. One Gy is the absorption of one joule of energy (from gamma radiation or X-rays) per kilogram of irradiated matter. The gray supersedes an older unit called the rad (1 Gy = 100 rads).

Because some types of radiation affect biological organisms more than others, the sievert is used as a measure of the impact of an absorbed dose. It uses additional factors, such as the kind of radiation and its energy, to quantify the effects on the body of equivalent amounts of different types of absorbed energy. (See also *Radiation units* box, overleaf.)

radical surgery

Extensive surgery that is aimed at eliminating a major disease, usually *cancer*, by removing all the affected tissue and any surrounding tissue that might also be diseased.

Some examples of radical surgery are radical *mastectomy* performed to treat

breast cancer, which involves removing the entire affected breast along with chest muscles, underarm *lymph nodes*, and other tissue; radical neck dissection (see *neck dissection, radical*), in which the lymph nodes in the neck are removed; and *amputation*, which is usually performed to prevent the spread of *gangrene* (tissue death).

radiculopathy

Damage to the *nerve roots* that enter or leave the *spinal cord*. Radiculopathy may be caused by *disc prolapse*, *spinal arthritis*, *diabetes mellitus*, or ingestion of heavy metals, such as lead. Symptoms of radiculopathy are severe pain and, occasionally, loss of feeling in the area supplied by the affected nerves. There may also be weakness, *paralysis*, and wasting of the muscles that are supplied by the nerves.

Where possible, the underlying cause is treated; otherwise, symptoms may be relieved by *analgesic drugs* (painkillers), *physiotherapy*, or, in some cases, surgery.

radioactivity

The emission of alpha particles, beta particles, and/or gamma *radiation* that occurs during the spontaneous disintegration of the nuclei (see *nucleus*) of unstable atoms.

Many radioactive substances, such as uranium ores, are naturally occurring. However, the majority of elements can be made radioactive by bombarding them with high-energy particles, such as neutrons.

radioallergosorbent test

See *RAST*.

radiography

The use of *radiation* to obtain images of parts of the body. Radiographers prepare patients for X-ray examinations, take and develop X-ray pictures, and assist with other *imaging techniques*, such as *radionuclide scanning*, *ultrasound scanning*, and *MRI* (magnetic resonance imaging). (See also *radiology*.)

radioimmunoassay

A sensitive laboratory technique that uses radioactive isotopes to measure the concentration of specific proteins, such as hormones or antibodies, in a person's blood. (See also *immunoassay*.)

radioisotope scanning

See *radionuclide scanning*.

RADIATION UNITS

In the SI system (the internationally agreed system of units), three main units are used to measure radiation levels – the becquerel, the gray, and the sievert. These three units are defined below, along with two other radiation units (the rad and rem) that have now been largely superseded but are still occasionally used for some purposes.

Becquerel

The SI unit of radioactivity. One becquerel (symbol Bq) is defined as one disintegration (or other nuclear transformation) per second. Although the number of becquerels is a measure of how strongly radioactive a particular source is, it takes no account of the different effects of different types of radiation on tissue; for medical purposes, the sievert is generally more useful.

Gray

The SI unit of absorbed dose of ionizing radiation, the gray (symbol Gy) has superseded the rad. One gray is defined as an energy absorption of 1 joule per kilogram of irradiated material. One gray is equivalent to 100 rads.

Rad

An acronym for radiation absorbed dose, the rad is a unit of absorbed dose of ionizing radiation. One rad is equal to an energy absorption of 100 ergs (an erg is a unit of work or energy) per gram of irradiated material. The rad has been superseded by the gray (the corresponding SI unit); 1 rad is equivalent to 0.01 grays.

Rem

An acronym for roentgen equivalent man, the rem is the absorbed dose of ionizing radiation that produces the same biological effect as 1 rad of X-rays or gamma rays. The rem was introduced as a result of the observation that some types of ionizing radiation, such as neutrons, produce a greater biological effect for an equivalent amount of absorbed energy than X-rays or gamma rays. In short, the rem is a measure of the biological effectiveness of irradiation. For X-rays and gamma rays, the rem is equal to the rad. For other types of radiation, the number of rems equals the number of rads multiplied by a special factor (called the quality factor or relative biological effectiveness) that depends on the type of radiation involved. The rem has been superseded by the sievert in the SI system of units; 1 rem is equivalent to 0.01 sieverts.

Sievert

The SI unit of equivalent absorbed dose of ionizing radiation, the sievert (symbol Sv) has superseded the rem. One sievert is the absorbed dose of radiation that produces the same biological effect as 1 gray of X-rays or gamma rays. One sievert is equivalent to 100 rems.

radiology

The medical speciality that uses *X-rays*, *ultrasound scanning*, *MRI* (magnetic resonance imaging), and *radionuclide scanning* to investigate, diagnose, and treat disease.

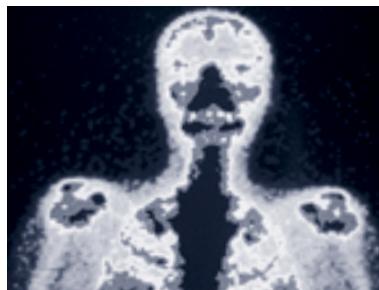

Radiological methods provide images of the body in a *noninvasive* way so that exploratory surgery is not required. The techniques also enable instruments (such as needles and *catheters*) to be accurately guided into different parts of the body both for diagnosis and for treatment, a subspecialty known as *interventional radiology*.

radiolucent

A term referring to anything that is almost transparent to *radiation*, especially to *X-rays* and gamma rays. Some X-ray imaging procedures require the introduction of *radioopaque* substances into the body to make *radiotransparent* and radiolucent organs and/or body tissues stand out more clearly.

radionuclide scanning

A diagnostic technique that is based on the detection of *radiation* emitted by radioactive substances introduced into the body. Different substances are taken up in different concentrations by different tissues, allowing specific organs to

Radionuclide bone scan

Here, the radionuclide has been absorbed by bone. Abnormalities (such as metastases) absorb it in greater amounts and appear as 'hot spots'.

be studied. For example, iodine is taken up mainly by the thyroid gland, so by "tagging" a sample of iodine with a radioactive marker (radionuclide), the thyroid gland's uptake of iodine can be monitored to investigate the functioning of the gland.

HOW IT WORKS

The radionuclide is swallowed or alternatively injected into the bloodstream and then accumulates in the target organ. The organ emits radiation in the form of gamma radiation, which is detected by a gamma camera and then an image is produced.

Cross-sectional images ("slices") can be obtained by using a computer-controlled gamma camera that rotates around the patient. This specialized form of radionuclide scanning is known as SPECT (single photon emission computed tomography). Moving images can also be taken with the use of a computer; a series of images is recorded immediately following the administration of the radionuclide.

WHY IT IS DONE

Radionuclide scanning is capable of detecting some disorders at an earlier stage than other types of *imaging techniques* because changes in the functioning of an organ often occur before the structure of the organ is affected. The technique is also used to detect disorders that affect only the function of an organ. Moving images can provide information about blood flow, the movement of the heart walls, the flow of urine through the kidneys, and bile flow through the liver.

RISKS

Radionuclide scanning is a safe procedure, requiring only minute doses of radiation that are excreted within hours. The radionuclides carry virtually no risk of toxicity or *hypersensitivity*.

radiopaque

A term describing anything that is able to block *radiation*, especially *X-rays* and gamma rays. As many body tissues are *radiolucent* (almost transparent to *X-rays*), some X-ray imaging procedures require the introduction of *radioopaque* substances into the body in order to make the organs stand out clearly. (See also *radiotransparent*.)

radiotherapy

Treatment of *cancer* and, occasionally, some noncancerous tumours, by the use of *X-rays* or other *radiation*. Radio-

active sources produce ionizing radiation, which destroys or slows down the development of abnormal cells. Normal cells should suffer little or no damage in the long term, but short-term damage is a side effect of radiotherapy.

WHY IS IT DONE

Radiotherapy may be used on its own in an attempt to destroy all the abnormal cells in various types of cancer, such as *squamous cell carcinoma* (a type of skin cancer) and *Hodgkin's disease* (a cancer of lymphoid tissue). It may also be used in conjunction with other cancer treatments. For example, surgical excision of

a cancerous tumour is often followed by radiotherapy to destroy any remaining tumour cells, such as in the treatment of *breast cancer*.

Radiotherapy may also be used to relieve the symptoms of a cancer that is too advanced to be cured. An example of such *palliative* treatment is radiotherapy to reduce the size of a *brain tumour* in order to relieve headaches and paralysis.

If the benefits of destroying diseased tissue outweigh the risks of damage to healthy tissue, radiotherapy may be used to treat noncancerous diseases; for

example, part of an overactive thyroid gland (see *thyrotoxicosis*) may be destroyed using radioactive iodine.

HOW IT IS DONE

Radiotherapy is usually performed on an outpatient basis. *X-rays* (or sometimes electrons), which are produced by a machine called a linear accelerator, are aimed at the tumour from many directions. Alternatively, a source of radiation, in the form of tiny pellets, is inserted into the tumour through a hollow needle (see *interstitial radiotherapy*) or into a body cavity (see *intracavitary therapy*). These techniques

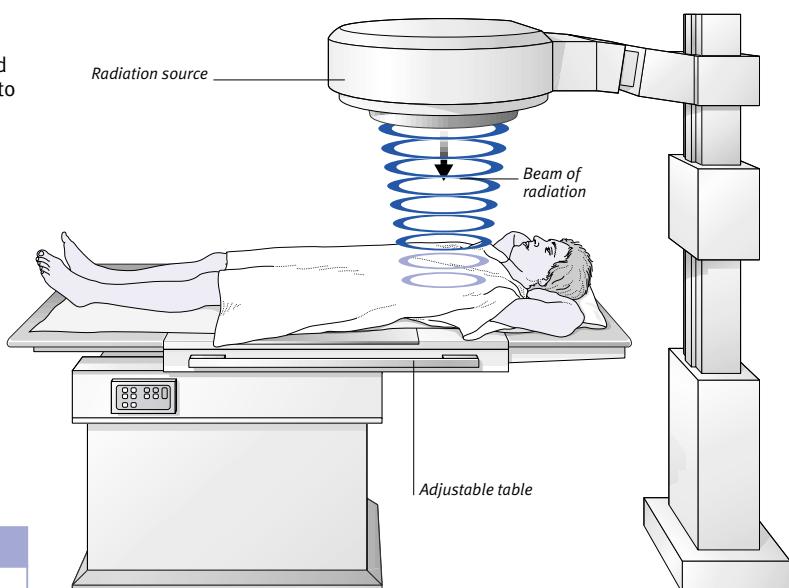

USE OF RADIOTHERAPY

Radiotherapy destroys cancer cells using radiation. A linear accelerator is used for external radiation (right). The position and dose of radiation are carefully calculated to minimize exposure of normal cells to the radiation, allowing them to recover with little or no long-term damage.

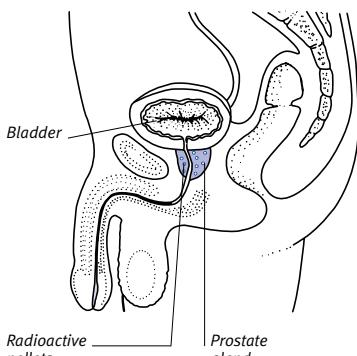

Internal radiation (below) involves placing radioactive materials in the body, directly into or around a cancer.

External radiation

The patient lies still on a table under the machine. A radiographer operates the machine, which sends X-rays, in the predetermined directions and amounts, through the diseased areas of the patient's body. The machine can be tilted to irradiate the cancer from different angles (see below, centre). The procedure causes no discomfort, and usually lasts a few minutes, but setting up the equipment may take 30 minutes.

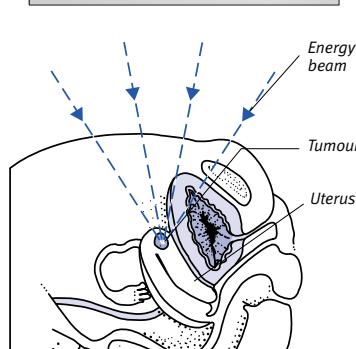

INTERNAL RADIATION

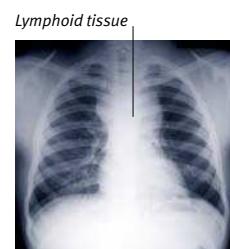

Use of radioactive pellets

Tiny radioactive pellets are inserted, via a hollow needle, directly into the organ or tissue to be treated (here, the prostate gland).

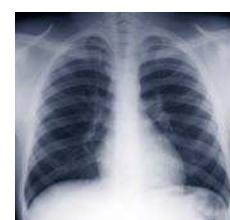

Rays from different directions

By aiming relatively low-energy rays coming from many directions at a tumour, a large enough dose of radiation is achieved in the locality of the tumour to destroy it completely (see above).

Before treatment
There is a proliferation of lymphoid tissue in this lung X-ray of a patient with Hodgkin's disease.

After treatment
The invading lymphoid tissue has diminished following radiotherapy.

are both types of brachytherapy. Radioactive iodine used to treat thyrotoxicosis is given by mouth.

COMPLICATIONS AND RESULTS

There may be some unpleasant side effects of radiotherapy, such as fatigue, nausea and vomiting (for which *anti-emetic drugs* may be prescribed), and loss of hair from irradiated areas. Rarely, there may be reddening and blistering of the skin, which can be alleviated by *corticosteroid drugs*.

Radiotherapy can be used successfully to treat most types of cancer; the chances of success increase the earlier the treatment is started.

radiotransparent

A term referring to anything that is entirely transparent to *radiation*, especially to *X-rays* and gamma rays. Some X-ray imaging procedures require the introduction of *radiopaque* substances into the body to make radiotransparent and *radiolucent* organs and/or body tissues stand out more clearly.

radium

A rare, radioactive, metallic element that occurs naturally only as compounds in *uranium* ores. Radium has four naturally occurring isotopes (varieties of the element that are chemically identical but differ in some physical properties): radium 226, radium 228, radium 224, and radium 223. Radium 226 was used to treat tumours but it has been superseded by other radioisotopes, such as cobalt 60.

radius

The shorter of the two long bones of the forearm; the other is the *ulna*. The radius is the bone on the thumb side of the arm, which articulates with the humerus (the upper arm bone) at the elbow and the carpal bones (upper wrist bones) at the wrist.

The radius takes most of the strain when weight is placed on the wrist, and it is a common site of fractures (see *Colles' fracture*; *radius, fracture of*). A fall or a blow may sometimes cause dislocation of the radius from the elbow joint, along with fracture of the ulna, a condition that is known as Monteggia's fracture.

radius, fracture of

A common type of fracture that may affect the lower end, upper end, or shaft of the *radius* (the shorter of the two long bones in the forearm).

Fracture of the radius just above the wrist (see *Colles' fracture*) is the most common of all fractures in people over 40. It is usually caused by falling on the palm of a hand, resulting in backward displacement of the wrist and hand.

Fracture of the disc-shaped head of the radius, just below the elbow, is one of the most common fractures in young adults. Treatment depends on the type and severity of the fracture. A minor fracture may heal if placed in a soft, supportive bandage; others may require surgical correction. If the head of the bone is crushed or splintered, it may need to be removed.

Fracture of the shaft of the radius may result in displacement of the broken ends of the bone. An operation may be required in order to reposition the bone ends and fix them together before the limb is immobilized.

Fractures of the radius usually take approximately six weeks to heal.

radon

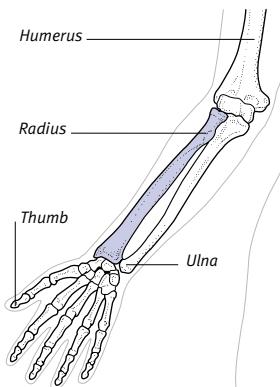

A colourless, odourless, tasteless, radioactive gaseous element produced by the radioactive decay of *radium*.

raloxifene

A drug that is prescribed to prevent and treat postmenopausal *osteoporosis*. Raloxifene has no beneficial effect on other menopausal problems, such as hot flushes. The drug may carry an increased risk of developing a deep vein thrombosis (see *thrombosis, deep vein*).

LOCATION OF THE RADIUS

The radius bone is on the outside of the forearm (here, the right), with the palm facing forwards, or on the inside with the palm facing backwards.

ramipril

An *ACE inhibitor drug* used in the treatment of *hypertension* (high blood pressure) and *heart failure* (reduced pumping efficiency). Ramipril is also used to prevent or delay kidney damage in patients with *diabetes mellitus*. Side effects may include a persistent dry cough, a disturbance in taste, *hypotension* (low blood pressure), and other effects common to all ACE inhibitors.

Ramsay-Hunt syndrome

A type of *herpes zoster* (shingles) that affects the *facial nerve*. Symptoms of Ramsay-Hunt syndrome include facial paralysis, intense ear pain, hearing loss, loss of taste, a painful rash on the affected part of the face, and pain in other parts of the body supplied by the facial nerve. Treatment of the condition is with *antiviral drugs* and, sometimes, *anti-inflammatory drugs*.

randomized controlled trial

A type of *controlled trial* used to evaluate the effectiveness of a drug or treatment in which subjects are randomly allocated to one of the study groups. This random allocation means an individual is equally likely to be selected to receive the treatment being investigated as to be part of the control group of the trial, which may be given a placebo (a chemically inert substance). A comparison is made between various results of the two groups to assess the benefit of the treatment in question.

ranitidine

An *ulcer-healing drug* belonging to the *H₂-receptor antagonist* group. Ranitidine is used to prevent and treat *peptic ulcers* and to treat *oesophagitis* (inflammation of the oesophagus). Side effects may include headache, skin rash, nausea, constipation, and lethargy.

ranula

A *cyst* in the floor of the mouth, which produces a translucent bluish swelling. Ranulas probably arise from damage to a *salivary gland*. Treatment of the ranula is by surgical removal.

rape

Sexual intercourse with an unwilling partner, achieved by the use or the threat of force or violence. Rape is rarely sexually motivated; it is a crime of dominance, anger, and hostility, not a crime of passion. Rape is a criminal offence.

EFFECTS

The rape victim may suffer a variety of physical injuries. Severe injury to the genitals is rare, but there may be swelling of the labia (folds of skin), bruising of the vaginal walls or cervix, and possibly tearing of the anus or the perineum (the area between the genitals and the anus).

The psychological effects of rape are often severe and may include significant *anxiety*, *depression*, or *post-traumatic stress disorder*. Nightmares or flashbacks of the event may also occur.

FORENSIC TESTS

Physical examination of a rape victim involves noting signs of bruising or injury, particularly to the genital area, and visual inspection of the vaginal canal. The doctor collects *swabs* from suspected bite marks, soiled areas of the body, and the vagina, anus, or throat, as well as fingernail scrapings or clippings and any loose strands of hair. Such specimens are analysed in a laboratory and *DNA* tests are performed on them. The results of these tests may be compared with test results on samples that are taken from a suspect.

TREATMENT

Physical injuries are treated as required. Emergency contraception (see *contraception, emergency*) may be prescribed. Treatment for *sexually transmitted infections* may be necessary in some cases.

In the treatment of psychological trauma, *counselling* can be beneficial. In some cases, psychiatric help may also be required. Many victims are now helped by local rape support groups.

rash

A group of spots or an area of red, inflamed skin. A rash is usually temporary and is only rarely a sign of a serious underlying problem. A rash may be accompanied by itching or fever.

TYPES

Rashes are classified according to whether they are localized (affecting a small area of skin) or generalized (covering the entire body) and also by the type of spots present.

A macular rash consists of spots that are level with the surrounding skin and discernible from it only by a difference in colour or texture. Nodular and papular rashes are composed of small, raised bumps, which may or may not be the same colour as the surrounding skin. A bullous rash has large blisters, a vesicular rash has small blisters, and a pustular

rash has blisters filled with pus. A butterfly rash is a skin eruption across the cheeks with a narrow connecting band across the nose; it is characteristic of systemic *lupus erythematosus*.

CAUSES

Rashes are the main sign of many infectious diseases, such as *chickenpox*, and are a feature of many *skin disorders*, such as *eczema* and *psoriasis*. A rash may also indicate an underlying medical problem, such as the rashes of *scurvy* or *pellagra*, which are caused by vitamin deficiency. The rashes that are characteristic of *urticaria* (nettle rash) or contact *dermatitis* may be caused by an allergic reaction (see *allergy*). Drug reactions, particularly those to *antibiotic drugs*, are another common cause.

DIAGNOSIS AND TREATMENT

Diagnosis is based on the appearance and distribution of the rash, the presence of any accompanying symptoms, and the possibility of allergy (for example, to drugs).

Any underlying cause of the rash is treated where possible. An itching rash may be relieved by a soothing lotion, such as *calamine*, or an *antihistamine drug*. (See also *meningococcal rash*.)

RAST

An abbreviation for radioallergosorbent test. RAST is a type of *radioimmunoassay* used to detect antibodies (proteins manufactured by the immune system) to specific *antigens* (substances that can trigger an *immune response*).

rats, diseases from

Rats are rodents that live close to human habitation. They damage and contaminate crops and food stores and can spread disease.

The organisms responsible for *plague* and one type of *typhus* are transmitted to humans by the bites of rat fleas. *Leprosy* (Weil's disease) is caused by contact with anything contaminated with rat's urine.

Rat-bite fever is a rare infection transmitted directly by a rat bite. There are two types of rat-bite fever, each caused by different bacteria. Symptoms include inflammation at the site of the bite and in nearby *lymph nodes* and vessels; bouts of fever; a rash; and, in one type, painful joint inflammation. Treatment for both types is with *antibiotic drugs*.

The *rabies* virus can be transmitted by the bites of infected rats. *Lassa fever*, another viral disease, may be contracted

from the urine of infected rats in West Africa. Rats also carry the viral infection lymphocytic chorio-meningitis, as well as the bacterial infection *tularemia*.

Raynaud's disease

A disorder of the blood vessels in which exposure to cold causes the small arteries supplying the fingers and toes to contract suddenly. This action cuts off blood flow to the digits, which become pale. The fingers are more frequently affected than the toes. The cause of Raynaud's disease is unknown, but young women are most commonly affected.

Symptoms develop with no known cause. On exposure to cold, the digits turn white due to lack of blood. As sluggish blood flow returns, the digits become blue; when they are warmed and normal blood flow returns, they turn red. During an attack, there is often tingling, numbness, or a burning feeling in the affected fingers or toes. In rare cases, the artery walls gradually thicken, permanently reducing blood flow, leading to painful ulceration or even *gangrene* (tissue death) at the tips of the affected digits.

Diagnosis is made from the patient's history. Treatment involves keeping the hands and feet as warm as possible. *Vasodilator drugs* or *calcium channel blockers* may be prescribed in severe cases. (See also *Raynaud's phenomenon*.)

Raynaud's phenomenon

A circulatory disorder affecting the fingers and toes that shares the mechanism, symptoms, and signs of *Raynaud's disease* but which results from a known underlying disorder.

Possible causes of Raynaud's phenomenon include arterial diseases, such as *atherosclerosis* (fat deposits on the artery walls); connective tissue diseases, such as *rheumatoid arthritis*; and various drugs, such as *beta-blocker drugs*. The disorder is a recognized occupational disorder of people who use pneumatic drills, chain saws, or other vibrating machinery, and other people whose fingers suffer repeated trauma.

Treatment is the same as for Raynaud's disease, along with treatment of the underlying disorder.

reactive arthritis

Inflammation of the joints due to an abnormal *immune response* (the body's defensive response to foreign substances) that occurs after an infection of

the genital tract, such as *chlamydial infection*, or of the intestinal tract, such as *gastroenteritis*. If there is additional inflammation elsewhere in the body, such as in the eyes, the condition is known as *Reiter's syndrome*.

reactive depression

A term that was formerly used to describe a type of *depression* (feelings of sadness, hopelessness, and a lack of interest in life) resulting from a stressful or emotional event or period of life. In contrast, another type of depression known as "endogenous depression" was seen to originate from biological factors within an individual. In the majority of cases, however, depression is a combination of these two types.

reactive hypoglycaemia

A form of *hypoglycaemia* (low blood glucose levels) that occurs within a few hours of eating foods that are rich in glucose. In reactive hypoglycaemia, the body overreacts to the sudden rise in blood sugar by releasing large amounts of *insulin*. This results in a rapid and excessive drop in the blood sugar level causing hypoglycaemic symptoms.

reagent

A term that is used for any chemical substance that takes part in a chemical reaction. The term usually refers to a chemical or a mixture of chemicals that are used in chemical analysis (see *analysis, chemical*) or used to detect a biological substance.

reboxetine

An *antidepressant drug* that blocks the reuptake of *noradrenaline* (norepinephrine) within the nervous system. Side effects of reboxetine include insomnia, sweating, and dizziness on standing.

receding chin

Underdevelopment of the lower jaw. The condition can be corrected by the use of *orthodontic appliances* if used in the growth spurt at adolescence or by *cosmetic surgery*.

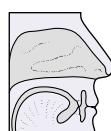

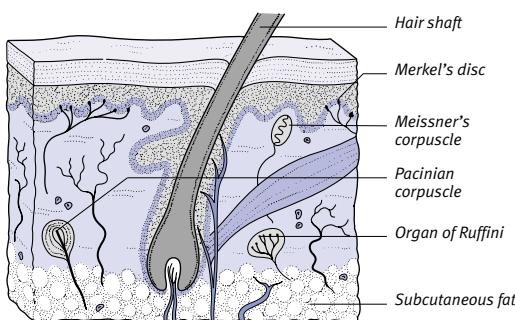

receding gums

Withdrawal of the gums from around the teeth, resulting in the exposure of part of the roots. The teeth may become sensitive to hot and cold substances and

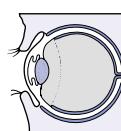

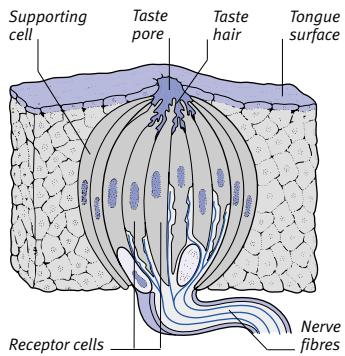

TYPES OF RECEPTOR

Stimuli are detected by the free endings of sensory nerve cells or by special structures forming the endings of these cells. These respond to specific stimuli (such as light of a certain wavelength) and send a signal indicating the presence of the stimulus to the spinal cord and/or the brain. Cell surface or chemical receptors (right) are tiny structures on the outer surface of a cell. They allow certain chemicals to bind to the cell and trigger some change within it.

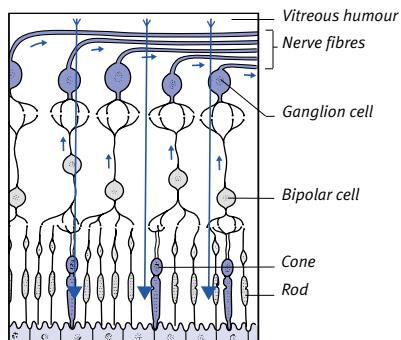

Skin receptors
The skin contains many types of receptor that respond to stimuli such as pressure, cold, heat, and hair movement, allowing the sensations of touch, temperature, and pain. They include such structures as pacinian corpuscles and Merkel's discs and are all special types of nerve cell ending.

Receptors in tongue
Each taste-bud (below) consists of many receptor cells. Each has surface receptors that respond to chemicals in food.

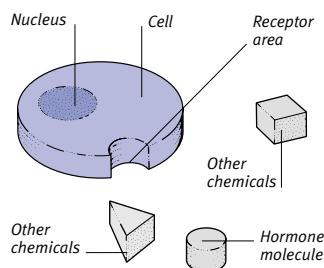

Receptors in eye
The retina, located at the back of the eye, contains receptor cells, called rods and cones, which are responsive to light.

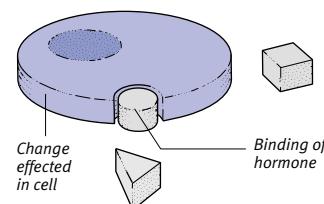

HOW CELL SURFACE OR CHEMICAL RECEPTORS WORK

Most cells have many surface receptors (only one is shown below). Their existence allows the activity of the cell to be influenced from outside.

1 A receptor allows only one specific chemical (which may be a hormone or a neurotransmitter substance) to bind to it. The chemical must have a configuration that "fits" the receptor.

2 The binding of chemical to receptor alters the outer cell membrane and triggers a change, such as contraction by a muscle cell or increased activity in an enzyme-producing cell.

the attachment of the tooth in the socket may weaken, causing the tooth to become loose. Severe cases of receding gums are usually a sign of gum disease (see *gingivitis*; *periodontitis*).

receding hairline

A feature that is characteristic of male-pattern baldness (see *alopecia*).

receptor

A general term for any sensory nerve cell (one that converts stimuli into nerve impulses). The term receptor is also used to refer to specific structures that occur on the surface of a cell (see *Types of receptor* box, left) that allow chemicals to bind with the cell in order to exert their effects.

recessive

A term used in genetics to describe one of the ways by which a *gene* is passed from parent to offspring. Many characteristics are determined by a single pair of genes, one of each pair being inherited from each parent. A recessive gene is overridden by an equivalent *dominant* gene. For example, the gene for blue eye colour is recessive; therefore, if a child inherits the gene for brown eyes from one parent and the gene for blue eyes from the other, the "blue eye" gene is overridden by the "brown eye" gene, and the child ends up with brown eyes. The child must inherit the recessive blue eye gene from both parents in order to develop blue eyes.

Many *genetic disorders* are determined by a recessive gene. Examples include *cystic fibrosis* and *sickle cell anaemia*. The child will only have the disease if he or she inherits the gene from both parents.

recombinant DNA

A section of *DNA* (genetic material) from one organism that has been artificially spliced into the DNA of another organism, often that of a viral or bacterial cell. This procedure may be carried out in order to make the recipient cell produce a substance that it would not normally be able to produce. An example of this technique is the addition of a DNA section containing the genetic code for the hormone *insulin* into a recipient cell. If this cell can be encouraged to replicate, it is possible for large amounts of the hormone to be obtained. (See also *genetic engineering*.)

reconstructive surgery

See *arterial reconstructive surgery*; *plastic surgery*.

recovery position

The position in which to place an unconscious, breathing casualty, while waiting for medical help to arrive.

The body is placed on its side with the upper leg bent at a right angle; the lower leg is kept straight. The lower arm is bent at a right angle; the upper arm is bent with the back of the hand placed against the lower cheek to support the head, which is tilted back to keep the airway open. Casualties with suspected spinal injuries should not be placed in the recovery position.

recovery room

A hospital unit situated near operating theatres and delivery rooms that contains specialized equipment and staff who have been trained in the monitoring and care of postoperative patients and women who have recently given birth. Patients leave the recovery room to return to general nursing care as soon as they are considered to be in a sufficiently safe and stable condition. (See also *intensive care unit*.)

rectal bleeding

The passage of blood from the *rectum* or *anus*. The blood may range in colour from bright red to dark brown or black. It may be mixed with, or on the surface of, *faeces* or passed separately. Rectal bleeding may or may not be accompanied by pain.

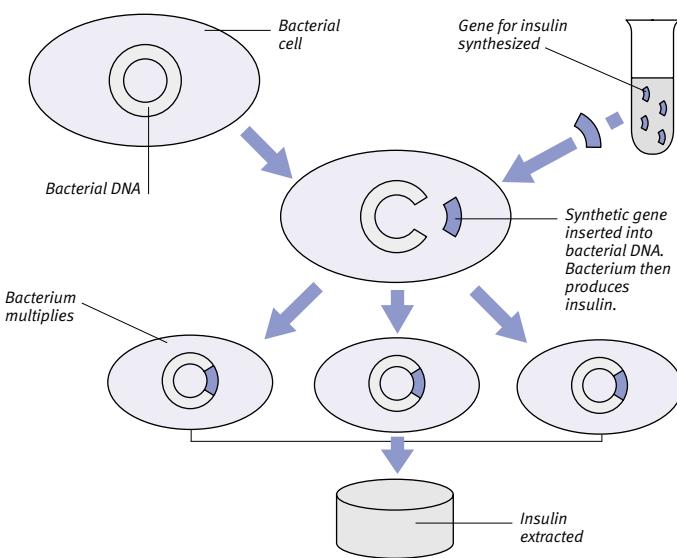

Haemorrhoids (swollen veins in the lining of the anus) are the most common cause of rectal bleeding. Small amounts of bright red blood appear on the surface of faeces or on toilet paper. *Anal fissure* (an ulcer or tear at the margin of the anus), *anal fistula* (an abnormal anal channel), *proctitis* (inflammation of the rectum), or *rectal prolapse* (protrusion of the rectal lining) may also cause rectal bleeding.

Cancer of the colon (see *colon, cancer of*) or the rectum (see *rectum, cancer of*) or *polyps* (grape-like growths) can also cause bleeding. Disorders of the colon, such as *diverticular disease*, may cause dark red faeces. Black faeces (see *melaena*) may be due to bleeding from high in the digestive tract. Bloody diarrhoea may be caused by *ulcerative colitis*, *amoebiasis*, or *shigellosis*.

Diagnosis may be made from a *rectal examination*, *proctoscopy*, *sigmoidoscopy*, or *colonoscopy* (internal examination using a

RECOMBINANT DNA AND GENETICALLY ENGINEERED INSULIN

Genetic engineering can force bacteria to produce human insulin. The insulin gene is obtained (by removing it from human DNA, then purifying it) and spliced into the DNA of a bacterium, causing it to produce human insulin. The bacterium is then cultured for large-scale insulin extraction.

rigid or flexible viewing instrument), or a double-contrast *barium X-ray examination*. Rectal bleeding in anyone over the age of 40 should be carefully investigated to rule out the possibility of colorectal cancer.

rectal examination

Examination of the *anus* and *rectum*, which may be performed as part of a general *physical examination*. A rectal examination is usually used to assess symptoms of pain, changes in bowel habits, the size of the prostate gland, or to check for the presence of *tumours* of the rectum or *prostate gland*.

rectal prolapse

Protrusion outside the *anus* of the lining of the *rectum*, usually brought on by straining to defaecate. The condition commonly causes discomfort, a mucus discharge, and *rectal bleeding*.

Rectal prolapse is usually temporary in young children, but it is often permanent in elderly people due to a weakening of the tissues that support the perineum (the area between the anus and the external genitals). In cases in which the prolapse is large, leakage of *faeces* may occur.

Treatment is with a fibre-rich diet. Surgery may also be performed, especially on older people.

rectocele

A bulging inwards and downwards of the back wall of the *vagina*, which occurs as a result of the *rectum* pushing against weakened tissues in the vaginal wall. A rectocele is usually associated with a *cystocele* (protrusion of the bladder into the front wall of the vagina) or a prolapsed uterus (see *uterus, prolapse of*).

There may be no symptoms or the rectocele may cause *constipation*. *Pelvic floor exercises* may help to relieve symptoms. If they do not, an operation to tighten the tissues at the back of the vagina may be recommended.

rectum

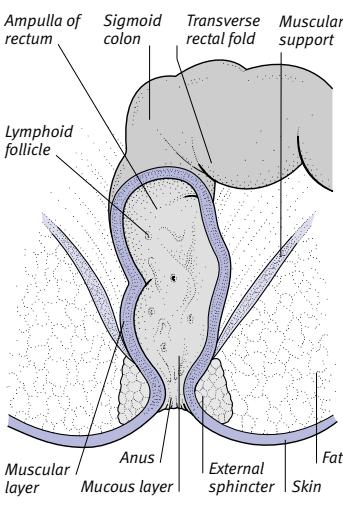

A short, muscular tube that forms the lowest part of the large intestine and connects it to the *anus*.

STRUCTURE

The first part of the rectum consists of four layers: an outermost serous layer; a muscular layer; a submucous layer; and an innermost mucous layer that lubricates the rectum. There is no serous layer in the last third of the rectum.

STRUCTURE OF THE RECTUM

The rectum is about 12 cm long; its wall consists mainly of longitudinal and circular muscle. An inner, mucous layer provides lubrication.

FUNCTION

The rectum collects *faeces* that have formed in the alimentary tract (the tube-like structure that extends from the mouth to the anus). Pressure on the rectal wall causes nerve impulses to pass to the brain; the urge to defaecate occurs when the collected faeces distend (stretch) the rectum.

DISORDERS

Rarely, a baby is born with no rectum or anus (see *anus, imperforate*).

There are a number of diseases and disorders that affect the rectum; these include *proctitis* (inflammation), *polyps* (grapelike growths), and cancer (see *rectum, cancer of*).

The rectum can become obstructed as a result of narrowing, which may be caused by *radiotherapy*, *granuloma inguinale* (a sexually transmitted infection), or a pelvic infection. In rare cases, an *ulcer* develops in the rectum, causing bleeding and a discharge.

Rectal prolapse occurs when the lining of the rectum protrudes outside the anus. In a *rectocele*, the rectum and rear wall of the vagina bulge downwards into the vagina.

Rectal disorders are usually diagnosed by means of *rectal examination* and *proctoscopy* or *sigmoidoscopy* (internal examination using a rigid or flexible viewing instrument).

rectum, cancer of

A malignant *tumour* in the *rectum* (the muscular tube that forms the last part of the large intestine). There may be a genetic basis for some types of rectal cancer. In particular, an inherited disorder called familial adenomatous *polyposis* (in which large numbers of polyps develop in the large intestine) increases the risk. In most cases, however, the precise cause is unknown. Dietary factors, such as eating a lot of meat and fatty foods and not enough fibre, may also increase the risk. Cancer of the rectum is most common between the ages of 50 and 70.

SYMPTOMS

Early symptoms of cancer of the rectum are *rectal bleeding* during defaecation and diarrhoea or constipation. Later, pain may occur. Left untreated, the cancer may eventually cause severe bleeding and pain and block the intestine, preventing the passage of faeces. The cancer may also spread to other organs.

DIAGNOSIS AND TREATMENT

Rectal cancer may be suspected from a positive result in a *faecal occult blood test*, which is used to check for hidden blood in the faeces. It may also be detected during a *rectal examination* and confirmed using *proctoscopy* or *sigmoidoscopy* (internal examination using a rigid or flexible viewing instrument) and a *biopsy* (removal of a small sample of tissue for microscopic analysis).

Treatment is usually with surgery. For a tumour in the upper rectum, the affected area and the last part of the colon are removed and the two free ends of the intestine are sewn together. To promote healing, a temporary *colostomy* (which diverts faeces through a surgical opening in the abdomen) may be made. For a growth in the lower rectum, the entire rectum and anus are removed. Because there is no outlet for faeces, a permanent colostomy is created.

Radiotherapy and *anticancer drugs* may be used in addition to, or instead of, surgery. The outlook depends on how widespread the cancer is at the time treatment is commenced.

recurrent pregnancy loss

Another term for *habitual abortion*.

red blood cell

Also known as an *erythrocyte*, a *blood cell* containing the red, oxygen-carrying pigment *haemoglobin*. The main function of a red blood cell is that of transporting

oxygen around the body. A mature red blood cell is a biconcave disc shape and does not possess a nucleus. (See also *white blood cell*.)

red-eye

Another name for *conjunctivitis*.

reduction

The process of manipulating a displaced part of the body back into its original position. Reduction may be carried out to realign fractured bone ends (see *fracture*), to replace a dislocated joint in its socket (see *dislocation, joint*), or to treat an abdominal *hernia* by pushing the protruding intestine back through the abdominal wall.

Reference Nutrient Intake (RNI)

Figures, based on the needs of a healthy individual, that establish the minimum daily requirements of vitamins and minerals. Requirements of certain vitamins and minerals may differ according to factors such as age, gender, and stage of life.

referred pain

Pain felt in a part of the body at some distance from its cause. Referred pain occurs because some remote parts of the body are served by the same *nerve* or group of nerves. Occasionally, nerve impulses that reach the brain from one of these areas may be misinterpreted as coming from another.

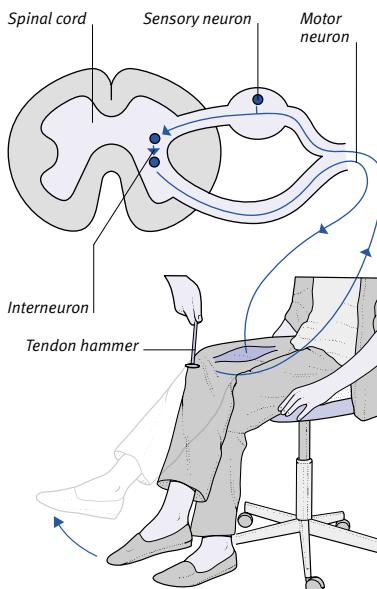

Common examples of referred pain are *sciatica* and the pain down the inside of the left arm caused by *angina pectoris* (chest pain due to impaired blood supply to the heart muscle) or a *myocardial infarction* (heart attack).

reflex

An action that occurs automatically and predictably in response to a particular stimulus; a reflex is independent of the will of the individual.

In the simplest reflex, a sensory nerve cell reacts to a stimulus, such as heat or pressure, and sends a signal along its nerve fibre to the *central nervous system* (the brain and spinal cord). There, another nerve cell becomes stimulated and causes a muscle to contract or a gland to increase its secretory activity. The passage of the nerve signal from original sensation to final action is known as a *reflex arc*.

Reflexes may be inborn or conditioned. Some inborn reflexes occur only in babies (see *reflex, primitive*), such as

Simple knee-jerk reflex

A tap with a rubber hammer just below the kneecap stretches a tendon of one of the thigh muscles. A signal passes via a sensory neuron (nerve cell) to the spinal cord, activating a motor neuron, which contracts the muscle, jerking the lower leg upwards.

the grasp reflex that occurs when an adult's finger is placed in the baby's palm. Inborn reflexes include those that control basic body functions, such as contraction of the bladder after it has filled beyond a certain point. Such inborn reflexes are managed by the *autonomic nervous system*.

Conditioned reflexes are acquired through experience in a process called *conditioning*. For example, a person may follow a familiar route home from work without making a conscious effort.

Several simple reflexes, such as the knee-jerk reflex and constriction of the pupil in response to light, are tested in a *physical examination*. Changes in reflexes may indicate damage to the nervous system. The examination of vital reflexes controlled by the brainstem is the basis for diagnosing *brain death*.

reflexology

A form of *complementary medicine* in which the practitioner massages parts of the patient's feet in an attempt to treat disorders affecting other areas of the body.

reflex, primitive

An automatic movement in response to a stimulus that is present in newborn infants but disappears during the first

few months after birth. Primitive reflexes are believed to represent actions that may have been important for survival in earlier stages of human evolution.

Primitive reflexes include the grasp reflex, which occurs when something is placed in the baby's hand, and the rooting reflex, which enables a baby to find the nipple (see *Types of primitive reflex box*, overleaf).

Primitive reflexes are tested after birth to give an indication of the condition of an infant's nervous system. Their persistence beyond the expected stage of development may point to a disorder of the developing *brain*.

reflux

An abnormal backflow of fluid in a body passage, which may result from failure of the passage's exit to close properly. A common type of reflux is the *regurgitation* of acidic fluid from the stomach into the oesophagus (see *acid reflux*). (See also *vesicoureteric reflux*.)

reflux oesophagitis

A type of *oesophagitis* (inflammation of the oesophagus) that is caused by poor functioning of the muscles in the lower oesophagus, leading to *acid reflux*.

reflux, vesicoureteric

See *vesicoureteric reflux*.

refraction

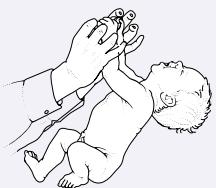

The bending of light rays as they pass from one substance to another. Refraction provides the mechanism by which images are focused on the *retina* in the eye, thereby permitting *vision*.

Refsum's disease

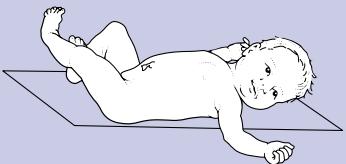

A rare *genetic disorder* that affects lipid metabolism (the processing of fats by the body). Refsum's disease causes excessively high levels of phytanic acid, a fatty acid, in the body.

One major symptom is *polyneuritis* (inflammation of nerves around the body). This may result in weakness and numbness, often affecting the limbs. Other common features of the condition are a visual defect called *retinitis pigmentosa* and *ataxia*, an unsteady gait caused by damage to the brain's *cerebellum*. Symptoms usually appear before the age of 20. The disease is progressive, although there are periods of remission.

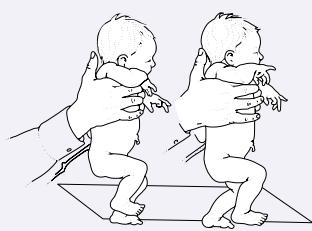

Phytanic acid may be obtained from the diet. Therefore, people with Refsum's disease are advised to avoid all

TYPES OF PRIMITIVE REFLEX**Grasping reflex**

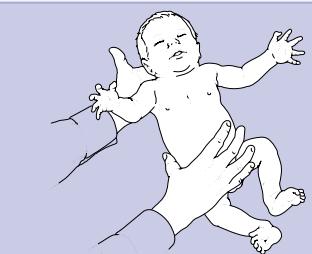

Certain automatic reflexes are present early in life before the baby becomes capable of voluntary movement. These reflexes disappear as the nervous system matures. For about the first four months, any object placed in the infant's palm will be firmly grasped.

**Tonic neck reflex**

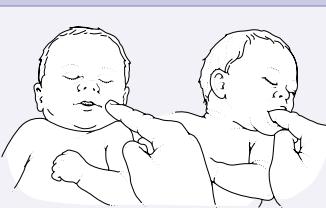

When the young baby turns the head, the arm, and leg of that side are stretched out while on the other side the arm and leg bend. This reflex normally disappears after the first few months except in premature babies. A strong reflex, persisting for longer than three months, suggests brain damage.

**Walking reflex**

When the baby is held upright with a foot touching the ground, a forward stepping movement is made by each leg as the weight is placed on the other foot. This occurs during the first two months of life and is then lost.

**Moro reflex**

If the baby's head is momentarily left unsupported, the arms will be swung outwards and then brought together in an embracing movement. At the same time the legs are extended and the baby cries. This symmetrical reflex disappears two or three months after birth.

**Rooting reflex**

This reflex enables the baby to find the nipple. It is evoked by touching the baby's cheek near the corner of the mouth. The baby's head turns and the mouth opens. The reflex is best shown if tried when the baby is hungry.

foods containing this substance. The main sources of phytanic acid are meat from animals that feed on grass (cows, sheep, and goats) and dairy products.

Regaine

A brand name for *minoxidil*. Regaine is used as a topical (applied to the skin) lotion in the treatment of male-pattern baldness (see *alopecia*).

regression

A term that is used in *psychoanalytic theory* to describe the process of returning to a childhood level of behaviour, such as thumb-sucking. (See also *fixation*.)

regurgitation

A backflow of fluid. In medicine, the term is commonly used to describe the return of swallowed food or drink from the stomach into the *oesophagus* and mouth. The term is also used to describe the backflow of blood through a *heart valve* that does not close fully because of a disorder such as *mitral incompetence*. (See also *reflux*.)

rehabilitation

Treatment aimed at enabling a person to live an independent life following injury (such as *spinal injury*), illness (such as a *stroke*), *alcohol dependence*, or

drug dependence. Treatment may include *physiotherapy*, *occupational therapy*, *psychotherapy*, or *speech therapy*.

In a rehabilitation centre, a person's *disability* or dependence is assessed by a doctor who specializes in rehabilitation medicine, and a treatment programme is developed. Industrial rehabilitation centres provide retraining for those who cannot return to their previous job. Drug and alcohol rehabilitation centres help people through *withdrawal* and provide psychological support to reduce the risk of a relapse (the recurrence of a condition after apparent recovery).

rehydration, oral

See *rehydration therapy*.

rehydration therapy

The treatment of *dehydration* by administering fluids, salts, and sugars usually by mouth (oral rehydration) or by *intravenous infusion*. The amount of fluid needed depends on the patient's age and weight and the degree of dehydration.

Mild dehydration, which occurs in many young children with diarrhoea, can usually be treated with oral solutions, which are available as an effervescent tablet or powder to be made up at home. In severe dehydration, or if the patient cannot take fluids by mouth because of nausea or vomiting, an *intravenous infusion* of *saline* and/or *glucose* solution may be given in hospital.

reimplantation, dental

The replacement of a *tooth* in its socket after an accident so that it can become reattached to supporting tissues. The front teeth are those that are most commonly reimplanted.

The tooth needs to be reimplanted soon after the accident; it is then maintained with the help of a splint (see *splinting, dental*) while healing takes place. Keeping the tooth sterile and moist (with saliva or milk, for example) increases the chances of success. Healing may take several weeks.

Reiter's syndrome

A condition in which there is a combination of *urethritis*, *reactive arthritis*, and *conjunctivitis*. There may also be *uveitis*. Reiter's syndrome is more common in men than in women.

Reiter's syndrome is caused by an *immune response* and usually develops only in people with a genetic predisposition. Most patients have the HLA-B27

tissue type (see *histocompatibility antigens*). The syndrome's development is induced by infection: usually by *non-gonococcal urethritis*, but sometimes by bacillary dysentery.

Reiter's syndrome usually starts with a urethral discharge, followed by conjunctivitis, and then arthritis. The arthritis usually affects one or two joints (generally the knee and/or ankle) and is often associated with *fever* and with *malaise*. Attacks can last for several months. *Tendons, ligaments*, and tissue in the soles of the feet may also become inflamed. Skin rashes are common.

Diagnosis is from the symptoms. *Analgesic drugs* (painkillers) and *nonsteroidal anti-inflammatory drugs* (NSAIDs) relieve pain and inflammation but may have to be taken long term. Relapses occur in about one third of cases.

rejection

An *immune response* that is aimed at destroying organisms or substances recognized as foreign by the body's *immune system*. Rejection also refers to nonacceptance of tissue grafts (see *grafting*) or organ transplants (see *transplant surgery*).

To avoid rejection, donor tissues are closely matched to recipient ones (see *tissue-typing*). *Immunosuppressant drugs*, such as *corticosteroid drugs* and *cyclosporin*, are given to organ transplant recipients to suppress rejection by damping down the activity of the immune system.

relapse

The recurrence of a disease after an apparent recovery, or the return of symptoms after a period of *remission*.

relapsing fever

An illness that is caused by infection with *spirochaetes* (spiral-shaped bacteria). Relapsing fever is transmitted to humans by *ticks* or *lice* and is characterized by high fever. The condition does not occur in the UK.

A high fever of up to 40°C suddenly develops, with shivering, headache, muscle pains, nausea, and vomiting. The symptoms persist for three to six days, culminating in a *crisis* with a risk of collapse and death. The affected person then seems to recover but suffers another attack seven to ten days later. If the fever is tick-borne, there may be several such relapses, each progressively milder.

The spirochaetes can be seen in a blood film and they can be eliminated with antibiotic drugs.

relationship counselling

Formerly known as marriage guidance, relationship counselling is a type of professional therapy for established partners aimed at resolving the problems within their relationship. The couple attends regular sessions together in which the counsellor promotes communication and attempts to help resolve differences. Relationship counselling is largely based on the ideas and methods of *behaviour therapy*. If some of the couple's problems are sexual, the counsellor may also refer them for *sex therapy*.

relaxation techniques

Methods of consciously releasing muscular tension to achieve a state of mental calm. Relaxation techniques can assist people with symptoms of *anxiety*, help to reduce *hypertension* (high blood pressure), and relieve stress. They may also be used to help pregnant women to cope with labour pains (see *childbirth, natural*).

Active relaxation consists of tensing and relaxing each of the body's muscles in turn. Passive relaxation involves clearing the mind and concentrating on a single phrase or sound. *Breathing exercises* help to prevent *hyperventilation* (rapid, shallow breathing), which often brings on or worsens anxiety. Traditional concentration methods, such as *yoga* and *meditation*, employ similar techniques.

releasing factors

A group of *hormones* produced by the *hypothalamus* in the brain that stimulate the release of other hormones. *Luteinizing hormone-releasing hormone* is one such releasing factor.

Relenza

The brand name for zanamivir, an *antiviral drug* used to treat at-risk people who develop influenza.

rem

An outdated unit of absorbed *radiation dose*, now superseded by the *sievert*. (See also *radiation unit*.)

remission

Temporary disappearance or reduction in severity of the symptoms of a disease, or the period during which this occurs.

REM sleep

The abbreviation for rapid eye movement *sleep*, the period of sleep during which the brain is more active and *dreaming* takes place. REM sleep alter-

nates with non-REM (NREM) sleep during the course of the night.

renal

Related to the *kidney*.

renal biopsy

See *kidney biopsy*.

renal calculus

A kidney stone (see *calculus, urinary tract*).

renal cell carcinoma

The most common type of *kidney cancer*.

renal colic

Spasms of severe pain on one side of the back, extending down to the groin, that are usually caused by a kidney stone (see *calculus, urinary tract*) passing down the *ureter* (a tube that carries urine from the kidney to the bladder). There may also be nausea, vomiting, sweating, and blood in the urine.

The treatment of renal colic usually consists of bed rest and plenty of fluids. Injections of a strong *analgesic drug* (painkiller), such as *diclofenac* or *pethidine*, help to ease the pain.

renal failure

See *kidney failure*.

renal transplant

See *kidney transplant*.

renal tubular acidosis

A condition in which the *kidneys* are unable to excrete normal amounts of acid made by the body. In renal tubular acidosis, the blood is more acidic than normal, and the urine less acidic.

Possible causes of renal tubular acidosis include kidney damage that may be due to disease, drugs, or a *genetic disorder*. However, in many cases the cause of the condition is unknown.

The acidosis may result in *osteomalacia* (softening of the bones), kidney stones (see *calculus, urinary tract*), *nephrocalcinosis* (calcification of the kidney), and *hypokalaemia* (an abnormally low level of potassium in the blood).

renin

An *enzyme* that is involved in the regulation of *blood pressure*. When the blood pressure falls, the *kidneys* release renin, which changes a substance called *angiotensinogen* into *angiotensin I*. This is rapidly converted into *angiotensin II*,

which acts to increase blood pressure by constricting (narrowing) blood vessels and stimulating the release of *aldosterone*, a hormone that causes the kidneys to retain *sodium* in the body.

Blood pressure can be lowered by drugs that affect the renin–angiotensin system, such as *beta-blocker drugs*, which inhibit the production of renin, and *ACE inhibitor drugs*, which interfere with the conversion of angiotensin I to angiotensin II.

renography

A technique, also known as renal scintigraphy, that uses a radioactive substance to measure *kidney* function. Renography is quick and painless and is used, for example, when obstruction of the passage of *urine* is suspected.

The radioactive substance is injected into the bloodstream and passes via the kidneys into the urine. *Radiation* counts are taken continually throughout the procedure and both kidneys are examined simultaneously to compare their function. Normally, the radiation count rises and then falls as the substance passes into the bladder. If an obstruction is present, the substance accumulates in the kidneys and the count continues to rise. (See also *kidney imaging*.)

repaglinide

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) that is used either alone or in combination with *metformin* in the treatment of type 2 *diabetes mellitus*.

Repaglinide stimulates the release of *insulin* (a hormone that regulates the level of glucose in the blood). Side effects of repaglinide may include abdominal pain, diarrhoea or constipation, nausea, and vomiting.

repetitive strain injury (RSI)

An *overuse injury* that affects people who do repetitive movements for long periods, such as keyboard workers and musicians, causing pain and weakness in the wrists, fingers, or arms. RSI can become chronic, with continuous pain that does not cease when the causative activity is stopped.

repression

A term used in *psychoanalysis* to refer to the burial of an unacceptable idea or memory deep from an individual's consciousness. The data that has been repressed is generally out of the reach of voluntary recall. One of the aims of psychoanalysis is to return repressed material to conscious awareness in order that it can be accepted and therefore dealt with in a rational manner.

reproduction, sexual

The process of producing offspring by the fusion of two cells from different individuals; this is achieved in humans by the fusion of one *sperm* and one *ovum*. This fusion (which is known as *fertilization*) may be achieved by *sexual intercourse* or *artificial insemination*.

reproductive system, female

The female organs involved in *ovulation*, *sexual intercourse*, nourishing a fertilized *ovum* (egg) until it has developed into a full-grown *fetus*, and *childbirth*. With the exception of the *vulva* (the external genitalia that protects the opening of the *vagina*), these organs lie within the pelvic cavity.

An ovum is released each month from one of the two *ovaries*, which also secrete *oestrogen hormones* and *progesterone hormones* – hormones that are involved in the control of the reproductive cycle, together with *follicle-stimulating hormone* and *luteinizing hormone*. The ovum travels through the *fallopian tubes* to the *uterus* (womb). *Fertilization* takes place if a *sperm* that has been released into the *vagina* during *sexual intercourse* or *artificial insemination* travels through the *cervix* and *uterus* to penetrate the ovum while it is in the fallopian tube.

The normal functioning of the female reproductive system begins at *puberty* with the onset of *menstruation*; the potential for reproduction ends at the time of the *menopause*.

reproductive system, male

The male organs involved in the production of *sperm* and in *sexual intercourse*. Sperm and male sex hormones (see *androgen hormones*) are produced in the testes (see *testis*), which are suspended in the *scrotum*. From each testis, sperm pass into an *epididymis* (a long coiled tube behind the testis), where they mature and are stored. Shortly before *ejaculation*, sperm are propelled into a duct called the *vas deferens*, which carries them to the *seminal vesicles* behind the *bladder*. These two sacs produce *seminal fluid*, which is added to the sperm to produce *semen*.

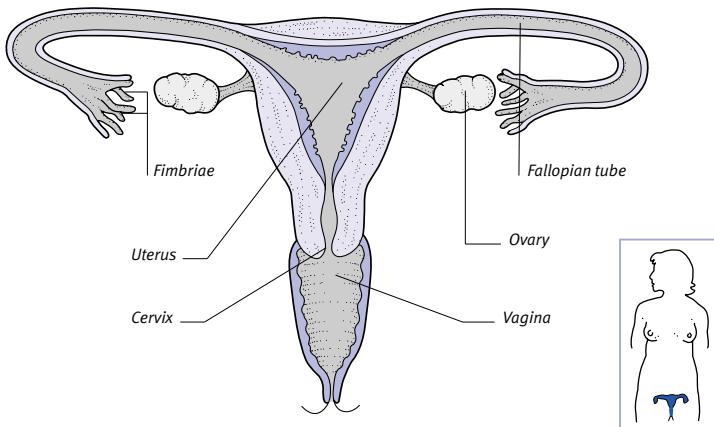

Semen travels along two ducts to the *urethra* (a tube that acts as a passage for urine and semen). The two ducts pass through the *prostate gland*, which produces secretions that are added to the semen. At *orgasm*, semen is ejaculated from the *urethra* through the *erect penis*, which is placed in the woman's *vagina* during sexual intercourse. (See also *fertilization*.)

rescue breathing

The forced introduction of air into the lungs of someone who has stopped breathing (see *respiratory arrest*) or who has inadequate breathing. Rescue breathing was known as *artificial respiration*.

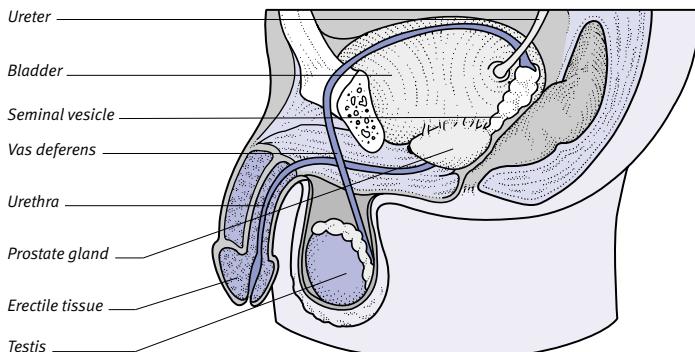

FEMALE REPRODUCTIVE SYSTEM

Each month an ovum from one ovary is carried along the fallopian tube. If fertilized, it begins to divide and implants into the endometrium (lining of the uterus) to develop into an embryo. If the ovum is not fertilized, the endometrium is shed in the form of menstrual bleeding.

MALE REPRODUCTIVE SYSTEM

Sperm made in the testes pass via the vas deferens to the seminal vesicle. Secretions from the prostate increase the volume of the semen, which is ejaculated from the penis via the urethra during orgasm.

As an emergency first-aid measure, rescue breathing can be given mouth-to-mouth or mouth-to-nose in order to prevent brain damage due to oxygen deprivation; a delay in breathing for more than three minutes can cause death. Cardiac compressions may also be necessary if the heartbeat stops (see *cardiopulmonary resuscitation*).

Mouth-to-mouth resuscitation involves opening the victim's airway, pinching the nose shut, and forcefully exhaling air into his or her mouth until help arrives or the victim begins breathing unaided. Mouth-to-nose resuscitation is an alternative if the victim has a facial injury. If there are no signs of circulation after rescue breathing has been given, cardiopulmonary resuscitation may also be required.

An alternative to rescue breathing that is commonly used by healthcare professionals is the "bag and mask" system. A mask is placed over the patient's face and the attached bag (which may be linked to a supply of oxygen) is squeezed hard to inflate the lungs. *Ventilation* can also be carried out in hospital by use of a mechanical ventilator.

resection

Surgical removal of all or part of a diseased or injured organ. An anterior resection is an operation that removes part of the large intestine as a treatment for colorectal cancer (see *colon, cancer of; rectum, cancer of*).

resistance

The ability to oppose. In medicine, the term resistance has several different meanings. For example, a resistance to

the flow of blood is exerted by the blood vessel walls. This resistance increases as the diameter of the blood vessels decreases, whether due to normal physiological processes or to narrowing as a result of disease. An increased resistance leads to raised blood pressure.

In *psychoanalysis*, resistance refers to the blocking off from consciousness of repressed memories or emotions (see *repression*). The psychoanalyst helps the patient to break down this resistance.

Resistance may also refer to an ability to withstand attack from poisons, irritants, or *microorganisms*. An individual's resistance to infection is called *immunity*.

Drug resistance is the ability of some microorganisms to resist attack from previously effective drug treatments. Certain bacteria have acquired *genes* (units of hereditary material) that confer protection against certain *antibiotic drugs*. Overuse of these antibiotics encourages the spread of resistant strains, so doctors now try to avoid the indiscriminate prescription of these drugs.

resorption, bone

Loss of substance from *bone*. Bone resorption and new bone formation are a normal part of bone physiology. In conditions such as *osteoporosis* (loss of bone tissue), however, the rate of bone resorption exceeds that of bone formation.

resorption, dental

The loss of substance from *teeth*. The loss may be external (affecting the surface of the root) or internal (affecting the wall of the pulp cavity).

External resorption is part of the process by which *primary teeth* are lost and is thought to be activated by pressure from the underlying *permanent teeth* as they erupt (see *eruption of teeth*). Some degree of external resorption also occurs as part of the aging process and may also be due to injury, inflammation of surrounding tissues (see *periodontitis*), or pressure, for example from an impacted tooth (see *impaction, dental*). Internal resorption is rare, occurring in only about one per cent of adults, and is of unknown cause.

Resorption is usually detected from a *dental X-ray*. Treatment of external resorption depends on the underlying cause. Internal resorption can usually be halted by *root-canal treatment*.

respiration

A term for the processes by which *oxygen* reaches body cells and is utilized by them (see *metabolism*) and by which *carbon dioxide* is eliminated.

Air, containing oxygen, is breathed into the *lungs* and enters the alveoli (tiny, balloonlike sacs; see *alveolus, pulmonary*). Oxygen diffuses into the blood, which then carries it to cells in the body, where it is used to metabolize *glucose* to provide energy. Carbon dioxide is produced as a waste product and passes into the blood from the body cells. It is transported via the blood to the lungs to be breathed out.

Respiration is controlled automatically by the respiratory centre in the *brainstem* (see *Respiration box*, overleaf). (See also *respiratory system*.)

respirator

See *ventilator*.

respiratory arrest

Sudden cessation of *breathing* that may be due to problems affecting the respiratory apparatus, such as severe *asthma*, sudden exacerbation of chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*), or obstruction of the airways; to any process that depresses the function of the respiratory centre in the *brainstem*, including prolonged *seizures*, an overdose of opioid *analgesic drugs*, *electrical injury*, serious *head injury*, or *stroke*; or to *cardiac arrest*.

Respiratory arrest leads rapidly to *anoxia* (lack of oxygen to tissues) and, if the condition is left untreated, it will progress to *cardiac arrest* (due to a reduced oxygen supply to the coronary

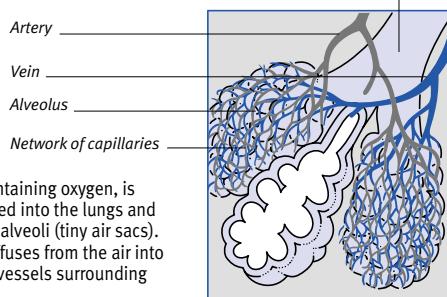

RESPIRATORY DISTRESS SYNDROME

RESPIRATION

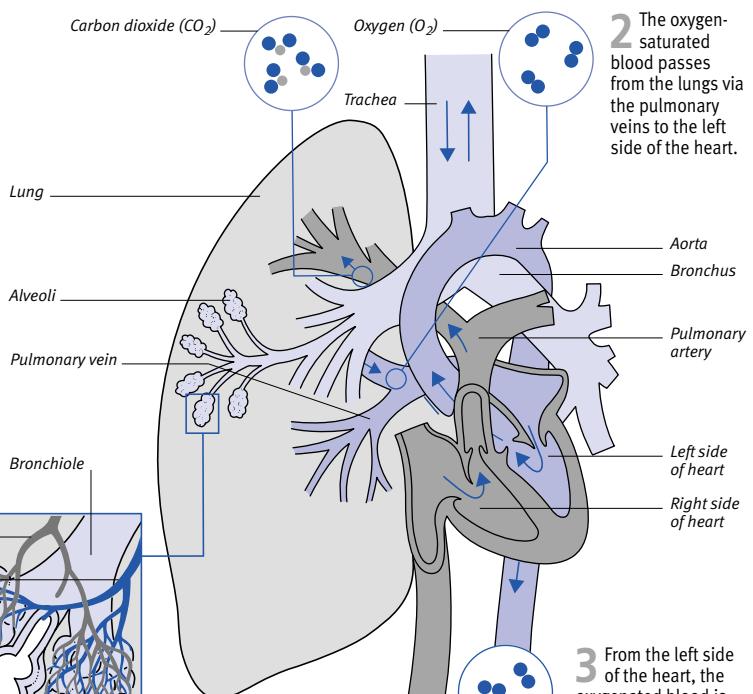

The function of respiration is to provide the energy needed by body cells. Cells obtain this energy mainly by metabolizing glucose with oxygen, and so they require a constant supply of oxygen. In addition, the waste products of the metabolic process (mainly carbon dioxide) must be carried away from the cells.

Respiration includes the breathing of air into the lungs, the transfer of oxygen from the air to the blood, the transport of oxygen in the blood to the body cells, the metabolism of glucose with oxygen in the cells, and the transport of carbon dioxide to the lungs to be breathed out.

During exercise, respiration increases to compensate for higher energy demands by muscle cells.

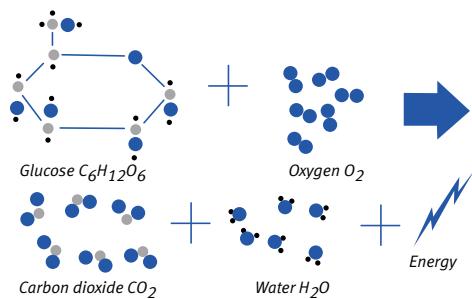

1 Air, containing oxygen, is breathed into the lungs and enters the alveoli (tiny air sacs). Oxygen diffuses from the air into the blood vessels surrounding the alveoli.

2 The oxygen-saturated blood passes from the lungs via the pulmonary veins to the left side of the heart.

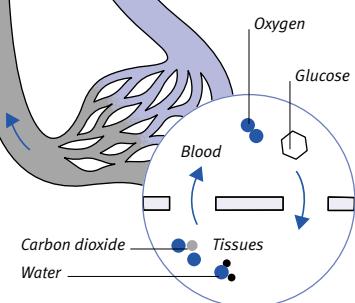

3 From the left side of the heart, the oxygenated blood is pumped via the aorta to the body tissues. The oxygen is carried within the blood by red cells.

CELLULAR RESPIRATION

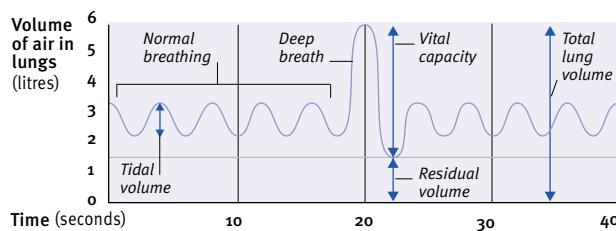

6 Carbon dioxide is carried back in the blood to the heart, then to the lungs, where it diffuses into the alveoli and is breathed out of the body.

5 Within body cells, glucose and oxygen take part in a complex series of reactions that provide energy to power the cells. During this cellular respiration (left), glucose is converted to carbon dioxide and water, which, as waste products, are picked up by the blood.

BREATHING VOLUMES

One way the body copes with varied demands for oxygen is through changes in breathing volume. The tidal volume – the amount breathed into and out of the lungs at each breath – may vary from 0.5 litre at rest, up to 4.5 litres (near the maximum or vital capacity) during heavy exercise.

4 As the blood passes through tissue capillaries, it gives up oxygen (and nutrients such as glucose) to the body tissues and cells.

arteries), brain damage, *coma*, and death. The patient should be given *rescue breathing* and, if necessary, placed on a *ventilator* without delay. The cause of the respiratory arrest will be treated.

respiratory distress syndrome

An acute lung disorder that makes breathing difficult and leads to *respiratory failure*, resulting in life-threatening *hypoxia* (an inadequate supply of oxygen to the tissues). The condition may also cause failure of other systems; for example, *heart failure* or *kidney failure*.

There are two types of respiratory distress syndrome. The first is seen in premature babies (see *prematurity*): the lungs are stiff and do not inflate easily due to a lack of *surfactant*, a group of chemicals that keep the alveoli (tiny air sacs in the lungs; see *alveolus*, *pulmonary*) open. In adults, the condition is known as acute respiratory distress syndrome (ARDS) and may develop as a result of a severe injury or overwhelming infection (particularly *septicaemia*).

Breathing becomes laboured and more rapid as the condition develops. Affected babies make grunting noises and the chest wall is drawn in when they breathe. If the condition worsens, progressive deoxygenation of the blood makes the sufferer turn blue (see *cyanosis*). Without any treatment, death may eventually occur.

Treatment is for the underlying cause, as well as with artificial *ventilation* and oxygen; inhaled surfactant is given to babies thought to be at risk of respiratory distress syndrome. In cases in which premature delivery is seen to be inevitable, the mother is given corticosteroid injections in order to promote the production of fetal lung surfactant.

respiratory failure

A condition in which there is a fall in the blood oxygen level (see *hypoxia*) caused by the inadequate exchange of gases in the lungs. Respiratory failure may have a number of causes: lung disorders, such as severe *asthma* or *pneumonia*; depression of the respiratory centre in the brainstem due, for example, to an overdose of opioid *analgesic drugs*, a *stroke*, or a *head injury*; damage to the chest wall, such as *flail chest*; and nerve and muscle diseases that affect breathing, including *poliomyelitis*.

The symptoms of respiratory failure include breathlessness, *cyanosis* (bluish coloration of the skin), confusion, and

agitation. Treatment is for the underlying cause, and oxygen and/or assisted *ventilation* may also be given if required. In some cases, a respiratory stimulant drug may be prescribed.

respiratory function tests

See *pulmonary function tests*.

respiratory syncytial virus (RSV)

A *paramyxovirus* that is responsible for some nose and throat infections. The RSV is one of the principal causes of *bronchiolitis* (inflammation of the bronchioles in the lungs) and *pneumonia* (inflammation of the lungs) in babies and young children.

respiratory system

The organs responsible for carrying *oxygen* from the air to the blood and expelling *carbon dioxide*.

The upper part of the respiratory system consists of two nasal passages, the *pharynx* (throat), the *larynx* (voice-box), and the *trachea* (windpipe). The lower part of the respiratory system consists of two *lungs*, which are enclosed in a double membrane called the *pleura*, and the lower airways (the *bronchi* and smaller bronchioles). These structures are encased in, and protected by, the bony ribcage. The airways terminate in millions of balloonlike sacs known as *alveoli* (see *alveolus*, *pulmonary*), where gas exchange with the tiny surrounding blood vessels takes place. These small blood vessels feed into larger pulmonary vessels for transport to and from the heart (see *Respiration* box, left).

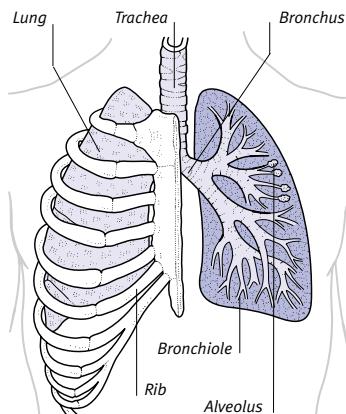

Air is inhaled and exhaled (see *breathing*) by the action of the dome-shaped diaphragm and the abdominal and chest muscles, including the intercostal muscles located between the ribs. Respiration is controlled by the respiratory centre in the *brainstem*.

DISORDERS

Some disorders of the respiratory system can affect the air passages, causing obstruction of the air flow into or out of the lungs; other disorders can affect the lung tissues, resulting in a poor exchange of oxygen and carbon dioxide. The functioning of the respiratory system may also be impaired by certain disorders (such as *poliomyelitis*) that have an adverse effect on the chest muscles and diaphragm, thereby impeding the inflation of the lungs. (See also *respiratory tract infection*).

LOCATION OF THE RESPIRATORY SYSTEM

The system includes the upper air passages, lungs, and the muscles that control breathing (not shown).

respiratory tract infection

Infection of the breathing passages, which extend from the nose to the alveoli (the tiny, balloonlike sacs in the lungs; see *alveolus*, *pulmonary*). This type of infection is divided into upper and lower respiratory tract infections.

Upper respiratory tract infections affect the nose, the *pharynx* (throat), the *sinuses*, and the *larynx* (voice-box). Examples are the common cold, (see *cold, common*) and inflammatory conditions such as *pharyngitis*, *tonsillitis*, *sinusitis*, *laryngitis*, and *croup*.

Lower respiratory tract infections, which involve inflammation of the *trachea* (windpipe), *bronchi*, and *lungs*, include acute *bronchitis*, acute *bronchiolitis*, and *pneumonia*.

restless legs

A syndrome characterized by unpleasant tickling, burning, prickling, or aching sensations in the leg muscles.

Symptoms of restless legs tend to come on at night in bed and can interrupt sleep; they may also be triggered by prolonged sitting. The condition tends to run in families and is most common in middle-aged women, people with *rheumatoid arthritis*, smokers, and pregnant women.

The cause of restless legs is unknown and there is no single cure; some patients benefit from cooling the legs; others from warming them. Relief may be obtained through movement, such

as walking. Treatment with *levodopa*, *benzodiazepine drugs* (such as clonazepam), or certain *anticonvulsant drugs* (such as carbamazepine) may help to improve the condition.

restoration, dental

The reconstruction of part of a damaged tooth. Restoration also refers to the material or substitute part used to rebuild the tooth.

Small repairs are usually made by filling the tooth (see *filling, dental*). For more extensive repairs, an inlay (see *inlay, dental*) or a crown (see *crown, dental*) may be fitted. Chipped front teeth may be repaired by bonding (see *bonding, dental*), in which the surface of the tooth is etched with an acidic solution and plastic or porcelain material is attached to the roughened surface.

restricted growth

See *short stature*.

resuscitation

See *cardiopulmonary resuscitation; rescue breathing*.

retardation

The slowing up of a process. The term mental retardation was once commonly used to refer to impaired intellectual development (see *learning difficulties*).

retching

Repeated unsuccessful, usually involuntary, attempts to vomit (see *vomiting*).

reticular formation

A network of *nerve* cells that are scattered throughout the *brainstem* (the stalk of nerve tissue that links the brain to the spinal cord).

reticulocyte

The medical term for a newly formed *red blood cell*. Reticulocytes are made in the bone marrow from *stem cells*. They remain in the bone marrow for between one and two days and then pass into the bloodstream, where they eventually mature into red blood cells.

reticulosarcoma

See *lymphoma, non-Hodgkin's*.

retina

The light-sensitive membrane that lines the back inner surface of the *eye*, and on which images are cast by the *cornea* (the transparent dome that forms the

front of the eyeball) and the *lens* (the part of the eye responsible for focusing). The retina contains specialized nerve cells (rods and cones) that convert light energy into nerve impulses. The impulses travel from the rods and cones through other cells in the retina and along the *optic nerve* to the *brain*.

The rods are extremely sensitive and respond to very dim light; the cones are responsible for *colour vision*, producing impulses that vary in strength depending on the colour of the light striking them. Near the centre of the retina is the fovea, the area of the eye that is responsible for detailed vision because it contains the highest concentration of light-sensitive cells. (See also *Disorders of the retina* box, opposite.)

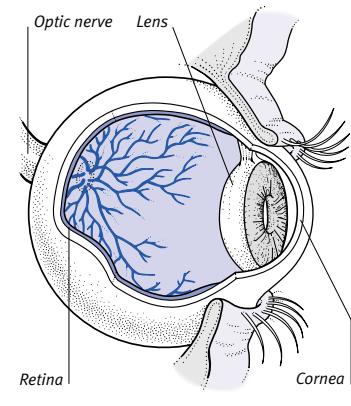

retinal artery occlusion

Blockage of an artery supplying blood to the *retina* (the light-sensitive inner layer at the back of the eye), most commonly due to *thrombosis* (abnormal blood clot formation) or *embolism* (in which a blood clot or fatty deposit is carried in the bloodstream to lodge in another area). Retinal artery occlusion may affect either the main retinal artery or one of its branches.

The disorder can result in sudden blindness or loss of part of the visual field, which is painless and can be permanent. The extent of visual loss depends on the artery affected and how quickly the condition can be treated. (See also *retinal vein occlusion*.)

LOCATION OF THE RETINA

The retina is like the light-sensitive film in a camera. It forms a concave membrane over the back inner surface of the eye.

retinal detachment

Separation of the *retina* (the light-sensitive inner layer at the back of the *eye*) from the outer layers at the back of the eye. Retinal detachment may follow an eye injury but usually occurs spontaneously. It is usually preceded by a *retinal tear* (a split in the retina), and is more common in highly myopic (shortsighted) people and in people who have had *cataract surgery*.

SYMPTOMS

Retinal detachment is painless. The first indication may be the appearance of bright flashes of light caused by stimulation of the light-sensitive cells as the tear occurs. This may be accompanied by *floaters* (fragments perceived to be floating in the field of vision) that result from the release of blood or pigment into the vitreous humour (the gel-like substance that fills the rear compartment of the eye). Alternatively, the appearance of a black "drape" that gradually obscures vision may be the first sign of retinal detachment.

TREATMENT

Urgent treatment is required to prevent detachment of the macula (the site of central vision) and usually involves surgical repair of the underlying tear. A soft silicone rubber sponge may be sewn onto the outside of the *sclera* (the outer layer of the eye) overlying the detachment. The sponge indents the sclera and results in the absorption of the fluid under the retina, causing the retina to settle back into place. The retina is then fixed in place by *cryopexy* (the application of extreme cold), by *diathermy* (the application of heat), which causes an inflammatory adhesiveness of the underlying tissues, or by *laser treatment*. If the macula has not been detached, the results can be excellent.

retinal haemorrhage

Bleeding into the *retina* (the light-sensitive inner layer at the back of the eye) from one or more blood vessels, due to *diabetes mellitus*, *hypertension* (high blood pressure), or *retinal vein occlusion* (blockage of a vein that drains blood from the retina).

When the macula (the site of central vision) is involved, vision is severely impaired. Peripheral haemorrhages may be detected only when the eye is examined using an *ophthalmoscope*.

retinal tear

The development of a split in the *retina* (the light-sensitive inner layer situated at the back of the eye), usually caused

DISORDERS OF THE RETINA

Despite its small size, the retina is subject to a wide variety of disorders, many of which seriously affect vision and, in some cases, result in blindness.

Congenital and genetic disorders

Colour blindness (see *colour vision deficiency*), an abnormality of retinal cones (colour receptors in the retina), usually has a genetic basis. Hereditary degenerative disorders of the macula may appear at any age, leading to serious impairment of central vision. Other degenerative disorders of the retina with a genetic basis include *Tay-Sachs disease* and *retinitis pigmentosa*.

Retrolental fibroplasia may result from exposure of a premature baby to excessive oxygen concentration (needed to treat lung immaturity), which causes abnormalities in the retinal vessels.

Infection

Toxoplasmosis is an infection of the retina that is acquired before birth and recurs later in life, causing progressive damage to the retina.

TOXOCARA CANIS is a parasitic worm whose larvae may lodge in the retina and cause severe retinal destruction, producing a white mass resembling a tumour (see *toxocariasis*). *Onchocerciasis*, an infestation by a tropical worm, may cause severe retinal damage.

Bacterial and fungal infections elsewhere in the body can be carried in the blood to the retina. People whose immune systems are impaired are more susceptible to infections that can involve the retina.

Tumours

Retinoblastoma is a cancerous tumour that usually appears in the first three years of life. There may be visual loss in the affected eye and a visible whiteness

in the pupil; *squint* often develops. The tendency to this cancer can be inherited.

Secondary cancerous tumours, spreading to the eye from primary tumours elsewhere in the body, can also occur. Malignant melanoma (see *melanoma, malignant*) can arise from the choroid (the layer beneath the retina). A variety of noncancerous tumours may also occur in the retina.

Injury

The retina may be torn or detached due to severe penetrating or blunt (non-penetrating) injury (see *retinal detachment; retinal tear*). Permanent damage may be caused by a retinal burn, which is sometimes caused by looking directly at an eclipse of the sun.

Metabolic disorders

Diabetes mellitus may cause *retinopathy*, with fluid leakage and haemorrhage into the retina (see *retinal haemorrhage*) and with the growth of new, fragile blood vessels on the retinal surface, which bleed readily. Vitreous haemorrhage (bleeding into the vitreous humour, the gel-like substance that fills the rear compartment of the eye) may occur from blood vessels, and fibrous tissue can grow forwards on to the vitreous humour in cases of "proliferative" retinopathy. This is a major cause of permanent loss of vision.

Impaired blood supply

Retinal vein occlusion (or *retinal artery occlusion*), a common cause of blindness, results from blockage of the central vein (or artery) of the retina. Hypertensive retinopathy is damage to the retina caused by high blood pressure, which leads to narrowing and *atherosclerosis* (fat deposits on the artery walls) of the retinal arteries, both of which may lead to retinal damage.

by degeneration. A retinal tear is more likely to occur in people who have severe *myopia* (shortsightedness) but the condition may also be caused by a severe eye injury. *Retinal detachment* usually follows a retinal tear.

If a retinal tear is diagnosed at a stage before detachment has occurred, the hole may be sealed by means of *laser treatment* or *cryopexy* (the application of extreme cold).

Poisons

A combination of heavy tobacco-smoking, heavy alcohol intake, and poor nutrition may lead to visual loss. Vitamin deficiency in combination with lead poisoning may cause visual loss. *Methanol* causes widespread and permanent destruction of certain retinal tissues, leading to blindness.

Drugs

Many drugs can damage the retina. Examples are *chloroquine*, used in large doses over a long period for the treatment of conditions such as rheumatoid arthritis.

Other disorders

Age-related *macular degeneration*, causing progressive loss of vision, is a common condition in older people. Detachment of the retina often occurs in the absence of any injury, and it may be more common in individuals who suffer from severe *myopia* (shortsightedness).

INVESTIGATION

Retinal disorders are investigated by checking the visual acuity and the visual fields (see *vision tests; retinoscopy*). After dilating the pupils with drops, the retinas are inspected by means of a direct or indirect ophthalmoscope (an instrument used to examine the eye). Fluorescein can be injected into an arm, where it is carried by the blood to outline the retinal vessels and to detect leaks. Electrophysiological tests can also be carried out to study certain ocular diseases. Ultrasound scanning can be used to study tumours in or under the retina.

retinal vein occlusion

Blockage of a vein carrying blood from the *retina* (the light-sensitive inner layer at the back of the eye). It usually results from *thrombosis* (abnormal blood clot formation) in the affected vein and is more common in people who have *glaucoma* (a condition in which the pressure of fluid in the eye is abnormally high). Retinal vein occlusion may affect either the main retinal vein or one of its branches.

Retinal vein occlusion may cause visual disturbances, glaucoma, and can result in blindness, depending on the vein affected and how quickly the condition can be treated. (See also *retinal artery occlusion*.)

retinitis

Inflammation affecting the *retina* (the light-sensitive inner layer at the back of the eye). (See also *retinopathy*.)

retinitis pigmentosa

An inherited condition in which there is degeneration of the rods and cones of the *retina* (the light-sensitive inner layer at the back of the eye) in both eyes.

The first symptoms of retinitis pigmentosa usually appear during or after adolescence and include night blindness (the inability to see well in dim light). Tests show a ring-shaped area of blindness which, over some years, extends to destroy an increasing area of the *visual field*, although central vision is often retained for many years.

Ophthalmoscopy (a noninvasive examination of the retina) reveals several masses of black pigment corresponding to the areas of visual loss. Affected individuals and their parents should seek *genetic counselling*.

retinoblastoma

A cancer of the *retina* (the light-sensitive inner layer at the back of the eye) that affects infants. The first indications of this disorder may be a *squint*, caused by blindness in the affected eye, or a visible whiteness in the pupil. Without early treatment, retinoblastoma can spread to the orbit (eye socket) and along the *optic nerve* to the brain.

Retinoblastoma has a genetic basis. People with this cancer lack part of one of the *chromosomes* in pair number 13. Newborn infants from affected families are given regular eye examinations; prospective parents in affected families should seek *genetic counselling*.

Treatment is by surgically removing the affected eye or by *radiotherapy*. If both eyes are involved, the one worse affected may be removed and the other given radiotherapy.

retinoids

A group of drugs derived from *vitamin A*, of which *tretinoïn* is an example.

retinol

The principal form of *vitamin A* found in the body.

retinopathy

Disease affecting the *retina* (the light-sensitive inner layer at the back of the eye), which is usually caused by *diabetes mellitus* or persistent *hypertension* (high blood pressure).

In diabetic retinopathy, the capillaries (tiny blood vessels) within the retina are affected by *aneurysms* (balloonlike swellings). They also leak fluid and

haemorrhage (bleed) into the retina. Abnormal capillaries then grow on the retinal surface and, as these are fragile, vitreous haemorrhage (bleeding into the *vitreous humour*, the gel-like substance that fills the rear compartment of the eye) may occur. Fibrous tissue may also grow into the vitreous humour. *Laser treatment* can often halt the progress of the condition.

In hypertensive retinopathy, the retinal arteries become narrowed. Areas of retina may be destroyed and bleeding and white deposits may occur in the retina. (See also *retrolental fibroplasia*.)

retinoscopy

A type of *vision test* in which a beam of light is shone from an instrument called a retinoscope into each eye in turn. The effect of different lenses on the beam of light determines whether glasses are needed to correct refractive errors such as *hypermetropia* (longsightedness), *myopia* (shortsightedness), or *astigmatism*. Retinoscopy is particularly useful for assessing the sight of babies and young children.

retractile testis

See *testis, retractile*.

retractor

A surgical instrument used to hold an incision open or to hold back surrounding tissue so that the *surgeon* has free access to the area being operated on.

retrobulbar neuritis

A form of *optic neuritis* in which the *optic nerve* becomes inflamed behind the eyeball.

retrograde

Moving backwards or in the opposite direction to normal. In retrograde ejaculation, for example, semen is forced into the bladder rather than out through the tip of the penis (see *ejaculation, disorders of*).

retrolental fibroplasia

A condition, also called *retinopathy* of prematurity, that mainly affects the eyes of premature infants. The usual cause of retrolental fibroplasia is high concentrations of *oxygen* being given to premature infants as part of the treatment for *respiratory distress syndrome* (an acute lung disorder that makes breathing difficult).

Excess oxygen causes the tissues at the margin of the *retina* (the light-sensitive inner layer at the back of the eye)

to shut down their blood vessels. When oxygen concentrations return to normal, the affected tissues may send strands of new blood vessels and fibrous scar tissue into the vitreous humour (the gel-like substance that fills the rear compartment of the eye), which may interfere with vision and cause *retinal detachment*.

Retrolental fibroplasia may be successfully treated by *laser treatment*.

retroperitoneal fibrosis

Inflammation and scarring of tissues at the back of the abdominal cavity. Retroperitoneal fibrosis often blocks the *ureters*, preventing urine flow from the kidneys to the bladder. In severe cases, this results in *kidney failure*.

Retroperitoneal fibrosis usually occurs in middle-aged men and is of unknown cause; it may be an *autoimmune disorder*. However, the condition may be associated with long-term treatment with the drug *methysergide* (used to treat *migraine*). Treatment may involve *corticosteroid drugs*, insertion of a stent (a rigid tube) to relieve obstruction of the ureters, and surgery.

retrosternal pain

Pain in the central region of the chest, behind the sternum (breastbone). Causes include irritation of the *oesophagus*, *angina pectoris* (chest pain due to impaired blood supply to the heart muscle), or *myocardial infarction* (heart attack). (See also *chest pain*.)

retrovirus

A type of *virus* whose genetic material is *RNA*, rather than *DNA*, and that uses an *enzyme* called reverse transcriptase to produce *DNA* from the *RNA* template. The *DNA* can then be incorporated into its host cells. One notable example of a retrovirus is *HIV* (human immunodeficiency virus).

Rett's syndrome

A *brain* disorder, thought to be a *genetic disorder*, that affects only girls. Symptoms usually first appear when the child is between 12 and 18 months old. Acquired skills, such as walking and communication skills, disappear and the girl becomes progressively handicapped, sometimes with signs of *autism*. Repetitive writhing movements of the hands and limbs and inappropriate outbursts of crying or laughter are characteristics of the condition.

There is no cure for Rett's syndrome and sufferers need constant care and attention. Parents of an affected child should receive *genetic counselling* if they are thinking of having another child.

reverse transcriptase inhibitors

A class of drugs used in the treatment of certain infectious diseases, including *HIV* infection and hepatitis B infection. The drugs affect the ability of the virus to reproduce by blocking reverse transcriptase, a key *enzyme*. Examples of reverse transcriptase inhibitors are *lamivudine*, *zidovudine* (AZT), efavirenz, and stavudine.

reversible monoamine oxidase inhibitors (RIMAs)

A reversible type of *monoamine oxidase inhibitor* (MAOI), which is a type of *anti-depressant drug*. Reversible monoamine oxidase inhibitors are reported to have fewer adverse interactions with other drugs and with foods such as cheese and red wine than other MAOIs. *Moclobemide* is currently the only RIMA available.

Reye's syndrome

A rare disorder in which brain and liver damage follow a viral *infection*. People over the age of 16 are rarely affected. The cause is unknown, but taking *aspirin* seems to be a predisposing factor to developing the condition; the drug is, therefore, not recommended for use by children under 16.

SYMPTOMS AND SIGNS

The disorder starts as the child recovers from the infection. Symptoms include uncontrollable vomiting, lethargy, memory loss, and disorientation. Swelling of the brain may cause seizures, disturbances in heart rhythm, *coma*, and cessation of breathing.

TREATMENT AND OUTLOOK

Brain swelling may be controlled by *corticosteroid drugs* and by *intravenous infusion of mannitol*. *Dialysis* or *blood transfusions* may be needed to correct changes in blood chemistry caused by damage to the liver. If breathing stops, the patient is placed on a *ventilator*.

The death rate in Reye's syndrome is at least ten per cent, and higher for those who have seizures, lapse into deep coma, and stop breathing. Patients who survive a serious attack may suffer permanent brain damage.

rhabdomyolysis

Destruction of *muscle* tissue accompanied by the release of *myoglobin* (the oxygen-carrying muscle pigment) into

the blood. The most common cause of rhabdomyolysis is a severe, crushing muscle injury (see *crush syndrome*). Other causes of the condition include *polymyositis* (a viral infection of muscle) and, rarely, excessive exercise.

There is usually temporary *paralysis* or weakness of the affected muscle. Except in cases of severe injury, the condition usually clears up without any form of treatment.

rhabdomyosarcoma

A very rare cancerous *muscle* tumour. Rhabdomyosarcoma may develop during infancy, usually affecting the throat, bladder, prostate gland, or vagina; it may also occur in old age when it may affect a large muscle in the arm or leg. The tumour grows rapidly and quickly spreads to other tissues. Treatment involves surgical removal, *radiotherapy*, and *anticancer drugs*.

Rhesus immunoglobulin

See *anti-D(Rh₀) immunoglobulin*.

Rhesus incompatibility

A mismatch between the blood group of a Rhesus (Rh)-negative pregnant woman and that of her baby. In certain circumstances, this mismatch may lead to *haemolytic disease of the newborn*.

CAUSES

The Rh system is based on the presence or absence in the blood of several factors, the most important of which is a substance called D *antigen* (a substance that can trigger an immune response). Rh-positive blood contains D antigen,

whereas Rh-negative blood does not. Blood type is determined by *genes* (units of the material of heredity).

A common way in which rhesus incompatibility results is if a Rh-negative woman is exposed to the blood of her Rh-positive baby while it is being born. There are usually no problems during the first pregnancy with a Rh-positive baby. However, the woman may produce *antibodies* (proteins manufactured by the immune system) against the D antigen; in a subsequent pregnancy with a Rh-positive baby, these antibodies may cross the placenta and attack the red blood cells of the fetus.

A Rh-negative woman can also be sensitized to Rh-positive blood if she has had a *miscarriage*, *abortion*, or *amniocentesis* in which the fetus's Rh-positive blood enters her circulation. A *placental abruption* (separation of part or all of the placenta from the wall of the uterus) may also cause a transfer of blood between the mother and the fetus.

TREATMENT

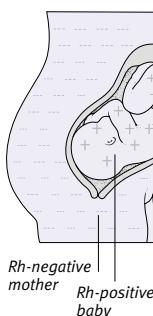

Rhesus incompatibility is now uncommon because injections of *anti-D(Rh₀) immunoglobulin* are given routinely to Rh-negative women during pregnancy and at delivery. This substance destroys any of the baby's blood cells that have entered the mother's system before she is able to become sensitized to them.

Anti-D(Rh₀) immunoglobulin is also given to Rh-negative women after miscarriage, abortion, amniocentesis, or following any other procedure that might result in exposure of the mother to fetal blood cells.

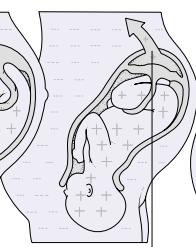

HOW RHESUS (Rh) INCOMPATIBILITY OCCURS

Without preventive treatment, an Rh-negative woman who is exposed to Rh-positive blood during pregnancy may develop antibodies that will attack the red blood cells of any future Rh-positive babies.

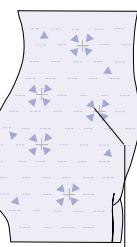

First pregnancy

Rh-negative mother
Rh-positive baby

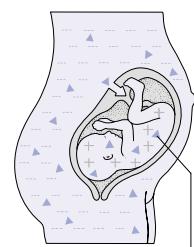

At birth, baby's blood enters mother's circulation

Antibodies against Rh-positive blood formed in mother following birth

Subsequent pregnancies

Antibodies cross placenta and destroy red blood cells of subsequent Rh-positive babies

rhesus isoimmunization

The development of *antibodies* (proteins that are manufactured by the immune system) against Rhesus (Rh)-positive blood in a person who has blood that is Rh-negative (see *haemolytic disease of the newborn*; *Rhesus incompatibility*).

rheumatic fever

A disease that causes inflammation throughout the body, especially in the *joints*. Now rare in developed countries, it is an important cause of heart disease in developing countries and is most common in children aged five to 15 years.

CAUSE

Rheumatic fever is believed to be an *autoimmune disorder* (in which the body's immune system attacks its own tissues) induced by certain strains of streptococcal bacteria. Rheumatic fever always follows a throat infection. The development of rheumatic fever can usually be prevented by treatment with *antibiotic drugs*.

SYMPOTMS AND SIGNS

Rheumatic fever causes fever with pain, inflammation, and swelling of one or more of the larger joints. The *heart valves* may be scarred, leading to *mitral stenosis* (narrowing of the mitral valve) or *mitral incompetence* (leaking of the mitral valve). If the *nervous system* is involved, *Sydenham's chorea* may be caused, in which there are irregular, uncontrollable, jerky movements and usually some emotional upset.

DIAGNOSIS AND TREATMENT

Rheumatic fever may be suspected whenever *arthritis* (joint inflammation) moves from joint to joint, but may be discovered only after development of heart failure or a heart murmur.

Treatment is with *penicillin drugs* to eradicate streptococci; with *aspirin* or other salicylate drugs to control joint pain and inflammation and to minimize heart damage; and, in some cases, with *corticosteroid drugs*. If damage to the heart valves occurs, *heart valve surgery* may be required.

rheumatism

A popular term for any disorder that causes pain and stiffness in *muscles* and *joints*. The term is used to refer both to minor aches and twinges as well as to disorders such as *rheumatoid arthritis*, *osteoarthritis*, and *polymyalgia rheumatica*.

rheumatoid arthritis

A type of *arthritis* (joint inflammation) in which the joints in the limbs, and sometimes in other parts of the body,

become painful, swollen, stiff, and, in severe cases, deformed. Tissues that are outside the joints, for example the heart, can also be affected.

CAUSES AND INCIDENCE

Rheumatoid arthritis is an *autoimmune disorder* (in which the body's immune system attacks its own tissues) that usually starts in early adulthood or middle age but can also develop in children (see *juvenile chronic arthritis*) or elderly people. Women are affected more commonly than men. There are usually recurrent attacks.

SYMPOTMS AND SIGNS

Early symptoms of rheumatoid arthritis include mild fever and aches followed by swelling, redness, pain, and stiffness in the joints, particularly in the morning. *Ligaments*, *tendons*, and *muscles* around the affected joint may also be involved. *Raynaud's phenomenon* (a condition in which the fingers turn white on exposure to cold) may occur and there may also be *rheumatoid nodules* (small lumps under the skin) over pres-

sure points, such as the elbows or finger joints. Swelling of the wrist may cause *carpal tunnel syndrome* (tingling and pain in the fingers due to pressure on the median nerve) and also *tenosynovitis* (inflamed, painful tendon sheaths).

Complications of severe rheumatoid arthritis may include *anaemia* (reduced level of the oxygen-carrying pigment haemoglobin in the blood), *pericarditis* (inflammation of the membranous heart covering), *ulcers* on the hands and feet, *pleural effusion* (accumulation of fluid around the lungs), *pulmonary fibrosis* (scarring and thickening of lung tissue), and *Sjögren's syndrome* (in which the eyes and mouth become excessively dry).

DIAGNOSIS AND TREATMENT

A diagnosis can be confirmed through *X-rays* of the affected joints and *blood tests* (including a check for specific antibodies known as *rheumatoid factor*).

Initially, rheumatoid arthritis may be treated with *nonsteroidal anti-inflammatory drugs* (NSAIDs) to relieve joint pain and stiffness; *corticosteroid drugs* may be

RHEUMATOID ARTHRITIS

One of the most serious forms of joint disease, rheumatoid arthritis may occur as a single episode or a succession of progressively severe attacks. It results from a disturbance in the body's immune system, causing the body to attack its own tissues. The joints are usually the worst affected, but other tissues such as the heart and lungs may also be involved.

The hands in rheumatoid arthritis

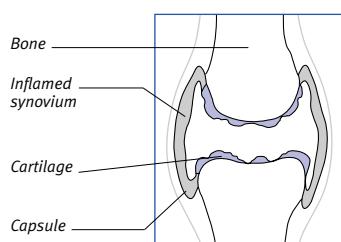

This condition commonly affects the fingers. In this photograph, there is pronounced swelling around the knuckles, particularly of the right hand.

Affected joints
Rheumatoid arthritis can affect virtually any joint, but especially the fingers, wrists, shoulders, knees, hips, and spinal joints in the neck.

Disease progression

The synovium (membrane lining the capsule of an affected joint) becomes inflamed and thickened (right). Later, inflammation may spread to the cartilage and bone.

given in the short term if NSAIDs are not effective. *Disease-modifying antirheumatic drugs* are then prescribed to slow or arrest the progress of the disease; these include antirheumatic drugs (such as *sulfasalazine*, *gold*, and *penicillamine*) and immunosuppressant drugs (such as *methotrexate*), which suppress the body's immune system if the anti-rheumatics have not proved effective.

Physiotherapy is needed to prevent or limit deformity and to help relieve symptoms and maintain mobility. People who are disabled by arthritis can be helped to cope with everyday tasks through *occupational therapy*.

In severe cases, surgery may be performed to replace damaged joints with artificial ones (see *arthroplasty*). Hip and knee replacements are the most common operations of this type.

Most sufferers must continue drug treatment for life, but many can achieve a near-normal level of activity with effective control of their symptoms.

rheumatoid factor

A specific autoantibody (a protein manufactured by the *immune system* that acts against the body's own cells) that attaches itself to naturally occurring *immunoglobulin G* (another type of antibody that, in this case, has actually triggered the immune response). This combination of immunoglobulin and autoantibody is a type of *immune complex*; it can settle in joints, causing *rheumatoid arthritis*. Most people with rheumatoid arthritis have rheumatoid factor in their blood. (See also *autoimmune disorders*; *hypersensitivity*.)

rheumatoid nodules

Small lumps that may develop under the skin in people suffering from *rheumatoid arthritis*. They may also develop in the lungs and can be identified on a chest X-ray. Rheumatoid nodules are *granulomas* (clumps of a type of cell associated with chronic inflammation); they are found particularly in areas of the body that are often under pressure, such as the elbows.

rheumatoid spondylitis

See *ankylosing spondylitis*.

rheumatology

The branch of medicine concerned with the causes, development, diagnosis, and treatment of diseases that affect the *joints*, *muscles*, and *connective tissue*.

rhinitis

Inflammation affecting the *mucous membrane* that lines the nose, which may lead to a feeling of stuffiness, with nasal discharge and sneezing.

TYPES

Viral rhinitis is a feature of the common cold (see *cold, common*), and may sometimes lead to *sinusitis*.

Rhinitis due to allergy (see *rhinitis, allergic*) may be seasonal (usually caused by pollens) or occur throughout the year (due to house dust, moulds, or pets). Allergic rhinitis commonly occurs with vasomotor rhinitis.

Vasomotor rhinitis may be intermittent or continual. The nose becomes over-responsive to stimuli such as pollutants, changes or extremes in temperature or humidity, certain foods or medicines, or certain emotions. Vasomotor rhinitis is common in pregnancy and in those taking combined *oral contraceptives* or other *oestrogen drugs*.

Hypertrophic rhinitis, which is characterized by thickening of the mucous membrane in the nose and chronic congestion of the nasal veins, can result from repeated nasal infections. The condition results in constant stuffiness and sometimes impairment of the sense of smell. In severe cases, treatment may involve surgical removal or shrinkage of part of the swollen tissue.

Atrophic rhinitis is characterized by wasting of the mucous membrane in the nose and can result from aging, chronic bacterial infections, or extensive nasal surgery. Features include persistent nasal infection, a nasal discharge, loss of smell, and an unpleasant odour. Treatment may include *antibiotic drugs* and nose drops.

rhinitis, allergic

A common condition that is characterized by inflammation of the *mucous membrane* lining the nose due to *allergy* to pollen, dust, or other airborne substances. Allergic rhinitis causes sneezing, a runny nose, nasal congestion, and, in most cases, watering eyes. The eyes, soft palate, and ears may also itch. The eyes may also be affected by *conjunctivitis*, making them red and sore.

CAUSES

In some people, the inhalation of particles of certain harmless substances, known as allergens, provokes an exaggerated response by the *immune system*, which forms *antibodies* against them. These allergens also trigger the release of

histamine and other chemicals that cause inflammation and fluid production in the linings of the nose and nasal *sinuses* (air cavities around the nose). Allergens that cause allergic rhinitis include tree, grass, and weed pollens; moulds; animal skin scales, hair, or feathers; house dust; and *house dust mites*.

Seasonal allergic rhinitis is pollen-induced and is commonly known as hay fever. Tree pollens are most prevalent in spring, grass pollens in summer, and weed pollens in summer and autumn. Sufferers are worst affected during hot and windy weather, especially in heavily vegetated, low-lying areas. People affected by household allergens, such as dust, tend to have less severe symptoms but are affected throughout the year, a condition that is known as perennial rhinitis.

PREVENTION AND TREATMENT

Antihistamine drugs and topical *corticosteroid drugs* are used to treat mild attacks of allergic rhinitis. The drug *sodium cromoglicate*, if inhaled regularly throughout the pollen season, may help to prevent attacks by blocking the allergic response. Long-term relief of symptoms can sometimes follow desensitization to an allergen by a course of injections (see *hypersensitization*).

rhinophyma

A bulbous deformity and redness of the nose that occurs almost exclusively in elderly men. Rhinophyma is a complication of severe *rosacea* (a skin disorder of the nose and cheeks). The tissue of the nose thickens, small blood vessels enlarge, and the *sebaceous glands* become overactive, which results in making the nose excessively oily.

An operation to cut away the swollen tissue, performed under general anaesthetic (see *anaesthesia, general*), can restore the nose to a satisfactory shape.

rhinoplasty

An operation that is carried out to alter the structure of the nose in order to improve its appearance or to correct a deformity caused by injury or disease.

Under either a local or general anaesthetic (see *anaesthesia*), incisions are made within the nose to avoid visible scars. The *septum* (the vertical wall of cartilage and bone that divides the nose) may be altered if breathing passages are blocked; the cartilage and bone are then reshaped. The nose is finally splinted in position for about ten days.

Rhinoplasty usually causes considerable bruising and swelling and the results may not be clearly visible for a number of weeks or months.

rhinorrhoea

The discharge of watery mucus from the nose, usually due to *rhinitis*. Rarely, the discharge consists of *cerebrospinal fluid* and is the result of a head injury. (See also *nasal discharge*.)

rhinovirus

Any one of a group of *RNA*-containing viruses that cause infections of the upper respiratory tract, typically the common cold (see *cold, common*).

rhythm method

See *contraception, natural methods of*.

rib

Any of the flat, curved bones that form a framework for the chest and a protective cage around the heart, lungs, and other underlying organs.

There are 12 pairs of ribs, each joined at the back of the ribcage to a vertebra in the spine (see *Anatomy of the ribs*, right). The upper seven pairs, known as "true ribs", link directly to the *sternum* (breastbone) at the front of the body by flexible costal cartilage (connective tissue formed of collagen). The next two or three pairs of "false ribs" connect indirectly to the sternum by way of cartilage attached to the cartilage of the ribs above. The lowest two pairs of ribs are not attached to the sternum at the front and, therefore, they are known as "floating ribs". Between and attached to the ribs are thin sheets of muscle (called intercostal muscles) that expand and relax the chest during *breathing*. The spaces between the ribs also contain nerves and blood vessels.

DISORDERS

The ribs can easily be fractured by a fall or blow (see *rib, fracture of*). A rib is also a common site for a noncancerous *bone tumour* or for a *metastasis* (a secondary cancerous tumour that has spread from elsewhere in the body). *Tietze's syndrome* is a condition in which chest pain is caused by inflammation of one or more areas of rib cartilage.

In rare cases a person is born with one or more extra ribs, known as *cervical ribs*, above the uppermost normal rib. Cervical ribs may cause a variety of problems, such as putting pressure on nerves supplying the arm.

ribavirin

An *antiviral drug*, also called tribavirin, used to treat children with severe *bronchiolitis* caused by respiratory syncytial virus. Ribavirin is administered by aerosol inhalation or by a *nebulizer*. Adverse effects are rare.

rib, fracture of

A crack or break in one or more of the *rib* bones. Such a fracture may be caused by a fall or blow or by stress on the ribcage, such as that produced by prolonged coughing.

The fracture of a rib causes severe pain, which worsens during periods of deep breathing, as well as tenderness and swelling of the overlying tissue. Pain may be relieved by *analgesic drugs* (painkillers) or by an injection of a local anaesthetic (see *anaesthesia, local*). *X-rays* may be used to confirm a diagnosis.

Most rib fractures are undisplaced (the bone ends remain in alignment) and usually heal without specific treatment. Strapping is rarely used because it hinders chest expansion and thereby increases the risk of *pneumonia*. Instead, the patient is encouraged to take deep breaths while holding the injured side.

A fracture that is displaced or splintered may pierce a lung, thereby causing lung collapse (see *pneumothorax*). Multiple rib fractures can result in *flail chest* (a chest injury in which part of the chest wall moves in the direction opposite to normal during breathing).

riboflavin

The chemical name of vitamin *B*₂ (see *vitamin B complex*).

ribonucleic acid

See *RNA*.

rickets

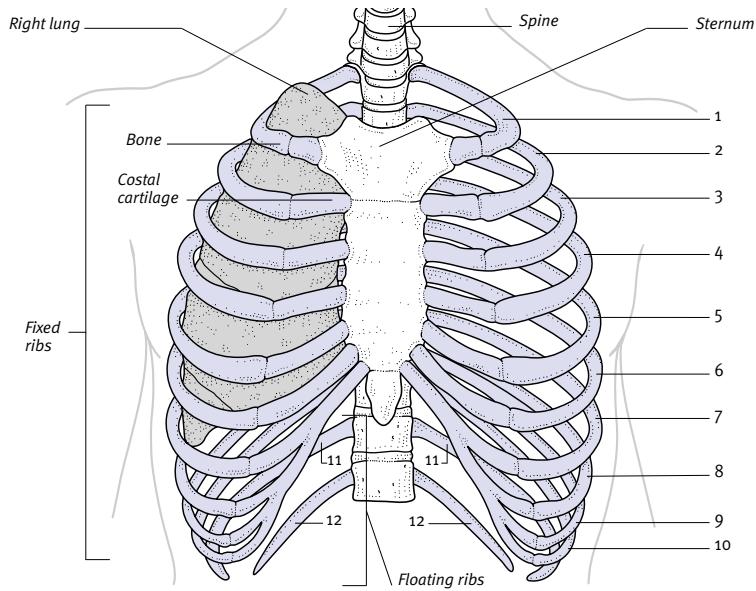

A disease caused by nutritional deficiency that results in *bone* deformities in childhood. Bones become deformed because inadequate amounts of *calcium* and *phosphate* are incorporated into them as they grow. A similar deficiency of calcium and phosphate in adults results in *osteomalacia*.

CAUSES

The most common cause of rickets is deficiency of *vitamin D*, which is vital for the absorption of calcium from the intestines into the blood and for its incorporation into bone. Vitamin D is

ANATOMY OF THE RIBS

There are seven true ribs attached to the sternum; three false ribs, each attached to a rib above; and two floating ribs, attached only to the spine, on each side. Every rib is attached to the spine at the back. The intercostal muscles (between the ribs) pull the ribs up, expanding the chest and drawing air into the lungs. The front ends of the true ribs are linked to the sternum by cartilages.

found in fat-containing animal substances, such as oily fish, butter, egg yolk, and liver. There are also small amounts in human and animal milk. Vitamin D is also made in the body through the action of sunlight on the skin.

Rickets occasionally develops as a complication of a digestive disorder that causes *malabsorption* (failure to absorb nutrients from the intestine). It may also occur in certain rare forms of kidney and liver disease.

SYMPOTMS AND SIGNS

The principal feature of advanced rickets is deformity of the bones, especially of the legs and spine. Typically, there is bowing of the legs and, in infants, flattening of the head as a result of softness of the skull. Infants with rickets often sleep poorly and show delay in crawling and walking. Other features that occur in rickets include *kyphoscoliosis* (spinal curvature), a tendency to *fractures*, and enlargement of the wrists, ankles, and ends of the ribs. There may also be pelvic pain and muscle weakness.

DIAGNOSIS AND TREATMENT

The doctor makes a diagnosis based on the child's physical appearance and the results of *X-rays* and *blood tests*.

Rickets due to dietary deficiency is treated with vitamin D supplements, which can restore normal bone growth. Deformities usually disappear as the child grows. The type of rickets that occurs as a complication of another disorder is treated according to the cause.

rickettsia

A type of parasitic microorganism. Rickettsiae resemble small *bacteria* but, much like viruses, they can multiply only by invading other living cells. Rickettsiae are primarily parasites of arthropods, such as ticks, lice, fleas, and mites, but they can be transmitted to the blood of larger animals via insect bites. Human diseases caused by rickettsiae include *Q fever*, *Rocky Mountain spotted fever*, and *typhus*.

rifabutin

A drug used in the treatment of *tuberculosis* and in the prevention of other *mycobacterial infections*.

rifampicin

An *antibacterial drug* used principally in the treatment of *tuberculosis*, but also that of *leprosy* and *legionnaires' disease*. Rifampicin may also be used to prevent meningococcal *meningitis* in people who

are in very close contact with the disease. The drug is usually prescribed in combination with other antibacterials because some strains of bacteria develop resistance to it if it is used alone.

Side effects of rifampicin include harmless, orange-red discolouration of the urine, saliva, and other body secretions; muscle pain; nausea and vomiting; diarrhoea; *jaundice* (yellowing of the skin and the whites of the eyes); flulike symptoms; rash; and itching. Rifampicin also interferes with the action of *oral contraceptives*.

Rift Valley fever

A viral disease found in East Africa and South Africa that is transmitted from animals to humans by mosquitoes. The symptoms of Rift Valley fever resemble those of *dengue* or *influenza*, although in some cases the condition may be symptomless. In extremely severe and rare cases, Rift Valley fever may lead to *retinitis* (inflammation of the retina), *encephalitis* (inflammation of the brain), haemorrhage (bleeding), and even death.

right bundle branch block

See *heart block*.

rigidity

Increased tone in one or more *muscles*, causing them to feel tight; the affected part of the body becomes stiff and inflexible.

Causes of rigidity include muscle injury, *arthritis* in a nearby joint, a neurological disorder (such as *Parkinson's disease*), *stroke* (damage to part of the brain caused by an interruption to its blood supply), or *cerebral palsy* (a movement disorder caused by damage to the brain). Rigidity of the abdominal muscles is a sign of *peritonitis* (inflammation of the membranous lining of the abdominal cavity). (See also *spasticity*.)

rigor

A violent attack of shivering, which is often associated with a fever. Rigor may also refer to stiffness or rigidity of body tissues, as in *rigor mortis*.

rigor mortis

The stiffening of *muscles* that starts three to four hours after death. Rigor mortis is usually complete after about 12 hours; the stiffness then disappears over the next 48 to 60 hours.

The greater the physical exertion before death, the sooner rigor mortis begins. Similarly, the sooner rigor mor-

tis begins, the quicker it passes. These facts are used, along with other factors, to help assess the time of death.

Riley-Day syndrome

A *genetic disorder* that affects the function of nerves in many parts of the body. The condition may begin in infancy.

SYMPTOMS

Children with Riley-Day syndrome often have diminished sensitivity to pain and may not notice when they hurt themselves. Problems with swallowing are common, and affected infants may develop pneumonia as a result of inhaling food into their airways (see *aspiration pneumonia*). Vomiting may also occur. The children may also suffer from lack of tears, increased sweating, poor coordination, problems with speech, and an unsteady gait. Puberty may be delayed (see *delayed puberty*).

INVESTIGATION AND TREATMENT

Genetic testing may be arranged to look for the specific gene abnormality. Any additional tests performed depend on the symptoms. For example, if the child is unwell with a cough, a *chest X-ray* may be arranged and may show evidence of pneumonia.

Treatment is aimed at relieving specific problems as they arise, such as giving *antibiotic drugs* for pneumonia.

RIMAs

The abbreviation for *reversible monoamine oxidase inhibitors*.

ringing in the ears

See *tinnitus*.

ring pessary

A plastic, ring-shaped device that may be inserted into the vagina in order to hold a prolapsed uterus (see *uterus, prolapse of*) in position.

ringworm

A popular name for certain fungal skin infections commonly found on the feet, groin, scalp, nails, or trunk. Ringworm causes ring-shaped, reddened, scaly, or blistery skin patches. (See also *tinea*.)

Rinne's test

A type of *hearing test* that is used to determine whether *deafness* is conductive (due to the faulty conduction of sound from the outer ear to the inner ear) or sensorineural (due to problems of the inner ear, the nerves, or the auditory area of the brain).

A vibrating tuning fork is placed against the mastoid process (the bone behind the ear) and then held close to the ear. A positive result, when the sound conducted by the air is heard more clearly than that conducted by the bone, indicates sensorineural deafness. A negative result, when the sound conducted by bone is heard more loudly, indicates conductive deafness. Rinne's test is used in conjunction with other hearing tests.

risk factor

Any feature or attribute that predisposes a person to increased risk of developing an illness. Tobacco *smoking*, working with asbestos (see *asbestos-related diseases*), or having a family history of a condition are all considered to be risk factors.

risperidone

An *antipsychotic drug* used in the treatment of acute psychiatric disorders and long-term psychotic illness such as *schizophrenia*. Possible side effects include insomnia, anxiety, headache, difficulty in concentrating, and weight gain. Risperidone has less sedative effect and is less likely to cause movement disorders than some other antipsychotics, however.

ritodrine

A drug used to prevent or delay premature labour (see *prematurity*) by relaxing the muscles of the uterus (womb). Possible side effects of ritodrine include tremor, chest pain, *palpitations*, nausea, vomiting, and hot flushes.

rivalry, sibling

See *sibling rivalry*.

river blindness

See *onchocerciasis*.

RNA

The abbreviation for ribonucleic acid. RNA and DNA (deoxyribonucleic acid) carry the inherited, coded genetic instructions in cells. In all animal and plant cells, DNA carries the instructions and RNA helps to decode them, but, in some viruses, the instructions are held by RNA. (See also *nucleic acids; protein synthesis*).

RNI

See *reference nutrient intake*.

Rocky Mountain spotted fever

A rare, infectious disease causing fever and a rash with spots that spread over the body, darken, enlarge, and bleed.

Rocky Mountain spotted fever occurs in North and South America and is caused by a microorganism called a *rickettsia* that is transmitted from small mammals to humans by tick bites (see *ticks and disease*). Treatment is with *chloramphenicol* or *tetracycline*.

rod

One of the two specialized types of nerve cell within the *retina* (the light-sensitive inner layer at the back of the eye) that convert light energy into nerve impulses. The rods are very sensitive and can respond to very dim light. (See also *cone*.)

rodent ulcer

A common name for *basal cell carcinoma*.

rofecoxib

A type of *COX-2 inhibitor drug* used to relieve the pain and inflammation of *osteoarthritis* and *rheumatoid arthritis*. Side effects may include mouth ulcers, sleep disturbance, and muscle cramps. Rofecoxib has, however, been found to increase the risks of *myocardial infarction* and *stroke*, and has now been withdrawn.

Rohypnol

The brand name for flunitrazepam, a *benzodiazepine drug* that was formerly used as a sleeping drug to treat *insomnia* but has now been withdrawn.

role-playing

The acting of a role (a pattern of behaviour expected in a given situation). The phrase "sick role" describes the type of passive behaviour expected and allowed of a patient; people with social or emotional problems may unconsciously adopt this role to gain sympathy.

root-canal treatment

A dental procedure that is performed in order to save a tooth in which the pulp (the living tissue within the tooth) has died or become untreatably diseased, usually as the result of extensive dental caries (see *caries, dental*).

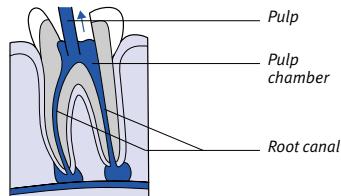

Root-canal treatment may be performed under a local anaesthetic (see *anaesthesia, local*). X-rays are first taken in order to establish the length of the root canal. The main stages of treatment are shown in the illustrations (right).

A hole is drilled into the crown to remove all material from the pulp chamber. The root canals are then slightly enlarged and shaped with fine-tipped instruments. The length is mea-

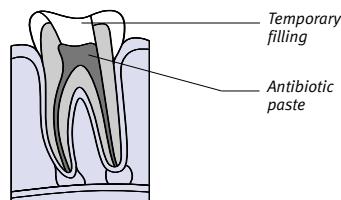

sured. The procedure is often monitored by X-rays. The cavity is washed out, and antibiotic paste and a temporary filling are packed into it. Some days later, the filling is removed and the canals are checked for sterility. If no infection is detected, the cavity is filled with a sealing paste and/or tapering solid "points" made of gutta-percha resin mixed with zinc and bismuth oxides. The roots are then sealed with cement. If the cavity is not filled completely, bacteria may enter, leading to *periodontitis* (inflammation of the tissues surrounding the teeth).

Treated teeth may turn grey but their appearance can be restored by the use of bonding techniques (see

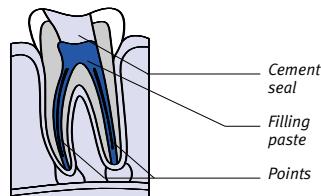

ROOT-CANAL TREATMENT

1 The pulp is removed from the pulp cavity through a hole drilled in the crown. The root canals are enlarged and shaped with fine-tipped instruments. X-rays may be used to monitor the procedure.

2 An antibiotic paste and a temporary filling are packed into the pulp chamber. A few days later, the filling is removed and the root canals are checked to ensure that no infection is present.

3 If no infection can be detected, the cavity is filled and the roots are sealed with cement and/or tapering solid "points" made of gutta-percha. The cavity is filled completely in order to avoid the risk of bacteria entering.

bonding, dental), by fitting an artificial crown (see *crown, dental*), or by bleaching (see *bleaching, dental*).

rooting reflex

An automatic reflex action seen in newborn infants (see *reflex, primitive*). The rooting reflex, which can be evoked by touching the baby's cheek with the fingertip, enables the baby to find the mother's nipple to suckle.

root pain

Pain resulting from damage to, pressure on, or disease of the roots of a *sensory nerve*. Root pain is felt in areas of skin supplied by the affected nerve roots.

Rorschach test

A psychological test based on a person's responses to a set of ink-blot pictures. The test was intended to reveal an individual's attitudes, conflicts, and emotions, but is now rarely used. (See also *personality tests*.)

rosacea

A chronic *skin* disorder in which the nose and cheeks are abnormally red. The cause is usually unknown. Rosacea is aggravated by the use of *corticosteroid* creams. The disorder is most common among middle-aged women.

Rosacea usually begins with temporary flushes, but may develop into permanent redness of the skin, sometimes accompanied by *acne*-like pustules. In elderly men, it may lead to *rhinophyma* (bulbous swelling of the nose).

Treatment includes oral *tetracycline* or topical (applied to the skin) *metronidazole*. Rosacea tends to recur for five to ten years before disappearing.

roseola infantum

A common infectious disease, caused by a type of *herpes* virus, that mainly affects children between the ages of six months and two years. Roseola infantum is characterized by an abrupt onset of irritability and fever. The child's temperature drops to normal after four or five days and, at about the same time, a rash appears on the trunk, often spreading to the neck, face, and limbs. The rash usually clears up within two days.

Other symptoms may include a sore throat and enlargement of *lymph nodes* in the neck. Convulsions (see *convulsion, febrile*) may occur during the fever, but there are no serious effects.

The only treatment for roseola infan-

tum is to keep the child cool and give *paracetamol* to reduce the fever.

rose spots

A rash of pink or red spots that erupts on the skin of the chest, the abdomen, and sometimes the thighs in the second week of *typhoid fever*. Rose spots last a few days.

rosiglitazone

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) that is used in combination with other oral hypoglycaemics (either *metformin* or a sulphonylurea) in the treatment of type 2 *diabetes mellitus*. Rosiglitazone acts by reducing peripheral *insulin* resistance. Side effects of rosiglitazone may include gastrointestinal disturbances, weight gain, and *anaemia* (a reduced level of the oxygen-carrying pigment haemoglobin in the blood).

rotator cuff

A reinforcing structure around the shoulder *joint*, composed of four muscle tendons that merge with the fibrous capsule enclosing the joint.

The rotator cuff may be torn as the result of a fall. A partial tear may cause *painful arc syndrome* (pain when the arm is lifted away from the body in a particular arc). A complete tear seriously limits the person's ability to raise the

arm and, in cases of severe disability, may require surgical repair.

rotavirus

A type of *virus* that is a common cause of *gastroenteritis*; rotavirus particularly affects young children.

roughage

See *fibre, dietary*.

roundworms

A class of elongated, cylindrical worms, also known as *nematodes*. Some types of roundworm are human *parasites* (the table below summarizes the main ones). The adult worms usually inhabit the human intestines, often without causing symptoms. Sometimes worm larvae pass through other parts of the body, which may cause symptoms.

The only common roundworm disease in the UK is *threadworm infestation*, which mainly affects children; occasionally, *ascariasis*, *whipworm infestation*, and *toxocariasis* occur. Some people return from abroad with *hookworm infestation*.

In tropical countries, roundworm diseases are much more common; they include those mentioned above as well as *strongyloidiasis*, *guinea worm disease*, and various types of *filariasis*. For the majority of roundworm in-fes-

DISEASES CAUSED BY ROUNDWORMS (NEMATODES)

Disease	Adult length	Distribution	How acquired
Ascarisis (common roundworm)	15–38 cm	Worldwide	By swallowing worm eggs that have contaminated food or fingers
Enterobiasis (threadworm)	0.2–1.5 cm	Worldwide	By swallowing worm eggs that have contaminated fingers
Trichuriasis (whipworm)	2.5–5 cm	Worldwide	By swallowing worm eggs that have contaminated food or fingers
Ancylostomiasis (hookworm)	1.5 cm	Tropics	By penetration of skin of feet by worm larvae in soil
Strongyloidiasis	0.2 cm	Tropics	By penetration of skin of feet by worm larvae in soil
Toxocariasis	Several cm	Worldwide	By swallowing worm eggs from dirt or dog faeces
Trichinosis (porkworm)	0.1 cm	Worldwide	By eating undercooked pork containing encysted worm larvae
Filariasis	2–50 cm	Tropics	By mosquito and other insect bites

tations, treatment is with the use of *anthelmintic drugs*.

Roussy-Levy disease

A rare *genetic disorder* affecting nerves and muscles; symptoms usually begin in early childhood. Roussy-Levy disease resembles *peroneal muscular atrophy* and results from degeneration of the nerves supplying the lower legs and forearms.

Features include weakness, muscle wasting, and poor coordination of the legs; *claw-foot*; and tremors of the hands. There may also be abnormal curvature of the spine (see *kyphoscoliosis*). Roussy-Levy disease displays an autosomal dominant pattern of inheritance.

RSI

The abbreviation used for *repetitive strain injury*, a type of overuse injury.

rubber dam

A rubber sheet used to isolate one or more teeth during certain dental procedures. The dam acts as a barrier against saliva and prevents the inhalation of debris. To fit a dam, the dentist punches small holes in a rubber sheet, through which the teeth protrude. The sheet is then secured in place with clamps and a frame.

rubefacient

A substance that causes redness of the skin by increasing blood flow to it. Rubefacients are sometimes included in ointments used to relieve muscular aches and pains and they work by producing counter-irritation: they stimulate nerve endings to create a superficial feeling of heat or cold and distract the brain from the deeper muscular pain. Examples of rubefacients include methyl salicylate and menthol.

rubella

A viral infection, also known as German measles. Rubella is serious only if it affects a nonimmune woman in the early months of pregnancy, when there is a risk that the virus will cause severe *birth defects* (known as congenital rubella syndrome) in the fetus.

TRANSMISSION AND SYMPTOMS

The rubella virus is spread through mother-to-baby transmission and from person to person in airborne droplets; it has an *incubation period* of two to three weeks. Infection usually occurs in children between the ages of six and 12 and is almost invariably mild.

The first symptoms may be a slight

fever, malaise, and enlarged *lymph nodes* at the back of the neck. A rash then appears on the face, spreads to the trunk and limbs, and disappears within about three days. In adolescents and adults the symptoms may be more marked, such as a headache before the rash appears and a more pronounced fever.

The virus may be transmitted from about a week before the rash appears until a few days after its onset. An unborn baby is at risk if the mother is infected during the first four months of pregnancy. The earlier the infection occurs, the more likely the infant is to be affected and the more serious the resulting abnormalities tend to be. The most common abnormalities are *deafness*, *congenital heart disease*, *learning difficulties*, *cataract*, *purpura*, *cerebral palsy*, and bone abnormalities. About one in five affected babies dies in early infancy.

DIAGNOSIS AND TREATMENT

Rubella is easily confused with other viral infections, *scarlet fever*, and drug reactions, which may produce similar symptoms. Rubella can be positively diagnosed only by laboratory isolation of the virus, for example from a throat swab or by tests to look for *antibodies* (proteins manufactured by the immune system) to the virus in the blood.

There is no specific treatment. *Paracetamol* can be given to reduce fever. Treatment of congenital rubella syndrome depends on the defects present.

PREVENTION

Rubella vaccine provides long-lasting immunity to the disease; it is now given in the MMR vaccine (see *MMR vaccination*) to babies aged 12 to 15 months, with a booster at school entry. Rubella infection also confers immunity.

Any woman who is planning a pregnancy should have her rubella status checked. If she is not immune, she should be vaccinated immediately. If a nonimmune pregnant woman comes into contact with a person who has rubella, passive immunization by *immunoglobulin injection* may help to prevent infection of the fetus.

rubeola

Another name for *measles*.

running injuries

Disorders resulting from the effects of jogging or running. Running injuries are common but most can be avoided by taking some simple precautions, such as wearing the correct footwear.

TYPES

Common types of running injury include *tendinitis* (inflammation of a tendon, particularly the *Achilles tendon*); *stress fractures* of bones in the leg and foot; *plantar fasciitis* (inflammation of tissue in the sole of the foot); torn *hamstring muscles* at the back of the thigh; back pain due to jarring of the spine; tibial *compartment syndrome* (painful cramp in the lower leg due to muscle compression); knee pain; ligament injuries in the ankle; and *shin splints* (pain along the tibia or shin).

PREVENTION

Shoes should fit snugly to provide stability but they should not cramp the foot; insoles help to cushion the jarring force on the legs and spine. Shoes that have become worn down should not be used because this can cause abnormal positioning of the foot during running, leading to foot strain.

Before running, warming-up exercises should be performed to reduce the risk of injury. Beginners should run only short distances at first and experienced runners should keep within sensible bounds. Runners should maintain an upright posture, with trunk, neck, and arms relaxed. Long periods of running uphill, downhill, or along the side of a slope should be avoided as they increase stress on the ankles and knees.

After a running injury has been diagnosed, assessment by a sports physiotherapist may be required in order to help prevent a recurrence of the injury.

rupture

A common term for a *hernia*. The term also refers to a complete break in a structure, as in *rupture of a tendon*.

Rynacrom

A brand name for *sodium cromoglicate*, an antiallergy drug. Rynacrom is used specifically in the prevention of allergic rhinitis (see *rhinitis, allergic*).

S

sac

A baglike organ or body structure.

saccharin

An *artificial sweetener*.

sacralgia

Pain in the *sacrum* (the triangular spinal bone below the lumbar *vertebrae*) that is caused by pressure on a spinal nerve. Sacralgia is usually the result of a *disc prolapse*. Rarely, it may be due to *bone cancer*. (See also *back pain*.)

sacralization

Fusion of the fifth (lowest) lumbar *vertebra* with the upper *sacrum* (the triangular spinal bone that is positioned below the lumbar vertebrae). Sacralization may be present at birth, in which case there are usually no symptoms. Sacralization may also be produced deliberately by a surgical procedure for the treatment of a *disc prolapse* or *spondylolisthesis*. (See also *spinal fusion*.)

sacroiliac joint

One of a pair of rigid *joints* on each side of the body that form an interface between the *sacrum* (the triangular spinal bone below the lumbar *vertebrae*) and the *ilium* (hip bone). The bony surfaces within the joint are lined with cartilage and have a small amount of synovial fluid between them. Strong ligaments positioned between the sacrum and ilium allow only minimal movement at the joint.

The sacroiliac joint can be strained, usually by childbirth or overstriding when running. Such an injury causes pain in the lower back and buttocks. The sacroiliac joint can also become inflamed (see *sacroilitis*).

sacroilitis

Inflammation of a *sacroiliac joint*, one of a pair of joints situated between each side of the *sacrum* (the triangular spinal bone below the lumbar vertebrae) and each *ilium* (hip bone).

Sacroilitis can be due to various disorders, such as *ankylosing spondylitis*, *Reiter's syndrome*, *rheumatoid arthritis*, or arthritis associated with *psoriasis*. The main symptom is pain in the lower back, buttocks, groin, and back of the thigh. Treatment is with *nonsteroidal anti-inflammatory drugs*.

sacrum

The large triangular bone in the lower *spine*. The sacrum lies in the centre back of the *pelvis*. Its broad upper part articulates with the fifth (lowest) lumbar *vertebra*, and its narrow lower part with the *coccyx*. The sides are connected by the *sacroiliac joints* to each *ilium* (hip bone). Disorders affecting the sacrum include *sacralgia*, *spondylolisthesis*, and *sacralization*. (See also *spine, disorders of*.)

SAD

The abbreviation for *seasonal affective disorder*.

sadism

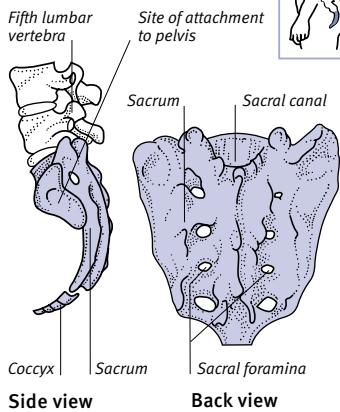

The tendency or practice of deriving pleasure, particularly sexual pleasure, from inflicting pain or suffering on others. (See also *sadomasochism*.)

sadomasochism

The tendency or practice of deriving sexual pleasure by inflicting pain (see *sadism*) and receiving abuse (see *masochism*); one

STRUCTURE OF THE SACRUM

The sacrum consists of five vertebrae (spinal bones) that are fused together to form a single solid structure.

trait usually predominates. It also describes a sexual relationship in which one partner is very dominant and one is submissive.

safe period

See *contraception, natural methods of*.

safer sex

Preventive measures that are undertaken to reduce the risk of *sexually transmitted infections*. These include taking simple precautions such as maintaining a monogamous sexual relationship with someone who is free of infection; avoiding casual sex or sex with multiple partners; avoiding activities that can damage the skin or mucous membranes, or that involve contact with body fluids; and using a *condom*.

S

salbutamol

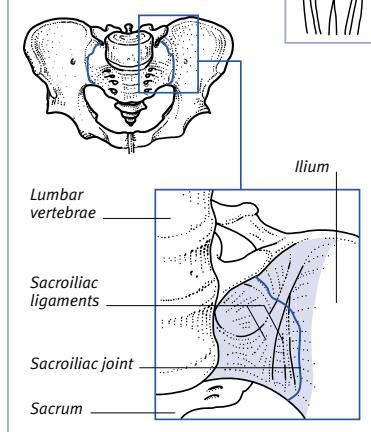

A *bronchodilator drug* that is used in the treatment of *asthma*, *chronic bronchitis*, and *emphysema*. It is also occasionally used to help prevent premature labour (see *prematurity*).

salicylate drugs

A group of drugs, including *aspirin* and *benorilate*, that have anti-inflammatory, fever-reducing, and mild *analgesic* action. An overdose of salicylate drugs causes *hyperventilation*, *tinnitus*, sweating, abnormal bleeding, biochemical disturbances, and, in severe cases, leads to convulsions and coma.

STRUCTURE OF THE SACROILIAC JOINT

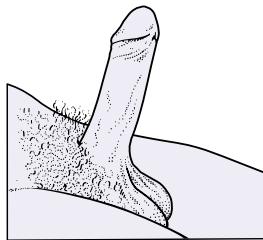

The joint forms an interface between the sacrum at the back of the pelvis and the ilium (hip-bone) on each side of the body.

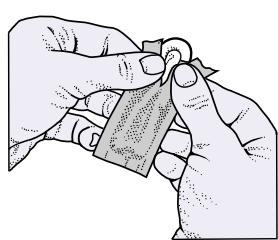

SAFER SEX: HOW TO USE A CONDOM

Using a condom is not a guarantee against transmission of HIV (the AIDS virus) or other sexually transmitted infections, but it does reduce the risks substantially. Condoms that are prelubricated with a spermicide offer extra protection against

pregnancy. Hypoallergenic condoms are available for people who are sensitive to rubber. In addition, condoms are available that are made from a thicker type of rubber and these should be used during anal intercourse.

1 The penis should be fully erect before the condom is put on. The condom should be in place before any vaginal or anal penetration by the penis and before oral sex.

2 Use a brand of condom that conforms to British Standards. Do not use one that has no teat, is beyond its "use by" date or appears to be defective. Open the condom carefully to avoid tearing it.

3 The teat-end should be squeezed so it is free of air and the condom unrolled fully over the penis. Do not stretch the condom tightly because a tight condom is more likely to burst.

4 The penis should be withdrawn soon after ejaculation. During withdrawal, the base of the condom should be held in order to prevent the semen from spilling out of the condom.

salicylic acid

A *keratolytic drug* that is used to treat skin disorders such as *dermatitis*, *eczema*, *psoriasis*, *dandruff*, *ichthyosis*, *acne*, *warts*, (including *verrucas*) and callosities (see *callus*, *skin*). Salicylic acid is also sometimes used to treat *fungal infections*. Side effects are few; and they may include irritation and dryness of the skin.

saline

A solution of salt (sodium chloride). Solutions with the same concentration of salt as body fluids are known as normal, or physiological, saline. Saline is used in contact lens solutions and may be given by *intravenous infusion* to replace fluids lost in severe dehydration.

saliva

The slightly alkaline fluid secreted into the mouth by the *salivary glands* and the *mucous membranes* lining the mouth. Saliva contains the digestive enzyme amylase, which helps to break down carbohydrates in food. In addition, saliva keeps the mouth moist, lubricates food to aid swallowing, and helps the tongue and mouth to register *taste*.

salivary glands

Three pairs of glands that secrete *saliva*, via ducts, into the mouth.

The largest, the *parotid glands*, lie on each side of the jaw, just below and in front of the ears; the ducts of these glands run forwards and inwards to open inside the cheeks.

The *sublingual glands* lie on the floor of the front of the mouth, where they form a low ridge on each side of the frenulum (the band of tissue that attaches the underside of the tongue to the floor of the mouth). This ridge has a row of small openings through which saliva is excreted.

The *submandibular glands* lie towards the back of the mouth, close to the sides of the jaw. Their ducts run for-

wards and open under the tongue at two small swellings, one on each side of the frenulum.

DISORDERS

The *parotid glands* can be infected with the *mumps* virus, and stones (calculi) can form in a salivary gland or duct. A stone in a duct causes a swelling that enlarges during eating because saliva flow is blocked; it may also cause pain. Surgical removal of a stone from a duct is usually straightforward, but if the stone is within the gland, the entire gland may have to be removed.

Poor *oral hygiene* may allow bacterial infection in a gland, sometimes leading to an abscess. Tumours may develop; however, they are rare, except for a type of parotid tumour that is slow-growing, noncancerous, and painless.

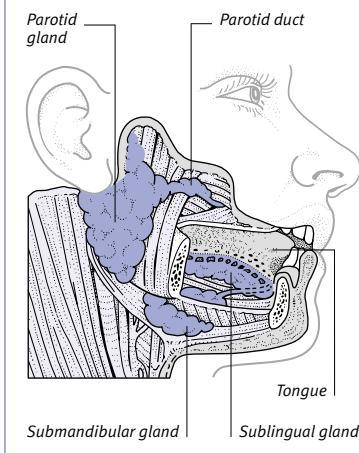

Insufficient salivation causes a dry mouth (see *mouth, dry*). This problem may be due to *dehydration* or *Sjögren's syndrome*, or it may occur as a side effect of certain drugs.

salivation, excessive

The production of too much *saliva*. Excess salivation sometimes occurs during pregnancy and prior to vomiting. Other causes include mouth problems such as irritation of the mouth lining, *gingivitis* (gum inflammation), or *mouth ulcers*; digestive tract disorders such as *peptic ulcers* and *oesophagitis*; and nervous system disorders such as *Parkinson's disease*. In some cases, it may be reduced by *anticholinergic drugs*.

ANATOMY OF THE SALIVARY GLANDS

Each gland consists of thousands of saliva-secreting sacs. Tiny ducts carry the saliva into the main ducts leading to the mouth.

salmeterol

A *bronchodilator drug* used in the treatment of *asthma*. The drug is usually inhaled twice a day to prevent asthma attacks. Side effects may include slight tremor, agitation, insomnia, and, rarely, a rapid heartbeat.

salmonella infections

Infections caused by any of the salmonella group of bacteria. One type of salmonella causes *typhoid fever*; another causes *paratyphoid fever*, others commonly result in bacterial *food poisoning*. Infants, elderly people, and those who are debilitated are most susceptible.

In many cases, the source of salmonella poisoning has been traced to poultry products, and particularly to hens' eggs and chicken meat. The infection of eggs can originate in the hen's ovaries or may occur as a result of faecal contamination via the egg shell.

SYMPOTMS

Symptoms of salmonella food poisoning usually appear suddenly 12–24 hours after infection and include headache, nausea, abdominal pain, diarrhoea, and sometimes fever. They usually last for only two or three days, but in severe cases *dehydration* or *septicaemia* (blood poisoning) may develop, especially in the very young and old.

TREATMENT

Treatment is by *rehydration therapy* to replace lost fluids. In severe cases, fluid may need to be replaced by means of *intravenous infusion*.

PREVENTION

In general, it is advisable to avoid foods that contain raw egg (such as home-made mayonnaise, mousses, and ice cream). The risk of infection is reduced in very fresh eggs. Salmonella organisms are not killed by light cooking, and eggs given to children or the frail or elderly should be well cooked.

salmon patch

See *stork mark*.

salpingectomy

Surgical removal of one or both *fallopian tubes*. Salpingectomy may be performed if the tube is infected (see *salpingitis*) or to treat *ectopic pregnancy*. (See also *salpingo-oophorectomy*.)

salpingitis

Inflammation of a *fallopian tube*. Salpingitis is commonly caused by infection (this is usually a sexually transmitted

type, such as *gonorrhoea* or *chlamydial infection*) spreading up from the vagina, cervix, or uterus. Salpingitis is also a feature of *pelvic inflammatory disease*.

Symptoms, include abdominal pain and fever, which may be severe. Pus may collect in the fallopian tube, and a pelvic *abscess* may develop.

Diagnosis is by examination of vaginal and cervical discharge, to identify the infectious organism, or *laparoscopy* to view the abdominal cavity. Blood tests may be carried out if *septicaemia* is suspected and the woman is very unwell. Treatment of the condition is with *antibiotics*. Surgery may be needed if an abscess has formed.

If the infection has damaged the inside of the fallopian tubes, *infertility* or an increased risk of an *ectopic pregnancy* may result. In some cases, damage to a tube can be corrected surgically.

salpingo-oophorectomy

Removal of one or both *fallopian tubes* and *ovaries*. This operation may be performed to treat some types of *ovarian cyst*. It may also be performed together with a *hysterectomy* to treat cancer of the ovary (see *ovary, cancer of*) or the uterus (see *uterus, cancer of*).

salt

A substance formed when an acid and a base react. The word is commonly used to refer to sodium chloride (table salt).

salve

A healing, soothing ointment.

sandfly bites

Bites from sandflies, which are found in many warm climates and can pass disease to humans. In tropical and subtropical areas they transmit *leishmaniasis*. In parts of Asia and the Mediterranean, they transmit sandfly fever, an illness like influenza. In the western Andes, they transmit bartonellosis, different forms of which cause either joint pain and fever or a rash. The risk of bites can be minimized by wearing clothing with long arms and legs that fits closely at the wrists and ankles, and using insect repellent, especially after dusk (when the flies are most active).

sanitary protection

A variety of articles, including pads and tampons, that are used to absorb blood and protect the clothing during *menstruation*. Most are disposable.

saphenous vein

A major vein that runs the length of the leg just under the skin (see *circulatory system*). The saphenous vein is sometimes removed and used to bypass blockages in blood vessels supplying the heart (see *coronary artery bypass*).

sarcoidosis

A rare disease of unknown cause in which there is inflammation of tissues throughout the body, especially the lymph nodes, lungs, skin, eyes, and liver. It occurs mainly in young adults.

Symptoms do not always occur. When they do, they include fever, generalized aches, painful joints, and eye problems such as conjunctivitis and uveitis (painful, bloodshot eyes). Sarcoidosis may also cause enlargement of the lymph nodes, breathlessness, *erythema nodosum* (purplish swellings on the legs), a purplish facial rash, and areas of numbness. Possible complications of sarcoidosis include *hypercalcaemia* (excess calcium in the blood), which may damage the kidneys, and *pulmonary fibrosis* (scarring of lung tissue).

Treatment is not always needed. Most people recover fully within two years, with or without treatment, but some develop a persistent, chronic form of the disease. *Corticosteroids* are given to treat persistent fever or erythema nodosum, to prevent blindness in an affected eye, and to reduce the risk of permanent lung damage.

sarcoma

A cancer of *connective tissue* (which holds body structures together). Types include *osteosarcoma*, *Kaposi's sarcoma*, *chondrosarcoma*, and *fibrosarcoma*.

SARS

The abbreviation for severe acute respiratory syndrome, a potentially serious viral infection that may cause pneumonia.

SARS is believed to be due to a new strain of coronavirus and, in most cases, is spread by close personal contact.

Symptoms appear after two to seven days and include acute fever (sometimes with chills), aching muscles, and headache. After a further three to seven days, a dry (non-productive) cough (accompanied by shortness of breath that may become severe) may develop, which may indicate pneumonia.

A number of investigations, including chest X-ray, sputum microscopy, and blood tests may be performed to exclude

other causes of pneumonia. Reliable tests to detect the presence of the virus are being developed.

Treatment includes oxygen therapy, (with artificial ventilation if necessary) and, sometimes, antibiotic and/or anti-viral drugs, although there is no specific drug therapy that is effective. There is no vaccine or curative treatment available at present, and therefore control of the disease depends on physical measures, which include the use of face masks, hand washing, and isolation of infected individuals.

Not all people with SARS will develop pneumonia; most recover with no specific treatment. However, the condition may be fatal in 1 in 7 people who develop pneumonia.

saturated fats

See *fats and oils; nutrition*.

scab

A crust that forms on the skin or on a mucous membrane at the site of a healing wound or infected area. (See also *blood clotting*.)

scabies

A skin infestation caused by the mite *SARCOPTES SCABIEI*, which burrows into the skin to lay eggs. Scabies is highly contagious by close physical contact. It is most common in infants, children, and young adults.

The mite's burrows may appear on the skin as grey, scaly swellings, usually between the fingers, on the wrists and genitals, and in the armpits. Later, small papules may appear on the limbs and trunk. The infestation causes intense itching, particularly at night, and scabs may form on the papules.

Treatment is with an insecticide lotion that is usually applied to all of the skin including the head. All occupants of the person's household, and any sexual partners, should be treated at the same time.

scald

A *burn* due to hot liquid or steam.

scalded skin syndrome

A rare skin disease that causes redness followed by peeling of large areas of skin. It is caused by certain toxins from the bacterium *STAPHYLOCOCCUS AUREUS*. Children are particularly susceptible. Treatment is with intravenous injection or infusion of antibiotics.

scaling, dental

Removal of hard deposits from the teeth (see *calculus, dental*) to prevent or treat *periodontal disease* in the tissues supporting the teeth.

scalp

The skin of the head and its underlying tissue layers. The scalp is normally covered with hair. The skin is tougher than other skin and overlies a sheet of muscle that extends from the eyebrows, over the top of the head, to the nape of the neck.

The scalp may suffer injuries such as cuts and tears; it is richly supplied with blood vessels, so such wounds bleed profusely. Disorders affecting the scalp include *dandruff*; *alopecia* (hair loss); *sebaceous cysts*; *psoriasis*; fungal infections such as *tinea* (ringworm); and parasitic infestations such as *lice*. *Cradle cap* is common in infants.

scalpel

A surgical knife for cutting tissue.

scan

An image produced by one of several *scanning techniques*.

scanning techniques

Methods of producing images of organ structure (or sometimes function) using sound waves, radio waves, *X-rays*, or other forms of radiation directed through body tissues.

Ultrasound scanning is a widely used technique in which inaudible, ultra-high-frequency sound waves are passed into the body. These sound waves are reflected by various body structures in a pattern that is detected by one or more transducers and displayed on a screen.

CT scanning uses *X-rays* to measure variations in the density of an organ. The method compiles an image or picture by computer analysis.

Radionuclide scanning, which is also known as *scintigraphy*, involves the injection into the body of radioactive substances, which are taken up in different amounts by different organs. Radioactive iodine, for example, becomes concentrated in the thyroid gland. A detector is positioned in close proximity to the organ being examined and the pattern of radiation being emitted is recorded and displayed on a screen.

MRI (magnetic resonance imaging) uses a powerful electromagnet to align the nuclei of atoms of hydrogen in the

body. The nuclei are then knocked out of position by radio waves; in realigning themselves with the magnetic field, the nuclei produce a radio signal that can be detected and transformed into a computer-generated image.

PET scanning (positron emission tomography) is based on the detection of positively charged particles that are emitted by radioactively marked substances introduced into the body. A computer is used to build up an image that reflects the chemical activity of the tissue that is being studied.

scaphoid

One of the eight *wrist bones*. It is the outermost bone on the thumb side of the hand, in the row of wrist bones nearest the elbow.

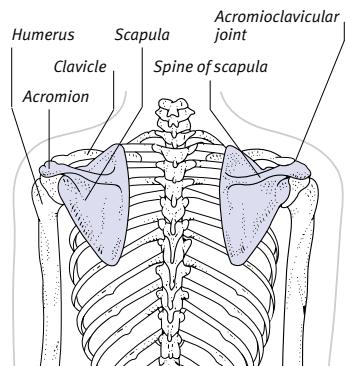

A fracture of the scaphoid is a common wrist injury usually caused by a fall on an outstretched hand. A characteristic symptom is tenderness in the anatomical snuffbox (the space between the tendons at the base of the thumb on the back of the hand). Treatment is by immobilizing the wrist in a *cast*.

scapula

The anatomical term for the shoulder-blade. The two scapulae are flat, triangular bones situated in the upper back. On the rear surface of each one is a prominent spine (which can be felt under the skin) that runs diagonally upwards and outwards to a bony prominence (the acromion) at the shoulder tip. The acromion articulates with the

LOCATION OF THE SCAPULAE

The two scapulae are the prominent wing-shaped bones in the upper back. They form a major part of the shoulder joint.

end of the *clavicle* (collarbone) to form the *acromioclavicular joint*. Just below the acromion is a socket (the glenoid cavity) into which the head of the humerus (upper arm bone) fits to form the shoulder joint.

The scapula serves as an attachment for some of the muscles and tendons of the arm, neck, chest, and back and aids movements of the arm and shoulder.

scar

A mark left where damaged tissue has healed. Scar tissue forms not only on the skin but on all internal wounds, such as at the site of a muscle tear or where surgery has been performed.

The body repairs a wound or other lesion by increasing production of the tough, fibrous protein *collagen* at the site of the damage. This helps to form new *connective tissue* around the lesion. If the edges of a lesion are brought together during healing, a narrow, pale scar forms; if they are left apart, more extensive scarring occurs.

ABNORMAL SCARS

A hypertrophic scar is a large, unsightly scar that may develop at the site of an infected wound. Some people have a family tendency to develop such scars.

A *keloid* is a large, irregularly shaped scar that continues to grow in size as the body continues to produce extra collagen after a wound has healed. This type of scar is more common in black people than in white.

Adhesions are areas of scar tissue that form between unconnected parts of internal organs. They are a potential complication of intestinal surgery.

scarlatina

Another name for *scarlet fever*.

scarlet fever

An uncommon infectious disease, more often seen in childhood, that is caused by a strain of streptococcal bacteria and spread by exhaled breath or coughing. Symptoms appear four to seven days after infection; they include a severe sore throat, high fever, vomiting, and a rapidly spreading rash of tiny red spots on the neck and upper trunk. The face is flushed, except around the mouth. A white coating with red spots may develop on the tongue ("strawberry tongue"), which then comes off after a few days to reveal a bright red colour. After this event, the fever soon subsides, the rash fades, and the skin may peel.

As with other streptococcal infections, *glomerulonephritis* (inflammation within the kidney) or *rheumatic fever* may, rarely, develop some weeks later. *Antibiotics* prevent this and promote a rapid recovery.

Scheie syndrome

A *mucopolysaccharidosis* (an inherited metabolic disorder) causing clouding of the cornea (surface of the eye), deformed hands, and aortic disease, but normal motor development.

Scheuermann's disease

A form of *osteochondritis juvenilis*, a bone disorder affecting children and adolescents. It causes degeneration of the thoracic *vertebrae* (the spinal bones that support the ribcage), leading to *kyphosis* (a forward bend in the spine).

Schilling test

A test used to measure intestinal absorption of vitamin B₁₂, in order to detect disorders such as *pernicious anaemia*

(failure to absorb vitamin B₁₂). A person is given a radioactive dose of the vitamin by mouth, then the urine is tested over 24 hours to see how much of the radioactive substance is excreted.

schistosome

A fluke (parasitic flatworm) that causes the tropical disease *schistosomiasis*.

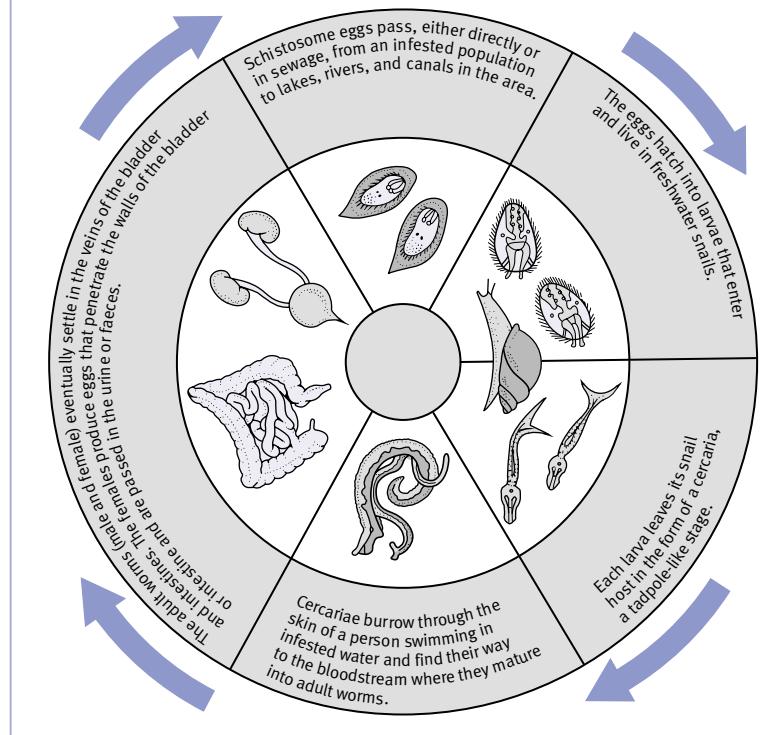

schistosomiasis

A parasitic tropical disease, also called bilharzia, that is caused by flukes (parasitic flatworms) called schistosomes, and acquired from infested lakes, rivers, or other waters. The larvae penetrate the skin and develop in the body into adult flukes, which settle in the veins of the bladder and intestines. Their eggs cause inflammatory reactions; there may be bleeding and ulceration in the bladder and intestinal walls, and the liver may be affected.

The first symptom is usually tingling and an itchy rash where the flukes have entered the skin. An influenza-like

CYCLE OF SCHISTOSOMIASIS

The disease affects a large proportion of the population in some parts of the world, such as the Nile valley in Egypt. Many methods have been tried to break the cycle of the disease in affected areas, with varying success. Methods used have included strict sanitary regulations and measures to eradicate freshwater snails.

illness may develop many weeks later, when the adults produce eggs. Subsequent symptoms include blood in the urine or faeces, abdominal or lower back pain, and enlargement of the liver or spleen. Complications of long-term infestation include liver *cirrhosis*, *bladder tumours*, and *kidney failure*.

Treatment is with the drug *praziquantel*. No vaccine is available, so people visiting infested areas should avoid bathing or wading in fresh water.

schizoid personality disorder

An inability to relate socially to other people. Individuals who have this trait, which is apparent from childhood, are often described as "loners" and make few, if any, friends. They are eccentric, seem to lack concern for others, and are apparently detached from normal day-to-day activities.

schizophrenia

A general term for a group of psychotic illnesses (disorders in which a person loses contact with reality) that are characterized by disturbances in thinking, emotional reaction, and behaviour. Schizophrenia is a disabling illness with a prolonged course that almost always results in chronic ill health and some degree of personality change.

Onset can be at any age but is most common in late adolescence and the early 20s. No causes have been identified, but many have been implicated. It is likely that inheritance plays a role. Disruption of the activity of some neurotransmitters (chemicals that transmit signals between nerve cells) in the brain is a possible mechanism. Brain imaging has revealed abnormalities of structure and function in affected people.

SYMPTOMS AND SIGNS

Schizophrenia may begin insidiously, with the person becoming slowly more withdrawn and losing motivation. In other cases, it comes on suddenly, often in response to external stress. The main signs are delusions (fixed, irrational ideas) such as those of persecution (which are typical of paranoid schizophrenia); *hallucinations* (perceptions that occur without any external stimulus), and thought disorder. Hallucinations are usually auditory (in which the person hears voices talking about him or her), but may also be visual or tactile. Thought disorder leads to impaired concentration and thought processes; it is often reflected in mud-

dled and disjointed speech and bizarre responses to questions. The person may believe that his or her thoughts are being controlled by outside forces or broadcast to others.

As the illness progresses, the person's emotions become blunted; he or she also becomes detached from others and loses interest in usual occupations. Behaviour is eccentric, and self-neglect common. In a rare form of schizophrenia, catatonia may occur. In this condition, rigid postures are adopted for prolonged periods, or there are outbursts of repeated movement.

DIAGNOSIS AND TREATMENT

Diagnosis may take some time, and in some cases, it may be difficult to make a diagnosis at all. Treatment is mainly with *antipsychotic drugs*, such as *phenothiazine drugs*, and the new atypical antipsychotic drugs such as risperidone. In some cases, the drugs are usually given as monthly depot injections. Once the symptoms are controlled, community care, vocational opportunities, and family counselling can help to prevent a relapse.

Some people may make a complete recovery; however, most sufferers have relapses punctuated with partial or full recovery. A small proportion have a severe life-long disability.

sciatica

Pain that radiates along the *sciatic nerve*. The pain usually affects the buttock and thigh, sometimes extending down the leg to the foot. In severe cases, the pain may be accompanied by numbness and/or weakness in the affected area.

The most common cause is a ruptured intervertebral disc pressing on the nerve root (see *disc prolapse*). Other causes include a muscle spasm, sitting awkwardly for long periods, or, less commonly, pressure on the nerve from a tumour. Sometimes the cause is unknown.

Treatment is with *analgesic drugs* (painkillers). If the pain is severe, a short period of bed rest may be helpful, although prolonged rest may cause the sciatica to worsen. *Physiotherapy*, *osteopathy*, or *chiropractic* may help in some cases, but neurosurgery may be needed for the relief of the nerve compression. It is important to try and maintain a healthy posture and weight.

sciatic nerve

The main *nerve* in each leg and the largest nerve in the body. It is formed from roots in the spinal cord. The sciatic nerve supplies the hip joint, some of the thigh muscles, and the back of the thigh. Lower down it branches to form the nerves supplying the lower leg and the foot.

nerve supplies the hip joint, some of the thigh muscles, and the back of the thigh. Lower down it branches to form the nerves supplying the lower leg and the foot.

SCID

The abbreviation for *severe combined immune deficiency*.

scintigraphy

A less common alternative name for *radionuclide scanning*. Renal scintigraphy is also known as *renography*.

scirrhou

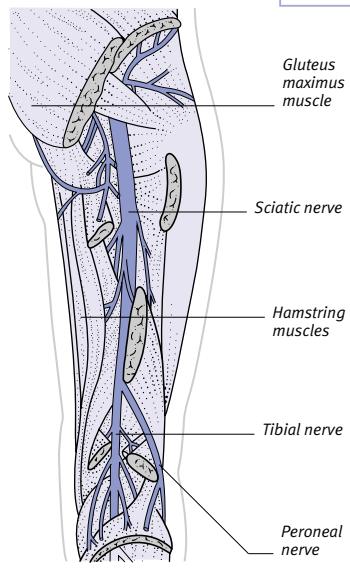

A term meaning "hard and fibrous". It is usually applied to cancerous tumours containing dense, fibrous tissue.

sclera

The white, fibrous, tough coating that protects the *eye*. The sclera may be injured by sharp objects. Disorders of the sclera include *scleritis* (inflammation) and *osteogenesis imperfecta* (in which the sclera is abnormally thin and may appear blue).

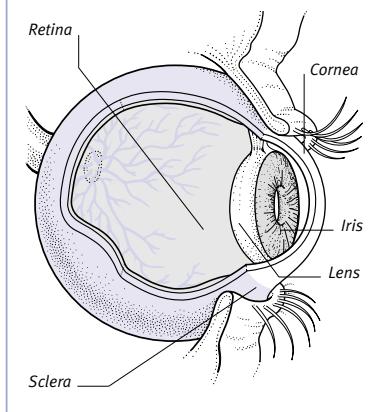

LOCATION OF THE SCIATIC NERVE

The diagram below shows the sciatic nerve in the back of the right thigh and knee. Branches of the nerve extend down the leg to the sole of the foot.

LOCATION OF THE SCLERA

The sclera is the white tissue at the front of the eye. It is about 0.5 mm thick and is continuous with the cornea. It is extremely tough and protects the eye's inner structures.

scleritis

Inflammation of the *sclera*. It usually accompanies a *collagen disease* such as *rheumatoid arthritis*, but also occurs in *herpes zoster ophthalmicus* and *Wegener's granulomatosis*. Scleritis may cause some parts of the sclera to become thin and perforated. It is usually persistent but often responds to *corticosteroid* eye-drops.

scleroderma

A slowly progressive condition that is characterized by hardening and thickening of the skin. With progression of the condition, the internal organs are affected (see *systemic sclerosis*).

scleromalacia

Softening of the *sclera* (the white outer coat of the eye). It is a common complication of *scleritis*, especially when associated with *rheumatoid arthritis*.

sclerosing cholangitis

A rare condition in which many of the bile ducts are narrowed, causing progressive liver damage for which the only treatment may be a *liver transplant*. In many cases, it is related to *inflammatory bowel disease*. (See also *cholangitis*.)

sclerosis

Hardening of a body tissue. The term is usually used to refer to hardening of blood vessels (as in *arteriosclerosis*) or of nerve tissue (as occurs in the later stages of *multiple sclerosis*).

sclerotherapy

A method of treating *varicose veins*, especially those that occur in the legs; *haemorrhoids*; and *oesophageal varices*. The affected vein is injected with an irritant solution, which causes inflammation in the lining; this reaction leads to scar tissue formation and the obliteration of the vein.

scoliosis

A deformity in which the *spine* is curved to one side. The thoracic (chest) or lumbar (lower back) regions are most commonly affected. Scoliosis usually starts in childhood or adolescence and becomes progressively more marked until growth stops. In many cases, another part of the spine curves to compensate, resulting in an S-shaped spine. Scoliosis may also be associated with *kyphoscoliosis*. The condition may be very mild and cause no symptoms, or it may be noticed by a doctor during investigation of back pain.

The cause of juvenile scoliosis is not known. Rarely, the condition is due to a congenital abnormality of the vertebrae (bones forming the spine). Sometimes it may occur temporarily as a result of a spinal injury.

If an underlying cause is found, it will be treated. In some cases, *physiotherapy* may be sufficient to control scoliosis of unknown cause. Progressive or severe scoliosis may require immobilization of the spine in a brace, followed by a surgical procedure (see *spinal fusion*) to straighten it.

scorpion stings

Injections of venom from the sting in scorpions' tails. Many species of scorpions are not dangerous, but some in North Africa, the southern US, South America, the Caribbean, and India are highly venomous. Some stings may cause only mild pain and tingling; but in more venomous species severe pain, restlessness, sweating, diarrhoea, and vomiting can occur. They are rarely fatal in adults, but pose a greater risk to children and elderly people.

Scorpion stings require prompt attention. If pain is the only symptom, *analgesics* and a cold compress may be enough. In severe cases, treatment with *antivenom* may be needed.

scotoma

An area of abnormal vision occurring within the *visual field*.

screening

The testing of apparently healthy people with the aim of detecting disease at an early stage when it is still treatable. (See also *cancer screening*.)

scrofula

Tuberculosis of the lymph nodes in the neck, often those just beneath the angle of the jaw. Scrofula is rare in developed countries. Antituberculous drugs clear up the condition in most cases.

scrofuloderma

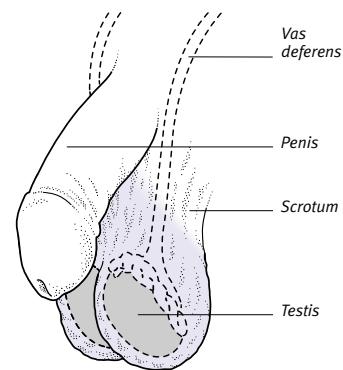

A type of *tuberculosis* in which the infection spreads from inside the body, most commonly from the lymph nodes in the neck (see *scrofula*), to the skin. It causes painless swellings under the skin that develop into *abscesses* or *ulcers*.

scrotum

The pouch that hangs behind the penis and contains the *testes*. It consists of an outer layer of thin, wrinkled skin over a layer of muscular tissue. Swelling of the scrotum may have a number of causes including *inguinal hernia*, a swollen testis, *hydrocele*, *varicocele*, or fluid accumulation due to *heart failure* or injury.

ANATOMY OF THE SCROTUM

The scrotum has oil-secreting glands and thinly scattered hairs on its surface. Internally it is divided by a membrane into two halves, each containing a testis.

scuba-diving medicine

A medical speciality concerned with the physiological hazards of diving with self-contained underwater breathing apparatus (SCUBA). Most hazards stem from the increase in atmospheric pressure

that occurs with depth. At a depth of 10 m, the total pressure is twice the surface pressure. At 30 m, it is four times the surface pressure.

MECHANICAL EFFECTS OF PRESSURE

During descent, divers must introduce gas into their middle-ear cavities and facial sinuses to prevent damage as the pressure mounts. This mounting pressure is what airline passengers experience during descent and repressurization (see *barotrauma*).

Whatever depth they attain, divers must be supplied with breathing mixtures at a pressure equal to the external water pressure. During ascent, gas in the lungs expands and can rupture lung tissues if the diver panics and inadvertently holds his or her breath. This is a serious condition, which is known as pulmonary barotrauma (burst lung). Symptoms may include coughing up of blood, inability to pass urine, breathing difficulties, and unconsciousness.

TOXIC EFFECTS OF GASES

Amateur divers breathe compressed air, which consists mainly of nitrogen and oxygen. These gases are harmless at surface pressures but become toxic at high pressure. Nitrogen impairs the nervous system when air is breathed at depth, causing slowed mental functioning and other symptoms that mimic alcohol intoxication (a condition known as nitrogen narcosis). Oxygen becomes toxic when air is breathed at increased pressure, and in such situations it can cause convulsions or lung damage.

To attain greater depths without risking nitrogen and oxygen poisoning, professional divers use gas mixtures other than air. A typical mixture consists of helium, with the addition of only small amounts of oxygen and nitrogen; the helium is relatively nontoxic.

THE BENDS

At depth, divers accumulate in their tissues excess quantities of any inert gas they are breathing (nitrogen, if air is being breathed). If pressure is released too quickly (that is, if the diver's ascent occurs too quickly) and if a large amount of gas has accumulated because the diver remained at depth for too long, this gas can no longer be held in solution in the body and may form bubbles in tissues and blood, causing *decompression sickness*.

OTHER HAZARDS

Additional hazards include *hypothermia* (dangerous chilling) due to immersion in cold water, and bites or stings from

marine animals (see *bites, animal; venomous bites and stings*). In addition, there is a risk of drowning.

ACCIDENT PREVENTION AND TREATMENT

Anyone who is thinking of taking up scuba diving should first have a medical checkup and undergo training at a recognized diving school.

Pressure-related accidents, such as burst lung and decompression sickness, are treated by recompression of the diver in a special pressure chamber. This allows any bubbles or pockets of gas that are in the blood or tissues to be reabsorbed. The following stage is slow release of the pressure.

scurvy

A disease, now rare in developed countries, caused by inadequate *vitamin C* intake. Scurvy disturbs the production of *collagen*, a protein in *connective tissue* (which supports body structures). The collagen is unstable, causing weakness of small blood vessels and poor wound healing. Haemorrhages (bleeding) may occur anywhere in the body, including the brain. If it occurs in the skin, the bleeding appears as bruising. Bleeding into the gums and loosening of teeth are common. Bleeding into the muscles and joints causes pain.

Scurvy is treated with large doses of vitamin C. Bleeding stops in 24 hours, healing resumes, and muscle and bone pain quickly disappear.

seafood poisoning

Bacterial or viral infections caused by eating shellfish that has been badly stored or cooked, or has been in water contaminated by human faeces. Symptoms include vomiting, diarrhoea, and abdominal pain. They may be relieved with plenty of fluids and salts (see *rehydration therapy*), but severe cases may need hospital treatment.

sealants, dental

Plastic coatings that are applied to the chewing surfaces of the back *teeth* to help prevent decay.

seasickness

A type of *motion sickness*.

seasonal affective disorder

A form of *depression* in which mood changes occur with the seasons. People with seasonal affective disorder, or SAD, tend to become depressed in winter, when natural light decreases, and feel

better in spring. In some people, exposure to bright light for two to four hours each morning seems to prevent it.

sebaceous cyst

A harmless, smooth nodule under the skin, most commonly on the scalp, face, ear, or genitals. The cyst contains a yellow, cheesy material and may become very large and infected by bacteria, making it painful. Large or infected cysts may be surgically removed.

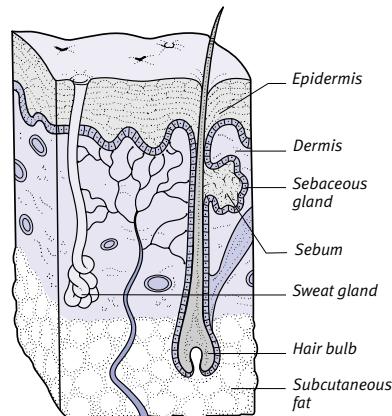

Sebaceous cyst on the scalp

These smooth nodules under the surface of the skin are filled with a cheeselike substance known as sebum. Those cysts that grow very large or become infected need to be removed surgically.

sebaceous glands

Glands in the *skin* that secrete a lubricating substance called *sebum*. Sebaceous glands either open into hair follicles or discharge directly on to the surface of the skin. These glands are most numerous on the scalp, face, and anus, but do not exist on the palms or the soles of the feet. Disorders of the glands may lead to *seborrhoea* or *acne vulgaris*.

Cross-section of skin with sebaceous gland

These glands occur in the skin and are most numerous on the scalp. They secrete a lubricating substance called sebum, which discharges directly on to the surface of the skin or into hair follicles.

seborrhoea

Excessive secretion of *sebum*, causing oiliness of the face and a greasy scalp. The cause is unclear, but *androgen hormones* play a part. Seborrhoea is most common in adolescent boys; those affected are more likely to develop seborrhoeic *dermatitis* and *acne vulgaris*. The condition usually improves in adulthood without any treatment.

seborrhoeic dermatitis

See *dermatitis*.

seborrhoeic wart

Also called a seborrhoeic *keratosis*, a small, harmless, brown or black skin growth with a rough, greasy surface.

sebum

The oily secretion that is produced by the *sebaceous glands*. Sebum has several functions: it lubricates the skin, keeps it supple, and protects it from becoming waterlogged or dried out and cracked. It also protects against bacteria and fungi. Sebum production is partly controlled by *androgen hormones*. Over-secretion (see *seborrhoea*) of sebum causes greasy skin and may lead to seborrhoeic *dermatitis* or *acne*.

secondary

A term applied to a disease or disorder that results from or follows another disease (the *primary* disease). It also refers to a malignant tumour that has spread from a primary cancer elsewhere in the body (see *metastasis*).

secondary haemorrhage

Bleeding that results from an injury or surgical procedure but that occurs at a later time, rather than immediately. Secondary haemorrhage may be the result of infection.

secondary infection

An infection that results from or follows a pre-existing infection. One example is a bacterial respiratory infection that follows a viral infection. (See also *superinfection*).

secretin

A hormone produced by the *duodenum* (the first part of the small intestine) when acidic food enters it from the stomach. Secretin stimulates the release of pancreatic juice, which contains sodium bicarbonate to neutralize the acid, and bile from the liver.

secretion

The manufacture and release by a cell, gland, or organ of substances (such as *enzymes*) needed for metabolic processes elsewhere in the body.

secretory otitis media

An alternative name for *glue ear*.

sectioning

A commonly used term for the implementation of a section of the *Mental Health Act* to detain a mentally ill person against his or her will.

security object

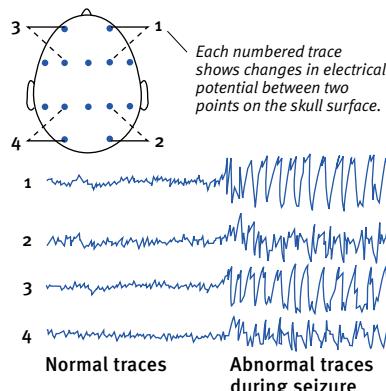

A significant item, such as a favourite blanket, garment, or soft toy, that provides comfort and reassurance to a young child. These items are sometimes referred to as transitional objects. The child may become deeply attached to the object and show great distress if it is lost or if any attempt is made to take it away from him or her.

Security objects are often important during the toddler stage and may be used for several years. However, most children grow out of the need for such an item by the time they are about seven or eight years old.

sedation

The use of a drug to calm a person. Sedation is used to reduce excessive *anxiety* and control dangerously aggressive behaviour. It may also be used as part of *premedication* (drugs given to prepare a person for surgery). *Sleeping drugs* are used for night sedation.

Location of electrodes

EEG changes during a seizure

The traces are recordings of electrical activity in a patient's brain, obtained from electrodes placed at various locations on the scalp and linked to an EEG machine. They show the change in activity at the onset of a seizure.

sedative drugs

A group of drugs that are used to produce *sedation*. Sedatives include *sleeping drugs*, *antianxiety drugs*, *antipsychotic drugs*, and some *antidepressant drugs*.

sedimentation rate

See *ESR*.

seizure

A sudden episode of abnormal electrical activity in the *brain*. Recurrent seizures occur in *epilepsy*.

Seizures may be partial or generalized. In a partial seizure, the abnormal activity is confined to one area of the brain. Symptoms include tingling or twitching of a small area of the body, *hallucinations*, fear, or *déjà vu*. In a generalized seizure, the abnormal activity spreads through the brain, causing loss of consciousness.

Causes of seizures include *head injury*, *stroke*, *brain tumour*, infection, metabolic disturbances, withdrawal in *alcohol dependence*, or hereditary alcohol intolerance. In children, high fever may cause seizures (see *convulsion*, *febrile*). *Anticonvulsant drugs* can control seizures or reduce their frequency.

selective serotonin reuptake inhibitors (SSRIs)

A type of *antidepressant drug* used to treat *depression*, *panic disorder*, *bulimia*, *premenstrual syndrome*, and *obsessive-compulsive disorder*. SSRIs block the reabsorption of *serotonin* following its release in the brain; the increased serotonin levels that result are associated with improved mood. Common SSRIs include *fluoxetine*, *paroxetine*, and *sertraline*. The drugs are usually taken orally once a day; beneficial effects may not be felt for up to three weeks. SSRIs usually produce fewer side effects than other types of antidepressant but may cause diarrhoea, nausea, restlessness, and anxiety. Stopping SSRIs suddenly can cause withdrawal symptoms.

selegiline

A drug that is used in the treatment of *Parkinson's disease*, either alone (in the disease's early stage) or in combination with *levodopa*. Selegiline is also used to treat the symptoms of *parkinsonism* due, for example, to repeated head injury; it is not used if the symptoms are drug induced. Side effects may include nausea, vomiting, diarrhoea or constipation, dry mouth, and sore throat.

selenium

A *trace element* that may help to preserve the elasticity of body tissues. The richest dietary sources are meat, fish, whole grains, and dairy products.

self-help organizations

Charity or voluntary organizations, usually set up by patients or their relatives, that provide people affected by particular conditions with information, support, and, sometimes, financial aid.

self-image

A person's view of his or her own personality and abilities. Some neurotic disorders stem from an incongruity between self-image and how others see one. *Psychotherapy* aims to treat neurosis by changing a person's self-image.

self-injury

The act of deliberately injuring oneself. It most often occurs in young adults, many of whom are drug or alcohol abusers, and is three times more common in women. It may take the form of cutting the wrists or burning the forearms with cigarettes. In some, it is a way of dealing with stress, such as that caused by *child abuse*. It may also occur as a feature of *autism*.

There are more unusual forms of self-harm, for example mutilation of the genitals, and these are usually due

to *psychosis*. Self-destructive biting features in Lesch–Nyhan syndrome, which is a rare *metabolic disorder*.

semen

Fluid discharged from the penis on *ejaculation*. Semen comprises fluid from the *seminal vesicles*, fluid from the *prostate* and Cowper's glands, and *sperm*. (See also *reproductive system, male*.)

semen analysis

Analysis of sperm concentration, shape, and motility (ability to move) to investigate male *infertility*. It is also performed about 12 weeks after *vasectomy* to ensure that semen no longer contains sperm.

semen, blood in the

A usually harmless condition in which a small amount of blood appears in the *semen*. Occasionally, there is an underlying cause (for example, infection or, very rarely, cancer of the testis) that requires treatment. Blood in the semen may also occur after a prostate *biopsy*.

semicircular canal

A structure in the inner ear that plays a role in *balance*. There are three semicircular canals in each ear, at right angles to each other, and connected via a chamber called the vestibule. The fluid-filled canals contain small hairs that

detect movement and acceleration and transmit information to the brain via the vestibular nerve.

seminal vesicle

One of a pair of sacs behind the bladder in the male that produce seminal fluid, which is mixed with sperm to make semen (see *reproductive system, male*).

seminoma

See *testis, cancer of*.

senile dementia

See *dementia*.

senile purpura

A skin condition in which some areas become purple or red-brown in appearance. Senile purpura occurs in middle to old age and is more common in women. It is caused by bleeding from small blood vessels beneath the skin due to thinning of supporting tissues.

senility

Old age or, more commonly, the decline in mental ability that may occur with age.

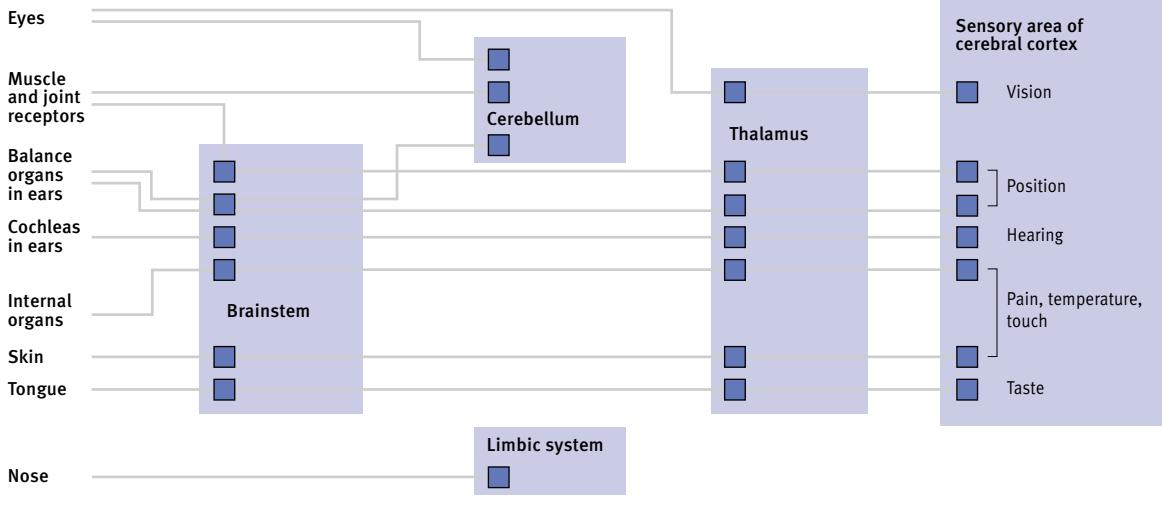

senna

A *laxative drug* from leaves and pods of the Arabian shrubs *CASSIA ACUTIFOLIA* and *CASSIA ANGUSTIFOLIA*. It stimulates bowel contractions and may darken the urine.

PRINCIPAL SENSORY PATHWAYS INTO THE BRAIN

Some information entering the brain passes via the brainstem and/or thalamus to the cerebral cortex (outer surface of the brain), where sensations are perceived. Other information does

not lead to conscious sensation. This includes certain data about body posture, processed in the cerebellum, and about internal body functioning, processed in the brainstem.

sensate-focus technique

A method taught to couples who are experiencing sexual difficulties caused by psychological rather than physiological factors. The technique's aim is to make people more aware of their own and their partner's pleasurable bodily sensations, and to reduce anxiety about performance. It is particularly effective in treating loss of sexual desire (see *sexual desire, inhibited*), or inability to achieve orgasm (see *orgasm, lack of*), and in helping men to overcome *impotence* or premature ejaculation (see *ejaculation, disorders of*).

sensation

A feeling or impression (such as a sound, smell, touch, or hunger) that has entered consciousness. The senses convey information about the external environment and the body's internal state to the *central nervous system* (the *brain* and *spinal cord*).

SENSORY RECEPTORS

Information is collected by millions of *receptors* (specialized nerve structures) found throughout the body in the skin, muscles, and joints, in the internal organs, in the walls of blood vessels, and in special sense organs such as the *eye* and *inner ear*.

Receptors are attuned to a particular stimulus, such as light of a certain wavelength, chemical molecules of a particular shape, vibration, or temperature. Each receptor "fires" (sends an electrical signal) when stimulated.

Some receptors are the terminals (free nerve endings) of long nerve cell fibres, others are specialized cells that connect to such fibres. When a receptor fires, a signal passes along the appropriate nerve fibre to the spinal cord and/or brain. A proportion of this information reaches the *sensory cortex* of the brain and is consciously perceived.

SPECIAL SENSES

The special senses include *vision*, *hearing*, *taste*, and *smell*. The receptor cells for these senses are collected into special organs: the retina in the eye, the auditory apparatus in the ear, the taste-buds in the *tongue*, and the organ for smell in the *nose*. Information from these organs passes directly to the brain via the *cranial nerves*. Much of the collected information passes to the cerebral cortex, although some goes to other areas of the brain (for example, from the eyes to the cerebellum, where it is used to help maintain balance).

NEUROLOGICAL SENSORY TESTING

When examining a patient's nervous system, a doctor usually includes several standard tests of touch, position, pain, and vibration senses, such as those below.

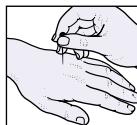

Light touch

With the patient's eyes closed, a wisp of cotton wool is brushed lightly across the face.

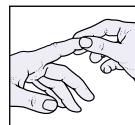

Vibration

A vibrating tuning fork is held against a prominent bone, such as the ankle bone or mastoid bone.

Pinprick

The prick tests pain sensation and may be repeated at different locations on the patient's body.

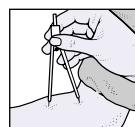

Position sense

The patient, with eyes closed, tells in which direction his or her finger is moved.

Pain pinch

Pain sense may be further tested by pinching the Achilles tendon at the back of the heel.

Two-point discrimination

Measures the ability to distinguish two pinpricks from a single prick.

INTERNAL AND TOUCH SENSES

These senses include pain, temperature, pressure, and proprioception (position), sensations. Proprioception relies on receptors in the muscles and joints to provide information on the position in space of parts of the body. Pain is one of the most primitive senses; its role is to warn of harmful stimuli through receptors that occur both at the surface of the skin and internally.

Many types of receptors are found in the skin. Some are sensitive to pressure, others to the movement of hairs or to temperature changes. Skin receptors are made up of the terminals of nerve fibres, which are wrapped around the roots of hairs, formed into discs, or surrounded by a series of membranes to form onionlike structures called pacinian corpuscles. Different patterns of stimulation of these receptors produce such sensations as pain, tickling, firm or light pressure, heat or cold. Certain skin areas (lips, palms of the hands, and genitals) have a particularly high concentration of receptors.

Most of the signals from these receptors pass, through the cranial or *spinal nerves* and tracts in the brain or spinal cord, to the *thalamus* and then to two regions of the sensory cortex called the somatosensory cortices. Sensations that are perceived at certain points within these regions correspond to the parts of the body from which the signals originated. Much larger areas of cortex are

devoted to sensations originating from the highly receptive hands and lips than from less sensitive parts.

sensation, abnormal

Dulled, unpleasant, or otherwise altered *sensations* in the absence of an obvious stimulus. Abnormal sensation is also known as paraesthesia,

TYPES

Numbness and *pins-and-needles* are common abnormal sensations, which are sometimes combined with pain or feelings of coldness or burning. *Neuralgia* is characterized by pain with a brief stabbing, repetitive quality.

More examples of unusual abnormal sensations include a feeling that fluid is trickling down the skin, tight constriction in part of the body, and the feeling that insects are crawling over the skin (known as *formication*).

The special senses can also be impaired or altered as a result of damage to the relevant sensory mechanism or nerve tracts (see *deafness*; *smell*; *tinnitus*; *vision, disorders of*).

CAUSES

Neuropathy (peripheral nerve damage) from thiamine (vitamin B₁₂) deficiency in alcoholics, *diabetes mellitus*, or certain types of poisons (such as lead) is a common cause of abnormal sensation. The sufferer may complain of tingling or a feeling of walking on cotton wool. The peripheral nerves may also be damaged or irritated by infections such as

herpes zoster (shingles) or by a tumour pressing on a nerve, which often causes severe pain. *Spinal injury, head injury, stroke*, and *multiple sclerosis* are other causes of disruption to nerve pathways in the brain or spinal cord.

Damage to the *thalamus* (a relay station for sensory pathways in the brain) can produce particularly unpleasant results, such as a spreading sensation like an electric shock that occurs after a simple pinprick. Damage that affects the parietal lobe in the brain can lead to loss of the ability to locate or recognize objects by touch.

DIAGNOSIS AND TREATMENT

Various tests may be needed to find the cause of abnormal sensation. These include simple neurological sensory testing; testing of *reflexes*; tests on blood and urine; and *CT scanning* and *MRI*.

Pressure on or damage to nerves can sometimes be relieved by surgery or other treatments for the cause. In other cases, distressing abnormal sensation can be relieved by drugs or by cutting the relevant nerve fibres or giving injections to block the transmission of signals.

senses

See *sensation*. (See also *hearing; taste; touch; smell; vision*.)

sensitization

The initial exposure of a person to an allergen or other substance recognized as foreign by the *immune system*, which leads to an immune response. On subsequent exposures to the same substance, there is a much stronger and faster immune reaction. This response forms the basis of *allergy* and other types of *hypersensitivity* reaction.

S

sensorineural deafness

A type of *deafness* that occurs as a result of problems either relating to the inner ear itself, or to the nerves connecting the inner ear to the brain, or to the auditory area of the brain.

sensory cortex

A region of the outer *cerebrum* of the brain in which sensory information comes to consciousness.

Pressure, pain, and temperature sensations are perceived in the parietal lobes of the cerebrum, as is taste. Visual sensations are perceived in the occipital lobes, at the back of the cerebrum; sound is perceived in the temporal lobes, at the sides.

sensory deprivation

The removal of normal external stimuli, such as sight and sound, from a person's environment. Prolonged sensory deprivation can produce feelings of unreality, difficulty in thinking, and *hallucinations* (perceptions occurring without any external stimulus).

sensory nerve

A type of *nerve* fibre that carries information from a *receptor* or sense organ towards the brain.

separation anxiety

The feelings of distress experienced by a young child parted from his or her parents or home. Signs include crying and clinging to a parent. This is a normal aspect of infant behaviour and usually diminishes by the age of three or four.

In separation anxiety disorder, the reaction to separation is greater than that expected for the child's age and maturity. The anxiety may manifest as physical symptoms such as headaches, nausea, and difficulty in sleeping. Separation anxiety disorder may sometimes be a feature of *depression*.

sepsis

Bacterial infection of a wound or body tissue that leads to the formation of *pus* or to the multiplication of the bacteria in the blood. (See also *bacteraemia; septicaemia; septic shock*.)

septal defect

A congenital heart abnormality in which there is a hole in the septum (partition) between the left and right sides of the heart. The hole can be between either the atrial (upper) or the ventricular (lower) chambers. Commonly known as a hole in the heart, septal defect varies in its effects according to its type and size. Usually, the cause is unknown.

TYPES

When the hole is in the septum separating the two ventricles, the abnormality is known as a ventricular septal defect; when it is in the septum between the two atria, it is called an atrial septal defect. In both types, the hole allows some of the freshly oxygenated blood in the left half of the heart (which supplies tissues throughout the body) to flow into the right half, mix with deoxygenated blood and recirculate through the lungs.

Some children are born with both types of defect. Either type may be

accompanied by one or more additional heart abnormalities and/or some other congenital defects.

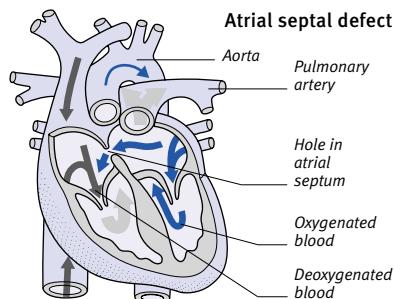

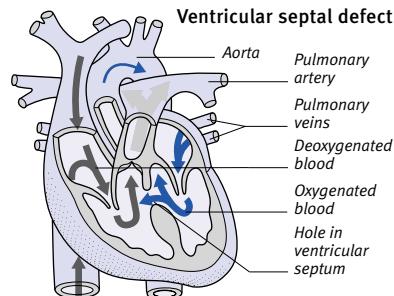

SYMPTOMS AND SIGNS

A small defect has little or no effect. A large ventricular hole may cause *heart failure* six to eight weeks after birth, causing breathlessness, feeding difficulties, pallor, and sweating. A large atrial defect may cause heart failure to develop around the age of 30 or there may be no heart failure at all, but fatigue may occur on exertion. *Pulmonary hypertension* (high blood pressure in the arteries supplying the lungs) may develop in both types of defect but is especially likely if there is a large ventricular defect.

With a ventricular defect there is also a slight risk of *endocarditis* (inflammation of the lining of the heart); in atrial septal defect, *atrial fibrillation* (rapid, irregular beating of the atria) may occur after the age of 30.

DIAGNOSIS AND TREATMENT

Diagnosis may be aided by a *chest X-ray, ECG, or echocardiography*. Atrial holes are repaired surgically if they cause symptoms or if complications develop. Small ventricular holes often become smaller, or even close, on their own as the child grows. A ventricular defect that is

Two types of septal defect

In both cases (atrial and ventricular), oxygenated blood is forced from the left to the right side of the heart through the hole in the septum. Too much blood passes to the lungs (via the pulmonary artery) and too little to the body tissues (via the aorta).

causing heart failure is treated with drugs such as *diuretics*. If the hole does not close spontaneously, it may be repaired by *open heart surgery*, usually before the child reaches school age. The operation has a very high success rate and most children go on to lead normal lives.

septate uterus

A defect in which the interior of the uterus (womb) is divided by a septum (wall of tissue). A septate uterus may result in *miscarriages*; however, it can be corrected surgically, and most women have successful pregnancies after treatment.

septic abortion

A complication of *miscarriage* or abortion (see *abortion, induced*) in which the uterus, and any tissue retained from the fetus and the placenta, become infected. Symptoms include fever, abdominal pain, and a vaginal discharge that may contain blood. Hospital treatment is needed to prevent *septic shock*. (See also *septicaemia*.)

septicaemia

A serious or even life-threatening condition, also called blood poisoning, in which bacteria multiply rapidly in the bloodstream and bacterial *toxins* are present in the blood.

Septicaemia is usually due to bacteria that have escaped from a site of infection, such as an *abscess*. The condition is more likely to occur in people whose resistance to infection is lowered by an *immunodeficiency disorder* or *immunosuppressant drugs*. Those with *cancer* or *diabetes mellitus*, and drug addicts who inject, are also at higher risk.

Signs include a high fever, chills, rapid breathing, headache, and clouding of consciousness. The sufferer may go into life-threatening *septic shock*.

Glucose and/or saline are administered by *intravenous infusion*, and *antibiotics* given by injection or infusion. Tests are performed to identify the bacteria and, if necessary, the site of infection. Surgery may be needed to remove tissue at the site. If treatment is given before septic shock develops, the outlook is good.

septic arthritis

A type of *arthritis* caused by a bacterial infection entering a joint via an open wound or from the bloodstream. Symptoms of septic arthritis appear suddenly and may include swelling, tenderness, and fever. If pus builds up, the joint may be permanently damaged.

Fluid is taken from the joint and is analysed to determine the presence of infection (see *aspiration*), and pus may be drained to help relieve pain. Initially, treatment is with intravenous *antibiotic drugs*, followed by oral antibiotics for several weeks or months after that.

septic shock

A life-threatening condition in which there is tissue damage (especially affecting the kidneys, heart, and lungs) and a dramatic drop in blood pressure as a result of *septicaemia* (multiplication of bacteria and the presence of bacterial toxins in the blood).

In many cases, the main danger comes from the toxins because they can damage cells and tissues, promote blood clotting in the smallest blood vessels, and seriously interfere with the normal circulation of the blood. Toxins may also cause fluid leakage from blood vessels and reduced ability of the vessels to constrict. This leads to a drop in blood pressure and may also lead to a further problem, *disseminated intravascular coagulation* (a clotting disorder).

CAUSES

Septic shock is most common in people who have debilitating disorders, such as *diabetes mellitus*, *cancer*, or liver *cirrhosis*, who also have an infection (often in the intestines and urinary tract) that has led to septicaemia. Septic shock is particularly likely to occur in people with an *immunodeficiency disorder*, and in individuals taking *immunosuppressant drugs*. Newborn babies are also particularly susceptible.

SYMPTOMS AND SIGNS

The symptoms vary with the extent and site of major tissue damage but they are broadly the same as those that occur in septicaemia. Additionally, however, there may be cold hands and feet, often with cyanosis (blue coloration) due to slowed blood flow, a weak, rapid pulse, and much reduced blood pressure. There may be vomiting and diarrhoea. Heart failure, abnormal bleeding, and damage to the kidneys, leading to kidney failure, may also develop.

TREATMENT

Septic shock requires immediate treatment with *antibiotic drugs*, and sometimes surgery to remove the focus of infection. Rapid fluid replacement to prevent kidney failure occurring is an essential aspect of treatment. Measures are also taken to raise blood pressure and promote better blood supply to the tissues.

Septrin

A brand name for the antibacterial drug *co-trimoxazole*.

septum

A thin dividing wall that occurs within or between parts of the body; an example is the nasal septum, the partition between the nostrils.

sequela

A condition that results from or follows a disease, disorder, or injury. The term is usually used in the plural (*sequelae*) to refer to complications of a disease.

sequestration

Separation of a sequestrum (a piece of dead bone) from healthy living bone. Sequestration also refers to loss of blood or other fluid into body spaces, removing it from the circulation and causing *hypotension*. Sequestration crises, in which blood pools in the spleen and liver, occur in *sickle cell anaemia*.

seroconversion

The development, in the blood *serum*, of *antibodies* (proteins made to combat a specific infection) that can be detected by testing (see *serology*).

serology

A branch of laboratory medicine concerned with analysis of blood *serum*. Applications of serological techniques include the diagnosis of infectious diseases by the identification of *antibodies*, the development of *antisera* preparations for passive *immunization*, and the determination of *blood groups* in *paternity testing* and forensic investigations.

seronegative

A term that is used to describe blood *serum* that has undergone testing for an infection (see *serology*) and is found to have no antibodies to the infectious organism under investigation. The term also refers to the absence of an auto-antibody (one that reacts against the body's own cells) in a specific condition. An example of this usage is the lack of rheumatoid factor that occurs in seronegative rheumatoid arthritis.

seropositive

A term that is used to describe blood *serum* that has undergone testing for a certain infection (see *serology*) and is found to contain antibodies to the infectious organism.

serotonin

Also known as 5-hydroxytryptamine (SHT), a substance found in many tissues, particularly in blood platelets, digestive tract lining, and brain. Serotonin is released from platelets at sites of bleeding, where its function is to constrict small blood vessels, thereby reducing blood loss. In the digestive tract, serotonin inhibits gastric secretion and stimulates smooth muscle in the intestine wall. In the brain, it acts as a *neurotransmitter* (a chemical that passes signals between nerve cells). Serotonin levels in the brain are reduced in people who are depressed, but certain *antidepressant drugs* raise the level. *Serotonin agonists* are used in the treatment of acute migraine attacks.

serotonin agonists

A group of drugs, also known as 5HT₁ agonists, used to treat acute attacks of *migraine*, in which the headache is caused by dilation of blood vessels in the brain. Serotonin agonists act on the same receptors in the brain as *serotonin* (a chemical messenger), returning the dilated vessels to their normal size and thereby relieving the symptoms of the migraine attack.

Common serotonin agonists include *naratriptan* and *sumatriptan*. These drugs can cause chest pain, particularly in people with heart disease. They should be used with caution in those at increased risk of coronary artery disease. Other side effects include flushing, tingling, and nausea.

serotonin antagonists

A group of drugs, also known as 5HT₃ antagonists, used to treat nausea and vomiting that is caused by *radiotherapy* and *anticancer drugs* or following general anaesthesia given for surgery. In these cases, the symptoms occur when *serotonin* stimulates the vomiting centre in the brain; the drugs prevent them by inhibiting the action of serotonin. Common serotonin antagonists include *granisetron* and *ondansetron*.

serous

A word that refers to blood *serum* or clear, watery body fluid. It is also used of body structures containing or producing these substances.

Seroxat

The brand name for *paroxetine*, an SSRI antidepressant drug.

Sertoli cell tumour

A tumour arising from the Sertoli cells (which support and nourish the developing sperm) within the testis. Some Sertoli cell tumours are malignant (see *testis, cancer of*).

sertraline

A *selective serotonin reuptake inhibitor* drug used in the treatment of *depression* and *obsessive-compulsive disorder*.

serum

The clear fluid that separates from *blood* when it clots. It contains salts, glucose, and proteins, including *antibodies*. Serum from the blood of a person who has had an infection usually contains antibodies to the infectious organism; if injected into other people, it can protect them from that disease. The serum preparation is called an *antiserum*; its use forms the basis of passive *immunization*. (see also *plasma*).

serum sickness

A type of *hypersensitivity* reaction that may develop about 10 days after injection with an *antiserum* of animal origin or after taking certain drugs, such as *penicillins*. Symptoms may include an itchy rash, joint pain, fever, and enlarged lymph nodes. In severe cases, a state that is similar to *shock* develops. Symptoms of serum sickness usually clear up in a few days; *antihistamine drugs* may hasten recovery. In severe cases, a *corticosteroid drug* may be prescribed.

severe acute respiratory syndrome (SARS)

See *SARS*.

severe combined immunodeficiency (SCID)

A rare *congenital* (present from birth) disorder in which the immune system functions inefficiently, or not at all. Babies born with severe combined immunodeficiency (SCID) are highly susceptible to infections. They may fail to thrive and have many severe infections (such as those of the respiratory and gastrointestinal tracts), skin rashes, recurrent oral thrush (see *candidiasis*), and *pneumonia*.

Early diagnosis of SCID is vital; the disorder is confirmed by blood tests to check levels of *lymphocytes* (a type of white blood cell). A *bone marrow transplant* offers the best chance of a cure, provided it is performed in the first few

months of life. Many children with SCID are treated successfully and are able to lead normal lives thereafter.

sex

Another term for gender; also a commonly used term for *sexual intercourse*.

sex change

Radical surgical procedures, usually combined with hormone therapy, that alter a person's anatomical gender. Sex-change operations are performed on transsexuals (see *transsexualism*) and on infants whose external sex organs are neither completely male nor completely female (see *genitalia, ambiguous*). The procedures are carried out in order to give a person the physical appearance that coincides with his or her psychological *gender identity*, or to provide a more defined sexual identity.

PROCEDURES

For transsexuals, sex-change procedures involve a series of major operations on the genito-urinary tract, which are carried out after courses of hormone therapy and extensive counselling. The male-to-female sex change operation is the one more commonly performed and the results are more satisfactory than the female-to-male procedure.

Babies with ambiguous genitalia are assigned a gender as soon as possible after birth, and given appropriate surgical and hormonal treatment.

OUTLOOK

Hormone therapy may need to be continued for life to maintain secondary sexual characteristics, such as body shape and hair distribution. Female transsexuals can have intercourse but cannot conceive; males cannot ejaculate, and achieve an erection only with mechanical aids.

sex chromosomes

The pair of *chromosomes* that determines a person's sex. All the cells in the human body (except for egg or sperm cells) contain a pair of sex chromosomes together with 22 other pairs of chromosomes known as *autosomes*. In women, the sex chromosomes are of similar appearance and are called X chromosomes. In men, one sex chromosome is an X and the other, smaller, one is a Y. The normal sex chromosome complement for women is XX, and for men, XY.

FUNCTION

Like all chromosomes, the X and Y chromosomes exert their effects in the

body through the activities of their constituent *genes*. These genes contain the coded instructions for chemical processes within cells and for aspects of growth and development within the whole body.

The X and Y chromosomes differ in one way: genes on the Y chromosome are concerned solely with *sex determination*. Their presence ensures a male: their absence a female. The X chromosome, occurring in both sexes, contains many genes vital to general development and functioning. Absence of the X chromosome is incompatible with life.

The presence of a single X chromosome and 22 pairs of autosomes in the nuclei of ordinary body cells appears to provide the blueprint for general body functioning and development, which seems to have an underlying female pattern. This can be seen in people with *Turner's syndrome*, who have only one sex chromosome, an X. Although full female sexual characteristics never develop, these people are unmistakably female in appearance and identity. The full complement of female sexual characteristics will develop only in the presence of a second X chromosome. It is the addition of a Y chromosome that is responsible for converting the female to the male pattern.

sex determination

The factors that determine biological sex. The underlying determinants are the *sex chromosomes* in a person's cells: two X chromosomes in females and one X and one Y chromosome in males. Early in embryonic development, these chromosomes cause the development of different gonads (the testes in males and the ovaries in females). In males, the testes then produce hormones that cause the development of a male reproductive tract, including a penis. In females, absence of these male hormones leads to a different pattern of development, with the formation of fallopian tubes, uterus, and vagina. At *puberty*, another surge of hormones from the gonads leads to the appearance of secondary *sexual characteristics*, such as facial hair in males, breasts in females, and pubic hair in both sexes.

Defects sometimes occur in the process of sex determination, and may result in ambiguous sex (see *genitalia, ambiguous*). Some people acquire an abnormal complement of sex chromosomes (see *chromosomal abnormalities*) and all the characteristics of one sex do

not develop. True *hermaphroditism* (the presence of both ovaries and testes in the body) is a very rare occurrence.

sex hormones

Hormones that control the development of primary and secondary *sexual characteristics* and that regulate sex-related functions, such as the menstrual cycle. There are three main types: *androgen hormones*, *oestrogen hormones*, and *progesterone hormone*.

sex-linked inheritance

The passing on to the next generation of a trait or disorder that is determined by the *sex chromosomes*, or by the *genes* that are carried on them.

Disorders due to an abnormal number of sex chromosomes include *Turner's syndrome* and *Klinefelter's syndrome*. Most other sex-linked traits or disorders are caused by *recessive genes* on the X chromosome (see *X-linked disorders*).

sex therapy

Counselling for and treatment of sexual difficulties not due to a physical cause. Sex therapy (also called psychosexual therapy) may involve changing the partners' attitudes towards sex, increasing their understanding of sexual needs, and teaching techniques, such as the *sensate-focus technique* or *pelvic floor exercises*, for specific problems. Sex therapy is particularly successful in treating certain disorders including *vaginismus*, premature ejaculation (see *ejaculation, disorders of*), lack of orgasm (see *orgasm, lack of*), and *impotence*.

sexual abuse

Subjection of a person to sexual activity that has caused, or is likely to cause, physical or psychological harm. (See also *child abuse; incest; rape*.)

sexual characteristics, primary

Physical features, which are present from birth, that show a person's sex, such as a penis and testes in a male or a vagina and vulva in a female.

sexual characteristics, secondary

Physical features appearing at *puberty* that indicate the onset of adult reproductive life. In girls, breast enlargement is the first sign. Shortly afterwards, pubic and underarm hair appears, and body fat increases around the hips, stomach, and thighs to produce the

female body shape. In boys, the first sign is enlargement of the testes, followed by thinning of the scrotal skin and enlargement of the penis. Pubic, facial, underarm, and other body hair appears, the voice deepens, and muscle bulk and bone size increase.

sexual desire, inhibited

Lack of sexual desire (*libido*) or of the ability to become physically aroused during sexual activity. Either condition may be physical or psychological.

LACK OF DESIRE

A high proportion of women and some men experience loss of sexual desire at some time in their lives. Common physical causes include fatigue, ill health, and discomfort after childbirth. Certain drugs, including sleeping pills, antidepressants, antihypertensives, oral contraceptives, and alcohol, can also reduce sexual desire. Psychological factors include *depression*, anxiety, stress, unsatisfactory relationships, fear of pregnancy, or a traumatic sexual experience.

LACK OF PHYSICAL AROUSAL

It is rare for anyone of either sex to be incapable of some degree of physical sexual arousal. A common reason for failure is the partner's poor or insensitive sexual technique, although guilt about the sex act or anxiety about sexual inadequacy may contribute to the problem.

TREATMENT

Sex therapy or *relationship counselling* may be helpful in resolving problems with a psychological basis. Sexual problems with a physical or chemical cause often improve once the underlying condition is resolved.

sexual deviation

See *deviation, sexual*.

sexual dysfunction

See *psychosexual dysfunction*.

sexual intercourse

A term sometimes used to describe a variety of sexual activities, but which specifically refers to the insertion of a man's penis into a woman's vagina. Sexual intercourse is the usual means of achieving *fertilization*. It is also a means of achieving *orgasm* for one or both partners.

sexuality

A term describing the capacity for sexual feelings and behaviour, or a person's sexual orientation or preference. *Heterosexuality* is sexuality directed towards

SEXUAL INTERCOURSE

The term sexual intercourse usually refers to the act during which the male's penis is inserted into the female's vagina. However, some people use the term more broadly to refer to a much wider range of sexual activity. Physiologically,

intercourse falls into four main stages – arousal (which generally includes a period of foreplay), a plateau (during which penetration usually occurs), orgasm, and resolution. The duration of each stage of intercourse varies.

Arousal in men

Sexual thoughts, the sight and feel of his partner's body, and foreplay may sexually arouse a man. Blood enters the penis so that it becomes firm and erect.

Plateau phase in men

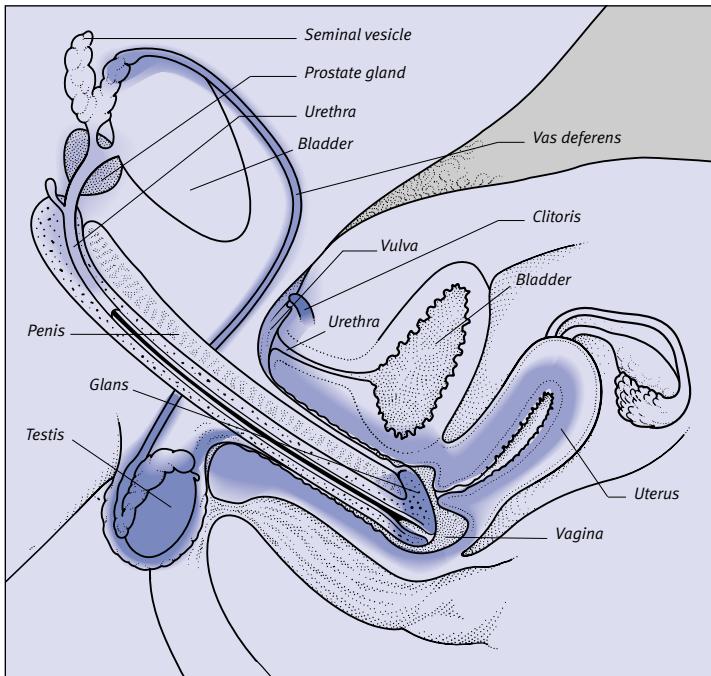

Vaginal penetration usually takes place during this phase and thrusting movements begin. The penis reaches maximum size and the testes elevate.

Orgasm in men

Muscular contractions in the ducts connecting the testes, prostate, and penis, force semen out of the penis, accompanied by intensely pleasurable sensations.

Resolution in men

The penis returns to half its fully erect size and the testes descend.

**Arousal in women**

Similar factors lead to arousal in women as in men, though foreplay may be more important. The clitoris lengthens, the vagina enlarges, and its walls secrete a lubricating fluid.

Plateau phase in women

Muscular contractions in the walls of the vagina help grip the penis. The uterus rises, and the clitoris may pull back beneath its hood of skin.

Orgasm in women

The walls of the outer part of the vagina contract rhythmically and strongly several times and an intense sensual feeling spreads from the clitoris and throughout the body.

Resolution in women

The clitoris subsides and, more gradually, the vagina relaxes and the uterus falls.

the opposite sex; *homosexuality* is attraction to the same sex; and *bisexuality* is attraction to both sexes.

sexually transmitted infection

An infection transmitted primarily (but not exclusively) by sexual intercourse. Common sexually transmitted infections (STIs) include *genital herpes*, *chlamydial infections*, *pubic lice*, *genital warts*, *trichomoniasis*, *gonorrhoea*, and *HIV* infection.

Certain sexual activities carry a high risk of infection with STIs. They include casual sex or having multiple partners (particularly if partners are not known to be free of disease); activities that involve contact with sperm or other body fluids; and activities that may damage the skin or mucous membranes. Practising *safer sex* can minimize these risks and help prevent STIs.

Antibiotics can be used to treat most bacterial STIs. Confidential tracing and treatment of an affected person's partners is essential in the management of STIs (see *contact tracing*).

sexual problems

Any difficulty associated with sexual performance or behaviour. Sexual problems are often psychological in origin; *sex therapy* may help such problems. They may also be due to physical disease, such as a disorder affecting blood flow; a hormonal dysfunction; or a disorder of the genitals. Such problems are addressed by treating the cause, where possible. See also *ejaculation*, *disorders of impotence*; *orgasm*, *lack of sexual desire*, *inhibited*; *vaginismus*.

Sézary syndrome

A rare condition in which there is an abnormal overgrowth of *lymphocytes* (white blood cells active in the immune system) in the skin, liver, spleen, and lymph nodes. It mainly affects middle-aged and elderly people. The first symptom is the appearance of red, scaly patches on the skin that spread to form an itchy, flaking rash. There may also be an accumulation of fluid under the skin; baldness; and distorted nail growth.

Sézary syndrome is sometimes associated with *leukaemia*. Treatment includes *anticancer drugs* and *radiotherapy*.

shared care

Management of a pregnant woman's care by her general practitioner and the community midwives (see *primary care*), in combination with a hospital antenatal team. The term shared care also refers increasingly to the management of certain chronic conditions, for example asthma and diabetes.

Sheehan's syndrome

A form of hypopituitarism (under-activity of the pituitary gland) in women who have just given birth. The disorder occurs when cells in the pituitary die as a result of heavy bleeding or *shock* during the delivery. The treatment for Sheehan's syndrome involves replacement of the deficient hormones.

shellfish poisoning

See *seafood poisoning*.

shell shock

See *post-traumatic stress disorder*.

shigellosis

An acute infection of the intestine by *SHIGELLA* bacteria; also called bacillary dysentery. The bacteria exist in faeces and are spread by poor hygiene. *Endemic* in some countries, shigellosis occurs in isolated outbreaks in the UK.

The disease usually starts suddenly, with bloody diarrhoea, abdominal pain, nausea, vomiting, generalized aches, and fever. Persistent diarrhoea may cause *dehydration*, especially in certain groups such as babies and elderly people. Occasionally, *toxaemia* (the presence of bacterial toxins in the blood) develops.

Shigellosis usually subsides after a week or so, but hospital treatment may be needed for severe cases. Dehydration is treated by *rehydration therapy*. *Antibiotics* may be given.

shingles

See *herpes zoster*.

shin splints

Pain in the front and sides of the lower leg that develops or worsens during exercise. There may also be tenderness and swelling in the area. Shin splints is a common problem in runners. Possible causes include inflammation of a tendon or muscle or *periostitis* (inflammation of the outer layer of a bone). (See also *compartment syndrome*.)

In most cases, the pain in the shins disappears after one or two weeks of rest; however, in cases where it is severe or recurrent, a course of *nonsteroidal anti-inflammatory drugs* or *corticosteroids* may be needed. In rare cases, surgery is performed in order to alleviate excessive pressure in a muscle. Some people benefit from *physiotherapy*.

shivering

Involuntary trembling of the entire body caused by rapid contraction and relaxation of muscles. Shivering is the body's normal automatic response to cold; it also occurs in fever.

When the body becomes cold, temperature-sensitive nerve cells in the hypothalamus (part of the brain) act as a thermostat, initiating the shivering reflex. This causes muscles to contract, generating heat. Shivering caused by cold usually disappears as soon as the body is warmed and starts to approach a near normal temperature.

Shivering during fever is caused by the release of certain substances by the white blood cells. The trigger for this release is usually an infection. These substances effectively "reset" the thermostat at a higher point, causing the body to shiver when it needs to lose, rather than retain, heat.

shock

A dangerous reduction of blood flow throughout the body tissues, which may occur with severe injury or illness. Shock in this sense is a physiological reaction, as distinct from the mental distress that may follow a traumatic experience.

In most cases, reduced blood pressure is a major factor in causing shock and it is also one of its main features. Shock may develop in any situation in which blood volume is reduced, blood vessels are abnormally widened, the heart's action is weak, blood flow is obstructed, or there is a combination of a few of these factors. Causes of shock include severe bleeding or burns, persistent vomiting or diarrhoea, *myocardial infarction* (heart attack), *pulmonary embolism* (a blood clot in the lung), *peritonitis* (inflammation of the abdominal lining) and some types of *poisoning*.

Signs include rapid, shallow breathing; cold, clammy skin; a rapid, weak pulse; dizziness; weakness; and fainting. If left untreated, shock can impair the oxygen supply to vital organs, such as the brain, which will eventually lead to collapse, coma, and death.

Emergency treatment is needed. This involves an *intravenous infusion* of fluid, a blood transfusion, *oxygen therapy*, and, if pain relief is necessary, *morphine* or similar powerful *analgesic drugs* (painkillers). Any further treatment that is given depends on the underlying cause. (See also *anaphylactic shock*; *hypovolaemia*; *septic shock*; *toxic shock syndrome*.)

shock, electric

The sensation that is caused by an electric current passing through the body, and its effects. A current of sufficient size and duration can cause loss of consciousness, cardiac arrest, respiratory arrest, burns, and tissue damage. (See also *electrical injury*.)

shock therapy

See *ECT*.

shock wave lithotripsy

See *lithotripsy*.

shortsightedness

See *myopia*.

short sight, operations for

See *LASIK*; *photorefractive keratectomy*.

short stature

A height that is significantly below the normal range for a person's age. Short stature in children is often due to hereditary factors or slow bone growth. In most cases, growth eventually speeds up, resulting in normal adult height. Less commonly, it is due to a disorder that interferes with bone growth, such as bone disease (as in untreated *rickets* or *achondroplasia*), or hormonal disorders including *growth hormone deficiency* and *hypothyroidism*. *Emotional deprivation*, chronic malnutrition, and *malabsorption* can also limit growth. Certain chromosomal disorders cause short stature: stunting occurs in *Down's syndrome*, and the normal pubertal growth spurt is absent in girls with *Turner's syndrome*. Other causes of restricted growth in children include prolonged use of *corticosteroids* and *anticancer drugs*. Severe untreated respiratory disease or congenital heart disease can also cause short stature by restricting the supply of oxygen to growing tissues.

The doctor will take into account the parents' height, and will look for signs of any underlying disease. An affected child's growth rate is monitored by regular measurement of height. *X-rays* and *blood tests* may help to identify an underlying cause, which will then be treated. Growth hormone is given for any hormone deficiency, and also as treatment for short stature due to disorders such as Turner's syndrome. (See also *growth*, *childhood*.)

short wave diathermy

The application of a high-frequency electric current to the body to relieve pain. The current produces an electromagnetic field that generates deep heat in the tissues. Short-wave diathermy may be used to treat certain soft-tissue injuries; joint disorders such as *osteoarthritis*; and inflammatory disorders such as *sinusitis* and *chronic pelvic inflammatory disease*. It may also be used to help speed wound healing. It must not be used, however, on any individuals with metal implants or other non-removable prostheses, or on people who are fitted with *pacemakers*.

shoulder

The area of the body where the arm attaches to the trunk. The rounded bony surface at the front of the shoulder is the upper part of the *humerus* (upper-arm bone); the bony surfaces that form the top and back of the shoulder are parts of the *scapula* (shoulderblade). The *clavicle* (collarbone) articulates with the acromion (the bony prominence at the outer top part of the scapula) at the *acromioclavicular joint* and extends across the top of the chest to the *sternum* (breastbone), to which it is attached at the sternoclavicular joint.

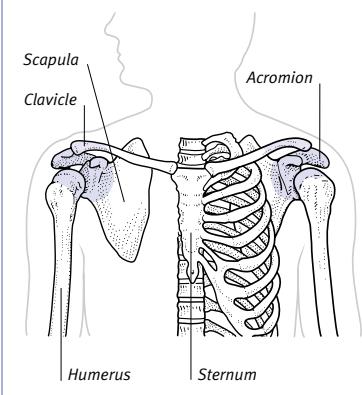

Just below the acromion, on the outer wall of the scapula, is a socket (called the *glenoid cavity*) into which the head of the humerus fits to form the shoulder joint. A *bursa* (fluid-filled sac) under the acromion reduces friction at the joint. The shoulder joint is a ball-and-socket joint with the widest range of movement of all joints; movement is produced by part of the *biceps muscle*, several small muscles that make up the *rotator cuff*, various muscles in the chest wall, and the *deltoid* muscle at the top of the upper arm and shoulder.

DISORDERS

Shoulder injuries are relatively common, including dislocation of the shoulder joint (see *shoulder, dislocation of*) or of the acromioclavicular joint, and *fractures* of the clavicle or of the upper part of the humerus. Fractures of the scapula are less common.

STRUCTURE OF THE SHOULDER

Three bones meet at the shoulder – the scapula (shoulderblade), clavicle (collarbone), and humerus (upper-arm bone). The shoulder is an example of a ball-and-socket joint.

The shoulder joint may be affected by any joint disorder, including *arthritis* and *bursitis* (inflammation of a bursa). In severe cases, a joint disorder may lead to *frozen shoulder* (a condition in which movements at the joint are severely restricted). Movement of the shoulder may also be painful and/or restricted because of *tendinitis* (inflammation of a tendon). Tendinitis or bursitis can cause *painful arc syndrome*, in which raising the arm to the side causes pain.

shoulderblade

The common name for the *scapula*.

shoulder, dislocation of

Displacement of the head of the *humerus* (upper-arm bone) out of the shoulder joint. The main symptom is pain, in the shoulder and upper arm, made worse by movement. A forward dislocation often produces obvious deformity; however, a backward dislocation usually does not.

Diagnosis is by *X-rays*. The head of the humerus is repositioned in the joint socket, and the shoulder is immobilized in a sling for about three weeks. In cases of recurrent shoulder dislocation, surgery may be required.

Complications of shoulder dislocation include damage to nerves, causing temporary weakness and numbness in the shoulder; damage to an artery in the upper arm, causing pain and discolouration of the arm and hand; and damage to the muscles that support the shoulder.

shoulder-hand syndrome

Pain and stiffness of one shoulder and the hand on that side; the hand may also become hot, sweaty, and swollen. Arm muscles may waste through lack of use.

The cause of shoulder-hand syndrome is not known, but the condition may sometimes occur as a complication of *myocardial infarction* (heart attack), *stroke*, *herpes zoster* (shingles), or shoulder injury. Recovery usually occurs in about two years. However, this recovery period may be shortened by *physiotherapy* and *corticosteroid drugs*. In rare cases, a cervical *sympathectomy* is performed.

shunt

An abnormal passage between two normally unconnected body parts (as in a *septal defect* of the heart). The term also refers to a passage created surgically between unconnected areas for purposes such as draining excess fluid.

Shy–Drager syndrome

A rare degenerative disorder of unknown cause that progressively damages the *autonomic nervous system*. It begins gradually between the ages of 60 and 70 and is more common in men. Symptoms include dizziness and fainting due to postural *hypotension*; urinary incontinence; impotence; reduced ability to sweat; and *parkinsonism*. The condition eventually leads to disability and sometimes premature death. There is no cure or means of slowing degeneration, but many symptoms are relieved by drugs.

SIADH

The abbreviation for “syndrome of inappropriate antidiuretic hormone (secretion)”, in which excessive secretion of antidiuretic hormone (ADH) results in water retention and a low sodium level in the body. SIADH is associated with certain lung disorders such as *COPD* (see *pulmonary disease, chronic obstructive*) or *pneumonia*. Other conditions, for example brain disorders such as *encephalitis* or *brain haemorrhage*, and some cancers including small cell carcinoma (see *lung cancer*) and cancer of the pancreas (see *pancreas, cancer of*), may also be associated with SIADH.

Siamese twins

See *twins, conjoined*.

sibling rivalry

A term that describes the intense competition that sometimes occurs between siblings.

sibutramine

A centrally acting *appetite suppressant* drug that is used to treat obesity in people who have not responded to other methods of weight loss, such as dieting and exercise. Common side effects include constipation, dry mouth, and *hypertension*. People taking this drug should have regular follow-ups with their blood pressure and pulse monitored.

sicca syndrome

Occurring in *Sjögren's syndrome*, dryness of the eyes, mouth, and other mucous membranes (such as the lining of the vagina) due to destruction of exocrine (such as tear, salivary, or sweat) glands.

sick building syndrome

A collection of symptoms reported by some workers in office buildings. Symptoms include loss of energy,

fatigue, poor concentration, headaches, and dry, itchy eyes, nose, and throat. Although the exact cause is unknown, various factors may be involved, including air conditioning, passive smoking, lack of natural light and ventilation, and psychological stress.

sickle cell anaemia

An inherited *genetic disorder* in which the red blood cells contain an abnormal type of *haemoglobin* (oxygen-carrying pigment) called haemoglobin S. When red cells enter capillaries (tiny blood vessels) under conditions of low oxygen (due to the atmosphere or infection or dehydration, for example), haemoglobin S crystallizes. The cells become sickle-shaped and fragile, leading to *haemolytic anaemia*. Also, because the abnormal cells are unable to pass easily through capillaries, they intermittently block the blood supply to organs. The result is a sickle cell crisis, which may also occur for no apparent reason.

CAUSE

Sickle cell anaemia occurs mainly in black African people, and the defective gene is inherited from both parents. (If the gene is passed on from only one parent, the result is sickle cell trait, in which "carriers" are at risk of passing the gene to their children.)

SYMPTOMS AND SIGNS

Symptoms usually appear after six months of age and often begin with painful swelling of the hands and feet. Chronic haemolytic anaemia causes fatigue, headaches, shortness of breath on exertion, pallor, and *jaundice*. Sickle cell crises start suddenly; there may be pains (especially in the bones), blood in the urine (from kidney damage) or damage to the lungs or intestines. If the brain is affected, *seizures*, a *stroke*, or unconsciousness may result.

In some affected children, the *spleen* becomes enlarged and traps red cells at a very high rate, which causes a life-threatening form of anaemia. After adolescence, the spleen usually stops functioning, thereby increasing the risk of infection in those affected.

People who have sickle cell trait generally have no disability, and may be protected from falciparum *malaria*, but they may experience similar blood-vessel blocking events if oxygen levels are low.

DIAGNOSIS AND TREATMENT

Diagnosis is made from examination of a blood smear and *electrophoresis* to detect haemoglobin S. Supportive treatment

may include supplements of *folic acid*, and *penicillin* and immunization to protect against infection. The treatment of life-threatening crises involves the use of *intravenous infusions* of fluids, *oxygen therapy*, *antibiotics*, and *analgesic drugs* (painkillers). If the crisis still does not respond, an exchange *blood transfusion* may be performed. This may be done regularly for people who suffer from frequent severe crises.

sick sinus syndrome

Abnormal function of the heart's *sinoatrial node* (its natural "pacemaker") that leads to episodes of *bradycardia* (slow heart rate), alternating bradycardia and *tachycardia* (fast heart rate), or very short episodes of *cardiac arrest*.

The cause of sick sinus syndrome is usually *coronary artery disease*; alternatively, it may be a *cardiomyopathy* (a condition that leads to weakened heart muscle contractions). Symptoms may include lightheadedness, fainting, and palpitations. The diagnosis is confirmed by a 24-hour *ECG* recording. The condition is usually treated with *antiarrhythmic drugs* and the fitting of an *artificial pacemaker*.

side effect

A reaction or consequence of medication or therapy that occurs in addition to the desired effect. The term is usually used with reference to an unwanted or adverse effect usually following a normal dose, rather than the toxic effects resulting from a *drug overdose*.

siderosis

Any condition in which there is too much iron in the body, including *pneumoconiosis*, when it is caused by inhalation of iron particles. (See also *haemosiderosis*.)

SIDS

An abbreviation for *sudden infant death syndrome*.

sievert

A unit for measuring doses of ionizing *radiation*. (See *radiation units*.)

sight

See *vision*.

sight, partial

Loss of vision short of total *blindness*. Partial sight may involve loss of *visual acuity* and/or *visual field*.

sigmoid colon

The S-shaped part of the *colon* in the lower abdomen, extending from the brim of the pelvis, usually down to the third segment of the *sacrum*. It is connected to the descending colon above and the *rectum* below.

sigmoidoscopy

Endoscopy (examination with a viewing instrument) of the *rectum* and *sigmoid colon* (parts of the large intestine).

Sigmoidoscopy is used to investigate symptoms relating to the lower gastrointestinal tract, such as bleeding from the rectum or lower colon, and to look for evidence of disorders, such as polyps (small noncancerous growths), *ulcerative colitis*, or cancer (see *colon, cancer of*). Attachments on the end of the sigmoidoscope allow a *biopsy* (removal of a tissue sample for analysis) to be performed if necessary.

sign

An objective indication of a disease or disorder (for example, jaundice) that is observed or detected by a doctor, as opposed to a *symptom* (for example, pain), which is noticed by the patient.

sign, vital

See *vital sign*.

sildenafil

A drug used in the treatment of *impotence*. Commonly known by its brand name Viagra, sildenafil is available only on prescription due to the potential risk of serious side effects in certain people. Sildenafil should be avoided in people who have had a recent heart attack or those being treated with nitrate drugs.

silent myocardial infarct

A heart attack (see *myocardial infarction*) that occurs without the usual signs and symptoms (such as sudden chest pain).

silicone

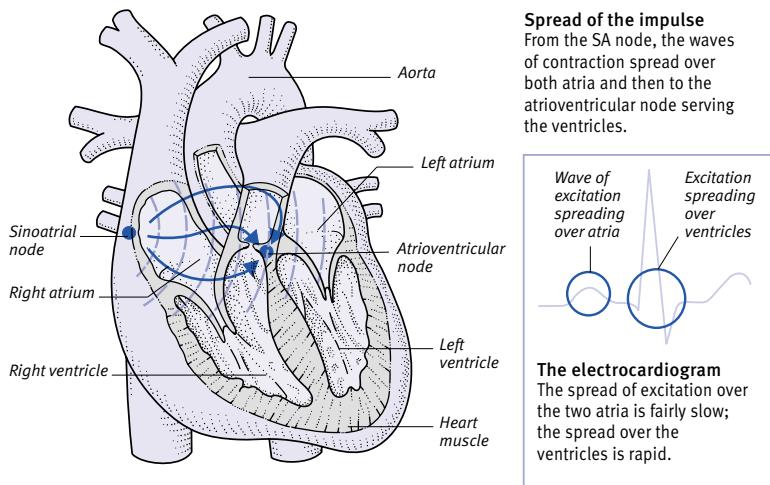

A long-chain, carbon-containing compound of silicon and oxygen. Synthetic silicone implants are sometimes used in *cosmetic surgery*. Leakage can occur and may cause autoimmune disorders (in which the immune system attacks the body's own tissues).

silicosis

A lung disease caused by the inhalation of dust containing silica from rock or sand. (See also *pneumoconiosis*.)

LOCATION AND FUNCTION OF THE SINOATRIAL NODE

The sinoatrial (SA) node is a small mass of specialized muscle cells in the right atrium of the heart. It sends out impulses at an inherent rate of about 100 impulses per minute. External control by the vagus nerve reduces the rate to about 70 per minute. Other mechanisms also affect the rate.

silver sulfadiazine

An *antibacterial drug* applied as a cream to prevent infection after skin grafts or in burns, leg ulcers, and pressure sores. Side effects may include permanent grey skin discolouration, rashes, or itching.

simian crease

A single deep, horizontal crease on the palm of the hand. This feature is associated with chromosomal disorders such as *Down's syndrome*.

simple linctus

See *lintus*.

simvastatin

A *lipid-lowering drug* that acts on the liver enzymes that produce *cholesterol*. Simvastatin may cause bowel upsets, headaches, and muscle pains. It may also raise liver enzyme levels, which must be monitored.

Sinemet

The brand name for co-careldopa, a preparation of *levodopa* and carbidopa, drugs for *Parkinson's disease*.

sinew

A nonmedical term for a *tendon*.

singer's nodes

Small, greyish-white nodules that develop on the vocal cords. Singer's nodes

sinoatrial node

The natural pacemaker of the *heart*. The sinoatrial node consists of a cluster of specialized muscle cells in the right atrial wall. These cells emit rapid electrical impulses that initiate the heart's contractions (beats). Various hormones and nervous system activities may alter the rate at which the node emits impulses. (See also *heart rate*.)

sinus

A cavity in a bone; in particular, one of the air-filled spaces in the bones surrounding the nose (see *sinus, facial*).

The term "sinus" also refers to any wide channel that contains blood, or to an abnormal, often infected, tract.

sinus arrhythmia

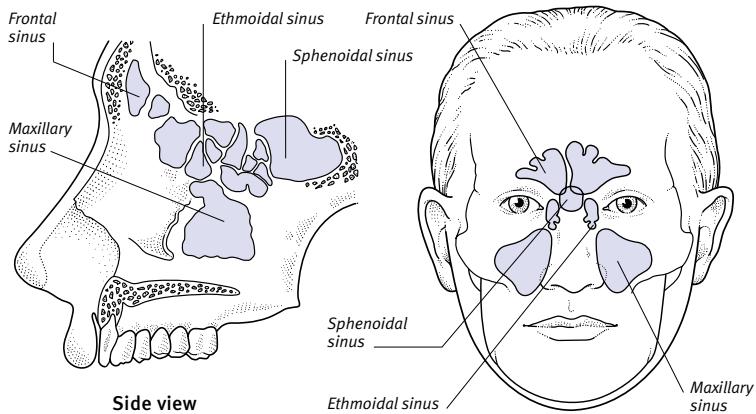

A normal variation in the heart rate that occurs with breathing and is particularly found in children and young adults. During inspiration (breathing in), the heart rate is increased; during expiration (breathing out) it decreases.

sinus bradycardia

A slow, but regular, heart rate (fewer than 60 beats per minute) that is the result of reduced electrical activity in the *sinoatrial node*. The symptom of sinus bradycardia is normal in athletes and people who are fit, but in others it may be caused by *hypothyroidism*, a *myocardial infarction*, or drugs such as *beta-blockers* or *digoxin*.

LOCATION AND FUNCTION OF THE SINUSES

The air spaces, or sinuses, in the skull bones lighten the skull and improve the resonance of the voice. The sinuses surround the nose and are lined with mucous membrane. Mucus produced by this membrane drains into the nasal cavity via narrow channels.

sinus, facial

Also referred to as a paranasal sinus, any of the air-filled cavities in the bones surrounding the nose. Facial sinuses include two frontal sinuses that are situated in the lower forehead; two ethmoidal sinuses between the eyes; two maxillary sinuses in the cheekbones; and the sphenoidal sinuses in the skull behind the nose. The sinuses decrease the weight of the skull and alter voice resonance. Each sinus is lined with mucous membrane; and mucus drains along a channel that opens into the nose.

sinusitis

Inflammation of the membrane that lines the facial sinuses (see *sinus, facial*). Sinusitis is most often due to infection, usually spread from the nose. The maxillary and ethmoidal sinuses are most commonly affected.

Sinusitis may cause pressure, headache, facial pain, and a feeling of fullness in the affected area; there may also be fever, a stuffy nose, and loss of the sense of smell. A common complication is the formation of pus, causing pain and nasal discharge.

Treatment of sinusitis is usually by *steam inhalations* and a *decongestant*, but in some cases antibiotics may be necessary. If sinusitis persists despite treatment, surgical drainage of the affected sinuses may be performed.

sinus tachycardia

A fast but regular heart rate (more than 100 beats per minute) due to increased electrical activity in the *sinoatrial node*. Such a heartbeat is normal in sudden stressful moments or during exercise. Persistent sinus tachycardia at rest may be caused by fever or *hyperthyroidism*.

situs inversus

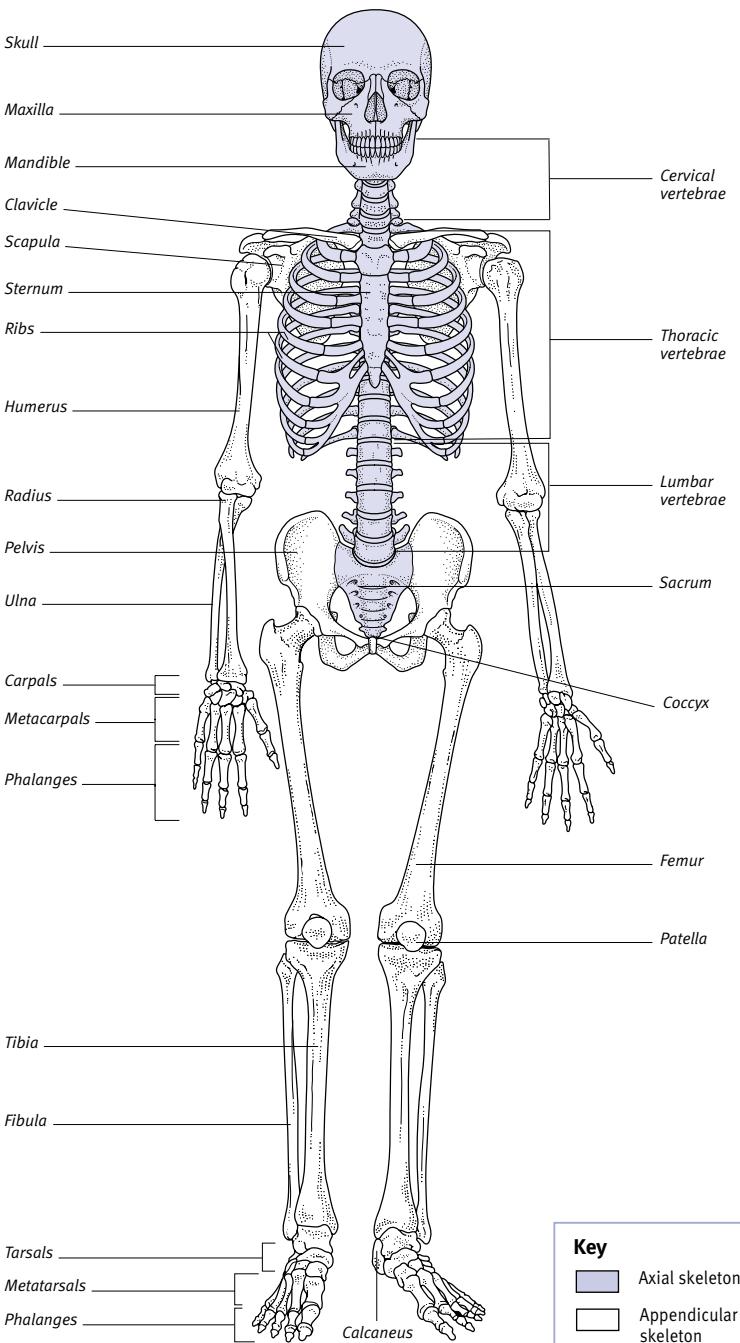

An unusual condition in which the internal organs are situated in a mirror image of their normal positions. No treatment is needed provided that all the organs are functioning normally.

Sjögren's syndrome

A condition, mostly affecting middle-aged women, in which the eyes and mouth are excessively dry. Other areas including the nasal cavity, throat, and vagina may also be affected. Sjögren's syndrome tends to occur with certain *autoimmune disorders* (in which the immune system attacks the body's own tissues), such as *rheumatoid arthritis* and

BONES OF THE SKELETON

There are two main parts to the skeleton, called the axial and appendicular skeletons (shown below). Some parts, such as the skull and pelvis, consist of several fused or associated bones. The skeleton is not merely an inert framework that supports and protects organs and makes movement possible; the bones are active living structures that are constantly producing blood cells and interchanging minerals with the blood.

Key

- [Purple square] Axial skeleton
- [White square] Appendicular skeleton

systemic *lupus erythematosus*. The dryness is due to destruction by the immune system of the lubricant-producing exocrine glands.

skeletal muscle

See *muscle*.

skeleton

The framework of bones that gives the body its shape and provides attachment points for the muscles and underlying

soft tissues. The average human adult skeleton has 213 *bones* (counting each of the nine fused vertebrae of the sacrum and coccyx as individual bones), joined to muscles by *tendons*, and joined with *ligaments* at sites called *joints*.

STRUCTURE

The skeleton consists of two main parts: the axial and appendicular skeletons.

The axial skeleton comprises the *skull*, *spine*, *ribs*, and *sternum* (breastbone). Together, these total 87 bones: 29 in the

skull (including the *hyoid* bone and three pairs of auditory *ossicles*); 33 in the spine (seven cervical, 12 thoracic, and five lumbar vertebrae, the five fused vertebrae of the sacrum, and the four fused vertebrae of the coccyx); and 25 in the chest (12 pairs of ribs and the sternum).

The appendicular skeleton consists of the limb girdles (the *shoulder* and the *pelvis*) and their attached limb bones. Altogether there are 126 bones: 64 in the shoulders and upper limbs and 62

DISORDERS AFFECTING THE SKIN

The skin is the largest and most vulnerable organ of the body. Skin conditions are seldom life-threatening, but many can be severely debilitating and can cause psychological problems.

Congenital disorders

A *birthmark* is a type of *naevus* (pigmented skin blemish) present from birth. Naevi include moles, freckles, and *haemangiomas*, such as port-wine stains and strawberry marks.

Infection and inflammation

Viral infections of the skin include *cold sores*, *warts*, and *molluscum contagiosum*. Systemic infections such as *chickenpox* and *herpes zoster* (shingles) also affect the skin. Bacterial infections include *boils*, *cellulitis*, *erysipelas*, and *impetigo*. Fungal infections, such as *tinea*, cause *athlete's foot* and ringworm.

Inflammation of the skin occurs in *dermatitis* and *eczema*; it may be caused by an allergic reaction to a substance (such as nickel), a detergent, a plant, or a drug. *Psoriasis* is a common and persistent skin disease of unknown cause that consists of large, red patches with silvery, scaly surfaces. *Prickly heat* is an irritating rash caused by blockage of the sweat glands.

Tumours

Benign (noncancerous) skin tumours are extremely common. These include seborrhoeic *keratoses* and most types of naevi. *Bowen's disease* is a skin disorder that may slowly become cancerous. Three common forms of skin cancer are *basal cell carcinoma*, *squamous cell carcinoma*, and malignant melanoma (see *melanoma, malignant*). Less common skin cancers include *Paget's disease of the nipple*, *mycosis fungoides*, and *Kaposi's sarcoma*.

Injury

The skin is vulnerable to many minor injuries, including cuts and bites (see *bites*, *animal*; *insect bites*) as well as more serious *wounds*. *Burns* can be among the most serious of all skin injuries and may cause extensive scarring or death.

Hormonal disorders

Acne is partly related to the action of androgens (male sex hormones) on the sebaceous glands; it is particularly common among adolescents.

Nutritional disorders

Deficiency of vitamins A, B, and C can cause *rashes* and other problems.

Impaired blood supply

Leg ulcers, which are particularly common in the elderly, may be caused by poor blood flow to the skin as a result of *atherosclerosis*, by poor drainage of blood through *varicose veins*, or by the leg swelling associated with heart failure.

Drugs

Many drugs, including antibiotics, barbiturates, and sulphonamides, may cause a rash. Some cause *urticaria* (hives), others cause *eczema* or a measles-like rash, and some cause *photosensitivity*.

Radiation

All forms of radiation are potentially damaging to the skin. Overexposure to sunlight (ultraviolet radiation) causes premature aging of the skin and increases the risk of skin cancer (see *sunlight, adverse effects of*). High doses of other forms of radiation, such as X-rays, may cause severe injury to the skin and may lead to cancer.

Autoimmune disorders

Many autoimmune disorders are systemic but have manifestations in the skin. They include *lupus erythematosus*, which may affect the skin alone or the skin and other organs; *vitiligo*, which is characterized by unpigmented patches and caused by destruction of the skin's pigment cells; *dermatomyositis*, which is characterized by a specific skin rash and muscle weakness; *morphea* and *systemic sclerosis*, in which there is progressive hardening of the skin and other tissues; and *pemphigoid* and *pemphigus*, in which large blisters develop on the skin.

Other disorders

A *keloid* is an abnormally large and protruding scar caused by the continuing production of scar tissue long after healing would usually be complete. *Striae* (stretch-marks) often develop during pregnancy and may also develop as a side effect of *corticosteroid drugs*.

Erythema simply means redness and has many possible causes. *Purpura* is a condition in which blood leaks into tissues, giving rise to petechiae (tiny pinpoints of blood) or larger bruises. *Xanthelasma* are fatty yellowish patches that tend to occur on the eyelids; they are associated with raised levels of cholesterol in the blood.

INVESTIGATION

Most skin disorders can be diagnosed from their physical characteristics. A skin *biopsy* (removal of a tissue sample for microscopic analysis) may also be performed, usually to confirm the diagnosis of a skin problem or to exclude skin cancer.

in the pelvis and lower limbs. There are two bones in each shoulder: the *clavicle* (collarbone) and *scapula* (shoulderblade); three in each arm: the *humerus* (upper-arm bone) and *radius* and *ulna* (forearm bones); eight carpal in each *wrist*; five *metacarpals* in each palm; and 14 *phalanges* in the digits of each hand (two in each thumb and three in each finger).

The pelvic girdle is made up of two hip bones. There are 30 bones in each of the lower limbs: a *femur* (thighbone), *patella* (kneecap), and *tibia* and *fibula* (lower-leg bones) in each leg; seven tarsals in the *ankle*, heel (see *calcaneus*), and the back part of the foot; five *metatarsals* in the middle section of each foot; and 14 phalanges in the toes (two of which are in each big toe and three in each of the other toes).

There are minor differences between the skeletons of men and women. In general, men's bones tend to be larger and heavier, but the female pelvic cavity is wider to facilitate childbirth.

FUNCTION

The skeleton plays an indispensable role in movement by providing a strong, stable, but mobile framework on which muscles can act to move the body. It also supports and protects internal body organs, notably the brain and spinal cord, which are encased in the skull and spine, and the heart and lungs, which are protected by the ribs.

However, the skeleton is not an inert frame. It is an active organ that produces blood cells (formed in bone marrow) and acts as a reservoir for minerals such as calcium, which can be drawn on, if required, by other parts of the body.

skin

The outermost covering of body tissue, which also forms the largest organ in the body. Skin has two layers: the epidermis (outer layer) and the dermis (inner layer), beneath which is the fatty subcutaneous tissue.

EPIDERMIS

The epidermis comprises sheets of flat cells, which resemble paving stones when viewed under the microscope. It varies in thickness, being thickest on the soles and palms and thinnest on the eyelids.

The outermost part of the epidermis is composed of dead cells, which form a tough, horny, protective coating. As these dead cells are worn away, they are replaced by new ones that are produced by the rapidly dividing living cells in the innermost part of the epidermis.

Between the outer and inner parts is a transitional region that consists of both living and dead cells.

Most of the cells produce the protein *keratin*, a tough substance that is the main constituent of the outermost part. Some of the cells make the pigment *melanin*, which protects the body from *ultraviolet light* in sunlight and determines skin colour.

DERMIS

The dermis is composed of *connective tissue* that is interspersed with hair follicles, sweat glands, sebaceous glands, blood and lymph vessels, and sensory receptors (specialized nerve structures) that are capable of detecting pressure, temperature, and pain.

FUNCTION

The skin's most important function is a protective one. It acts as the main barrier between the environment and the internal organs of the body, shielding them from injury, the harmful rays of sunlight, and infection with microorganisms such as bacteria.

The skin is a sensory organ containing many cells that are sensitive to touch, temperature, pain, pressure, and itching. The skin also plays a role in keeping body temperature constant. When the body is hot, the sweat glands cool it by producing perspiration and

the blood vessels in the dermis dilate (widen) to dissipate heat; if the body gets cold, blood vessels in the skin constrict (narrow), to conserve the body's heat.

The epidermis contains a fatty substance that waterproofs the skin and stops it soaking up moisture like a sponge. The outer epidermis also has an effective water-holding capacity, which contributes to its elasticity and helps maintain the body's balance of fluid and electrolytes. If the water content drops below a certain level, the skin becomes cracked and its barrier effect less efficient.

skin allergy

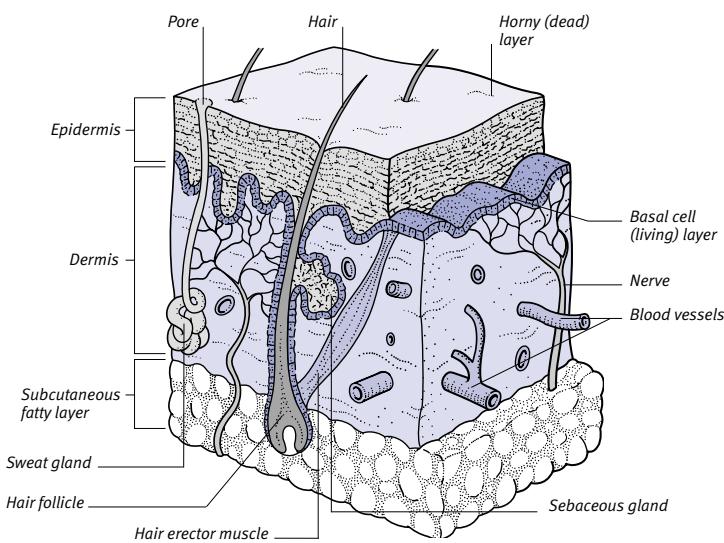

Irritation of the skin following contact with an allergen (a substance that provokes an inappropriate reaction from the *immune system*).

There are two main types of allergic skin reaction. In contact allergic *dermatitis*, red, itchy patches develop a few hours to two days after skin contact. Trigger substances include adhesives in plasters, nickel in jewellery, and cosmetics. In contact *urticaria*, red, raised areas appear a few minutes after skin contact. Possible causes include certain chemicals, plants, and insect bites.

If possible, contact with the trigger substance should be kept to a minimum. In many cases the trigger is

STRUCTURE OF SKIN

The skin consists essentially of two distinct layers – the dermis (true skin), which contains most of the living elements, and the epidermis, which is a tough protective covering that has an outer layer of dead cells.

obvious, but sometimes *skin tests* are needed to identify the allergen. (See also *atopic eczema*.)

skin biopsy

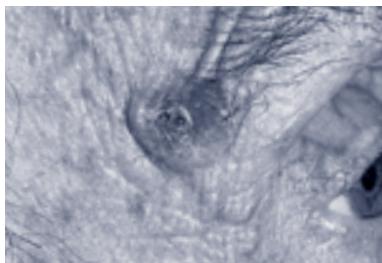

Removal of a portion of skin for laboratory analysis to diagnose a skin disorder.

skin cancer

A malignant skin tumour. *Basal cell carcinoma*, *squamous cell carcinoma*, and malignant melanoma (see *melanoma*, *malignant*) are forms associated with exposure to sun. *Bowen's disease*, a rare disorder that can become cancerous, may also be related to sun exposure. Less common types include *Paget's disease of the nipple* and *mycosis fungoides*. *Kaposi's sarcoma* is a type usually found in *AIDS* patients. Most skin cancers are curable if treated early.

skin flap

A surgical technique in which a section of skin and underlying tissue, sometimes including muscle, is moved to

Basal cell carcinoma

This is the most common form of skin cancer. Also called a rodent ulcer, a basal cell carcinoma develops most commonly on the face.

cover an area from which skin and tissue have been lost or damaged by injury, disease, or surgery. Unlike a *skin graft*, a skin flap retains its blood supply. Therefore, skin flaps can be either attached (in which they remain attached to their donor site) or free (in which they are reattached to blood vessels at the recipient site by *microsurgery*). Skin flaps adhere well, even where there is exten-

sive loss of deep tissue. For this reason, they may be used to cover areas that have lost their blood supply.

skin graft

A technique that is carried out in order to repair areas of lost or damaged *skin* that are too large to heal naturally, that are slow to heal, or that would otherwise leave tightening or unsightly scars. A skin graft is often used in the treatment of burns or sometimes for ulcers that are not healing.

A piece of healthy skin is detached from one part of the body and transferred to the affected area. New skin cells grow from the graft and cover the damaged area. In a meshed graft, donor skin is removed and made into a mesh by cutting. The mesh is stretched to fit the recipient site; new skin cells grow to fill the spaces in the mesh. In a pinch graft, multiple small areas of skin are pinched up and removed from the donor site. Placed on the recipient site, the new skin cells gradually expand to form a new sheet of healthy skin. (See also *skin flap*.)

skin patch

See *transdermal patch*.

skin peeling, chemical

A cosmetic procedure to remove acne scars, freckles, delicate wrinkles, or other skin blemishes. The procedure involves application of a caustic paste to peel away the outer layers of skin.

skin tag

A harmless, small, brown or flesh-coloured flap of skin that is often found on the neck, under the breasts, or in skin folds. A skin tag may appear spontaneously, or it may result from poor healing of a wound.

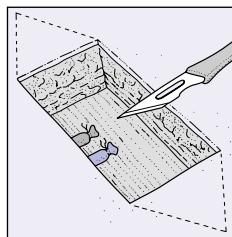

skin tests

Procedures to determine how the body reacts to various substances by applying them to the skin (usually on patches) or by injecting a small quantity of a substance under the skin.

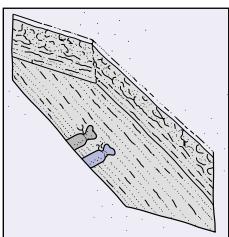

Patch tests are used in the diagnosis of contact allergic *dermatitis*; allergens will cause patches of reddened or blistered skin. Injections are used to help identify substances causing allergic illnesses such as *asthma*. They may also be used to test immunity to certain infectious diseases (as in the *tuberculin test* for tuberculosis).

TECHNIQUE FOR A FREE SKIN AND MUSCLE FLAP

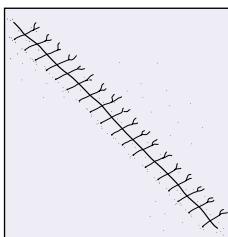

A flap of skin and underlying tissue can be moved to a new site to replace lost tissue; if its blood supply is reconnected, the flap will heal in place. Microsurgery to rejoin blood vessels facilitates the technique.

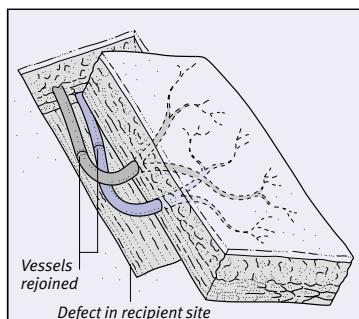

1 The donor area needs a good blood supply if muscle is also to be taken.

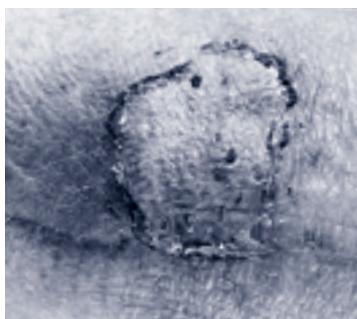

2 The ends of the donor area need to be tapered to allow satisfactory closure.

3 The skin may have to be undercut and freed before the wound is closed.

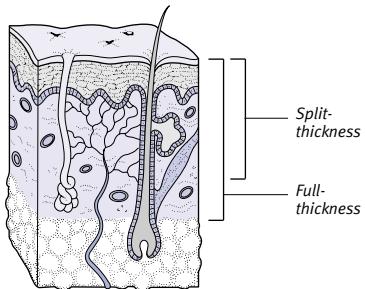

4 At the recipient site, an artery and a vein of suitable size must be available to be joined to blood vessels in the flap.

Skin flaps are particularly useful where there has been an extensive loss of deep tissue. The results are usually excellent.

TYPES OF SKIN GRAFT

The two main types of skin graft are split-thickness (in which less than the full thickness of skin is removed from the donor site) and full-thickness (in which a deeper thickness is removed). There are advantages to each of these types.

Split-thickness graft

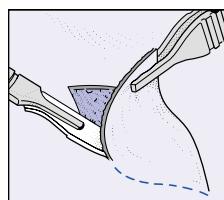

When large areas need to be covered, such as after burns, split-thickness grafts are used and the donor sites are left to regenerate, which they do in a few days. Such sites can be repeatedly harvested.

Full-thickness graft

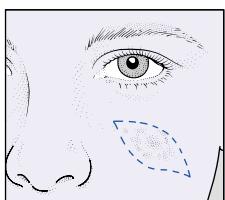

Full-thickness skin grafts are usually preferred for the face because they more closely match the appearance of normal skin. However, donor sites are limited and must be sutured (stitched).

HOW A FULL-THICKNESS GRAFT IS DONE

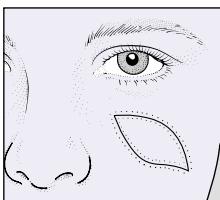

Most skin grafts are performed under general anaesthesia. Full-thickness grafts can be obtained easily with a scalpel. Subcutaneous fat is avoided and any bleeding at the recipient site prevented.

1 Skin for a full-thickness graft is often taken from behind the ear.

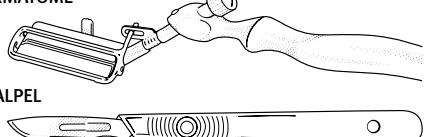

2 The graft must be slightly larger than the area to be covered, to allow for shrinkage.

3 Precise fitting and firm pressure are needed to ensure there is a satisfactory "take".

DERMATOME

SCALPEL

Instruments

Split-skin grafts are cut, usually from the abdomen or thigh, with an instrument called a dermatome. If necessary, the skin can be expanded into a trellis-like mesh on the donor site.

there are many holes for the passage of nerves and blood vessels. The largest of the holes, called the foramen magnum, is situated in the occipital bone (which forms part of the base and back of the cranium); this hole allows the *brainstem* to enter the spinal canal, where it continues as the spinal cord.

The skull rests on the atlas (the first cervical vertebra), which is a ring-shaped bone that articulates with the occipital bone and permits nodding movement of the head. Turning the head is a function of the joint between the atlas and the second cervical vertebrae, which is called the axis. The occipital bone, atlas, and axis are connected together by numerous small muscles.

DISORDERS

The skull may be affected by any disorder that involves the skeleton, such as *Paget's disease*, but the most common disorder is injury. A blow to the head may cause a fracture (see *skull, fracture of*), possibly leading to brain damage. (See also *head injury*.)

skull, fracture of

A break occurring in one or more of the *skull* bones as a result of a *head injury*. In most skull fractures, there are no complications. In a severe injury, however, the broken bones may be displaced. If this happens, bone fragments may rupture blood vessels in the *meninges* (the membranes covering the brain) or, rarely, tear the meninges, resulting in bleeding and, in some cases, brain damage.

An uncomplicated fracture of the skull usually heals by itself. However, if there is any damage to brain structures neurosurgery is often required. (See also *depressed skull fracture*; *extradural haemorrhage*; *subarachnoid haemorrhage*; *subdural haemorrhage*.)

S

Skull fracture

In this X-ray image, a fracture of the back of the skull is visible as a long, dark, horizontal line across the orbit of the right eye (left on the image).

skin tumour

A growth developing on or in the *skin* that may be cancerous (see *skin cancer*) or noncancerous. *Keratoses* and *squamous papillomas* are common types of noncancerous tumour; other types include *sebaceous cysts*, *cutaneous horns*, *keratoacanthomas*, and *haemangiomas*.

skull

The bony skeleton of the head, which protects the brain; houses the special sense organs (eyes, ears, tongue, and nose); provides points of attachment for

facial, scalp, and neck muscles; and forms part of the respiratory and digestive tracts.

STRUCTURE

All the skull bones, except the mandible (lower jaw) are fixed to one another by immovable sutures; the skull bones do not fuse until about 18 months of age (see *fontanelle*). The cranial cavity houses the brain; other skull structures include the nasal cavity and eye orbits.

Several of the skull bones, especially those around the nasal area, contain *sinuses* (air spaces). In the cranium,

skull X-ray

A technique for providing images of the skull. The X-rays are taken after some cases of *head injury* to look for a fracture or foreign body, or to evaluate disorders affecting the skull bones.

slapped cheek syndrome

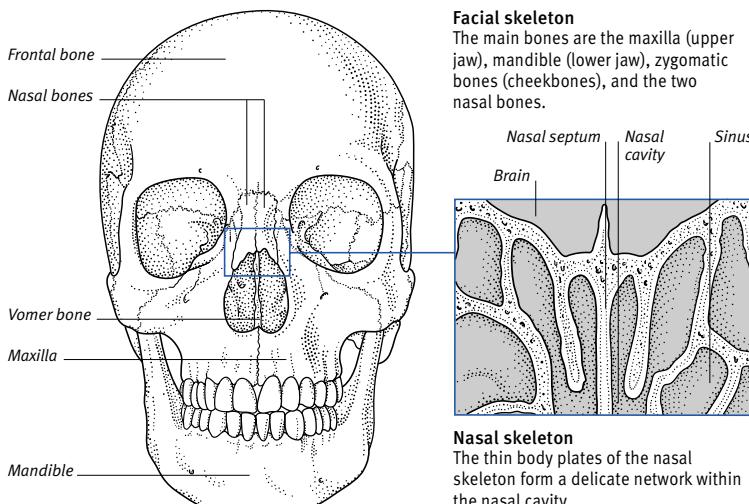

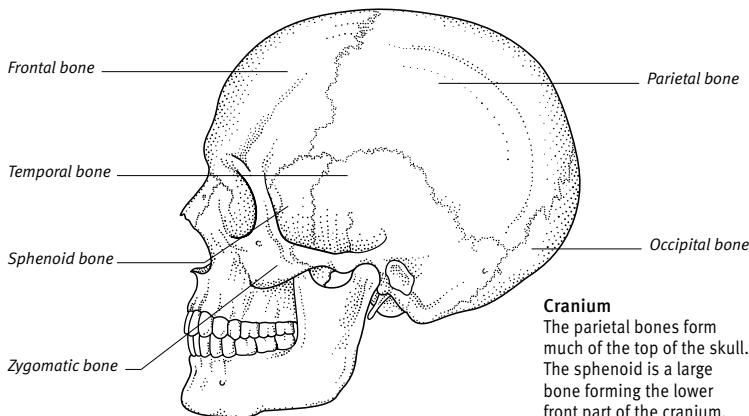

Another name for *fifth disease*. Slapped cheek syndrome is an infection caused by erythrovirus, in which the predominant feature is reddening of the cheeks.

SLE

The abbreviation for the disorder systemic *lupus erythematosus*.

STRUCTURE OF THE SKULL

The skull consists of the cranium, surrounding the brain, and the facial skeleton. The cranium is formed by the frontal bone, two temporal bones, two parietal bones, the occipital bone at the back, the ethmoid bone behind the nose, and the sphenoid. The face consists of 14 bones, including nasal, cheek, and jaw bones.

**sleep**

A natural state of lowered consciousness and reduced *metabolism*. Sleep takes up about one third of an average life.

PHYSIOLOGY

EEG recordings of the electrical impulses produced by the brain during sleep show that there are two distinct types of sleep: REM (rapid eye movement) and NREM (nonrapid eye movement). These types alternate in cycles lasting approximately 90 minutes throughout the sleep period. NREM sleep, which accounts for the major part of sleep, starts with drowsiness; brain waves become increasingly deeper and slower until brain

activity and metabolism fall to their lowest level. Dreams are infrequent.

In REM sleep, the brain suddenly becomes more active and its temperature and blood flow increase. The eyes move rapidly and *dreaming* occurs. REM sleep, also known as paradoxical sleep, periodically interrupts NREM sleep. The first REM period usually takes place 90 to 100 minutes after the onset of sleep and lasts about five to 10 minutes. REM sleep periods increase in length as sleep continues; the last of a night's four or five REM sleep periods may last about an hour.

FUNCTIONS OF SLEEP

Sleep is a fundamental human need, as is shown by the detrimental effects of *sleep deprivation*. The way in which sleep is beneficial is not understood, however.

SLEEP REQUIREMENTS

The need for sleep decreases with age. A one-year-old infant needs about 14 hours of sleep a night, a five-year-old child about 12 hours, and adults seven or eight hours on average. (Some adults, however, need more than 10 hours' sleep, while others can manage on five hours or less.) Elderly people tend to sleep less than young adults at night, but doze during the day.

SLEEP DISORDERS

Sleep disorders are divided into four main categories: difficulty in falling or remaining asleep (see *insomnia*); difficulty in staying awake (see *narcolepsy*); disruption of the sleeping/waking cycle, for example, by working shifts or travelling across time zones (see *jet-lag*); and other miscellaneous problems such as *bedwetting*, *night terrors*, or *sleepwalking*. (See also *sleep apnoea*.)

sleep apnoea

A disorder in which breathing briefly stops several times (for periods of 10 seconds or longer) during sleep. Affected people may not be aware of any problem during the night, but may be sleepy during the day, with poor memory and concentration. Severe sleep apnoea is potentially serious; it may lead to *hypertension*, *heart failure*, *myocardial infarction* (heart attack), or *stroke*.

Obstructive sleep apnoea is the most common form. It may affect anyone, but more often occurs in middle-aged men, especially those who are overweight. The most common cause is over-relaxation of the muscles of the soft *palate*; another possible cause is enlarged *tonsils* or *adenoids*. These problems cause obstruction of the airway,

and result in snoring. If complete blockage occurs, breathing stops. This triggers the brain to restart breathing; the person may gasp and wake briefly.

In central sleep apnoea, breathing stops because the chest muscles and **diaphragm muscle** temporarily cease to work, probably due to a disturbance in the brain's control of breathing. Causes include paralysis of the diaphragm and disorders of the **brainstem** (the part of the brain that controls breathing). Snoring is not a main feature.

Overweight people may find that losing weight helps. (In contrast, alcohol and sleeping drugs aggravate sleep apnoea.) In one treatment, air from a compressor is forced into the airway via a mask worn over the nose. Night-time artificial **ventilation** may be needed. **Tonsillectomy**, **adenoidectomy**, or surgery on the soft palate may be performed.

sleep deprivation

Insufficient sleep. Irritability and a shortened attention span may occur after a short night's sleep. Longer sleepless periods leave a person less able to concentrate or perform normal tasks. Three or more sleepless nights may lead to **hallucinations** and, sometimes, to **paranoia**.

sleeping drugs

COMMON DRUGS

- BENZODIAZEPINE DRUGS** •Flurazepam
•Loprazolam •Lormetazepam •Nitrazepam
•Temazepam
- OTHERS** •Clomethiazole •Diphenhydramine
•Promethazine •Zolpidem •Zopiclone

A group of drugs that are used for the treatment of **insomnia**. Sleeping drugs include **benzodiazepine drugs**; **antihistamine drugs**, which are often available over-the-counter; **antidepressant drugs**; and chloral hydrate. These drugs promote sleep by reducing the activity of nerve cells in the brain.

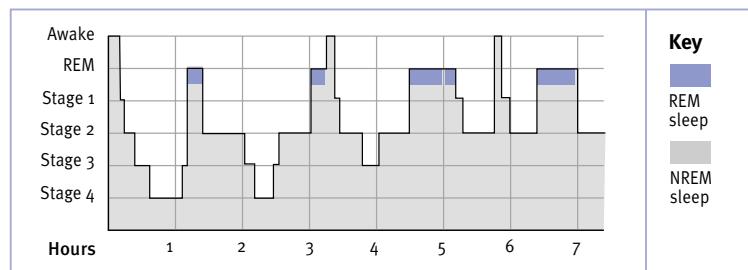

Sleeping drugs should always be taken in the smallest effective dose for the shortest period of time. In general, they should be used for no more than three weeks, and preferably not every night. Sleeping drugs do not treat the underlying cause of insomnia, which needs to be investigated.

ADVERSE EFFECTS

Sleeping drugs may cause drowsiness, unsteadiness, and impaired concentration on waking. They can be especially hazardous to anyone driving or operating machinery. Long-term use may

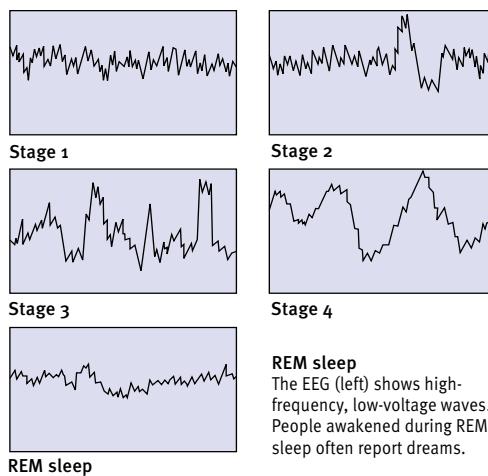

SLEEP PATTERNS

The brain does not rest when a person is sleeping, but there is some reorganization of activity within it. EEGs (electroencephalograms) and other recordings reveal cyclical patterns to this activity.

Phases of sleep

There are two types of sleep, REM (rapid eye movement) and NREM (nonrapid eye movement). They can be distinguished by the presence or absence of REMs and by EEGs or other recordings. The chart shows how a sleeper passes in cycles between the four stages of NREM sleep during the night, with bursts of REM sleep.

NREM sleep

This is sometimes called orthodox sleep; in adults it makes up about 80 per cent of the sleeping pattern. It has four stages of progressively greater "depth" of sleep, characterized by EEG waves (left) of increasingly larger voltage (amplitude) and lower frequency (number of waves per second). People awakened during NREM sleep often report they were "thinking" about everyday matters but rarely report dreams.

induce **tolerance** (needing a higher dose to achieve the same effect) and **dependence** (withdrawal symptoms when the person stops taking the drug).

sleeping sickness

A serious infectious disease of tropical Africa caused by the protozoan parasite **TRYANOSOMA BRUCEI**, which is transmitted to humans by the bite of a tsetse fly.

One form of the disease, which occurs in West and Central Africa, takes a slow course, with bouts of fever and lymph-node enlargement. After months or years, the disease spreads to the brain, causing headaches, confusion, and, eventually, severe lassitude. Without treatment, coma and death follow. The other, East African, form runs a faster course. Fever develops after a few

weeks of infection, and the heart may suffer fatal effects before the disease has reached the brain.

Drugs may effect a cure, but there may be residual brain damage if the infection has already spread to the brain. People in infested areas should wear long clothing fastened at the wrists and ankles to help prevent tsetse fly bites.

sleep paralysis

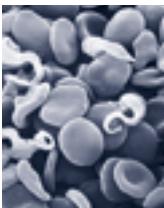

The sensation of being unable to move at the moment of going to sleep or waking up. It usually lasts only a few seconds, and may be accompanied by **hallucinations**. Sleep paralysis most often occurs in people with **narcolepsy**.

sleep terror

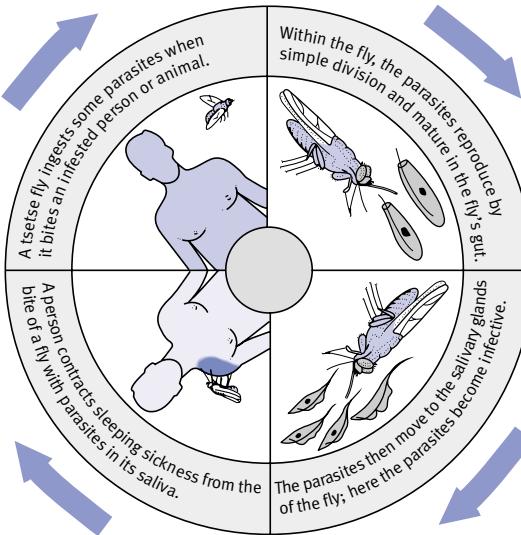

See **night terror**.

LIFE-CYCLE OF TRYPANOSOMES IN SLEEPING SICKNESS

The life-cycle of the trypanosomes that cause sleeping sickness is shown. They multiply in a person's blood and lymph vessels and may spread to the brain or heart with serious effects.

Trypanosomes
The parasites (pale, irregular shapes) are shown here in blood.

**sleepwalking**

Walking while asleep, also known as somnambulism. It occurs during NREM (nonrapid eye movement) sleep, or during arousal from this type of sleep, and does not represent the acting out of dreams. Some people regularly sleepwalk.

Usually a sleepwalker gets calmly out of bed, wanders around aimlessly for a few minutes, and then goes back to bed. Sometimes, however, sleepwalking occurs with *night terror*, in which case the person may show distress or cry out. Waking a sleepwalker can be difficult and is not necessary; he or she should simply be steered gently back to bed.

In children, sleepwalking is not normally a cause for concern and tends to disappear with age. In adults, it may be related to anxiety or the use of sleeping drugs, especially in the elderly.

slimming

See *weight reduction*.

sling

A triangular bandage used to immobilize, support, or elevate an injured arm. The arm may be supported horizontally or held elevated, depending on the injury.

slipped disc

See *disc prolapse*.

slipped femoral epiphysis

See *femoral epiphysis, slipped*.

small intestine

The section of the digestive tract (see *digestive system*) that lies between the stomach and large intestine. The small intestine, which consists of the *duodenum*, *jejunum*, and *ileum*, is the area in which nutrients are extracted from food and absorbed into the body.

smallpox

A highly infectious disease, caused by the variola virus, that was declared to be eradicated in 1980 following a global vaccination campaign.

Smallpox was transmitted from person to person. It caused an illness resembling influenza and was characterized by a rash that spread over the body and eventually developed into pus-filled blisters. The blisters became crusted and would sometimes leave deeply pitted scars. Complications included blindness, pneumonia, and kidney damage. There was no effective treatment for the disease, which killed up to 40 per cent of its victims.

Eradication of smallpox was achieved through cooperative international use of a highly effective vaccine. Routine vaccination has now been discontinued throughout the world. Recently, however, vaccination is being considered in certain circumstances (see *bioterrorism*).

smear

A specimen for microscopic examination prepared by spreading a thin film of cells (such as blood cells) on to a glass slide. Common types of smear include cells collected from the inside of the cheek (known as a buccal smear), the neck of the uterus (see *cervical smear test*).

smegma

An accumulation of sebaceous gland secretions under the foreskin in an uncircumcised male, usually due to poor hygiene. Fungal or bacterial infection of smegma may cause *balanitis* (inflammation of the foreskin and the head of the penis).

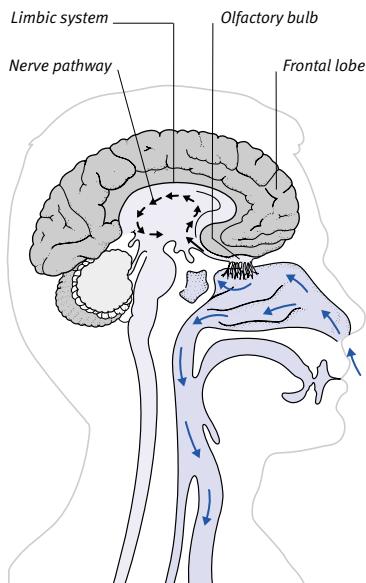

smell

One of the five senses. In the nose, hair-like projections from smell receptor cells lie in the mucous membrane. When the receptors are stimulated by certain molecules, they transmit impulses along the olfactory nerves to the smell centres in the *limbic system* and the temporal and frontal lobes of the brain, where smell is perceived.

THE SENSE OF SMELL

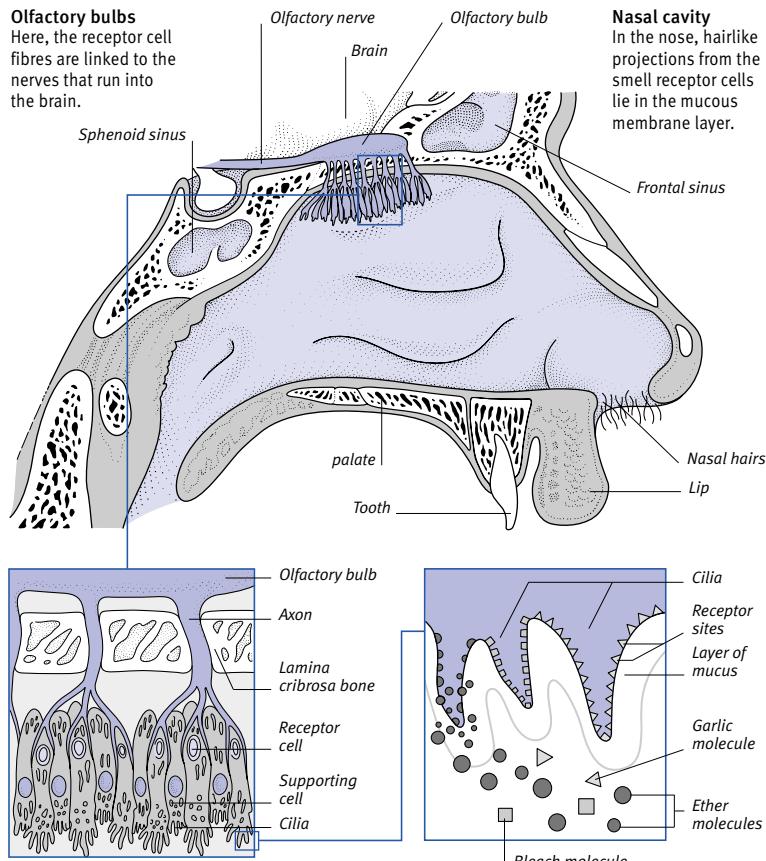

The smell receptors are specialized nerve cell endings that are situated in a small patch of mucous membrane lining the roof of the nose. The axons (fibres) of these sensory cells pass up through tiny perforations in the overlying bone to enter the two elongated olfactory bulbs lying on top of the bone. These

bulbs are swellings at the ends of the olfactory nerves; the nerves contain millions of nerve fibres and enter the brain on its lower surface. The olfactory nerves carry sensory information to smell centres (parts of the limbic system and frontal lobes) situated within the brain.

Physiological basis of smell

The receptor cell bodies that are situated in the nasal cavity are swollen at their lower ends; each one has several cilia that extend down to the surface of the mucous membrane. The cilia contain the receptor sites at which stimulation by the molecules of odorous substances gives rise to nerve impulses. These nerve impulses pass from the olfactory bulb along the olfactory nerve to smell centres in the brain (which include parts of the limbic system and frontal lobes). Although we know that we are able to distinguish between as many as several thousand different odours, the exact basis of this high degree of specificity is uncertain. No microscopic difference in structure can be detected among the different receptors.

Probable mechanism of smell

The smell process is probably based on a physical "fit" between the odour molecules and the receptor sites. For example, the receptors on some cells may fit only with ether molecules, others with molecules

of bleach. The molecules must dissolve in the mucus before they can stimulate the receptors. The sensitivity of the system is remarkable; as few as four molecules can give a recognizable smell.

S

Loss of sense of smell may result from inflammation of the nasal membrane, as in a common *cold*; cigarette *smoking*; hypertrophic *rhinitis*, in which a thickened nasal membrane obscures olfactory nerve endings; atrophic rhinitis, in which the nerves waste away; head injury that tears the nerves; or a tumour of the *meninges* (membranes covering the brain) or nasopharynx (upper part of the throat).

The perception of illusory, unpleasant odours may be a feature of *depression*, *schizophrenia*, some forms of *epilepsy*, or alcohol withdrawal.

smelling salts

A preparation of *ammonia* that was once used to revive a person who felt faint.

Smith's fracture

A break that occurs in the lower part of the radius (one of the two bones of the forearm) in which the fragment underneath the fracture is displaced forwards. The wrist joint is deformed, but in contrast to a *Colles' fracture* (a type of wrist fracture), the hand and wrist are moved forward of their normal position. This type of fracture usually results from a

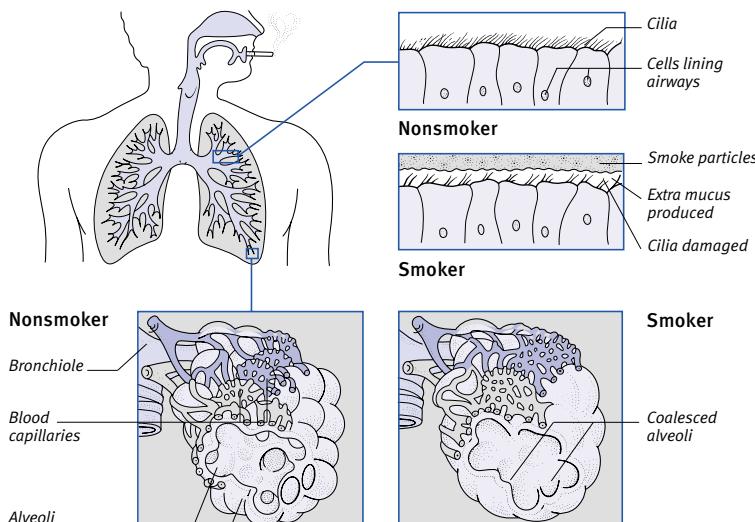

fall on to the back of the hand, which caused bending of the wrist joint forwards so that it breaks.

smoking

Inhalation of *tobacco* smoke from cigarettes, cigars, or pipes. More than 100,000 deaths per year in the UK are attributed to smoking. It causes serious diseases such as *lung cancer*, *bronchitis*, *emphysema*, *coronary artery disease*, and *peripheral vascular disease*, and also increases the risk of *mouth cancer*, *lip cancer*, and *throat cancer* (see *pharynx*, *cancer of*).

EFFECTS OF SMOKING

About 20 per cent of all deaths in the UK are attributed to smoking. The main harmful effects of smoking are respiratory diseases (lung cancer and COPD) and cardiovascular diseases (coronary artery disease and peripheral vascular disease). Smoking also causes a range of other cancers, including cancer of the bladder, cervix, tongue, larynx, and stomach. Smoking kills around half of all smokers.

**How smoking damages the lungs**

Smoke particles irritate the lungs' airways, causing excess mucus production (top right). The smoke particles also indirectly destroy the walls of the lungs' alveoli, which merge together

(above right), resulting in a smaller area overall for oxygen absorption. Both factors reduce lung efficiency. In addition, tar in tobacco smoke has a direct cancer-causing action.

Smoking is extremely harmful during pregnancy. Babies of women who smoke are smaller and are less likely to survive than those whose mothers are nonsmokers. Children with parents who smoke are more likely to suffer from *asthma* or other respiratory diseases.

There is also evidence that *passive smokers* are at increased risk of tobacco-related disorders. Also, passive smokers suffer immediate discomfort when breathing in smoke as demonstrated by coughing, wheezing, and sore eyes.

Tobacco is known to contain many toxic chemicals. Addiction to tobacco is caused by *nicotine*. Nicotine acts as a tranquilizer but also stimulates the release of *adrenaline* into the bloodstream, which can raise blood pressure. Tar in tobacco produces chronic irritation of the respiratory system and is thought to be a major cause of lung cancer. Carbon monoxide passes from the lungs into the bloodstream, where it easily combines with *haemoglobin* in red blood cells, interfering with oxygenation of tissues. In the long term,

persistently high levels of carbon monoxide in the blood cause hardening of the arteries, which greatly increases the risk of *coronary thrombosis*.

smooth muscle

A type of *muscle*.

snails and disease

Snails act as host to a variety of flukes, such as *liver flukes*, that infest humans.

snail track ulcer

A shallow, greyish mouth ulcer. Snail track ulcers are a characteristic symptom that occur during the secondary stage of *syphilis*.

snake bites

Every year, hundreds of thousands of people all over the world are bitten by snakes, but the chance of death or serious injury following a bite is relatively small. Most bites are by nonvenomous species of snake; furthermore, medical treatment of poisonous bites is usually effective, provided the victim can be

**Snake bite**

Following an adder bite, this boy's arm has become bruised and swollen, and the lymph nodes in his armpit have become enlarged.

taken to hospital quickly. Even the most powerful snake venom takes hours or days to kill a human being.

VENOMOUS SPECIES

Venomous snakes are found mainly in the tropics; the only poisonous species native to the UK is the adder, a member of the Viperidae (viper family). Round the world, this group of snakes includes lance-headed vipers, water moccasons (cottonmouths), and American rattlesnakes. The saw-scaled or carpet viper, which is native to parts of Africa, the Middle East, and the Indian subcontinent, probably kills more people than any other species of snake.

Another group of venomous snakes, Elapidae, includes cobras, coral snakes, kraits, and mambas. Venomous bites are caused by other snakes including Atractaspididae (burrowing asps), Hydrophiidae (sea snakes), and a relatively small number of the Colubridae family.

EFFECTS OF A BITE

The effects of a venomous bite depend on the species and size of the snake, the amount of venom injected, and the age and health of the victim.

A bite from a viper such as a rattlesnake is characterized by two distinct puncture wounds. Typically, there is an immediate burning pain and swelling at the site, followed by dizziness and nausea. The blood pressure drops and heart rate increases. A pins-and-needles sensation, thirst, and headache are other common symptoms. The venom may prevent the blood from clotting, causing bleeding from the wound and bruising under the skin. There may also be internal bleeding from the urinary tract, mouth, rectum, or vagina.

Elapidae also make puncture wounds but may chew the skin. Their venom primarily affects the nervous system. Serious symptoms develop from 10 minutes to eight hours after the bite and may include drooping eyelids, slurred

speech, and double vision. The victim becomes drowsy or delirious and may have convulsions. If treatment is not given, respiratory paralysis will eventually lead to death.

TREATMENT

Snakebite victims need medical help as quickly as possible. *Antibiotic drugs* and *tetanus* antitoxin injections are given for all bites, venomous or not, to prevent infection and tetanus. For a venomous bite, an injection of *antivenom* (a serum that contains antibodies against the poison) is given. Most victims recover completely with prompt treatment.

sneezing

An involuntary expulsion of air through the nose and mouth as a result of irritation of the upper respiratory tract. Sneezing may result from the common *cold*, allergic *rhinitis*, the presence of mucus, or inhaling an irritant substance.

Snellen chart

A method of measuring *visual acuity* used during *vision tests*. The Snellen chart has several rows of letters, of standard sizes, with each row smaller than the one above. The patient is positioned 6 m from the chart, then each eye in turn is covered and the patient is asked to read down the chart as far as possible with the open eye.

snoring

Noisy breathing through the open mouth produced by vibrations of the soft palate during sleep. Snoring is often caused by a condition that hinders breathing through the nose, such as a *cold*, allergic *rhinitis*, or enlarged *adenoids*. It is also a feature of *sleep apnoea*. Snoring is more common in people sleeping on their backs. If the underlying cause can be treated, it may stop.

snow-blindness

A common name for *actinic keratopathy*.

snuff

A preparation of powdered *tobacco* (often with other substances) for inhalation. Snuff is addictive because it contains *nicotine*; it also irritates the nasal lining and increases the risk of cancer of the nose and throat.

snuffles

A general term that is used to describe nasal obstruction, especially that occurring in infants suffering from an upper *respiratory tract infection*.

soap

A substance made from fat (often vegetable oil or purified animal fat) and alkali that is used to cleanse the body.

social and communication disorders

A collective term for disorders such as *Asperger's syndrome* and *autism*, which are marked by difficulties in social interaction with obsessive behaviour. Problems begin in childhood and tend to persist throughout life.

social skills training

A type of behaviour modification in which individuals are encouraged to improve their ability to communicate. It is an important part of *rehabilitation* for people with *learning difficulties* or those with chronic psychological disorders, such as *schizophrenia*. *Role-playing* is a commonly used technique in which various social situations are simulated in order to improve the individual's confidence and performance.

sociopathy

An outdated term for *antisocial personality disorder*.

sodium

A mineral that helps to regulate the body's water balance and maintain normal heart rhythm. Sodium is also involved in the conduction of nerve impulses and contraction of muscles. The level of sodium in the blood is controlled by the kidneys, which eliminate any excess in the urine.

Almost all foods contain sodium naturally or as an ingredient added during processing or cooking; the main forms are sodium chloride (salt) and sodium bicarbonate. Consequently, deficiency is rare and usually results from excessive loss of sodium through persistent diarrhoea or vomiting, or profuse sweating. Signs include weakness, dizziness, and muscle cramps. In severe cases, there may be a drop in blood pressure, leading to confusion, fainting, and palpitations.

Treatment is with supplements, which, in hot climates, may help to prevent *heat disorders* by compensating for sodium lost through heavy sweating.

Excessive intake of sodium is thought to be a contributory factor in *hypertension* (high blood pressure). Another adverse effect is fluid retention, which may cause dizziness and swelling of the legs in severe cases.

sodium aurothiomalate

An injected preparation of *gold*.

sodium bicarbonate

An alkali used to neutralize acid in *cystitis* and severe *acidosis* (blood acidity) in kidney failure. It is also an ingredient in over-the-counter *antacid drugs* for *indigestion*, *heartburn*, and *peptic ulcer*. Sodium bicarbonate often causes symptoms such as belching and abdominal discomfort. Long-term use can cause swollen ankles, muscle cramps, tiredness, and nausea.

sodium citrate

A drug used to relieve discomfort in urinary infections such as *cystitis*, by making the urine less acidic.

sodium cromoglicate

A drug given by inhaler to control mild *asthma* in children and allergic or exercise-induced asthma in adults. The drug is also used as a nasal spray to treat allergic *rhinitis*, in eye-drops for allergic *conjunctivitis*, and orally for *food allergy*. Side effects include coughing and throat irritation on inhalation of powder.

sodium picosulfate

A stimulant *laxative* drug used to treat *constipation* and to empty the bowel prior to procedures such as X-ray, *endoscopy*, and intestinal surgery. Side effects may include abdominal cramps and diarrhoea. The drug should be avoided in cases of intestinal obstruction.

sodium valproate

An *anticonvulsant drug* used to treat *epilepsy*. Side effects may include drowsiness, abdominal discomfort, temporary hair loss, weight gain, and rash. Long-term treatment may, rarely, cause liver damage.

Sofradex

A brand name for the corticosteroid drug *dexamethasone* used as drops or ointment to treat inflammatory conditions of the ears and eyes.

soft-tissue injury

Damage, such as a *sprain* or *tendinitis*, to the tissues (such as *ligaments*, *tendons*, or *muscles*) that surround bones and joints. (See also *sports injuries*.)

soiling

Inappropriate passage of *faeces* that, in children, occurs after the age at which bowel control is achieved (usually

at about two or two and a half years). It can also occur in elderly people and those with physical or mental disability.

Causes include slowness in developing bowel control, longstanding *constipation* (in which faecal liquid leaks around hard faeces blocking the large intestine), poor *toilet-training*, and emotional stress (caused, for example, by starting school). Soiling due to constipation is usually resolved with treatment. If no physical cause can be found, a course of *psychotherapy* may help.

Encopresis is type of soiling in which children deliberately pass faeces in inappropriate places, such as behind furniture. Such children have no specific physical problem, but often refuse to use a potty or toilet. Encopresis usually improves with time and is rare after the age of 10.

solar keratoses

A crumbly yellow-white crust occurring on the skin in older people as a result of repeated overexposure to sunlight. The skin growth is also known as an actinic *keratosis*.

solar lentigo

Also known as a liver spot, a flat, brown frecklelike patch that appears on exposed skin. Solar lentigos occur in older white people. (See also *lentigo*.)

solar plexus

The largest network of autonomic nerves in the body, located behind the stomach between the adrenal glands. The solar plexus incorporates branches of the *vagus nerve* and the splanchnic (visceral) nerves, and sends branches into the stomach, intestines, and other abdominal organs.

S

Solpadeine

A brand-name *analgesic drug* (pain-killer) containing *paracetamol*, *caffeine*, and *codeine*.

solvent abuse

The practice of inhaling the intoxicating fumes given off by certain volatile liquids. Glue-sniffing is the most common form. The usual method of inhalation is from a plastic bag containing the solvent, but sometimes aerosols are sprayed into the nose or mouth. Solvent abuse is usually a group activity, especially among boys.

Inhalation of solvent fumes produces a feeling of intoxication similar to that produced by alcohol. Solvent abuse can

cause headache, vomiting, confusion, and coma. Death may occur due to a variety of reasons including a direct toxic effect on the heart, a fall, choking on vomit, or asphyxiation by a clinging plastic bag. The effects of repeated solvent abuse include erosion of the lining of the nose and throat, and damage to the kidneys, liver, and nervous system.

The signs of solvent abuse include intoxicated behaviour, a flushed face, ulcers around the mouth, a smell of solvent, and personality changes, such as moodiness and nervousness. Acute symptoms such as vomiting or coma require urgent medical attention. In the longer term, counselling may be helpful in discouraging the behaviour.

somatic

A term meaning "related to the body" (*soma*), as opposed to the mind (*psyche*), or "related to body cells", as opposed to germ cells (eggs and sperm). It also refers to the body wall, in contrast to "visceral" (of the internal organs).

somatization disorder

A condition in which a person complains over a period of several years of various physical problems for which no organic cause can be found. The disorder, previously classified as *hysteria*, usually begins before age 30 and leads to numerous tests by many doctors. Unnecessary surgery and other treatments may result.

The symptoms that are most commonly complained of are neurological (such as double vision, seizures, weakness), gynaecological (painful menstruation, pain on intercourse), and gastrointestinal (abdominal pain, nausea). The condition is often associated with *anxiety*, *depression*, or substance abuse.

The physical symptoms in somatization disorder are caused by underlying emotional conflicts, anxiety, and depression that the person is unable to confront and unconsciously displaces onto the body. (See also *conversion disorder*; *hypochondriasis*.)

somatostatin analogues

Synthetic versions of somatostatin, a hormone that acts on the *pituitary gland* controlling the release of growth hormone. The drugs are used to treat *acromegaly* and symptoms associated with some other hormone-secreting tumours (particularly in *carcinoid syndrome*). *Octreotide* is a common somatostatin analogue.

somatotype

A person's physical build.

somatropin

A synthetic *growth hormone* given to children to treat *short stature* as a result of growth-hormone deficiency.

somnambulism

See *sleepwalking*.

sorbitol

A carbohydrate that is used as a substitute for cane sugar in foods manufactured for diabetics. Sorbitol is also used in disorders of carbohydrate metabolism and in drip feeding. (See also *artificial sweeteners*.)

sore

A term that is used to describe any disrupted area of the skin or mucous membranes. The word is also used as a description of an unpleasant feeling of pain or tenderness.

sore throat

A rough or raw feeling in the back of the throat that causes discomfort, especially when swallowing.

Sore throat is a common symptom, usually caused by *pharyngitis* and occasionally by *tonsillitis*. It is often the first symptom of the common *cold*, *influenza*, *laryngitis*, *infectious mononucleosis*, and many childhood viral illnesses, such as *chickenpox*, *measles*, and *mumps*.

A sore throat may be relieved by gargling with salt water. Sore throats that are due to bacterial infection are usually treated with *antibiotic drugs*. (See also *strep throat*.)

space medicine

A medical speciality that is concerned with the physiological effects of space flight. Examples are the effects of acceleration or *motion sickness* that are caused by weightlessness.

spacer device

A plastic device that is used to aid the delivery of drugs from metered-dose *inhalers* as part of the treatment of *asthma* and other lung conditions. The mouthpiece of the inhaler is slotted in to one end of the spacer and the user's mouth is positioned tightly over the other end. During administration of a dose, the inhaler is compressed so that the drug enters the air in the spacer, then the user breathes in and out slow-

ly, drawing the drug particles into the lungs. A valve prevents the gas from escaping out of the spacer except during the time it is being inhaled through the mouthpiece. Spacers are particularly helpful for people who have difficulty coordinating their breathing with activating an inhaler.

spasm

An involuntary contraction of a *muscle*. Spasms are not necessarily painful. Examples of spasm include cramps (often affecting the calf muscles), *hiccups* (in which the diaphragm goes into spasm) and *tics* (which frequently affect the facial muscles).

Less commonly, a spasm may be caused by an abnormality in the central nervous system (brain and spinal cord) or a symptom of a muscle disorder. Spasms caused by disease of the nervous system include *myoclonus* and *chorea*. Other disorders that are characterized by spasm include *trigeminal neuralgia* (affecting the muscles of the face and head), *tetany* (spasm caused by a drop in blood calcium level), and *tetanus* (a serious bacterial infection). *Bronchospasm* is a contraction of muscles in the small airways of the lungs that occurs in asthma. In *vasospasm* (which is one of

the symptoms of *Raynaud's disease*) there is a tightening of the muscles in the walls of blood vessels.

spasm, clonic

A type of spasm in which the affected muscle undergoes rapid contractions and relaxations. (See also *clonus*.)

spasm, facial

See *tic*.

spasm, infantile

A severe condition that affects infants and is associated with deterioration of brain function. The spasms involve forward flexion of the head, neck, and trunk and extension or flexion of the arms and legs.

spasm, tonic

A prolonged, involuntary muscular contraction. (See also *tetany*; *tetanus*; *tonic-clonic seizure*.)

spastic diplegia

Also called spastic paraparesis, a condition in which the lower body muscles are paralysed and abnormally rigid.

spasticity

Increased rigidity in a group of *muscles*, causing stiffness and restricted move-

ment. It occurs in *Parkinson's disease*, *multiple sclerosis*, *cerebral palsy*, and *tetanus*.

spastic paralysis

Inability to move a part of the body, accompanied by rigidity of the muscles. Causes of spastic paralysis include *stroke*, *cerebral palsy*, and *multiple sclerosis*. (See also *paralysis*.)

specific gravity

The ratio of the *density* of a substance to that of water. The specific gravity of urine, for example, indicates whether the urine has a large amount of material dissolved in it (near 1.030) or whether it is almost water (near 1.010).

specific learning disability

Difficulty in one or more areas of learning in a child of average or above-average intelligence. Specific learning disabilities include *dyslexia*, in which the child cannot recognize letters, and *dyscalculia*, in which the child has a problem with mathematics.

specimen

A sample of tissue, fluids, waste products, or an infective organism taken from the body for analysis, identification, and/or diagnosis. The specimen may be prepared in a particular way for examination under a *microscope*.

SPECT

The abbreviation for single photon emission computed tomography, a type of *radionuclide scanning*.

spectacles

See *glasses*.

speculum

A device for holding open an orifice (body opening) to enable a doctor to perform an examination. For example, a speculum is used to perform a cervical smear or gynaecological swab.

speech

A system of sounds by which humans communicate. Speech involves the muscles that are used in breathing and the larynx (voicebox), tongue, palate, lips, jaw, and face.

SPEECH PRODUCTION

The production of speech sounds originates in two regions of the cerebral cortex, on each side of the *brain*, that are linked to the centre for language expression (Broca's area) in the dominant

SPEECH DEVELOPMENT IN CHILDHOOD

3 months	Period of babbling begins. The child produces strings of sounds for pleasure. Babbling is important in building sequences of muscle movements that will be used later to produce meaningful speech sounds.
9 months	The child echoes the speech of others, but words are not yet used with meaning. By listening to and copying adults, the child learns that clusters of sounds refer to specific objects, people, or situations.
12 to 18 months	The child begins to utter simple words with meaning, often accompanied by gestures. Examples include "bye-bye", "dog", "hot", and "daddy". Single words are used, with vocabulary gradually increasing from two or three words initially.
18 to 24 months	The child begins to combine concepts to form two-word sentences (e.g. "Hello John" or "That hot!"). By the age of two years, the child may be using 100 or more different words.
2 to 3 years	The child's sentences become longer (e.g. "I like cake" or "Peter hit Mary"). He or she also begins to incorporate adjectives and adverbs into sentences (e.g. "That's daddy's old coat" or "I want lunch now"). By the age of three years, the average sentence length is four words. Most sounds have developed, with the possible exceptions of "the", "r", "j", "ch", and "sh".
3 years and older	More elaborate sentences with several nouns, verbs in past and future tenses, and linked phrases begin to be used (e.g. "We went to Amy's and we had milk and biscuits" or "I think mummy went downstairs"). However, mistakes are often made (e.g. "What did you played?"), reflecting the child's linguistic immaturity. Language skills continue to develop throughout childhood.

hemisphere of the brain. The areas send signals down nerve pathways to muscles controlling the larynx, tongue, and other parts involved in speech; the cerebellum, at the back of the brain, plays a part in coordinating movements of these parts. Air from the lungs is vibrated through the vocal cords in the larynx. The vibration produces a noise that is amplified in the cavities of the throat, nose, and sinuses. The vibrated air is shaped by movements of the tongue, mouth, and lips in order to produce speech sounds.

Children learn speech by listening to and imitating the speech of others. Normal speech development occurs in several stages (see *Speech development in childhood* table, previous page). It depends on maturation of the child's nervous system and muscles, normal hearing, and the child's interaction with other people and the environment.

speech disorders

Defects or disturbances in *speech* that lead to inability to communicate effectively. Some of these disorders are more accurately described as disturbances of language rather than speech, as they are caused by impaired ability to understand or to form words in the language centres of the brain, rather than any fault of the apparatus of speech production. Most people who have speech disorders can be helped with the use of *speech therapy*.

DISORDERS OF LANGUAGE

Damage to the language centres of the brain (usually due to a *stroke*, *head injury*, or *brain tumour*) leads to *dysphasia* (difficulty with, or disorder of, language skills). Both children and adults can be affected. The ability to speak and write and/or to comprehend written or spoken words is impaired to a varying degree, depending on the site and extent of the damage.

Delayed development of language in a child is characterized by slowness to understand speech and/or slow growth in vocabulary and sentence structure. Delayed development has many causes, including hearing loss (see *deafness*), lack of stimulation, or emotional disturbance (see *developmental delay*).

DISORDERS OF ARTICULATION

Articulation is the ability to make speech sounds. A defect of articulation is sometimes referred to as *dysarthria*. Damage to nerves passing from the brain to muscles in the larynx (voicebox), mouth, or lips can make speech slurred, indistinct,

slow, or nasal. The causes of the damage are similar to those that cause aphasia or dysphasia (including stroke, head injury, *multiple sclerosis*, or *Parkinson's disease*), although they affect different regions of the brain. A structural abnormality of the mouth, such as a *cleft lip and palate*, can also be a cause of poor articulation.

DISORDERS OF VOICE PRODUCTION

Disorders of voice production include hoarseness, inappropriate pitch or loudness, and abnormal nasal resonance. In many cases, the cause is a disorder affecting closure of the vocal cords (see *larynx, disorders of*). A voice that is too high or low or too loud or soft may be caused by a hormonal or psychiatric disturbance or by hearing loss.

Abnormal nasal resonance is caused by too much air (hypernasality) or too little air (hyponasality) flowing through the nose during speech. Hypernasality may result from damage to the nerves supplying the palate (roof of the mouth) or from cleft palate, and causes deterioration in the intelligibility of speech. Hyponasality is caused by blockage of the nasal airways which may be a result of congestion or excess mucus.

DISORDERS OF FLUENCY

Disorders of fluency include *stuttering*, which is marked by hesitant speech and sound repetition. The underlying cause of such problems is not understood.

speech therapy

A form of treatment for people who suffer from a *speech disorder*. A speech therapist tests speech and *hearing* and devises exercises to improve the deficient aspect of speech.

sperm

The male sex cell, also called a spermatozoon (or spermatozoa in the plural), which is responsible for *fertilization* of the female cell (ovum). Each sperm is about 0.05 mm long and consists of a head, which contains genetic material,

Human sperm magnified 350 times

Each sperm consists of a head that contains the hereditary material (DNA) and a long, whiplike tail that propels it along.

and a tail, which propels the sperm through the woman's reproductive tract after *ejaculation*. The top of the sperm's head contains enzymes that enable it to penetrate the ovum's outer covering.

Sperm production starts at *puberty*. The sperm are formed in the seminiferous tubules of the *testes* and mature in the *epididymis*, just behind each testis. This process depends on *testosterone* and *gonadotrophin hormones* secreted by the *pituitary gland*. Oligospermia (low sperm count) or azoospermia (absence of sperm) can be causes of *infertility*. (See also *reproductive system, male*; *semen analysis*.)

spermatic cord

The structure, in males, that runs from the abdomen to the scrotum and contains the *vas deferens* (a tube that conveys *sperm*). (See also *reproductive system, male*.)

spermatocoele

A harmless cyst of the *epididymis* (the tube that conveys sperm from the testis) containing fluid and sperm. A very large or uncomfortable spermatocoele is usually removed surgically.

spermatozoa

See *sperm*.

spermicides

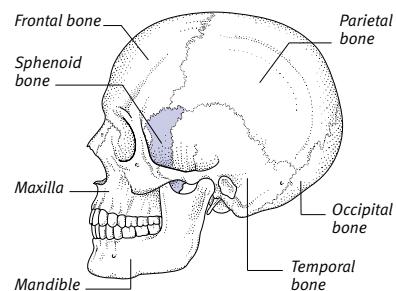

Contraceptive preparations in the form of creams, gels, foams, and pessaries that kill *sperm*. They are usually recommended for use with a barrier device such as a condom or diaphragm.

SPF

The abbreviation for *sun protection factor*.

sphenoid bone

A bone at the base of the *cranium* (the part of the skull holding the brain). It contains the sphenoidal sinuses (see

Location of the sphenoid bone

The sphenoid bone is a bat-shaped bone that lies in front of the temporal bones at the base of the skull.

sinuses, facial); channels for the *optic nerve* and other nerves; and a space for the *pituitary gland*.

spherocytosis, hereditary

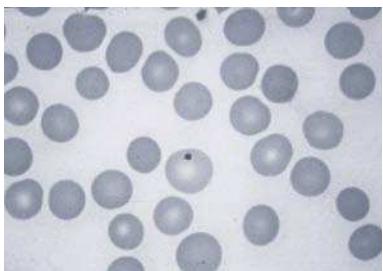

An inherited disorder in which there are a large number of unusually small, round red blood cells (spherocytes) in the circulation. These abnormal cells are fragile and easily broken up when blood passes through the *spleen*. At times, the rate of red blood cell destruction (*haemolysis*) exceeds the rate at which new cells can be made in the bone marrow, leading to *anaemia*.

SYMPOTMS

The characteristic symptoms of anaemia, such as tiredness, shortness of breath, and pallor, may develop. Other symptoms include *jaundice* (yellowing of the skin and whites of the eyes) and enlargement of the spleen. Occasionally, crises occur (usually triggered by infection) in which all of the symptoms worsen. *Gallstones* are a frequent complication of hereditary spherocytosis.

DIAGNOSIS AND TREATMENT

The diagnosis of spherocytosis is made by blood tests. *Splenectomy* (removal of the spleen) usually leads to permanent improvement.

Spherocytes in blood

A person with hereditary spherocytosis has a large number of these unusually small, round, fragile, red cells in the blood.

sphincter

A ring of muscle around a natural body opening or passage that regulates inflow or outflow, such as the anal sphincter.

sphincter, artificial

A surgically created valve or other device used to treat or prevent urinary or faecal *incontinence*.

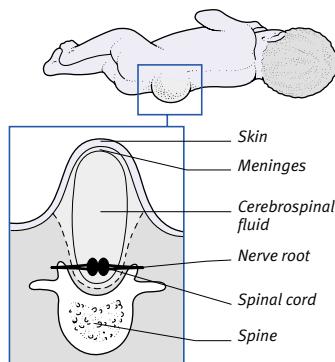

sphincterotomy

A surgical procedure that involves cutting a *sphincter* muscle that closes a body opening or constricts the opening between body passages.

TYPES OF SPINA BIFIDA

There are different forms of spina bifida. In one type (spina bifida occulta), the only defect is a failure of the fusion of the bony arches behind the spinal cord. When the bone defect is more extensive, there may be a meningocele, with protrusion of the meninges (the membranes surrounding the cord) or, more seriously, a myelomeningocele, with malformation of the spinal cord itself.

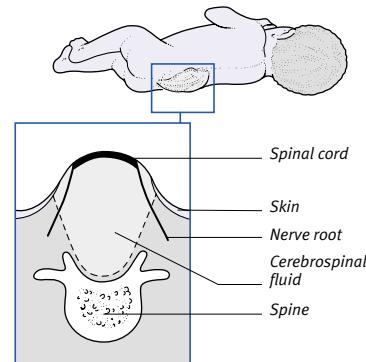

MENINGOCELE

Meningocele

In this type of spina bifida, the nerve tissue of the spinal cord is usually intact; there is skin over the bulging sac and therefore there may be no functional problems. However, repairs are necessary early in life.

MYELOCELE

Myelomeningocele

In this type of the condition, the baby is born with a raw swelling over the spine. It consists of malformed spinal cord, which may or may not be contained in a membranous sac. The child is likely to be disabled.

sphygmomanometer

An instrument for measuring *blood pressure*. A cuff attached to the device is wrapped around a person's arm and inflated until it compresses the main artery in the arm; it is then deflated while the user listens to the blood flow with a stethoscope. Depending on the device used, the blood pressure measurement may be read off a graduated, mercury-filled glass column, a graduated dial, or a digital display.

spider bites

Almost all spiders produce venom, which they use to kill their prey. Only a few species, such as the black widow in North America, are harmful to humans, however. *Antivenoms* are available as an antidote for many of the potentially fatal spider bites.

spider naevus

A red, raised pinhead-sized dot, from which a number of small blood vessels radiate. A spider naevus is formed by a dilated minor artery and its connecting capillaries. Small numbers of spider naevi are common in children and pregnant women, but larger numbers may indicate liver disease.

spina bifida

A *congenital* defect in which one or more of the *vertebrae* fails to develop completely in a fetus. As a result, when the baby is born a portion of the *spinal cord* is left exposed. Spina bifida is a type of *neural tube defect*.

spinal anaesthesia

Injection of an anaesthetic into the cerebrospinal fluid in the spinal canal to block *pain* sensations before they reach the *central nervous system*. Spinal anaesthesia is used mainly during surgical procedures on the lower abdomen and legs and in obstetrics. (See also *epidural anaesthesia*.)

spinal canal decompression

see *decompression, spinal canal*.

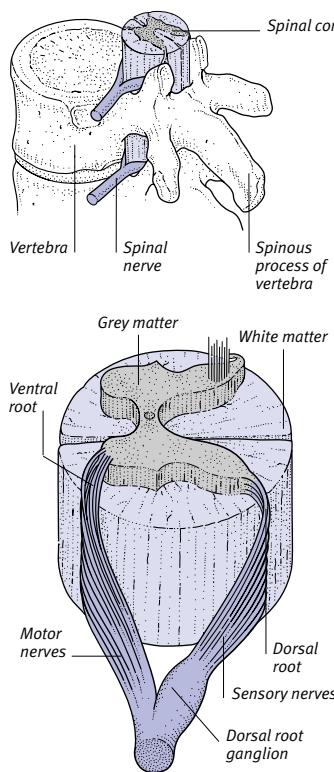

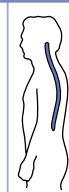

spinal cord

A cylinder of *nerve tissue*, about 45 cm long and about the width of a finger, that runs from the *brain* down the central canal in the *spine* to the first lumbar vertebra. Below that point, the lowest nerve roots continue within the canal as the *cauda equina*. The spinal cord is a major component of the *central nervous system*.

SPINAL CORD

LOCATION OF THE SPINAL CORD

The cord runs about 45 cm downwards from the brain via a canal in the spine, tapering at its lower end. It is covered by meninges, which are continuous with the covering of the brain.

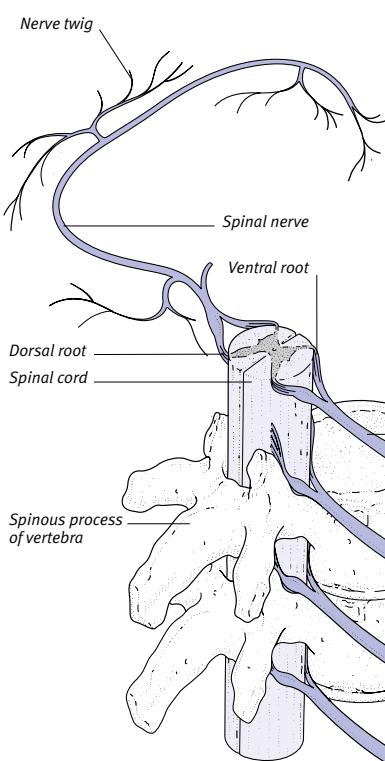

Structure of the spinal cord

The grey matter contains nerve cell bodies, whereas the white matter consists of tracts of nerve fibres. Spinal nerves join the cord at regular intervals.

S

ANATOMY OF THE SPINAL NERVES

The 31 pairs of nerves are divided into groups – cervical, thoracic, lumbar, and sacral – according to the section of spine from which they emerge. Those emerging from the middle of the spinal cord encircle the body, branching to supply a fairly distinct segment of trunk. Those emerging from the top and bottom of the spine join to form networks, called plexuses, from which branches arise to supply the arms and legs.

Brain

Cervical nerves

Thoracic nerves

Spinal cord

Lumbar nerves

Sacral nerves

Cauda equina

Distribution

The branches of each nerve divide as they travel further from the spinal cord. As a result, all parts of the trunk, arms, and legs are supplied with a network of nerve twigs.

Spinal nerve

Ventral root

Dorsal root

Spinal cord

Spinal nerve

Nerve bundle

Nerve axon

Vertebra

Intervertebral discs

Structure

Each nerve consists of bundles of the axons, or fibres, of individual nerve cells that have their cell bodies in or close to the spinal cord.

STRUCTURE

At the core of the spinal cord is grey matter, which contains the cell bodies of nerve cells, along with various supporting cells. Some of the nerve cells are motor neurons from which long projecting fibres (called axons) pass out of the spinal cord in bundles with the *spinal nerves* and extend to glands or muscles in the trunk and limbs. Surrounding the grey matter are areas of white matter, which consist of bundles of nerve cell axons running lengthwise through the cord.

Sprouting from each side at regular intervals are the sensory and motor

spinal nerve roots. These combine to form the spinal nerves, which link the cord to all areas of the trunk and limbs. The cord is bathed in *cerebrospinal fluid* and surrounded by three protective membranes known as the *meninges*.

FUNCTION

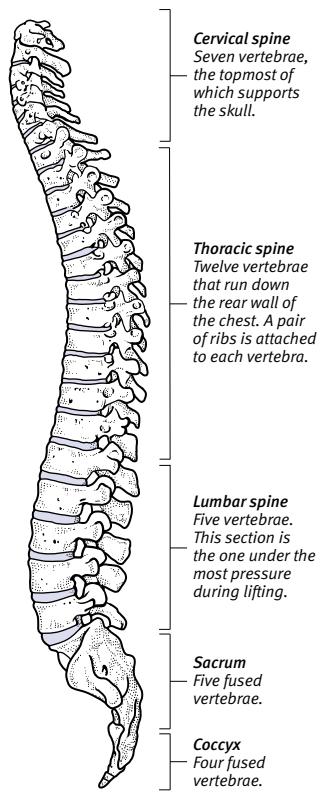

The nerve tracts in the white matter act mainly as highways for sensory information passing up to the brain or motor signals passing down; however, the cord processes some sensory information, and provides motor responses, without any involvement of the brain. Many reflex actions are controlled in this way.

DISORDERS

The spinal cord may be injured by trauma to the spine (see *spinal injury*). Severing of nerve tracts interrupts communication between the brain and the parts of the body served from the section of the cord below the injury. This can lead to various types of paralysis and/or loss of sensation, which are usually permanent because nerve cells and fibres within the cord are not able to regenerate. However, the reflexes that are controlled by the spinal cord are usually maintained. Pressure on the cord, which may be caused by a blood clot or a tumour, for example, can also

STRUCTURE OF THE SPINE

The spine is made up of a column of 33 roughly cylindrical bones called vertebrae. Running through the centre of this bony structure is the spinal cord.

affect movement and sensation but can sometimes be relieved by surgery.

Infections of the spinal cord are rare but can cause serious damage. An example of such an infection is *poliomyelitis*. In *multiple sclerosis*, a degenerative disease, there is patchy loss of the insulating sheaths around nerve fibres.

spinal fusion

Major surgery in which two or more adjacent vertebrae are joined together. It is performed if there is abnormal movement between adjacent vertebrae that causes severe back pain or risks damaging the spinal cord.

spinal injury

Damage to the spine and sometimes to the spinal cord. Spinal injury is most often the result of falling from a height or of a road traffic accident.

DISORDERS OF THE SPINE

Many disorders of the spine, despite their different causes, result in just one symptom: *back pain*.

Congenital disorders

Some children are born with a gap in the vertebrae because part of one or more vertebrae has failed to develop completely. This leaves part of the spinal cord exposed. The condition, known as *spina bifida*, may cause paralysis of the lower limbs and incontinence.

Infection

Osteomyelitis (infection of bone and bone marrow) may in rare cases affect a vertebra, destroying both bone and disc. The most common cause of osteomyelitis is the spread of an infection, such as *tuberculosis*, from elsewhere in the body.

Inflammation

In *ankylosing spondylitis*, and in some cases of *rheumatoid arthritis*, the joints in the spine become inflamed and eventually fuse, causing permanent stiffness. *Osteochondritis juvenilis* (inflammation of the growing area of bone in children and adolescents) can affect the vertebrae, when the disease may cause deformity of the spine.

Injuries

Lifting heavy objects, twisting suddenly, or adopting bad posture can cause any of the following spinal injuries: sprained ligament, torn muscle, *spondylolisthesis* (dislocated vertebrae), dislocated facet joint, or *disc prolapse* (rupture of the tough outer layer of the disc).

A direct blow, a fall from a height, or sudden twisting can result in fracture of one or more vertebrae.

Tumours

Tumours of the bones of the spine are usually malignant; in most cases, they have spread from cancer elsewhere in the body (see *bone cancer*).

Degeneration

Osteoarthritis (degeneration of joint cartilage due to wear and tear) affects the spine joints of virtually everyone over 60, particularly people who do heavy manual work or those whose spines have already been affected by disease or injury.

Osteoporosis (thinning and softening of bone), which is most common in postmenopausal women, can weaken the vertebrae. Vertebrae may fracture and collapse, under the weight of the trunk.

Other disorders

In some people, the spine is abnormally curved. Excessive curvature may be inwards in the lower back (see *lordosis*), outwards in the upper back (see *kyphosis*), or to one side (see *scoliosis*). Causes include infection, osteoporosis, and congenital and muscle disorders.

INVESTIGATION

Spinal disorders are investigated by *X-rays*, *CT scanning*, and *MRI*. Other bone imaging techniques, such as *radionuclide scanning*, may also be performed.

Damage to the vertebrae and their ligaments usually causes severe pain and swelling of the affected area. Damage to the spinal cord results in *paralysis* and/or loss of sensation below the site of injury.

X-rays and/or *MRI* or *CT scanning* of the spine are carried out to determine the extent of damage. If the bones are dislocated, surgery is needed to manipulate them back into position. Treatment with the drug *methylprednisolone* within a few hours of an injury aids recovery from spinal-cord damage. Surgery may be needed to remove pressure on the cord, but damaged nerve tracts cannot be repaired. *Physiotherapy* may stop

joints locking and muscles contracting due to paralysis.

If there is no spinal-cord damage, recovery is usually complete. In cases of spinal-cord damage, some improvement may occur for up to 12 months.

spinal nerves

A set of 31 pairs of *nerves* that connect to the spinal cord. The nerves emerge in two rows from either side of the spinal cord and leave the spine through gaps between adjacent vertebrae. They then branch out to supply all parts of the trunk, arms, and legs with sensory and motor nerve fibres.

Disc prolapse may lead to pressure on a spinal nerve, which causes pain. Nerve injury may result in loss of sensation or movement in the specific area that is supplied by the nerve.

spinal tap

See *lumbar puncture*.

spine

The column of bones and cartilage that extends from the base of the skull to the pelvis, enclosing the *spinal cord* and supporting the trunk and head.

STRUCTURE AND FUNCTION

The spine is made up of 33 roughly cylindrical bones called *vertebrae*. Each pair of adjacent vertebrae is connected by a facet *joint*, which helps both to stabilize the spine and allow movement in it. Between the vertebrae lie pads of tough fibrous cartilage with a jellylike core, called intervertebral discs (see *disc, intervertebral*). These pads act as shock-absorbers during such movements as running and jumping.

In a normal spine, the topmost section, consisting of seven vertebrae and known as the cervical spine, curves forward; the thoracic spine, made up of the 12 vertebrae at the rear of the chest, curves backwards; the lumbar (lower back) section curves forwards, particularly in women; and the pelvic section curves backwards.

The spine encloses the *spinal cord*, a column of nerve tracts running from the brain. *Spinal nerves* branch off from the spinal cord, at the nerve roots, to form the peripheral nerves (see *peripheral nervous system*), the roots of which pass between the vertebrae to supply every part of the body.

The vertebrae are bound together by two long, thick *ligaments* running the length of the spine and by smaller ligaments between the individual bones. Attached to the spine are several groups of *muscles*, which control its movement and help to support it. See *Structure of the spine* box and *Disorders of the spine* box, previous page.

spiral fracture

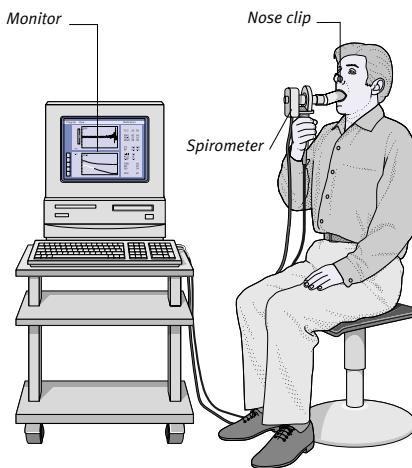

A type of *fracture* in which the bone is broken by severe twisting.

spirochaete

Any of a group of spiral-shaped bacteria that cause various infections, including *syphilis, leptospirosis, relapsing fever*, and *Lyme disease*.

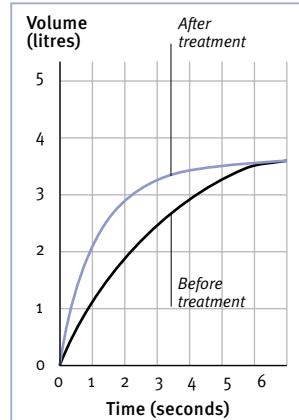

SPIROMETRY

A spirometer is used to measure the volume of air (in litres) that you can inhale and exhale over a period of time. The results of spirometry show whether or not the airways are narrowed as a result of lung disorders such as asthma. The procedure can also be used to monitor the effectiveness of certain treatments for lung disorders, such as bronchodilator drugs, which widen the airways.

Using the spirometer

The patient is asked to inhale and exhale fully through a mouthpiece several times. The volume of air inhaled and exhaled is displayed on the monitor.

Spirometry graph

This graph shows the effect of drug treatment to widen the air passages in a person with asthma. The volume of air that is exhaled in 1 second rises from about 1 litre to 2 litres soon after the drugs have been taken.

helps to fight infection by producing some of the *antibodies* (proteins) and *lymphocytes* and *phagocytes* (types of white blood cell) that destroy invading microorganisms.

The spleen enlarges in many diseases, including infections such as *malaria* and *infectious mononucleosis*; blood disorders such as *leukaemia, thalassaemia*, and *sickle cell anaemia*; and tumours such as *lymphomas*. Enlargement may be accompanied by *hypersplenism* (over-activity of the spleen). The organ may be ruptured by a severe blow to the abdomen; this may cause potentially fatal haemorrhage, needing an emergency *splenectomy* (removal of the spleen).

splenectomy

Surgical removal of the *spleen*. Splenectomy is performed after the spleen has been seriously injured, or to treat *hypersplenism* or certain forms of *anaemia*. The absence of the spleen does not normally cause any problems because its function is largely taken over by other parts of the *lymphatic system* and the *liver*. People who have had a splenectomy are more susceptible to certain infections

and are given pneumococcal, meningococcal, Hib, and influenza vaccines and long-term *antibiotics*.

splint

A device used to immobilize a part of the body. Splints are usually made of firm or rigid material and sometimes they are padded. An uninjured part of a person's own body may also be used as a "splint".

splinter haemorrhage

Bleeding under the fingernails, visible as tiny, splinter-like marks. Although splinter haemorrhage is usually due to trauma, it can also be a sign of infective *endocarditis*.

splinting

The application of a *splint*, most often used to immobilize a fractured or otherwise injured limb or digit.

splinting, dental

The mechanical joining of several teeth to hold them in place while an injury heals or while *periodontal disease* is treated.

split personality

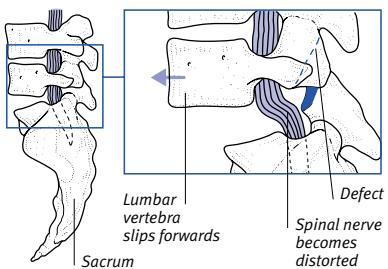

A common term for *multiple personality*. It is also used, incorrectly, to describe *schizophrenia*.

spondylitis

Inflammation of the joints between the vertebrae in the *spine*. Spondylitis is usually caused by *osteoarthritis*, *rheumatoid arthritis*, or *ankylosing spondylitis*.

spondylolisthesis

The slipping of a *vertebra* over the one below it. In most cases, the fifth (lowest) lumbar vertebra slips; in other cases, it is the fourth lumbar vertebra or a cervical (neck) vertebra. The displaced bone may press on nearby spinal nerves.

Normal spine

Lumbar spondylolisthesis

If the lowest lumbar vertebra slips forwards over the sacrum, it may distort or press on a spinal nerve, causing symptoms such as backache or sciatica.

Lumbar spondylolisthesis may be due to bone weakness caused by *spondylosis* or *osteoarthritis*, and may result in *back pain* and *sciatica*. Cervical spondylolisthesis may be due to neck injury, spinal abnormality, or *rheumatoid arthritis*; it leads to neck pain and stiffness and, in severe cases, pain, numbness, and weakness in the hands or arms.

Treatment may include *traction*, immobilizing the area in a plaster corset or with an orthopaedic collar, and *physiotherapy*. If there is nerve damage or severe back pain, *spinal fusion* may be needed to fuse the affected vertebrae.

spondylolysis

A disorder of the *spine* in which the arch of the fifth (or, rarely, the fourth) lumbar vertebra consists of soft fibrous tissue instead of normal bone. As a result, the arch is weak and prone to damage under stress, which may produce *spondylolisthesis*. Otherwise, the condition is usually symptomless.

spongiform encephalopathy

A brain disorder in which the brain tissue shrinks and spaces develop in it, which produces severe signs such as paralysis and dementia. (See also *Creutzfeldt-Jakob disease*; *encephalopathy*; *kuru*; *slow virus diseases*.)

spontaneous abortion

See *miscarriage*.

spontaneous remission

A situation in which the signs and symptoms of a disease lessen or disappear temporarily (see *remission*) for no known reason.

sporotrichosis

A chronic infection caused by the fungus *SPOROTrix SCHENCKII*, which grows on plants. The infection is most often contracted through a skin wound; gardeners are particularly vulnerable. An ulcer develops at the site of the wound; nodules then form in lymph channels around the site. Potassium iodide solution taken orally usually clears up the infection. Rarely, in people with reduced immunity, sporotrichosis spreads to other parts of the body and requires treatment with amphotericin, an *antifungal drug*.

sports, drugs and

The use of drugs to improve athletic performance has been universally condemned by authorities because it both

endangers the health of users and gives them an unfair advantage. Random tests on urine and other body fluids to detect abuse are performed in most sports, especially during competitions.

PROHIBITED DRUGS

Various classes of drugs are prohibited in international sports and their use may lead to an athlete being banned from competitions. The main types include the following:

Stimulants Drugs included in this group prevent fatigue and increase confidence. However, they also impair judgement and may cause excessive aggression.

Stimulants such as *amphetamines* carry the risk of causing cardiac *arrhythmias* (irregularities of heartbeat); prolonged use may cause *heart failure* (reducing pumping efficiency) and increase the risk of a *brain haemorrhage*.

Caffeine in coffee, tea, and some soft drinks, and also as tablets, is a popular stimulant. Most sports authorities prohibit its use only in high doses.

Hormones Types of hormone drugs that may be abused include anabolic steroids (see *steroids, anabolic*) to speed muscle recovery after exercise, and to increase muscle strength; erythropoietin to boost the blood's *haemoglobin* content, which may increase stamina; and *growth hormone* to stimulate muscle growth.

Risks of abusing anabolic steroids include liver damage and liver tumours. In men, these drugs can cause infertility and impotence; in women, *virilization*. If taken in childhood, anabolic steroids can cause *short stature* by affecting the growing areas of bones.

The main side effect of erythropoietin, a hormone also produced by the kidneys, is raised blood pressure. Growth hormone may cause excessive bone growth (see *acromegaly*) and *diabetes mellitus*.

Other drugs *Analgesic drugs* may be used to mask the pain of an injury and are prohibited if they contain *opioids*. *Beta-blockers* are taken to reduce tremor in sports that require a steady hand. *Diuretic drugs* may be used for quick weight loss and to dilute urine, making prohibited substances more difficult to detect. Many authorities now prohibit these drugs unless there is proof of a medical condition requiring their use.

sports injuries

Any injury that arises during participation in sports. Typical sports injuries include *fractures*, *head injury* (including *concussion*), *muscle strain* or *compartment*

syndrome, tendinitis or tendon rupture, *ligament sprain*, and joint *dislocation* or *subluxation*. Some 'sports' injuries, such as *tennis elbow*, are in fact a type of *overuse injury*. (See also *running injuries*.)

sports medicine

A medical speciality concerned with the assessment and improvement of *fitness* and the treatment and prevention of injuries and disorders related to sports.

spot

A general term for a small lump, mark, or inflamed area on the skin.

spotting

See *breakthrough bleeding*.

sprain

Tearing or stretching, due to a sudden pull, of the *ligaments* that hold the bone ends together in a joint. The *ankle* is the most commonly sprained joint. A sprain causes painful swelling, and the joint cannot be moved without increasing the pain. There may also be spasm of surrounding muscles.

Treatment consists of applying an *ice-pack*, wrapping the joint in a bandage, resting it in a raised position, and taking *analgesic drugs*. In severe cases, surgical repair may be necessary.

sprue

An intestinal disorder that prevents the small intestine absorbing sufficient nutrients from food. There are two forms: *tropical sprue* (see *sprue, tropical*), and *coeliac disease*, which is more common and is caused by sensitivity to gluten.

sprue, tropical

A disease of the small intestine that interferes with the absorption of nutrients from food. Occurring mainly in India, the Far East, and the Caribbean, sprue may be due to an intestinal infection. Symptoms include loss of appetite and weight, an inflamed mouth, and fatty diarrhoea. Sprue leads to *malnutrition* and megaloblastic *anaemia*.

Diagnosis is confirmed by *jejunal biopsy* (taking a tissue sample from the small intestine). The condition responds well to *antibiotic drug* treatment and vitamin and mineral supplements.

sputum

Also called phlegm, mucous fluid that is produced by cells lining the airways in the lungs. Sputum production may be

increased by *respiratory tract infection*, an allergic reaction, or inhalation of irritants.

squamous cell carcinoma

Also known as SCC, a cancer that arises in epithelial cells, which line most hollow structures within the body and cover the body's surface. SCC can occur in many body organs, including the mouth (see *mouth cancer*) and lungs (see *lung cancer*). SCC of the skin is one of the most common types of *skin cancer* and is linked to long-term exposure to sunlight; it is most common in fair-skinned people over 60.

SCC of the skin starts as a small, painless lump or patch, usually on the lip, ear, or back of the hand. It enlarges fairly rapidly, often resembling a wart or ulcer. It can also arise from a preexisting solar keratosis (a patch of rough or thickened skin). Left untreated, the cancer may spread to other parts of the body and prove fatal.

Diagnosis is based on a *skin biopsy*. The tumour is removed surgically or destroyed by *radiotherapy*. (See also *basal cell carcinoma*; *melanoma*, *malignant*.)

Squint

This child has a convergent squint of the left eye (right in image), in which the eye is directed too far inwards, towards the nose. Left untreated, a squint can lead to permanent loss of sight in one eye.

In adults, squint may be a symptom of *stroke*, *diabetes mellitus*, *multiple sclerosis*, *hyperthyroidism*, or a tumour. A squint in adults causes double vision.

Treatment in children up to six to seven years may include covering the normal eye with a patch, which forces the child to use the weak eye. Deviation of the squinting eye may be controlled by glasses and/or surgery. The sudden onset of a squint in adults may have a serious underlying cause and must be investigated promptly.

SSRIs

See *selective serotonin reuptake inhibitors*.

stable

A term used in medicine to describe a patient's condition that is neither deteriorating nor improving; a personality that is not susceptible to mental illness; or a chemical substance that is resistant to changes in its composition or physical state, or is not radioactive.

stage

A term that is used in medicine to describe a phase in the course of a disease; it is used particularly to describe the progression of *cancer*. Staging is a method of assessing cancer according to the size of the main tumour, the degree to which it has invaded surrounding tissues, and the extent to which it has spread to other parts of the body. Treatment and outlook of diseases depend on the stage, hence the importance of staging investigations.

staghorn calculus

A large kidney stone, with several branches, that forms in the renal pelvis (the central area of the kidney, where urine collects before leaving the organ). (See *calculus, urinary tract*.)

Squamous cell carcinoma

The tumour has spread to cover much of the area around the side of this patient's nose. It can be treated with radiotherapy. Squamous cell carcinoma is the second most common form of cancer.

squint

Known medically as strabismus, a deviation of one eye in relation to the other. A squint can be either convergent (in which case the eye turns inwards) or divergent (in which case it turns outwards).

Many babies have a squint because the mechanism for aligning the eyes has not yet developed. A squint that starts later in childhood is usually due to breakdown of the alignment mechanism; longsightedness is a common contributory factor. In some cases, there is an additional problem in that the brain suppresses the image from the deviating eye, leading to *amblyopia* (reduced sharpness of vision).

staining

The process of dyeing specimens of cells, tissues, or microorganisms to make them clearly visible or easily identifiable under a *microscope*.

stammering

See *stuttering*.

Stanford–Binet test

A type of *intelligence test*.

stanazolol

A type of anabolic steroid drug (see *steroids, anabolic*).

stapedectomy

An operation on the *ear* to replace the *stapes* (the innermost of the three sound-conducting bones in the middle ear) with a device that takes over the bone's function. It is used to treat *deafness* due to *otosclerosis*.

stapes

The innermost of the three tiny, sound-conducting bones in the middle *ear*. The stapes is the smallest bone in the body. Its head articulates with the *incus* and its base fits into the oval window in the wall of the inner ear.

In *otosclerosis*, the stapes becomes fixed and cannot transmit sound to the inner ear. The resultant hearing loss can be treated by *stapedectomy*.

staphylococcal infections

Infections caused by *bacteria* of the genus *STAPHYLOCOCCUS*. Different species of staphylococci are responsible for a range of disorders, including skin infections such as *pustules*, *abscesses*, and *boils*, and a rash in newborn babies (see *necrolysis, toxic epidermal*); *pneumonia*; *toxic shock syndrome* in menstruating women; *urinary tract infection*; and *food poisoning*. If the bacteria enter the circulation, they may cause *septicaemia* or *septic shock*, infectious *arthritis*, *osteomyelitis*, or bacterial *endocarditis*.

Staphylococcus aureus

A species of *STAPHYLOCOCCUS* bacterium that produces toxins, causing a range of *staphylococcal infections*.

stapling

A surgical procedure to treat severe *obesity*, in which the *stomach* is partitioned using surgical staples, to leave only a small volume for digestion and food storage. Staples are also used for *suturing*.

starch

See *carbohydrates*.

startle reflex

A reflex action seen in newborn babies that is similar to the *Moro reflex*.

starvation

A condition that results from lack of food over a long period and results in weight loss, changes in *metabolism* (the body's chemical processes) and extreme hunger. (See also *anorexia nervosa; fasting; nutritional disorders*.)

stasis

Slowing down or cessation of flow.

stasis ulcer

An open sore that develops on the lower leg (see *leg ulcer*) as a result of poor blood flow in that area.

statins

A type of *lipid-lowering drug* used to treat high blood levels of *cholesterol*, or to lower blood lipid (fat) levels in people with *coronary artery disease*.

statistics, medical

The collection and analysis of numerical data that relates to medicine. Information on the *incidence* and *prevalence* of various conditions is an important aspect of medical statistics.

statistics, vital

Assessment of the health of a country's population, which relies on the collection of data on birth and death rates and on causes of death.

status asthmaticus

A severe and prolonged *asthma* attack. This condition is potentially life-threatening and needs urgent treatment.

status epilepticus

Prolonged or repeated epileptic seizures in which there is no recovery of consciousness between the attacks. Status epilepticus is a medical emergency, which may be fatal if it is not treated promptly. It is more likely to occur in people with epilepsy if *anticonvulsant drugs* are taken erratically or are withdrawn suddenly. (See also *epilepsy*.)

STDs

The abbreviation for sexually transmitted diseases; another name for *sexually transmitted infections*.

steal syndrome, subclavian

See *subclavian steal syndrome*.

steam inhalation

A method of relieving some of the symptoms of colds, sinusitis, and laryngitis by breathing in vapour from a bowl of hot water. The moisture loosens secretions in the nose and throat, making them easier to clear.

steatorrhoea

The presence of excessive fat in the faeces. Steatorrhoea causes bulky, loose, pale-coloured, greasy, and offensive-smelling faeces that float in the toilet. Steatorrhoea may occur in *pancreatitis* and *coeliac disease* (which interfere with the breakdown of fat from food) and after the removal of substantial segments of small intestine. It is also a side effect of some *lipid-lowering drugs*.

Stein–Leventhal syndrome

See *ovary, polycystic*.

stem cell

A basic cell in the body from which more specialized cells are formed. Stem cells in the *bone marrow* produce *blood cells*. The cells are also found in blood and in a baby's umbilical cord.

Stem cells can be transplanted as an alternative to *bone marrow transplantation*. This procedure is used mainly for people being treated for leukaemia and other cancers but may, in the future, be used for noncancerous disorders. Cells may be taken from a donor sibling, a matched but unrelated donor, or from stored umbilical blood. Patients can also act as their own donors: they may have their stem cells harvested and stored, to be reinfused later after treatment has damaged the bone marrow.

stenosis

Narrowing of a duct, canal, passage, or tubular organ.

stenosis, pyloric

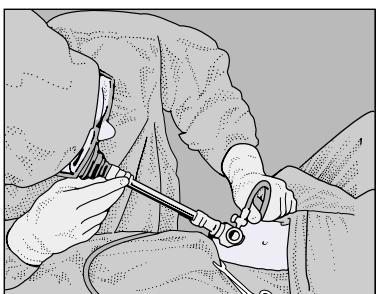

See *pyloric stenosis*.

stent

A rigid metal or plastic tube that is surgically inserted to open up, or keep open, a body canal that has become narrowed or closed due to disease. Stents are used to open narrowed *coronary arteries* or to relieve a blockage caused by a tumour (in the bile duct, for a tumour of the *pancreas*, for example).

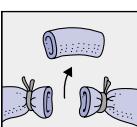

FEMALE STERILIZATION

Laparoscopic sterilization (below) is the most common method. Both fallopian tubes must be cut, sealed, or obstructed so that eggs and sperm cannot meet for fertilization. Sterilization is usually permanent.

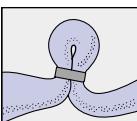

Laparoscopic sterilization

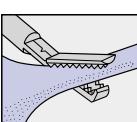

An endoscope (viewing tube) and an operating instrument are passed through separate small incisions in the abdomen.

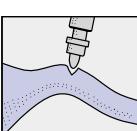

Cutting
A small loop of the fallopian tube may be drawn up, secured by a tight ligature, and then cut off.

Constriction
A loop of the fallopian tube may be constricted at the base by a tight band, preventing eggs from passing through.

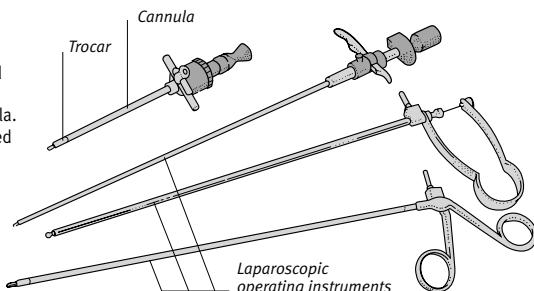

Clipping
A plastic or metal clip may be applied to the fallopian tube, sealing it so that eggs cannot pass through.

Cautery
Electrocoagulation (diathermy) can be used to burn through, and thus seal, the fallopian tube.

Instruments

The trocar is a sharp-pointed inner stylus surrounded by a close-fitting tube, the cannula. The instrument can be passed through the abdominal wall. After insertion, the trocar is removed, leaving the hollow cannula in place. Other instruments are passed through the hollow cannula.

sterculia

A bulk-forming *laxative* that is used to treat constipation. Sterculia is especially useful when stools are small and hard. However, it should only be used if fibre intake cannot be increased. During the use of sterculia, adequate fluid intake must be maintained to avoid intestinal obstruction. Side effects may include flatulence, bloating, and gastrointestinal obstruction or impaction.

stereotaxic surgery

Brain operations that are carried out by the insertion of delicate instruments through a surgically created hole in the skull and guiding them, with the aid of *CT scanning*, to a specific area. Stereotaxic procedures can be used to treat *pituitary tumours*; for a *brain biopsy*; or to destroy small areas of the brain as treatment for some disabling neurological disorders.

usually performed by *laparoscopy*, a procedure that involves two small incisions in the abdomen. Sometimes it is performed by *minilaparotomy*, in which a single incision is made in the pubic area. The fallopian tubes are sealed using clips or by cutting and tying. The operations have a low failure rate. Although sterilization is usually permanent, fertility can sometimes be restored using *microsurgery*.

sterilization, male

See *vasectomy*.

sterilizer

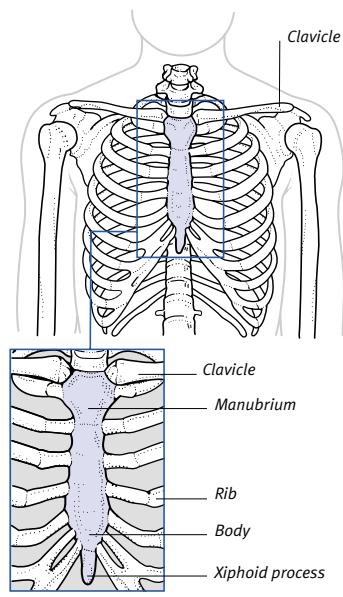

A piece of apparatus that is used to make medical equipment *sterile*. (See also *autoclave*.)

sternum

The long, narrow, flat plate of bone at the front of the chest. The sternum consists of the manubrium (uppermost part); the body (long middle part); and the xiphoid process, or xiphisternum (a small, leaf-shaped projection). The top of the sternum articulates with the inner ends of the *clavicles* (collarbones).

LOCATION OF THE STERNUM

The sternum, or breastbone, is joined to the ribs and clavicles by flexible couplings that allow the chest to move while breathing in and out.

sterile abscess

An *abscess* in which the contents are not pyogenic (pus-forming) and they do not grow bacteria when cultured (see *culture*).

sterility

The state either of being germ-free or of permanent *infertility*.

sterilization

Complete destruction or removal of living microorganisms, which is usually carried out to prevent the spread of infection. The term also refers to a procedure that renders a person infertile. (See also *sterilization, female*; *vasectomy*.)

sterilization, female

A usually permanent method of *contraception* in which the fallopian tubes are sealed in order to prevent sperm from reaching the ova. Female sterilization is

The ribs are attached to the sides by cartilage. Between the manubrium and the body is a *symphysis* that joins the two parts firmly but allows the sternum to move slightly during breathing.

Great force is required to fracture the sternum, the main danger of which is the possibility of the broken bone being driven inwards, damaging the heart, which lies behind the sternum.

steroid

A term used to describe either a naturally occurring hormone or a steroid drug. Steroid hormones include the *sex hormones* and hormones produced by the adrenal glands (see *corticosteroid hormones*). Steroid drugs include *corticosteroid drugs* and anabolic steroids (see *steroids, anabolic*).

steroids, anabolic

COMMON DRUG

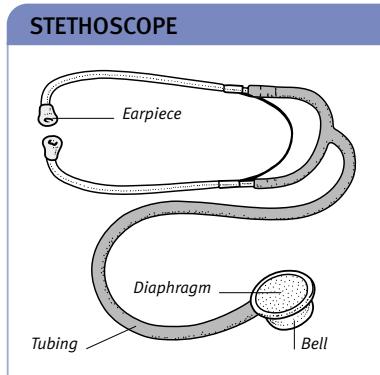

• Nandrolone

Drugs that have an anabolic (protein-building) effect similar to *testosterone*. Anabolic steroids build tissue, promote muscle recovery after an injury, and strengthen bones. They are used medically to treat some types of *anaemia*. The drugs may, however, be abused by athletes (see *sports, drugs in*).

Possible adverse effects of anabolic steroids include acne, *oedema*, liver damage, *infertility*, *impotence* in men, and *virilization* in women.

stethoscope

An instrument used for listening to sounds within the body, particularly those made by the heart or lungs (see *auscultation*). A stethoscope has ear pieces; a diaphragm, which picks up high-pitched sounds; and a bell-shaped piece, which picks up low sounds.

Stevens–Johnson syndrome

A rare, life-threatening type of *erythema multiforme* that is characterized by severe blistering and sometimes bleeding in the mucous membranes of the eyes, mouth, nose, and genitals.

sticky eye

A sign of the eye condition *conjunctivitis* in which the eyelids become stuck together with discharge.

stiff neck

A common symptom, which is usually due to muscle spasm at the side or back of the neck. In most cases, it occurs suddenly and for no apparent reason. It may result from a neck injury, such as a ligament sprain, *disc prolapse*, or *whiplash injury*. A rare cause of stiff neck is *meningitis*.

Mild stiffness may be relieved by massage, warming, and use of a *liniment*. Severe or persistent stiffness requires medical attention. (See also *torticollis*.)

stiffness

A term for difficulty in moving a joint or stretching a muscle. Morning joint stiffness is characteristic of conditions such as *rheumatoid arthritis*. In degenerative conditions, such as *osteoarthritis*, pain and stiffness may be worse at the end of the day. *Cramp* and *spasticity* (muscle rigidity) may cause stiffness.

stilbestrol

See *diethylstilbestrol*.

stillbirth

Delivery of a dead fetus after the 24th week of *pregnancy*.

CAUSES

The cause of stillbirth is often unknown. Some stillborn babies have severe malformations, such as *anencephaly*, *spina bifida*, or *hydrocephalus*. Other possible causes include a maternal disorder that damages the placenta (the organ supplying nutrients to the baby), such as *antepartum haemorrhage* or *hypertension*; *diabetes*; *kidney disease*; or severe *Rhesus incompatibility* (in which *antibodies* from the mother attack the baby's red blood cells).

Infectious diseases such as *rubella*, *chickenpox*, *influenza*, *toxoplasmosis*, *cytomegalovirus*, and *herpes simplex*) may harm the fetus if contracted during pregnancy, increasing the risk of stillbirth.

PSYCHOLOGICAL EFFECTS

After a stillbirth, the parents usually experience a sense of loss as intense as

if any other loved one had died. Often, they experience feelings of depression, guilt, anger, and inadequacy. Emotional support from friends, relatives, and self-help groups is useful; some people are helped by professional counselling.

Still's disease

See *juvenile chronic arthritis*.

stimulant drugs

COMMON DRUGS

CENTRAL NERVOUS SYSTEM STIMULANTS • Caffeine

• Dexamphetamine • Methylphenidate

RESPIRATORY STIMULANTS • Doxapram

Drugs that increase *brain* activity by initiating the release of *noradrenaline* (norepinephrine). There are two types of stimulant drug: central nervous system stimulants (such as *amphetamines*), which are used in the treatment of *narcolepsy* and *ADHD*; and respiratory stimulants (see *anaesthetic drugs*), which encourage breathing.

stimulus

Anything that causes a direct response in the entire body or any individual part of the body.

stings

Sharp structures, on plants or animals, that discharge venom or irritants. Stinging animals include scorpions, some insects, jellyfish, and some fish (see *venomous bites and stings*). Stinging plants may cause an allergic skin reaction. (See also *poisonous plants*.)

STIs

See *sexually transmitted infections*.

stitch

A temporary, sudden, sharp pain in the abdomen or side that occurs during severe or unaccustomed exercise. A stitch is also the common name for a suture (see *suturing*) to close a wound.

St John's wort

A herbal remedy that is derived from the plant *HYPERICUM PERFORATUM*. Tablets, capsules, or infusions taken orally are effective in treating mild depression. St John's wort is also used in creams for burns, wounds, and joint problems. It interacts with a wide variety of other medications, however, so St John's wort preparations should not be used unless a doctor or pharmacist has been consulted beforehand.

stockinette

A soft, elasticated fabric used for items such as bandages.

Stokes–Adams attacks

Recurrent episodes of temporary loss of consciousness due to insufficient blood flow from the heart to the brain. Stokes–Adams attacks are caused by an irregular heartbeat (see *arrhythmia, cardiac*), which prevents the heart from pumping properly, or by complete *heart block*, which causes the heart to stop briefly. Most affected people are fitted with a *pacemaker* to prevent attacks.

stoma

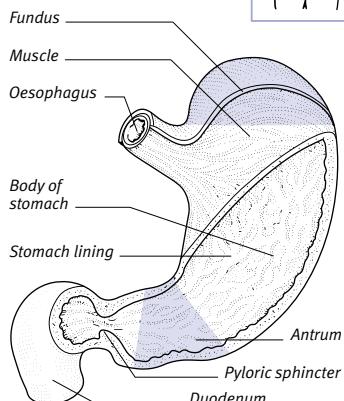

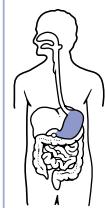

A term with the literal meaning mouth or orifice. A common use of the term is to describe the stoma that can be created surgically in the abdominal wall (see *colostomy; ileostomy*) to allow the intestine to empty into a bag or pouch on the surface of the skin.

stomach

A hollow, baglike organ of the *digestive system* located in the left side of the abdomen under the diaphragm. At its upper end, the stomach is connected to

ANATOMY OF THE STOMACH

Food enters the stomach from the oesophagus and exits into the duodenum. The stomach lining secretes gastric juice and protective mucus.

**Parts of the stomach**

The fundus, the body of the stomach, and the antrum are the three main parts; the lower oesophageal segment and pyloric sphincters control entry and exit of food.

the *oesophagus* (gullet), and at the lower end it joins the *duodenum* (the first part of the small intestine).

STRUCTURE

The stomach is flexible and in the average adult can expand to hold around 1.5 litres of food. Its wall consists of layers of

longitudinal and circular muscle, lined by special glandular cells that secrete gastric juice, and supplied by blood vessels and nerves. A strong muscle at the lower end of the stomach forms a ring called the *pyloric sphincter* that can close the outlet leading to the duodenum.

DISORDERS OF THE STOMACH

Disorders of the stomach have a variety of causes. Because the stomach is a reservoir, disorders of the emptying of stomach contents occur. Other problems relate to the stomach's role in the preparation of ingested food for digestion.

Infection

The large amount of hydrochloric acid secreted by the stomach protects it from some infections by destroying many of the bacteria, viruses, and fungi that are taken in with food and drink. When the protective power is insufficient, a variety of gastrointestinal infections may occur.

Tumours

Stomach cancer is one of the commonest forms of cancer. Early symptoms are often mistaken for *indigestion*, and diagnosis is often delayed until it is too late for a cure. Any change in the customary functioning of the digestive system is important, especially after the age of 50. A persistent feeling of fullness, or pain before or after meals, should never be ignored. Unexplained loss of appetite or frequent nausea should always be reported to a doctor. A tumour in the upper part of the stomach, near the opening of the oesophagus, can cause obstruction and difficulty in swallowing. Sometimes a stomach tumour remains "silent" and the first signs are due to the appearance of secondary growths elsewhere in the body.

Benign (noncancerous) *polyps* can also develop in the stomach.

Ulceration

The acid and other digestive juices secreted by the stomach sometimes attack the stomach lining. The healthy stomach is prevented from digesting itself mainly by the protective layer of mucus secreted by the lining and by the speed with which damaged surface cells are replaced by the deeper layers. Many influences can upset this delicate balance. One of the most important is

excessive acid secretion. The resulting *peptic ulcers* are probably the most common serious stomach disorder. Peptic ulcers are most often caused by *HELICOBACTER PYLORI* infection, but are sometimes caused by stress, severe injury such as major burns, or after surgery and serious infections; often they occur for no apparent reason. The stomach lining can be damaged by large amounts of aspirin or alcohol, sometimes causing *gastritis* (inflammation of the stomach lining). This may eventually lead to ulceration.

Autoimmune disorders

Pernicious anaemia (see *anaemia, pernicious*) is caused by the failure of the stomach lining to produce intrinsic factor, a substance that facilitates the absorption of vitamin B₁₂ (necessary for red blood cell formation). Failure to produce intrinsic factor occurs if there is atrophy of the stomach lining, which also causes failure of acid production. Tests that determine a person's ability to absorb vitamin B₁₂ are important in the investigation of this condition. Pernicious anaemia is usually due to an *autoimmune disorder*.

Other disorders

Enlargement of the stomach may be caused when scarring from a chronic peptic ulcer occurs at the stomach outlet. It may also be a complication of *pyloric stenosis*, a rare but serious condition in which there is narrowing of the stomach outlet. Rarely, the stomach may become twisted and obstructed, a condition called *volvulus*.

INVESTIGATION

Stomach disorders are investigated primarily by *barium X-ray examinations* and/or *gastroscopy*. Occasionally, a *biopsy* (removal of a tissue sample for microscopic analysis) is performed.

FUNCTION

The main function of the stomach is to contribute to the breakdown of food that is started in the mouth and completed in the small intestine. However, it also acts as a storage organ; if storage were not possible, food would have to be eaten about every 20 minutes.

The sight and smell of food, and its arrival in the stomach, stimulate the stomach lining to secrete gastric juice. This fluid contains pepsin, an enzyme that breaks down protein; hydrochloric acid, which kills bacteria and creates the optimum pH for pepsin activity; and intrinsic factor, which is essential for absorption of vitamin B₁₂ in the small intestine. The lining also secretes mucus to stop the stomach from digesting itself.

The layers of muscle in the stomach wall produce rhythmic contractions about every 20 seconds that churn the food and gastric juice. This process converts semi-solid food into a creamy fluid (chyme). At regular intervals, the stomach muscles contract, as the pyloric sphincter relaxes, propelling partly digested food into the duodenum.

stomachache

Discomfort in the upper abdomen. (See also *indigestion*.)

stomach cancer

A malignant tumour that arises from the lining of the *stomach*. The exact cause is unknown, but *HELICOBACTER PYLORI* infection is linked to increased risk. Other likely factors include smoking and drinking alcohol. Diet may also play a part, particularly eating large amounts of salted or pickled foods. Pernicious *anaemia*, partial *gastrectomy*, and belonging to blood group A also seem to increase the risk. Stomach cancer rarely affects people under 40 and is more common in men, especially Japanese men. Symptoms may start with loss of appetite and weight loss; they may also be indistinguishable from those of *peptic ulcer* and may include burning abdominal pain, nausea, and vomiting.

Diagnosis is usually made by *gastroscopy* and *biopsy*, or by *barium X-ray examination*. Partial gastrectomy may be performed if the tumour is detected early; otherwise, the only effective treatment is *gastrectomy* (removal of the stomach). In advanced cases, in which the tumour has spread, *radiotherapy* and *anticancer drugs* may prolong life.

stomach imaging

See *barium X-ray examinations*.

stomach pump

See *lavage, gastric*.

stomach ulcer

Also called a *gastric ulcer*, a type of *peptic ulcer*.

stomatitis

Any type of inflammation or ulceration of the mouth.

stones

Small, hard collections of solid material within the body. (See also *calculus, urinary tract; gallstones*.)

stool

Another word for *faeces*; in particular, a quantity of faeces passed in one bowel movement.

stork mark

A harmless small, flat, pinkish-red, skin blemish found in many newborn babies, usually around the eyes or at the nape of the neck. Stork marks, a type of *haemangioma*, may be only temporary.

strabismus

A medical term for a *squint*.

straight leg raising

A neurological test carried out during investigation of lower-back or leg pain. With the patient lying down, the leg is fully extended and slowly raised by the examiner, who aims to reach a 90° angle from the horizontal. The patient's reactions will be noted at each degree of elevation. The limit of the test is reached, and the angle noted, when pain is felt or the pelvis moves.

strain

Tearing or stretching of *muscle* fibres as a result of suddenly pulling them too far. There is bleeding into the damaged area of muscle, causing pain, swelling, muscle spasm, and bruising.

Treatment may include resting the affected part (in a raised position if possible) and applying an *ice-pack* to reduce pain and swelling; taking *analgesic drugs*; and *physiotherapy*. (See also *sprain*.)

strangulation

Constriction (usually by twisting or compression) of a tube or passage in the body, blocking blood flow and

interfering with the function of the affected organ. Strangulation may occur with a *hernia*, for example.

Strangulation of the neck is a life-threatening accidental or deliberate injury involving compression of the *jugular veins*, preventing blood from flowing out of the brain, and compression of the windpipe, which restricts breathing. The victim loses consciousness; brain damage and death caused by lack of oxygen follow.

strangury

A painful and frequent urge to empty the bladder, although only a few drops of urine can be passed. Causes include inflammation (see *cystitis; prostatitis*), bladder stones (see *calculus, urinary tract*), and bladder cancer (see *bladder tumours*).

strapping

The application of adhesive tape to part of the body to exert pressure and thus reduce pain and swelling, or to support a weakened area.

strawberry naevus

A bright red, raised spot appearing in early infancy. Strawberry naevi are a type of *haemangioma*. Treatment is not usually needed unless they occur near the eye, where they might interfere with visual development.

strawberry tongue

A white coating with red spots that develops on the tongue in a person with *scarlet fever*.

strep throat

A *streptococcal infection* of the *throat* that is most common in children. The bacteria are spread in droplets coughed or breathed into the air.

In some people, the bacteria cause no symptoms. In others, sore throat, fever, and enlarged lymph nodes in the neck occur. In some cases, the bacterial toxins produce a rash (see *scarlet fever*).

Treatment is usually with a *penicillin drug*. Untreated, strep throat may lead to *glomerulonephritis* (inflammation in the kidneys) or *rheumatic fever*.

streptococcal infections

Infections caused by *bacteria* of the *STREPTOCOCCUS* genus. Streptococci are spherical bacteria that grow in lines, like beads on a string. They are among the most common disease-causing bacteria in humans.

Certain types of streptococci are present harmlessly in the mouth and throat of most people. If the bacteria enter the bloodstream (which may happen after dental treatment), they are usually destroyed. However, in some people with heart-valve defects, bacteria can settle in the heart to cause bacterial *endocarditis*. Another type of streptococcus is normally present harmlessly in the intestines but can spread to cause a *urinary tract infection*.

Haemolytic streptococci can cause *tonsillitis*, *strep throat*, *scarlet fever*, *otitis media* (middle-ear infection), *pneumonia*, *erysipelas*, and wound infections.

Streptococcus pneumoniae

Also called *PNEUMOCOCCUS*, a type of *STREPTOCOCCUS* bacterium that can cause pneumonia and other serious disorders such as *meningitis* and *septicaemia*.

streptokinase

A *thrombolytic drug* that is used to dissolve blood clots following a *myocardial infarction* (heart attack) or *pulmonary embolism* (a clot which blocks a blood vessel in a lung). Streptokinase is given under strict supervision due to the side effect of excessive bleeding; other adverse effects include nausea, rash, and cardiac *arrhythmias*.

streptomycin

An *antibiotic drug* that is used to treat certain uncommon infections, including *tuberculosis*, *tularaemia*, *plague*, and *brucellosis*. It may damage nerves in the inner ear, disturbing balance and causing dizziness, *tinnitus* (noises in the ears), or deafness. Other side effects include facial numbness, tingling in the hands, and headache.

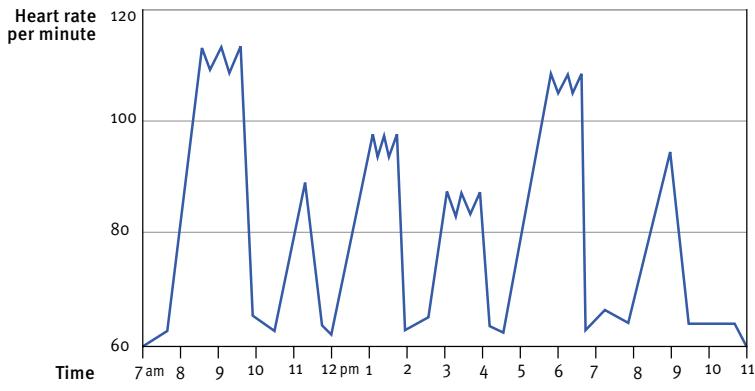

S

stress

Any disturbance of a person's mental and physical wellbeing. Stress may be felt in response to a range of physical and emotional stimuli. In stressful situations, the body responds by increasing production of the hormones *adrenaline* (epinephrine) and *hydrocortisone*, which produce changes in heart rate, blood pressure, and metabolism to improve performance. Above a certain level, however, they impair a person's ability to cope. Continued exposure to stress often leads to mental and physical symptoms such as *anxiety* and *depression*, *indigestion*, palpitations, and muscular aches and pains. *Post-traumatic*

STRESS AND HEART RATE

The graph shows how a person's heart rate varies over a typical day. Exercise and stress both activate the body's "fight-or-flight" system and increase heart rate, but repeated alerting of the system without accompanying physical activity is probably harmful. Although the home and workplace both present stress, for many city workers the most stressful parts of the day are those spent commuting.

stress disorder is a severe response to a specific stressful event. (See also *relaxation techniques*; *stress ulcer*.)

stress fracture

A *fracture* that results from repetitive jarring of a bone. Common sites include the metatarsal bones in the foot (see *march fracture*), the *tibia* and *fibula* (lower leg bones), the neck of the *femur* (thigh bone), and the lumbar spine (lower back). The main symptoms are pain and tenderness at the fracture site. Diagnosis is by *bone imaging*. Treatment consists of resting the affected area for four to six weeks, depending on the site; the fracture may be immobilized in a *cast*.

stress ulcer

An acute (of sudden onset) *peptic ulcer* that develops after *shock*, a severe burn or injury, or during major illness. Stress ulcers are usually multiple and most commonly occur in the stomach. The exact cause is unknown. Severely ill hospital patients are often given drugs to prevent stress ulcers from developing.

stretcher

A horizontal frame used to carry seriously ill or injured people. The stretcher keeps the person's body flat and still, minimizing the risk of further injury or disturbance to the body.

stretch-mark

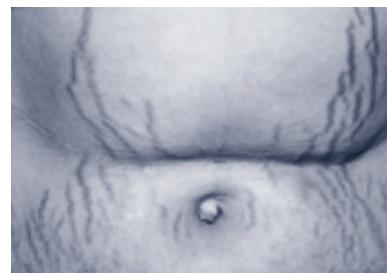

See *striae*.

striae

Also called a stretch-mark, a line on the skin caused by thinning and loss of elasticity in the dermis. Striae appear as red, raised lines, before turning purple; they eventually fade to form shiny, silvery streaks.

Striae often develop, during the adolescent growth spurt, on the shoulders in boys and on the hips and thighs in athletic girls. They are a common feature of pregnancy, occurring on the breasts, thighs, and lower abdomen. Purple striae are a characteristic feature of *Cushing's syndrome*.

The marks are thought to be caused by an excess of *corticosteroid hormones*, which decreases the level of *collagen* (fibrous tissue) in the skin. There is no means of prevention, but in some cases laser treatment may be used.

Striae

Commonly known as stretch-marks, striae often develop on the abdomen, thighs, and breasts of pregnant women. The striae shown here result from obesity associated with *Cushing's syndrome*.

stricture

Narrowing of a passage in the body. Stricture may be due to inflammation, development of scar tissue, or a growth such as a tumour. In some cases, it may be *congenital* (present at birth).

stridor

An abnormal sound, on breathing, that is due to narrowing or obstruction of the *larynx* or *trachea*. Stridor is most common in young children and usually occurs in *croup*. Other causes include *epiglottitis*, an inhaled *foreign body*, *hypocalcaemia*, and some larynx disorders.

stroke

Damage to part of the *brain* due to interruption to its blood supply. The most common cause is blockage of a cerebral artery by a blood clot, which may have formed in the artery (see *thrombosis*) or may have been carried in the circulation from another part of the body (see *embolism*). Stroke may also result from localized haemorrhage due to a ruptured blood vessel (including an *aneurysm* or *bleeding disorder*) in or near the brain.

The incidence of stroke rises with age and is higher in men. Certain factors increase the risk; the most important are *hypertension* and *atherosclerosis*, which damage artery walls. *Smoking* increases the risk of stroke by increasing the risk of all these disorders; and the risk of atherosclerosis is increased with *diabetes*. *Atrial fibrillation* (irregular, very rapid heartbeats), a damaged *heart valve*, or a recent *myocardial infarction* (heart attack) can cause clots in the heart that may migrate to the brain.

SYMPOTMS AND SIGNS

Symptoms usually develop abruptly and depend on the site, cause, and extent of the brain damage. The movement, function, or sensation controlled by the damaged area of the brain is impaired (see *Types and causes of stroke* box, overleaf). The possible complications of a major stroke include *pneumonia* and blood clots in the legs (see *thrombosis*, *deep vein*), which could lead to pulmonary embolism. Roughly one third of major strokes are fatal, a third result in some disability, and the final one third have no lasting ill effects (see *transient ischaemic attack*).

DIAGNOSIS AND TREATMENT

A range of techniques may be used to investigate the cause and extent of brain damage. These include *ECG*, *CT scanning*,

chest X-rays, *blood tests* (which may include clotting tests), *angiography*, *MRI*, and *carotid doppler scanning* (to assess narrowing of the carotid artery).

In some cases of stroke, urgent treatment may improve the chances of recovery. If a scan shows that the stroke is due to thrombosis, *thrombolytic drugs* may be given to dissolve the clot. *Anticoagulants* may be given if there is an obvious source of an embolism, such as atrial fibrillation. Antiplatelet agents such as *aspirin* may be used in order to help prevent further clotting.

Attention to hydration and pressure areas, and good nursing care, are important influences on outcome. *Physiotherapy* may restore lost movement or sensation; *speech therapy* may help language disturbances.

stroma

The tissue that forms an organ's framework, as distinct from functional tissue (the *parenchyma*) and the fibrous outer layer that holds the organ together.

strongyloidiasis

An infestation of the intestines by the parasitic worm *STRONGYLOIDES STERCORALIS*. Strongyloidiasis is a widespread disease in the tropics. It is contracted in affected areas by walking barefoot on soil that is contaminated with faeces. Larvae penetrate the soles and migrate via the lungs and throat to the small intestine, where they develop into adults and produce larvae. Most of the larvae are passed out in the faeces, but some enter the skin around the anus to begin a new cycle. An individual may be infested for more than 40 years.

The larvae cause itching and red weals where they enter the skin. In the lungs they may cause *asthma* or *pneumonia*. Heavy intestinal infestation may cause symptoms such as swelling of the abdomen and diarrhoea. Occasionally, an infected person with reduced immunity dies of complications, such as *septicaemia* or *meningitis*.

Treatment with an *anthelmintic drug*, usually *tiabendazole*, kills the worms.

strontium

A metallic element occurring in various compounds in certain minerals, seawater, and marine plants.

A radioactive variety, strontium 90, is produced during nuclear reactions and may be present in nuclear fallout. Strontium 90 accumulates in bone, where

the *radiation* it emits may cause *leukaemia* and/or *bone tumours*. Other forms of radioactive strontium have been used in the diagnosis and treatment of certain types of bone tumour.

Strümpell-Marie disease

Another name for *ankylosing spondylitis*.

strychnine poisoning

Strychnine is a poisonous chemical found in the seeds of *STRYCHNOS* species (a group of tropical trees and shrubs). Its main use is in some rodent poisons; most cases of strychnine poisoning occur in children who accidentally ingest such poisons.

The symptoms, which begin soon after ingestion of the poison, include restlessness, stiffness of the face and neck, increased sensitivity of hearing, taste, and smell, and *photosensitivity*, followed by alternating episodes of seizures and floppiness. Death may occur from *respiratory arrest*.

The victim is given intravenous injections of a *tranquillizer* or *barbiturate*, with a *muscle-relaxant drug* if needed, to help prevent seizures. Breathing may be maintained by a *ventilator*. With prompt treatment, recovery usually occurs in about 24 hours.

stuffy nose

See *nasal congestion*.

stump

The end portion of a limb that remains after *amputation*.

stupor

A state of almost complete *unconsciousness* from which a person can be aroused only briefly and by vigorous external stimulation. (See also *coma*.)

Sturge-Weber syndrome

A rare, *congenital* condition, affecting the skin and the brain, in which there is abnormal distribution of blood vessels. Typically, a large, purple birthmark (port wine stain) extends over one side of the face, including the eye. Malformation of cerebral blood vessels may cause weakness on one side of the body, progressive *learning difficulties*, and *epilepsy*. *Glaucoma* may develop in the affected eye, leading to loss of vision.

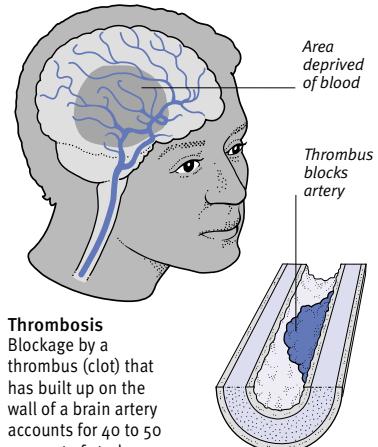

Seizures can usually be controlled with *anticonvulsant drugs*. However, in severe cases of this syndrome, brain surgery may be necessary.

TYPES AND CAUSES OF STROKE

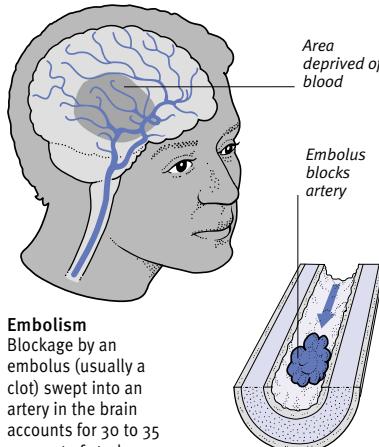

Stroke may be caused by any of three mechanisms (below): cerebral thrombosis, cerebral embolism, or haemorrhage. Thrombosis and embolism both lead to cessation of the blood supply to part of the brain and thus to infarction

(tissue death). Rupture of a blood vessel in or near the brain may cause an intracerebral haemorrhage or a subarachnoid haemorrhage. Any part of the brain may be affected by a stroke; accordingly the symptoms vary considerably.

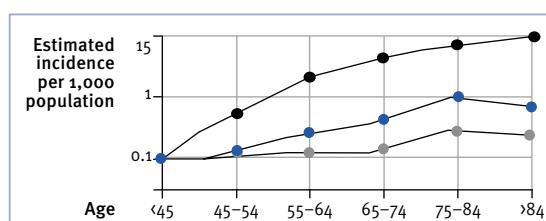

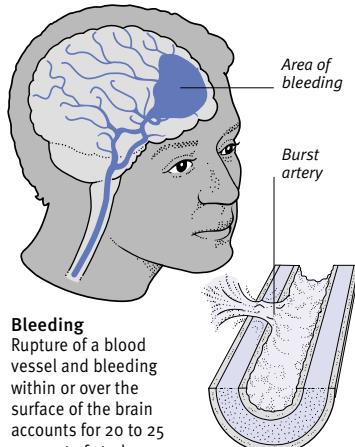

CEREBRAL THROMBOSIS

CEREBRAL EMBOLISM

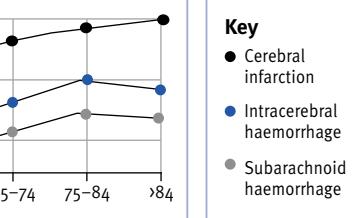

HAEMORRHAGE

Incidence with age

Strokes are rare under age 45. Incidence of cerebral infarction increases with age, but

Key

- Cerebral infarction
- Intracerebral haemorrhage
- Subarachnoid haemorrhage

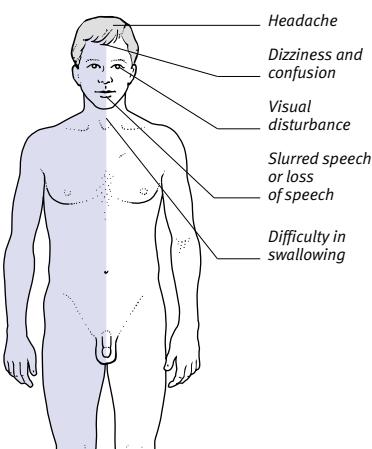

Haematoma

SYMPTOMS

The symptoms of a stroke usually develop abruptly over minutes or hours, but occasionally over several days. Depending on the size, site, cause, and extent of damage, any or all of the symptoms shown on the right may be present, in any degree of severity. A serious stroke may lead to rapid loss of consciousness, coma, and death. Up to 30 per cent of people are dependent on others after stroke, but some strokes cause barely noticeable symptoms.

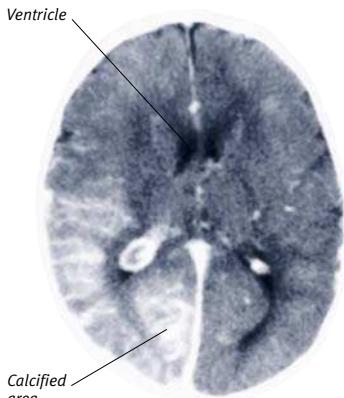

Hemiplegia

Weakness, paralysis, or loss of sensation on one side of the body are the more common effects of a serious stroke.

RISK FACTORS

- Age
- High blood pressure
- Atherosclerosis (narrowing of arteries by fatty deposits)
- Heart disease
- Diabetes mellitus
- Smoking
- Polycythaemia
- Hyperlipidaemia
- Obesity

**Sturge-Weber syndrome**

Sturge-Weber syndrome is evident in this MRI of the brain. The black areas are the fluid-filled ventricles, and the white section (bottom left of the image) is part of the brain that has calcified.

stuttering

A speech disorder in which there is repeated hesitation and delay in uttering words, unusual prolongation of sounds, and repetition of word elements. Stuttering usually starts before the age of eight and may continue into adult life. It is more common in males, twins, and left-handed people, and may occur with *tics* or *tremors*. The severity may be related to social circumstances. The exact cause is unknown, although it tends to run in families. *Speech therapy* often helps.

St Vitus' dance

See *Sydenham's chorea*.

sty

Also called a hordeolum, a small, pus-filled *abscess* at the base of an eyelash that is caused by bacterial infection.

**Stye on eyelid**

Caused by infection at the base of an eyelash, a stye most often forms near the inner corner of the eye. This stye has formed in the centre, resulting in swelling and inflammation of the upper eyelid.

subacromial bursitis

Inflammation of the fluid-filled sac that cushions the acromion, part of the *scapula* (shoulderblade). The con-

dition occurs if the bursa becomes trapped in the shoulder joint after a fall or overuse of the arm (for example, in sports involving throwing). It causes pain and restricted movement of the shoulder, particularly when lifting the arm sideways.

Treatment of subacromial bursitis usually includes rest, *analgesic drugs* and *nonsteroidal anti-inflammatory drugs*; *physiotherapy* may be given to help maintain mobility in the joint. For persistent cases, a corticosteroid injection into the joint may be needed.

subacute

A term that is used to describe a disease that runs a course between *acute* (sudden or short-term) and *chronic* (long-term).

subacute bacterial endocarditis

See *endocarditis*.

subacute combined degeneration of the spinal cord

Progressive damage to columns of nerves running through the spinal cord due to vitamin B_{12} deficiency. Subacute combined degeneration of the spinal cord may occur as a complication of *pernicious anaemia*. Symptoms may include tingling and numbness of the limbs. Weakness and *dementia* (deterioration in brain function) may eventually develop. If left untreated, the disease may be fatal after around five years. Treatment is with vitamin B_{12} injections.

subacute sclerosing panencephalitis

A rare and fatal type of *encephalitis* in children and young adults that is caused by the *measles* virus. Subacute sclerosing panencephalitis, which may not begin until several years after initial infection, causes progressive deterioration in brain function over several weeks or months, and results in *seizures*, *spasticity*, personality change, *coma*, and, eventually, death.

subarachnoid haemorrhage

A type of *brain haemorrhage* in which a blood vessel ruptures and blood leaks into the space between the middle and inner meninges (the membranes lining the brain). Subarachnoid haemorrhage is most common in individuals between the ages of 35 and 60. Bleeding usually occurs spontaneously but may follow unaccustomed exercise; the most com-

mon source of the bleeding is a *burst berry aneurysm* (a swollen, weakened area of artery wall).

An attack may cause loss of consciousness, sometimes preceded by a sudden, violent headache at the back of the head. If the person remains conscious, *photophobia* (abnormal sensitivity to light), drowsiness, nausea, vomiting, and a stiff neck may develop. Both conscious and unconscious patients can recover, but it is common to have further attacks, which are often fatal.

Diagnosis of a subarachnoid haemorrhage is by *CT scanning* and *angiography*. Treatment includes life-support procedures and control of blood pressure to prevent recurrence. Burst or leaking aneurysms are usually treated by surgery. Ninety per cent of those people who survive for a month survive for at least a year; some of these have a complete recovery, and some may have a residual disability such as paralysis.

subclavian steal syndrome

Recurrent attacks of blurred or double vision, loss of coordination, or dizziness when one arm (usually the left) is moved. The cause of subclavian steal syndrome is narrowing of the arteries that supply the arms, usually due to *atherosclerosis*. The blood supply is sufficient while the arm is at rest, but during movement extra blood is diverted from the base of the brain in order to supply the arm. Treatment of the syndrome is by *arterial reconstructive surgery*.

subclinical

A term for a disorder that produces no symptoms or signs, being either mild or in the early stages of development.

subconjunctival haemorrhage

Bleeding under the *conjunctiva* (the clear membrane covering the white of the eye), due to rupture of tiny, fragile

**Subconjunctival haemorrhage**

The bleeding causes a bright red area to appear in the white of the eye. A subconjunctival haemorrhage may look alarming but is usually harmless.

blood vessels. A subconjunctival haemorrhage is usually harmless and disappears in a few days without any treatment.

subconscious

A term that is used to describe various mental events (such as thoughts) of which one is temporarily unaware but that can be recalled under the right circumstances.

subcutaneous

A term meaning "beneath the skin".

subdural haemorrhage

Bleeding into the space between the outer and middle *meninges* (the membranes surrounding the brain), usually following *head injury*. The trapped blood forms a large clot within the skull that presses on brain tissue.

Signs and symptoms tend to fluctuate and may include headache, confusion, drowsiness, and one-sided weakness or *paralysis*. Bleeding occurs slowly; the interval between the injury and start of symptoms varies from days to months.

Diagnosis is by *CT scanning* or *MRI* to locate the clot. In many cases, surgery is needed. This involves drilling burr holes in the skull (see *craniotomy*) to drain the blood and repair damaged blood vessels. If treatment is carried out at an early enough stage, the person usually makes a full recovery. A small subdural haemorrhage that produces few symptoms may not require treatment. The affected person is usually monitored with regular scans, and the clot may clear up on its own. (See also *extradural haemorrhage*.)

sublimation

In *psychoanalytic theory*, the unconscious process by which primitive, unacceptable impulses are redirected into socially acceptable forms of behaviour.

sublingual

A term meaning "under the tongue". Drugs taken sublingually, either as tablets or spray, are rapidly absorbed through the lining of the mouth into the bloodstream. For example, nitrate drugs are given sublingually to provide rapid relief of an angina attack.

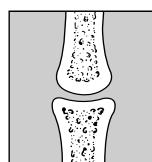

subluxated tooth

A tooth displaced in its socket following an accident. The upper front teeth are the most vulnerable. A subluxated tooth can usually be manipulated back into position before being immobilized (see

splinting, dental). If the blood vessels of the tooth are torn in the accident, *root canal treatment* is required.

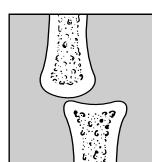

subluxation

Incomplete *dislocation* of a *joint*, in which the bone surfaces are displaced but remain in partial contact.

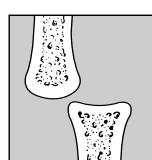

Normal

The diagram on the left shows the normal position of the bony surfaces in a simple joint, such as the joint in the middle of a finger.

Subluxation

In a subluxation, the surfaces of the bones are slightly displaced from their normal positions relative to each other but are still in contact.

Dislocation

Here, there is almost complete loss of contact between the bone surfaces and, in most cases, considerable damage to surrounding tissues.

submucous resection

Also called septoplasty, surgery to correct a deviated *nasal septum* (deformed partition between the nostrils).

subphrenic abscess

An *abscess* under the diaphragm (the sheet of muscle dividing the chest from the abdomen).

substance abuse

The use of drugs or other substances for a purpose other than the recommended one, usually to cause intoxication or alter mood. Stimulant drugs, solvents, and glue are all commonly abused. Problems may arise due to adverse effects or from the habit-forming potential of the substance. (See also *drug abuse*.)

substrate

A substance on which an *enzyme* acts.

sucking chest wound

An open wound in the chest wall through which air passes, causing the lung on that side of the body to collapse. Severe breathlessness and a life-threatening lack of oxygen result. (See also *pneumothorax*.)

suckling reflex

See *rooting reflex*.

sucralfate

An *ulcer-healing drug* used to treat *peptic ulcer*. Possible side effects are constipation and abdominal pain.

sucrose

The chemical name for culinary sugar, which is obtained from sugar cane and sugar beet (see *carbohydrates*.)

suction

The removal of unwanted fluid or semi-fluid material from the body with a syringe and a hollow needle or an intestinal tube and a mechanical pump.

suction lipectomy

See *body contour surgery*.

Sudafed

The brand name for the *decongestant drug* pseudoephedrine.

sudden death

See *death, sudden*.

sudden infant death syndrome (SIDS)

Also known as cot death, the sudden, unexpected death of an infant that cannot be explained.

Possible risk factors include: laying the baby face-down to sleep; overheating; parental smoking after the birth; *prematurity* and low birth weight; and poor socioeconomic background.

Preventive measures include: ensuring that the baby sleeps on its back at the foot of the cot; regulating the baby's temperature (using one light layer of clothing and blankets more than an adult would need); and stopping smoking.

Sudeck's atrophy

Swelling and loss of use of a hand or foot after a *fracture* or other injury. Treatment includes elevation of the affected hand or foot, gentle exercise, and *heat treatment*. Full recovery is usual within about four months.

suffocation

A condition in which there is a lack of oxygen due to obstruction to the passage of air into the lungs. (See also *asphyxia; choking; strangulation*.)

sugar

See *carbohydrates*.

sugar-free medicines

Drugs in liquid form that do not contain any sugar. These products have been developed in an attempt to reduce the exposure of children's teeth to excessive amounts of sugar.

suicide

The act of intentionally killing oneself. Suicide results from a person's reaction to a problem that he or she perceives as overwhelming, such as social isolation, death of a loved one, serious physical illness, or financial problems. Suicide is often the result of a psychiatric illness, such as severe *depression* or *schizophrenia*.

Suicide is most common among elderly people. More men than women commit suicide, although women attempt the act more often but are unsuccessful (see *suicide, attempted*). The most common method of suicide is poisoning, usually by drug overdose.

suicide, attempted

A deliberate act of self-harm that is or is believed to be life-threatening but proves to be nonfatal.

Attempted suicide occurs more commonly in women and is most common in the 15–30 age group. The rate is highest in people who have personality disorders and in those who live in deprived urban areas or have alcohol or drug problems. Trigger factors for attempted suicide include the death of a loved one, breakdown of a relationship, financial worries, or severe loss of any kind that results in *depression*. The most common method is drug overdose.

Urgent treatment is needed for *drug poisoning*. Longer-term therapy aims to provide support and treat depression.

sulfasalazine

A *disease-modifying antirheumatic drug* that is also used to relieve intestinal inflammation in *Crohn's disease* and *ulcerative colitis*. Important side effects include aplastic anaemia (see *anaemia, aplastic*) and reduction in white blood cells and platelets (see *thrombocytopenia*); regular blood counts are usually carried out. Sulfasalazine may also cause other adverse effects including nausea, headache, fever, and appetite loss.

sulfinpyrazone

A drug that is used to reduce the frequency of attacks of *gout*. The side effects of sulfinpyrazone include nausea and abdominal pain.

sulindac

A *nonsteroidal anti-inflammatory drug* (NSAID) that is used to relieve joint pain and stiffness in *arthritis* and acute *gout*. Side effects of sulindac are the same as for other NSAIDs and include indigestion and sometimes bleeding or ulcers in the stomach.

sulphasalazine

See *sulfasalazine*.

sulphinpyrazone

See *sulfinpyrazone*.

sulphonamide drugs

COMMON DRUGS

- Sulfadiazine • Sulfa methoxazole

A group of *antibacterial drugs*. They have largely been superseded by more effective and less toxic alternatives.

sulphonylurea drugs

A type of oral hypoglycaemic drug (see *hypoglycaemics, oral*) used to treat type 2 *diabetes mellitus*.

sulphur

A mineral that is a constituent of vitamin B₁ (see *vitamin B complex*) and several essential *amino acids*. In the body, it is needed to make *collagen*, which is found in bones, tendons, and skin, and is a constituent of *keratin* (the protein in skin, hair, and nails). Sulphur is also used as a cream in the treatment of *acne*.

sulpiride

An *antipsychotic drug* used in the treatment of *schizophrenia* and *Gilles de la Tourette's syndrome*.

sumatriptan

A *serotonin agonist drug* that is used to relieve acute attacks of *migraine*, especially those that have not responded to *analgesic drugs* (painkillers); it is particularly effective in treating cluster headaches. Sumatriptan may cause chest pain and tightness, tingling, flushing, dizziness, and weakness.

sunbed

A bedlike device, with a hinged cover, that encloses both sides of the body and exposes the skin to *ultraviolet light* to give a fast suntan. Concerns have been raised about the possible long-term effects of sunbed use and, in particular, the risks of *skin cancer*.

sunburn

Inflammation of the *skin* caused by overexposure to the sun. The *ultraviolet light* in sunlight may destroy cells in the outer layer of the skin and damage tiny blood vessels beneath. Severe sunburn in childhood increases the risk of *skin cancer* in later life.

Fair-skinned people are most susceptible. The affected skin becomes red and tender and may blister. The dead skin cells are later shed by peeling.

Calamine lotion soothes burnt skin. *Analgesic drugs* can relieve discomfort. Avoiding exposure to the midday sun, wearing protective clothing, and applying a high protection factor *sunscreen* help to prevent sunburn.

sunlight, adverse effects of

Problems resulting from overexposure to the sun and in particular from the effects of the *ultraviolet light* in sunlight. Fair-skinned people are most susceptible. Short-term overexposure causes *sunburn* and, in intense heat, can lead to *heat exhaustion* or *heatstroke*. Repeated overexposure over a long period can cause premature aging of the skin and *solar keratoses*, and increases the risk of *skin cancer*. Protecting the skin with *sunscreens* helps to prevent sun damage.

Other adverse effects of sunlight include *photosensitivity* (an abnormal sensitivity to sunlight), resulting in a rash. Exposure to sunlight can also affect the eyes, causing irritation of the conjunctiva, actinic *keratopathy*, or *ptygium*. Good quality sunglasses help to prevent eye problems.

sun protection factor (SPF)

A measure of the amount of UVB radiation that a *sunscreen* absorbs and thus the degree of protection that it provides against sunburn. It is given as a number (SPF number); the higher the SPF number, the greater the protection. The number refers to how many times longer an individual can stay out in the sun without burning.

sunscreens

Also called sunblocks, preparations that help to protect the skin from the harmful effects of sunlight. To remain effective, however, sunscreens must be reapplied on a regular basis.

WARNING

Some suntanning preparations do not contain a sunscreen and therefore provide no protection against sunburn.

sunstroke

A common form of *heatstroke*.

suntan

Darkening of the *skin* after exposure to sunlight. Specialized cells in the epidermis (the outer skin layer) respond to *ultraviolet light* by producing the protective pigment *melanin*. Even if a suntan develops, however, the skin may suffer damage from overexposure to the sun. (See also *sunburn; sunlight, adverse effects of*.)

superego

The part of the personality, as described in *psychoanalytic theory*, that is thought to be responsible for maintaining a person's standards of behaviour. Popularly termed the "conscience", the superego arises as a result of a child incorporating the moral views of those in authority (usually parents).

superficial

Situated near the surface.

superinfection

A second *infection* that occurs during the course of an existing infection. The term usually refers to an infection by a microorganism that is resistant to drugs being used against the original infection. One example is candidiasis (thrush) caused by treatment with antibiotic drugs. The antibiotic destroys the body's normal flora (microorganisms that are present in the body but do not produce any ill effects), which usually keep the candida yeast under control, preventing it from proliferating.

superiority complex

An individual's exaggerated and unrealistic belief that he or she is better than other people. In modern *psychoanalytic theory*, a superiority complex is considered to be a compensation for unconscious feelings of inadequacy or low self-esteem.

superior vena cava obstruction

A condition in which blood flow through the superior vena cava (the major vein that returns blood to the heart from the upper body) is restricted, often by pressure in the chest. The restriction is most commonly the result of a tumour, particularly *lung cancer* or *lymphoma*. Pressure may build up in the blood vessels behind the obstruction, causing swelling of the face, neck, and arm.

supernumerary

A term meaning "more than the normal number". Supernumerary teeth can also occur; they are usually extracted.

supernumerary nipple

One or more nipples in excess of the usual number.

**Supernumerary (extra) nipple**

Additional nipples can develop along a line that extends from the armpit to the groin; the extra nipples are not usually associated with underlying glandular tissue.

supination

The act that involves turning the body to a supine position (lying on the back with the face upwards) or of turning the hand to a position in which the palm faces forwards. The opposite position to supination is *pronation*.

suppository

A solid medical preparation, of cone or bullet shape, designed to be placed in the rectum to dissolve. Suppositories are used to treat rectal disorders such as *haemorrhoids* or *proctitis*, or to soften faeces and stimulate defaecation. They may also be used to administer drugs into the general circulation via blood vessels in the rectum, if vomiting is likely to prevent absorption after oral administration or if the drug would cause irritation of the stomach.

suppressor T-cell

A type of white blood cell, also known as a suppressor T-lymphocyte (see *lymphocyte*) that is involved in the *immune system*. These cells act to prevent the immune response.

suppuration

The formation or discharge of *pus*.

suprarenal glands

Another name for the *adrenal glands*.

suprasellar cyst

See *craniopharyngioma*.

supraspinatus syndrome

Inflammation of the supraspinatus tendon, which is in the shoulder, causing *painful arc syndrome*.

supraventricular tachycardia

An abnormally fast but regular heart rate that occurs in episodes that vary in duration from several hours to a number of days. Supraventricular tachycardia occurs when abnormal electrical impulses that arise in the atria (upper chambers) of the *heart* take control of the heartbeat from the *sinoatrial node* (the cluster of cells that stimulates heartbeats). Symptoms include palpitations, breathlessness, chest pain, or fainting (see *Stokes–Adams syndrome*).

Diagnosis is by an *ECG*. An attack can sometimes be stopped by *Valsalva's manoeuvre* or by drinking cold water. Recurrent attacks are treated with *antiarrhythmic drugs*. Occasionally, supraventricular tachycardia may require application of an electric shock to the heart (see *defibrillation*).

surfactant

A substance that reduces surface tension in a liquid. Pulmonary surfactant is secreted by the alveoli in the lungs, preventing them from collapsing during exhalation. Because surfactant is absent in significantly premature babies, breathing difficulties can occur that can lead to *respiratory distress syndrome*. In such cases, *artificial ventilation* and an artificial surfactant need to be given.

surfer's nodules

Multiple bony outgrowths on the foot bones and on the bony prominence just below the knee.

surgeon

A medical practitioner who is qualified to carry out *surgery*, although this definition does not include dental surgeons, who are not medically qualified.

surgery

Treatment of injury or other disorders by direct physical intervention, often with instruments. The word is also used for aspects of medicine that deal with the study, diagnosis, and management of disorders treated surgically.

surgical emphysema

The presence of gas trapped under the skin tissues following an injury or surgical procedure.

surgical spirit

A liquid preparation, consisting mainly of ethyl alcohol, that has a soothing and hardening effect when applied to the skin. It may be used before injections as an *antiseptic*.

surrogacy

The agreement by a woman to become pregnant and give birth to a child with the understanding that she will surrender the child after birth to the contractual parents. Pregnancy may be achieved either by *artificial insemination* or by *in vitro fertilization*.

susceptibility

Total or partial vulnerability to an infection or disorder.

Sustac

A brand name for *glyceryl trinitrate*, a drug used to prevent attacks of *angina pectoris*.

Sustanon

A brand name for the male sex hormone *testosterone*, given as a treatment to males whose bodies produce too little testosterone.

suture

A type of *joint*, found only between the bones of the skull, in which the adjacent bones are mobile during birth but then become so closely and firmly joined by a layer of connective tissue that movement between them is impossible.

The term "suture" is also used to refer to a surgical stitch (see *suturing*).

suturing

The closing of a surgical incision or a wound by sutures (stitches) to promote healing. Suturing may be carried out by means of a single continuous stitch under the skin (subcuticular) or by using individual stitches (interrupted). Some materials used in suturing, such as catgut, eventually dissolve in the body; skin sutures made of other materials are removed about one to two weeks after insertion, depending on the site in the body.

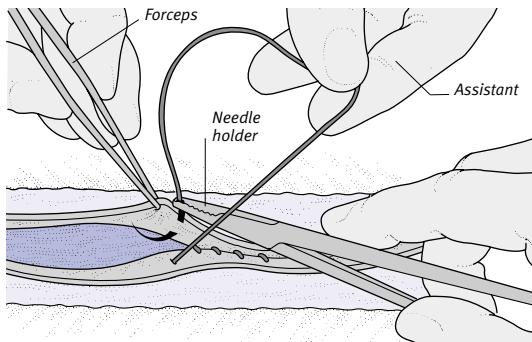

swab

A wad of absorbent material used to apply antiseptics or soak up body fluids during surgery or to obtain a sample of bacteria from an infected patient.

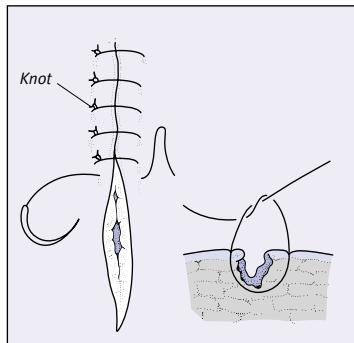

A surgical swab is commonly a folded piece of cotton gauze held in the hand

METHODS OF SUTURING

Suturing is carried out under either a general or a local anaesthetic. The type of stitch used depends on the nature of the wound or incision (two types are shown below). In all cases the surgeon sews the wound edges together to produce minimal distortion of tissue.

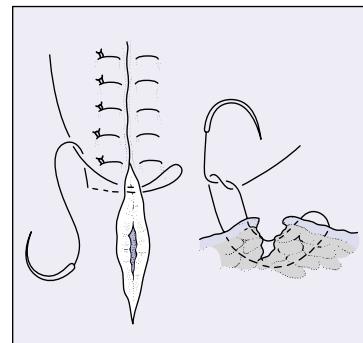

Technique
The surgeon grasps the edge of the wound with forceps held in one hand and inserts the needle through the skin using the other hand. In this illustration, the surgeon is using a needle holder, which gives greater control for very fine stitches. In other cases, the needle may be held in the hand. Suturing sometimes requires assistance.

Standard interrupted sutures

The needle is passed into one skin edge, through the full depth of the wound, and out of the other skin edge. Each stitch is then knotted at the side.

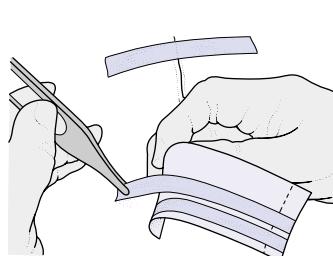

Mattress sutures

For deeper wounds, the needle is passed through the wound twice: first shallowly, close to the skin edges, and then more deeply, farther from the edges.

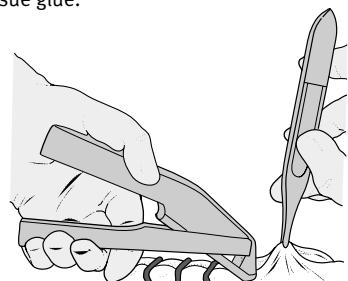

OTHER METHODS OF CLOSURE

Alternatives to suturing include removable staples and clips (staples are also used internally), adhesive tape, and tissue glue.

Adhesive tape

When the wound is shallow, tape may be applied directly. For deeper wounds, absorbable stitches are first inserted just beneath the skin.

Inserting staples

The wound edges are held up with forceps and staples, which are spaced out at equal intervals, are inserted using an automatic stapling device.

or in a clamp. It is used to apply cleansing and antiseptic solutions to the skin before an incision is made and to soak up blood and other fluids during an operation. The swab often contains material opaque to X-rays to enable it to be detected if it is accidentally left in the body after an operation.

A microbiological swab consists of a twist of cotton wool at the end of a thin stick, supplied in a sterile container. The swab is applied to an infected area of the body to absorb pus or mucus for microscopic examination.

swallowing

The process by which food or liquid is sent from the mouth to the stomach via the oesophagus.

In the mouth, food is chewed and mixed with saliva to form a soft mass called a bolus; the tongue then pushes the bolus to the back of the mouth and voluntary muscles in the palate push it into the throat.

The rest of the swallowing process occurs by a series of *reflexes*. Entry of food into the throat causes the epiglottis to tilt down to seal the trachea (windpipe) and the soft palate to move back to close off the nasal cavity. The throat muscles push the food into the oesophagus (gullet). Waves of contractions (peristalsis) along the oesophagus propel the food towards the stomach.

swallowing difficulty

Known medically as dysphagia, a common symptom with various possible causes. These include a foreign object in the throat; insufficient production of saliva (see *mouth, dry*); a disorder of the oesophagus, such as *oesophageal stricture*; pressure on the oesophagus, for example from a *goitre*; a nervous system disorder such as *myasthenia gravis* or *stroke*; or a psychological problem such as *globus hystericus*.

Investigations of swallowing difficulty may include barium swallow (see *barium X-ray examinations*) or *oesophagoscopy*. Treatment depends on the cause.

swamp fever

Another name for *leptospirosis*, a disorder caused by contact with water contaminated by rats' urine. The term is also sometimes applied to *malaria*.

sweat glands

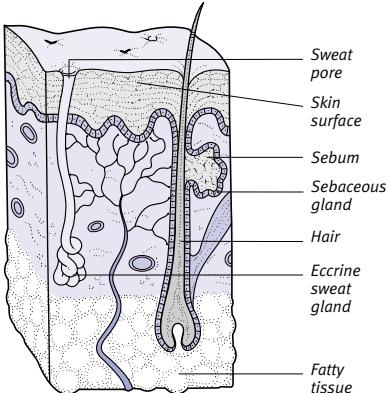

Structures deep within the *skin* that produce sweat (a fluid composed mainly of

water with some dissolved substances, including salt).

There are two types of sweat gland: known as eccrine and apocrine glands. Eccrine glands are the most numerous, and they open directly on to the skin's surface. Apocrine glands open into a hair follicle. Developing at puberty, they occur only in hairy areas, particularly the armpits, pubic region, and around the anus.

The sweat glands are controlled by the *autonomic nervous system*. They usually release sweat in order to keep the body cool, but they may also do this in response to anxiety or fear. Sweat is odourless until bacteria act on it, producing *body odour*.

Disorders of the sweat glands include *hyperhidrosis* (excessive sweating); and *hypohidrosis* (insufficient sweating); and hidradenitis suppurativa (a disorder of the apocrine glands in which painful resistant papules, nodules, and scars occur in the armpit and groin).

Cross-section of skin showing sweat gland
Sweat produced by the numerous eccrine sweat glands is carried up through the sweat duct and directly on to the skin's surface. Apocrine sweat glands open on to a hair follicle.

sweating

The process by which the body cools itself. (See also *hyperhidrosis*, *hypohidrosis*; *sweat glands*.)

sweeteners, artificial

See *artificial sweeteners*.

swimmer's ear

A common name for *otitis externa*.

swimmer's itch

A skin rash that occurs after swimming in fresh water contaminated with a form of *fluke* that infests snails and wildfowl. The itching is caused by fluke larvae burrow-

ing through the skin. Swimmer's itch may be a manifestation of *schistosomiasis*.

sycosis barbae

Inflammation of the beard area. The disorder is due to infection of the hair follicles, usually with *STAPHYLOCOCCUS AUREUS* bacteria contracted from razors or towels. Pus-filled blisters appear around the follicles. Treatment is usually with *antibiotic drugs*.

Sycosis barbae

Caused by infection and inflammation of the hair follicles in the beard area, sycosis barbae tends to affect men with greasy skin, and may be persistent.

Sydenham's chorea

Formerly called St Vitus' Dance, a rare childhood disorder of the *central nervous system*. The condition, which usually follows *rheumatic fever*, causes involuntary jerky movements of the head, face, limbs, and fingers; voluntary movements are clumsy, and the limbs become floppy.

Sydenham's chorea usually clears up after two to three months and has no long-term adverse effects.

Symmetrel

A brand name for the antiviral drug *amantadine*.

sympathectomy

An operation in which the ganglia (nerve terminals) of certain sympathetic nerves are destroyed to interrupt the nerve pathway.

WHY IT IS DONE

The sympathetic nerves form part of the *autonomic nervous system* and control involuntary (automatic) activities in the body, including widening and narrowing of blood vessels. In *peripheral vascular disease* (a disorder in which the blood vessels in the legs, and sometimes the arms, become narrowed), stimulation from the sympathetic nerves produces spasms in the blood vessels and worsens the narrowing. Sympathectomy prevents these spasms from occurring and may improve the blood supply flowing to the affected area.

The sympathetic nerves also play an important part in producing the sensation of *pain*. In some cases of *causalgia* (persistent severe pain usually caused by nerve injury), only sympathectomy can provide relief.

sympathetic nervous system

One of the two divisions of the *autonomic nervous system*, which, along with the parasympathetic nervous system, controls many of the involuntary activities in the body. The sympathetic nervous system increases body activities (it quickens the heartbeat and widens blood vessels in muscles, for example) in preparation for coping with stress (see *fight-or-flight response*).

sympathomimetic drugs

Drugs that stimulate the *sympathetic nervous system* by mimicking the effects of natural chemicals that control functions such as heart rate, blood flow, and digestion. Sympathomimetic drugs include *decongestant drugs*, which work by constricting blood vessels in the nasal membranes, and *bronchodilator drugs*, which work by widening the small airways of the lungs.

symphysis

A type of *joint* in which two bones are firmly joined by tough cartilage. Such joints occur in various parts of the body: between the *vertebrae*; between the pubic bones, at the front of the *pelvis*; and between the upper and middle parts of the *sternum* (breastbone).

symptom

An indication of a disease or disorder that is noticed by the sufferer him- or herself. By contrast, the indications that a doctor notes are called signs. (See also *withdrawal syndrome*.)

symptoms, first rank

Certain features of mental illness, the presence of which indicate a likely diagnosis of *schizophrenia*. They include auditory *hallucinations* (the person hears voices having a conversation or commenting on him or her); thought broadcasting (the belief that one's thoughts are being broadcast to the outside world); thought insertion (the belief that thoughts are being put into one's head); thought withdrawal (thoughts are being removed from one's head); and passivity (thoughts and actions are being controlled from an

external source). Such symptoms may be caused by other conditions, such as psychiatric problems related to the toxic effects of certain illegal drugs (see *drug psychosis*), and these other problems must be ruled out before the diagnosis of schizophrenia can be confirmed.

sympothermal method

See *contraception, natural methods of*.

Synacthen

A brand name for *tetracosactide*, a drug that is used to assess the function of the adrenal glands.

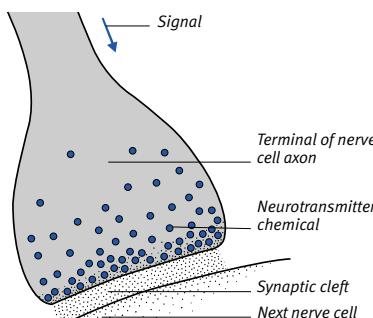

synaesthesia

A condition in which stimulation of one of the senses produces an unusual response in addition to the normal perception that is associated with the particular stimulus; for example, when a sound causes a person to see a colour as well as hear the noise.

synapse

A junction between two *neurons* (nerve cells) across which a signal can pass. At a synapse, the two neurons do not come directly into contact but are separated by a gap called the synaptic cleft. When an electrical signal passing along a neuron reaches a synapse, it causes the release of a chemical called a *neurotransmitter*. The neurotransmitter crosses the synaptic cleft to the next neuron, where it stimulates an electrical signal in that neuron. Signals can cross a synapse in one direction only.

Most drugs affecting the nervous system work as a result of their effects on synapses. Such drugs may affect the release of neurotransmitters, or they may modify their effects.

Structure of a synapse

When a signal arrives at the terminal of a nerve cell axon, it causes the release of a neurotransmitter; this chemical crosses the synaptic cleft and has an effect on the next cell.

syncope

The medical term for *fainting*.

syncope, micturition

See *micturition syncope*.

syndactyly

A *congenital* defect in which two or more fingers or, more commonly, toes are joined. Syndactyly is often inherited and is more common in males. In mild cases, adjacent digits (fingers or toes) are joined by only a web of skin; in more serious cases, the bones are fused. Surgery to separate the digits may be performed in early childhood.

Syndactyly

The congenital fusion of digits, syndactyly may range in severity from a slight degree of webbing between fingers, as shown here, to almost complete fusion.

Syndol

A brand-name *analgesic drug* (pain-killer) containing *paracetamol*, *caffeine*, *codeine*, and *doxylamine*.

syndrome

A group of symptoms and/or signs that, when they occur together, constitutes a particular disorder. An example is *irritable bowel syndrome*, which includes a range of symptoms including abdominal pain, wind and bloating, and irregular bowel movements.

syndrome of inappropriate antidiuretic hormone (secretion)

See *SIADH*.

syndrome X

A term that is used to describe two types of cardiovascular problem. The first, which is also called cardiac syndrome X, is a condition in which there are symptoms of *angina pectoris* (chest pain), and *exercise ECGs* show changes suggesting *ischaemic heart disease*, but the coronary arteries appear normal when viewed by *angiography*.

The term “syndrome X” is also used for a group of factors that are often found in people with ischaemic heart disease, and whose presence is associated with an increased risk. These risk factors include excessive fat around the abdomen (central obesity), *hyperlipidaemia* (high levels of fats in the blood), *hypertension* (high blood pressure), and *insulin resistance*.

synergistic muscles

Muscles that work together to produce a particular movement.

synovectomy

Surgical removal of the membrane lining a joint capsule to treat recurrent or persistent *synovitis*, usually in cases of severe *rheumatoid arthritis*.

synovitis

Inflammation of the membrane lining the capsule of a movable *joint*. The condition may be *acute*, in which case it is usually caused by an attack of *arthritis*, injury, or infection; or *chronic*, due to a disorder such as *rheumatoid arthritis*. The joint becomes swollen, painful, and often warm and red.

To find the cause of synovitis, joint aspiration (taking a sample of the joint's lubricating fluid) or *biopsy* (taking a sample of the membrane) may be needed. Symptoms are relieved by rest, supporting the joint with a splint or cast, *analgesics*, *nonsteroidal anti-inflammatory drugs*, and, occasionally, a *corticosteroid* injection. Chronic synovitis may be treated by *synovectomy*.

synovium

The membrane lining the capsule around a movable *joint*. The synovium also forms a sheath for certain tendons of the hands and feet. It secretes synovial fluid, which lubricates the joint or tendon. The synovium can become inflamed; in a joint this problem is known as *synovitis*, while in a tendon sheath it is known as *tenosynovitis*.

syphilis

An infection caused by *TREPONEMA PALLIDUM* bacteria. Syphilis is spread by sexual intercourse or other intimate body contact; the organism enters the body through broken skin or *mucous membranes*, then spreads rapidly via the bloodstream and lymphatic system. Syphilis can also be spread by nonsexual means, such as through broken skin or

saliva, but this occurs mainly in the Middle East and Africa. Rarely, it may be transmitted from mother to fetus during pregnancy (congenital syphilis).

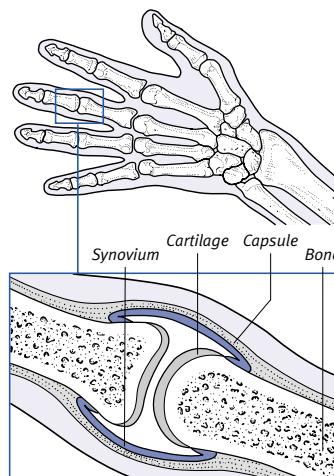

SIGNS AND SYMPTOMS

In sexual infection, the first sign is a painless ulcer (chancre) that develops on the genitals, anus, rectum, lips, throat, or fingers and heals in four to eight weeks. A rash then develops, which may be transient or recurrent, or may last for months. Other possible signs include lymph-node enlargement, headache, bone pain, loss of appetite, fever, and fatigue. Thickened, grey or pink patches may develop on moist areas of skin and are highly infectious. *Meningitis* may also develop.

Following this symptomatic phase, the disease becomes latent (hidden) for a few years, or sometimes indefinitely. A few untreated cases proceed, eventually, to a final stage characterized by widespread tissue destruction. Other serious effects include cardiovascular syphilis, which affects the aorta and leads to *aneurysm* and *heart-valve* disease; *neurosyphilis*, with progressive brain damage and paralysis; and *tabes dorsalis*, a disorder affecting part of the spinal cord.

LOCATION OF SYNOVIA

Every movable joint is enclosed within a fibrous capsule. The inner lining of the capsule is known as the *synovium*.

Function

The membrane secretes a thick fluid, called synovial fluid, that lubricates the joint. If the joint is injured, excess fluid may accumulate and cause pain.

Signs of congenital syphilis include a rash, persistent snuffles, bone abnormalities, jaundice, and enlargement of the liver and spleen. *Keratitis* (inflammation of the cornea), a characteristic flat face, peg-shaped teeth, arthritis, and learning difficulties may appear later in childhood.

DIAGNOSIS AND TREATMENT

Diagnosis is by examination of chancre serum or by blood tests. All forms of syphilis are treated with *antibacterial drugs*. Organ damage already caused by the disease cannot be reversed.

PREVENTION

Practising *safer sex* can help to prevent syphilis infection. People with syphilis are infectious in the early stages but not in the latent and final stages.

syringe

A hollow, cylindrical instrument that is commonly used with a needle to inject fluid into, or withdraw fluid from, a body cavity, blood vessel, or tissue.

syringe driver

A portable device comprising a syringe of medication attached to a small pump. It is used to provide continuous pain relief in conditions such as cancer. The syringe driver delivers a certain amount of an *analgesic* (painkiller), over a set period of time, through a needle inserted into the skin.

syringe, oral

A form of syringe with no needle, used to give medicines by mouth, especially to young children. A small, accurately measured dose of a drug is drawn up into the syringe, then the tip of the device is placed inside the child's mouth and the drug is directed against the inside of the cheek.

syringing of ears

The flushing of excess *earwax* or a foreign body from the outer ear canal by introducing water from a syringe into the ear canal.

syringomyelia

A rare, progressive condition, of unknown cause, in which a cavity forms in the *brainstem* (the lowest part of the brain) or in the *spinal cord* at neck or thoracic level. The cavity gradually expands, filling with *cerebrospinal fluid* and compressing nearby nerve fibres. Syringomyelia is usually a congenital condition and may be associated with congenital

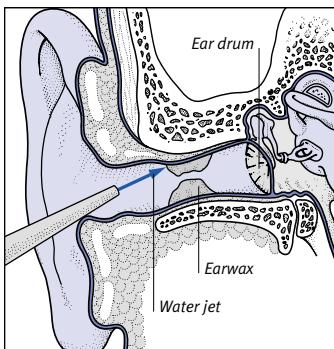

deformity of the brain. It may also occur after spinal cord injury.

Signs usually appear in early adulthood and include lack of temperature or pain sensation; muscle wasting in the neck, shoulders, arms, and hands; and some loss of the sense of touch. Later, there is difficulty in moving the legs and controlling the bladder and bowel, and the joints may become deformed.

There is no drug treatment. Surgery can relieve pressure in the central cavity to prevent further enlargement, relieve pressure on the distended spinal cord (see *decompression, spinal canal*), or slow the deterioration.

EAR SYRINGING

This procedure should be carried out by a doctor or nurse; amateur attempts can damage the eardrum.

Syringing the ear

After softening with sodium bicarbonate, a jet of warm water is directed (avoiding the eardrum) along the upper wall of the ear canal to dislodge earwax or a foreign body.

syrinx

An abnormal cavity in the brainstem or spinal cord; a feature of *syringomyelia*.

system

A group of interconnected or interdependent organs with a common function, as in the *digestive system*.

systemic

A term applied to something that affects the whole body rather than a specific part of it. For example, fever is a systemic symptom, whereas swelling is a localized symptom. The term "systemic" is also applied to the part of the blood circulation that supplies all parts of the body except the lungs.

systemic lupus erythematosus

See *lupus erythematosus*.

systemic sclerosis

A progressive form of scleroderma, systemic scleroderma is a rare *autoimmune disorder* (in which the immune system attacks the body's own tissues). The condition can affect many organs and tissues, particularly the skin, arteries, kidneys, lungs, heart, gastrointestinal tract, and joints. Systemic sclerosis is three times as common in women as in men and is most likely to appear between the ages of 30 and 50.

The disease varies in severity. It often begins with the symptoms of *Raynaud's phenomenon*, a disorder in which the fingers and toes become white, numb, and painful when exposed to cold. This is followed some years later by thickening and tightness of the skin of the face, hands, forearms, and feet. In more severe cases, internal organs are affected. Symptoms may include heartburn or difficulty swallowing because of damage to the oesophagus. *Pulmonary hypertension* (high blood pressure in the arteries supplying the lungs) may develop, sometimes up to 15 years after the onset of the disease.

Systemic sclerosis often progresses rapidly in the first few years and then slows down or even stops. In a minority of people, degeneration is rapid, and leads to death from *heart failure, respiratory failure, or kidney failure*. There is no cure for systemic sclerosis, but many of the symptoms can be relieved by drug treatment or *physiotherapy*.

systole

Muscular contraction of a chamber of the *heart* that alternates with a resting period (*diastole*). There are two stages of systole, namely atrial and ventricular. With each heartbeat, the atria (upper chambers) contract, squeezing blood into the ventricles (lower chambers). This action is followed by ventricular systole, in which the ventricles squeeze blood into the arteries.

The first of the two heartbeat sounds is associated with systole and represents the closing of the valves between the atria and ventricles; this action prevents blood from flowing back into the atria. The second sound relates to the diastole and signifies the closing of the aortic and pulmonary valves at the exits of the ventricle. (See also *pulse, sphygmomanometer*.)

systolic murmur

A heart murmur (a sound, made by the heart, that can be detected by a doctor) that occurs during *systole*, the phase of the heartbeat during which the heart muscle contracts.

A systolic murmur is usually caused by backflow of blood through the mitral or tricuspid *heart valves* between the upper and lower heart chambers. It can also be due to a type of *hypertrophic cardiomyopathy* called hypertrophic obstructive cardiomyopathy (narrowing of the outflow passage from the left ventricle). Heart-valve problems such as hardening (sclerosis) or narrowing (stenosis) of the aorta (see *aortic stenosis*) or pulmonary valve (see *pulmonary stenosis*) are also possible causes.

T

tabs dorsalis

A rare complication of untreated *syphilis* that appears years after infection. The condition affects the spinal cord and causes abnormalities of sensation, sharp pains, incoordination, and incontinence.

tablet

A type of drug preparation in the form of a compressed plug. As well as the drug itself, a tablet contains other ingredients, such as disintegrating agents (to help the tablet dissolve), binding agents, and lubricants, and may have a sugar or membrane coating.

tachycardia

An adult heart rate of over 100 beats per minute. The average heart rate is 72–78 beats per minute. Tachycardia occurs in healthy people during exercise. At rest, tachycardia may be due to *fever*, *anxiety*, *hyperthyroidism* (overactivity of the thyroid gland), *coronary artery disease*, high *caffeine* intake, or treatment involving *anticholinergic drugs*.

There are various types of tachycardia, which originate in different areas of the heart; these include *atrial fibrillation*, *sinus tachycardia*, *supraventricular tachycardia*, and *ventricular tachycardia*.

The symptoms of tachycardia may include palpitations, breathlessness, and lightheadedness.

tachypnoea

An abnormally fast rate of breathing, which may be caused by exercise, anxiety, or lung or cardiac disorders.

Taenia

A genus of tapeworms (see *tapeworm infestation*), some species of which can infest humans. These include *TAENIA SOLIUM*, which is passed on through contaminated pork, and *TAENIA SAGINATA*, whose larvae develop in beef.

Tagamet

A brand name for *cimetidine*, an *ulcer-healing drug*.

T'ai chi

A Chinese exercise system based on a series of over 100 postures between which slow, continuous movements are made. The aim is to exercise the muscles and integrate mind and body.

Takayasu's syndrome

A disorder, also known as Takayasu's arteritis, in which the arteries branching from the *aorta* become inflamed and progressively blocked. The cause is unknown. The condition is rarely diagnosed outside Asian countries such as Japan. Absence of a pulse in the arms or neck is characteristic, and blood pressure is increased. Symptoms such as paralysis of facial muscles and episodes of unconsciousness may occur due to minor *strokes*.

talipes

A *birth defect* (commonly called club-foot) in which the foot is twisted out of shape or position. Most cases are thought to be due to pressure on the baby's feet from the mother's uterus in late pregnancy. A genetic factor is also sometimes present. The most common form of talipes is an equinovarus deformity, in which the heel turns inwards and the rest of the foot bends down and inwards. Also, the tibia (shinbone) may be twisted inwards and the lower-leg muscles may be underdeveloped. Both feet may be affected. This defect is twice as common in boys as in girls.

**Talipes equinovarus**

This birth defect, commonly known as club foot, affects about one baby in 900. Treatment is by gentle manipulation, repeated several times a day.

TREATMENT

Talipes equinovarus is treated by repeated manipulation of the foot and ankle, starting soon after birth. A plaster *cast*, *splint*, or *strapping* may be used to hold the foot in position. If these measures are not successful by the time the baby is three to six months of age, surgery may be performed.

talus

The square-shaped foot bone that forms the ankle joint together with the *tibia* and *fibula* bones of the lower leg.

tamoxifen

An *anticancer drug* used to treat certain forms of *breast cancer* and some types of *infertility*. It may cause nausea, vomiting, hot flushes, swollen ankles, and irregular vaginal bleeding. Use of the drug is associated with a slight increased risk of endometrial cancer (see *uterus, cancer of*) and deep vein thrombosis (see *thrombosis, deep vein*).

tampon

A plug of absorbent material inserted into a wound or body opening to soak up blood or other secretions. The term commonly refers to a vaginal tampon, used to absorb menstrual blood.

tamponade

Compression of the heart by fluid within the *pericardium* (the membrane surrounding the heart), which may cause breathlessness and collapse. Causes include *pericarditis* (inflammation of the pericardium), complications after heart surgery, or a chest injury.

A diagnosis is made by *echocardiography*. Treatment of tamponade involves removing the fluid.

tamsulosin

An *alpha-blocker drug* used to treat urinary symptoms due to enlargement of the prostate gland (see *prostate, enlarged*). Side effects include low blood pressure, drowsiness, dry mouth, and gastrointestinal disturbances.

tan

See *suntan*.

Tangier disease

A rare autosomal recessive disorder (see *genetic disorders*) in which *cholesterol* builds up in various body organs, including the tonsils, liver, and spleen.

tannin

Also known as tannic acid, a chemical that occurs in many plants, particularly tea. It may cause constipation, and large amounts cause liver damage.

tantrum

An outburst of bad behaviour, common in toddlers, usually indicating frustration and anger. During a tantrum, the child

may scream, cry, yell, kick, bang the feet and fists, roll on the floor, go red in the face, spit, and bite. Some toddlers hold their breath, turning blue and, in rare cases, momentarily losing consciousness (see *breath-holding attacks*).

CAUSES

Tantrums occur at the age when a child starts to gain independence and becomes frustrated by restraints imposed by others, but is not yet able to express feelings verbally. Outbursts are more likely when a child is tired or when normal routine is disrupted, for example, by the birth of another baby. Occasional tantrums are considered normal; frequent outbursts may indicate an underlying *behavioural problem* or communication difficulty.

TREATMENT

Firm and consistent handling of the child is essential. Tantrums should be ignored as much as possible; a child's attention can often be diverted to a game or project. Most children grow out of tantrums when they develop the ability to express their feelings.

tapeworm infestation

Ribbon-shaped worms that infest the intestines of humans and animals. Tapeworms (cestodes) are usually acquired by eating undercooked meat or fish. An adult tapeworm has a flat, segmented body and suckers or hooks on its head, by which it attaches itself to the intestinal wall.

TYPES

Three large species of tapeworms are acquired by eating undercooked, infected beef, pork, and fish. The adults may grow up to 6 to 9 m long. Typically, tapeworms such as this have life-cycles that usually involve another animal host (see illustrated box). Tapeworms occur worldwide but infestations are largely prevented in countries that have adequate measures for inspecting meat and disposing of sewage.

The much smaller dwarf tapeworm, which is only 2.5 cm long, can be acquired through accidental transfer of worm eggs in human faeces to fingers and then to mouth. This worm is most common in the tropics and primarily affects children.

Humans may also act as intermediate hosts to the larvae of a tapeworm for which dogs are the main host.

SYMPTOMS

Despite their size, tapeworms from beef, pork, and fish usually only cause mild abdominal discomfort or diarrhoea. However, if eggs of pork worms are ingested, the hatched larvae burrow into tissues to form cysts. This leads to cysticercosis, the symptoms of which are muscle pain and convulsions. Rarely, fish tapeworms cause anaemia. Tapeworm larvae acquired from dogs grow and develop into cysts in the liver and lungs, a condition called *hydatid disease*.

DIAGNOSIS AND TREATMENT

A diagnosis is made from the presence of worm segments or eggs in the faeces. Treatment with *anthelmintic drugs* is usually effective.

tar

A dark, sticky substance distilled from organic materials such as peat, coal, or wood. Coal tar is used as an ingredient in some skin preparations for the treatment of *psoriasis* and *eczema*, and in some soaps and shampoos.

Tar residue from burning tobacco in cigarette smoke collects as deposits in smokers' lungs.

tardive dyskinesia

Abnormal, uncontrolled movements, mainly of the face, tongue, mouth, and neck. Tardive dyskinesia may be caused by prolonged use of *antipsychotic drugs*, and is distinct from the movement disorder *parkinsonism*.

tarsal

A term denoting or relating to any of the seven bones that make up the *tarsus*.

tarsalgia

Pain in the rear part of the foot, usually associated with *flat-feet*.

tarsal tunnel syndrome

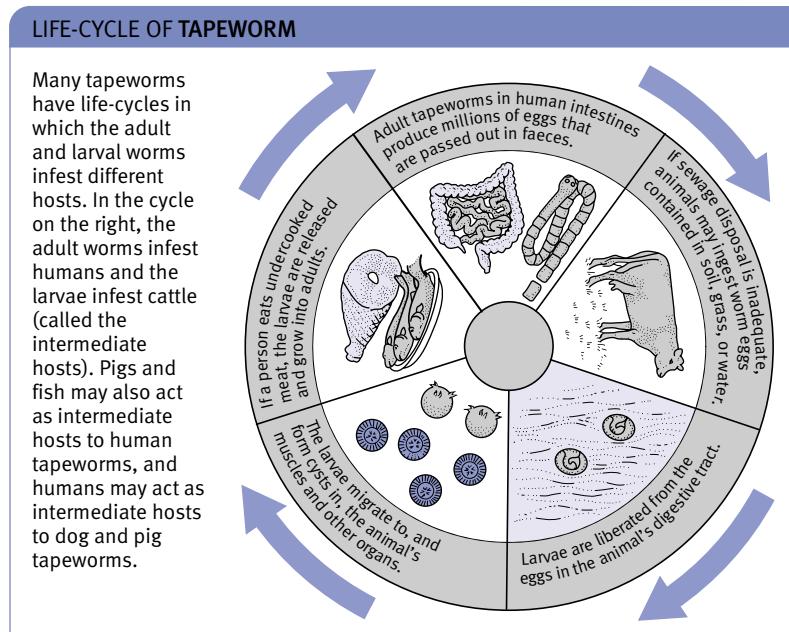

An uncommon disorder arising from abnormal pressure on the tibial nerve in the foot. Where this nerve curves round the inside of the ankle, it passes through the tarsal tunnel, a space formed between the bones of the ankle joint and bands of supporting fibrous tissue. If this space becomes constricted, the nerve is trapped and compressed.

Tarsal tunnel syndrome sometimes occurs when injury, or stress from over-activity, damages foot structures. It is also more common in people with flat feet. The usual symptoms are pain and a burning or tingling sensation on the sole of the foot.

Rest and *anti-inflammatory drugs* may be all that is needed. Persistent cases may be treated by *physiotherapy*, injections of *corticosteroid drugs* or, possibly, surgery to open up the tarsal tunnel.

tarsorrhaphy

Surgery in which the upper and lower eyelids are partially or completely sewn together. Tarsorrhaphy may be used as part of the treatment of corneal ulcer, or to protect the corneas of people who

TARSUS

cannot close their eyes or those with *exophthalmos* (bulging eyes). The eyelids are later cut apart and allowed to open.

tarsus

The seven bones that make up the back of the foot and the ankle.

tartar

See *calculus, dental*.

tartrazine

A yellow dye that is commonly used as a food colouring in soft drinks, confectionery, and ready-prepared meals. (See also *food additives*.)

taste

One of the five senses. Taste can distinguish between sweet, salt, sour, and bitter, but in combination with the sense of *smell*, many different flavours can be distinguished. A fifth taste, umami, has now been recognized. Tastes are detected by structures called *taste buds*.

taste bud

One of 10,000 specialized structures located mainly on the *tongue*, with some at the back of the throat and on the palate. Each bud contains about 50 sensory receptor cells, with tiny taste hairs that respond to food and drink.

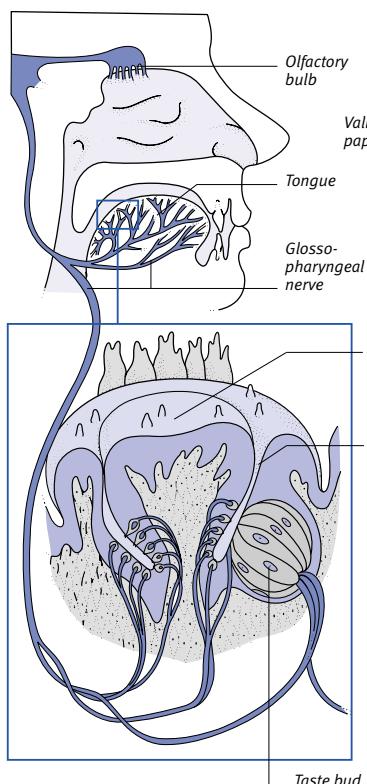

Taste buds on different parts of the tongue sense the five basic *tastes*: bitter, sour, salty, sweet, and umami.

taste, loss of

Loss of the sense of *taste*, usually as a result of loss of the sense of *smell*. The most common cause is inflammation of the nasal passages. Other causes include any condition that causes a dry mouth (see *mouth, dry*); natural degeneration of the *taste buds* with age; damage to the taste buds from *stomatitis* (inflammation of the mouth), *mouth cancer*, or *radiotherapy* to the mouth; or damage to nerves that carry taste sensations.

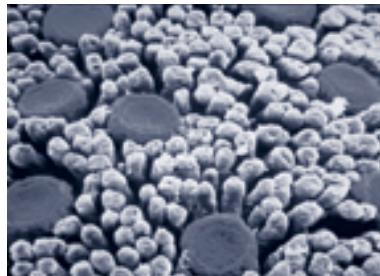

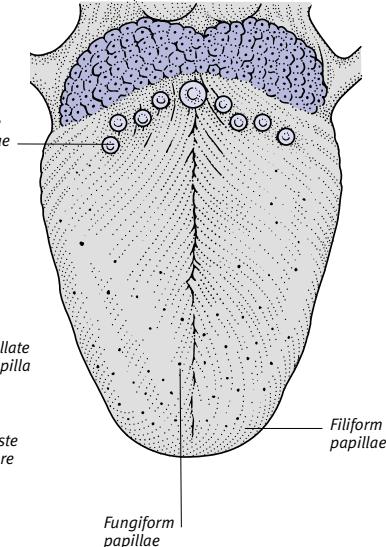

THE SENSE OF TASTE

Tastes are detected by special structures, which are called taste buds. Every person has some 10,000 taste buds, mainly situated on the tongue, with a few at the back of the throat and on the palate. These taste buds surround pores within

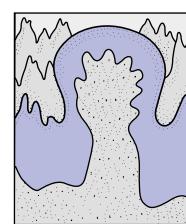

How a substance is tasted

Chemicals in food or drink dissolve in saliva and enter pores in the papillae on the tongue. Around these pores are groups of taste receptor cells – the taste buds. The chemicals stimulate hairs projecting from the receptor cells, causing signals to be sent from the cells along nerves to taste centres in the brain.

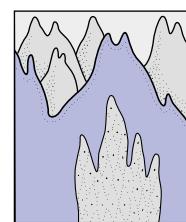

Magnified photograph of tongue surface
This photograph shows large (fungiform) and small (filiform) papillae. Taste buds are arranged around pores in the surface of the papillae.

Fungiform papillae
These mushroom-shaped papillae occur in small numbers at random over the tongue surface, mainly at the tip and sides.

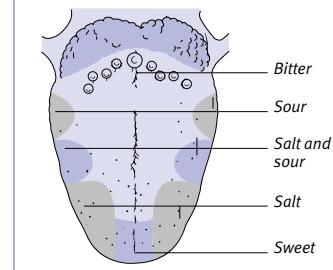

Filiform papillae
These smaller peak-shaped protuberances occur in large numbers over all except the back of the tongue's upper surface, and on the palate.

TASTE CENTRES

Taste buds sensitive to sweet, salty, sour, or bitter are grouped in particular areas on the surface of the tongue. The areas sensitive to umami are not yet known.

tattooing

The introduction of permanent colours under the skin surface. Tattooing is used to create a picture on the skin for decorative purposes or may be carried out therapeutically (for example to "draw" on a nipple following breast surgery). Tattooing, even by professionals, is potentially dangerous. Unless strict sterile procedures are followed, the viruses that cause *hepatitis* and *AIDS* may be transmitted through the tattooist's needles.

Tattoo removal is usually difficult and rarely satisfactory. Small tattoos can be cut out; larger ones can sometimes be removed by *dermabrasion* or *laser treatment*.

taxanes

A group of *anticancer drugs* used to treat certain cancers, such as ovarian cancer (see *ovary, cancer of*) and *breast cancer*. They work by preventing the growth of cancer cells. Common taxane drugs include *paclitaxel* and *docetaxel*.

Tay-Sachs disease

A serious inherited metabolic disorder (see *metabolism, inborn errors of*) that causes premature death. The cause is deficiency of the enzyme hexosaminidase A, which results in a buildup in the brain of a harmful substance. Symptoms usually appear after the age of six months and include blindness, paralysis, and seizures, leading to death by age three to five years.

Diagnosis is made by analysis of the enzymes of white blood cells. Tay-Sachs disease is now largely prevented by *genetic counselling* of high-risk groups such as Ashkenazi Jews.

TB

An abbreviation for *tuberculosis*.

T-cell

A class of *lymphocyte*.

tear duct

One of the channels, also known as a nasolacrimal duct, through which tears drain into the nose. (See also *lacrimal apparatus*.)

tear gas

See *CS spray*.

tears

The watery, salty secretion produced by the lacrimal glands, part of the *lacrimal apparatus* of the *eye*. Tears keep the *cornea* and *conjunctiva* moist to maintain transparency of the cornea and prevent

ulcers; to aid blinking; and to wash away foreign particles. Tear production increases in response to eye irritation and emotion. (See also *artificial tears*.)

technetium

A radioactive element used in *radionuclide scanning*.

teeth

Hard, bonelike projections set in the jaws and surrounded by the gums. The teeth are used for *mastication* (chewing), help to form speech, and give shape to the face. At the centre of each tooth is the pulp, which contains blood vessels and nerves and is surrounded by hard dentine. The crown, the part of the tooth above the gum, is covered by enamel, the hardest substance in the body. The roots of the tooth, which fit into the jawbone, are covered by bonelike cementum. (See *Structure and arrangement of teeth* box, overleaf.)

Adult humans have 32 *permanent teeth*, which erupt after the *primary teeth* are lost, starting from about the age of six. These teeth comprise chisel-shaped, biting incisors; sharp, pointed canines; grinding premolars; and larger grinding molars. (See also *anodontia*.)

teeth, care of

See *oral hygiene*.

teething

The period when a baby cuts his or her *primary teeth* (see *eruption of teeth*). Usually, the first signs of teething occur at about six months of age.

SYMPOTMS AND SIGNS

While teething, a baby may be irritable, fretful, clingy, may have difficulty sleeping, and may cry more than usual. Extra saliva may be produced, resulting in dribbling, and the baby tends to chew on anything that comes to hand.

Before a tooth emerges, the gum may become red and swollen. When molars erupt, the cheek may feel warm and look red on the affected side.

TREATMENT

Symptoms may be relieved by the use of painkilling gels that are rubbed on the gums, or liquid preparations.

teichopsia

A visual disturbance in which shimmering, jagged patterns of light appear in front of the eyes. Teichopsia is sometimes experienced just before the onset of a *migraine* attack.

telangiectasia

An increase in the size of small blood vessels beneath the surface of an area of skin, causing redness and a "broken veins" appearance. Telangiectasia is most commonly found on the nose and cheeks. There may be no obvious cause for telangiectasia, or the condition may be caused by many years of excessive alcohol consumption, the skin condition *rosacea*, overexposure to sunlight, or a disease of connective tissue such as *dermatomyositis*.

Telangiectasia is not a cause for concern, but if very unsightly the veins can be removed in some cases by electrodesiccation (electrical destruction of the upper layers of the skin) administered by a dermatologist or by laser treatment. (See also *spider naevus*.)

Cosmetic laser surgery for telangiectasia

A hand-held laser is used to remove the broken veins. Although often referred to as "broken", the blood vessels are, in fact, simply larger than usual.

telecardiography

The recording of an *ECG* by transmission of impulses (such as via a telephone line) to a site that is remote from the patient. (See also *Holter monitor*.)

temazepam

A *benzodiazepine drug* that is used to treat *insomnia*. It is also a drug of abuse.

temperature

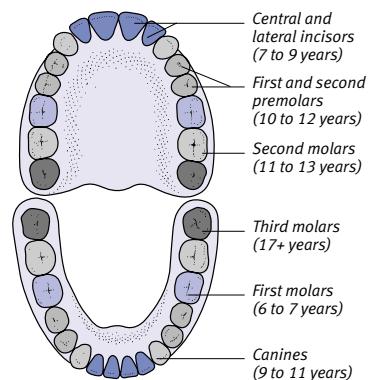

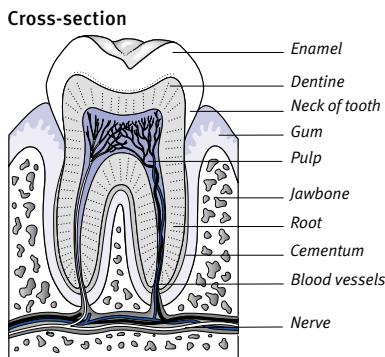

In the human body, temperature must be maintained at around 37°C for optimum functioning. This varies slightly, not only among individuals but also in the same person, as temperature is affected by such factors as exercise, sleep, eating and drinking, time of day, and, in women, the stage of the menstrual cycle.

TEMPERATURE REGULATION

Body temperature is maintained by the *hypothalamus*, an area in the brain, which monitors blood temperature and

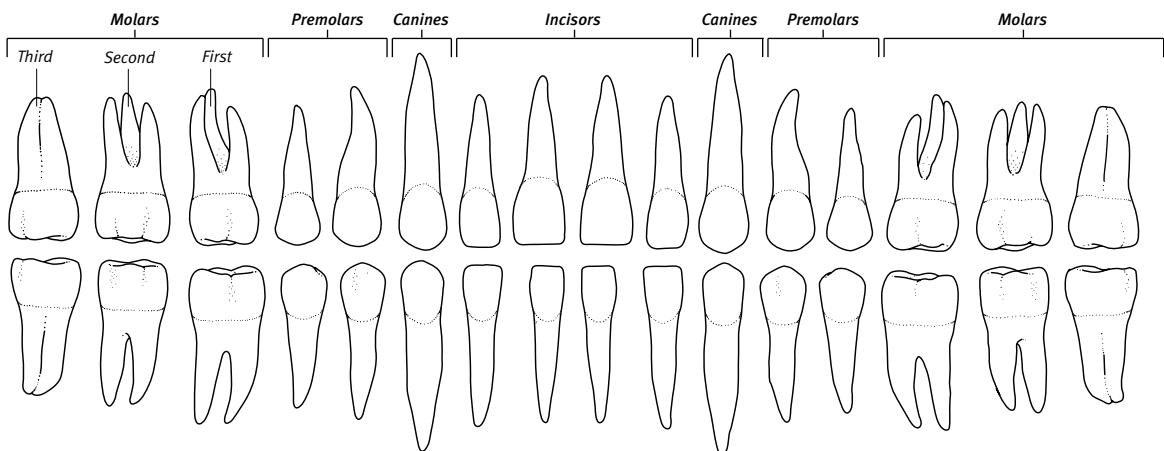

STRUCTURE AND ARRANGEMENT OF TEETH

At the heart of each tooth is the living pulp, which contains blood vessels and nerves. A hard substance called dentine surrounds the pulp. The part of the tooth above the gum, the crown, is covered by enamel. The roots of the tooth, which fit into sockets in the jawbone, are covered by a sensitive, bonelike material, the cementum. The periodontal ligament connects the cementum to the gums and to the jaw. It acts as a shock absorber and prevents jarring of the teeth and skull when food is being chewed.

The permanent teeth
The illustration above shows the arrangement in the jaw of the permanent teeth – eight incisors, four canines, eight premolars, and 12 molars. The ages when these teeth erupt are indicated.

X-ray of teeth
The panoramic X-ray on the left shows all the teeth (there are no wisdom teeth) of the upper and lower jaw and their surrounding structures. The tooth roots, buried in jawbones, can be clearly seen; several teeth have been filled.

**Molars**

The molars are large, strong teeth, efficient at grinding food. The third molars, or wisdom teeth, are the last to erupt; in some people, the wisdom teeth never appear.

Premolars

Also known as bicuspids, because of their two distinct edges, the premolars are concerned with grinding food. There are no premolars among the primary (milk) teeth.

Incisors

These teeth have a chisel-shaped, sharp cutting edge that is ideal for biting. The upper incisors overlap the lower incisors slightly when the jaws are closed.

Canines

These are sharp, pointed teeth, ideal for tearing food. They are larger and stronger than the incisors, with very long roots. The upper canines are often known as eye teeth.

activates mechanisms automatically to compensate for any changes.

When body temperature falls, the hypothalamus sends nerve impulses to stimulate *shivering*, which creates heat by muscle activity. Nerve impulses are also sent to constrict blood vessels in the skin, which minimizes heat loss. When the body temperature rises, the hypothalamus stimulates *sweating* and

dilates (widens) blood vessels in the skin to increase heat loss. A large number of factors (such as infections or extremes of heat and cold) may disrupt the body's heat-regulating system, making temperature too high or too low. (See also *fever*; *heatstroke*; *hypothermia*.)

temperature method

See *contraception, natural methods of*.

temporal

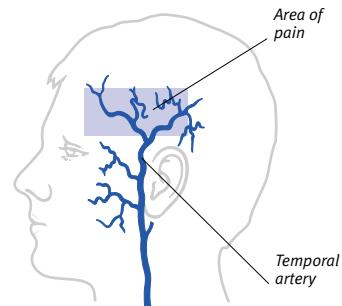

A medical term meaning of or near the temples or a temple.

temporal arteritis

An uncommon disease of older people in which the walls of the arteries in the scalp over the temples become inflamed. Other arteries in the head and neck may also be affected, as may the aorta (the

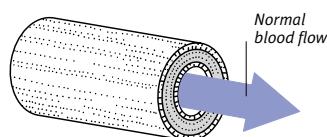

TEMPORAL ARTERITIS

In this disorder, the temporal artery and other arteries in the head are inflamed. Early treatment of temporal arteritis is vital, because if the condition is left untreated, there is a risk of sudden blindness.

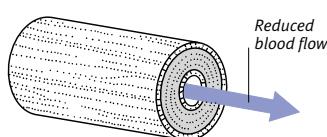

Telltale symptoms

If the temporal artery is inflamed, it is usually prominent and there is a persistent severe headache and scalp tenderness in the area of the head shown above.

Normal artery

In a normal artery, there is a smooth lining, and the blood flow through it is sufficient to meet the needs of the tissues it supplies.

Inflamed artery

In arteritis, the walls of the artery become disrupted and thickened, and blood flow through it is therefore markedly reduced.

artery that carries oxygenated blood from the heart) and its main branches. The inflamed vessels become narrowed, reducing blood flow through them.

CAUSES

The cause of temporal arteritis is unknown, but the condition may be associated with *polymyalgia rheumatica* (pain and stiffness in the muscles of the hips, thighs, shoulders, and neck).

SYMPOTMS

The most common symptom is a severe headache on one or both sides of the head. The temporal artery (located at the side of the head above the earlobe) may be prominent and the scalp tender. In

about half of the cases, the ophthalmic arteries supplying the eyes are affected, which may cause sudden blindness if untreated. Other symptoms and signs include fever and poor appetite.

DIAGNOSIS AND TREATMENT

Early reporting of symptoms is essential due to the risk of blindness. The diagnosis of temporal arteritis is made by *blood tests*, including *ESR* (erythrocyte sedimentation rate), and in some cases by a *biopsy* (tissue sample) of the artery.

Treatment with a *corticosteroid drug* usually has a rapid effect; otherwise, *immunosuppressant drugs* may be given. Temporal arteritis usually clears up completely within two years.

temporal artery biopsy

A procedure in which a small segment of tissue is taken from the temporal artery (situated at the side of the scalp) and examined under a microscope. Temporal artery biopsies are performed to detect signs of inflammation and thereby to diagnose *temporal arteritis*.

temporal lobe epilepsy

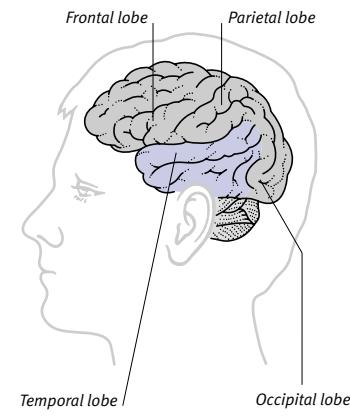

A form of *epilepsy* in which abnormal electrical discharges occur in the temporal lobe (most of the lower side of each half of the *cerebrum*) in the *brain*.

CAUSES

The usual cause of this type of epilepsy is damage to the temporal lobe, which may be due to a *birth injury*, *head injury*, *brain tumour*, *brain abscess*, or *stroke*.

LOCATION OF THE TEMPORAL LOBE

The temporal lobe forms much of the lower side of each half of the cerebrum (main mass of the brain).

SYMPTOMS

Attacks of this form of epilepsy cause dreamlike states, unpleasant *hallucinations* of smell or taste, the perception of an illusory scene, or *déjà vu*. There may also be grimacing, rotation of the head and eyes, and sucking and chewing movements. The affected person may have no memory of activities during an attack, which can last for minutes or hours. Sometimes, the seizure develops into a *grand mal* seizure.

DIAGNOSIS AND TREATMENT

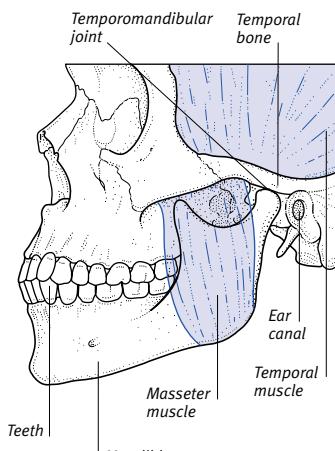

Diagnosis and drug treatment is the same as for other forms of epilepsy.

temporomandibular joint

The joint between the mandible (lower jaw bone) and the skull.

LOCATION OF THE TEMPOROMANDIBULAR JOINT

The head of the mandible (jawbone) fits neatly into a hollow situated on the underside of the temporal bone of the skull at the joint.

temporomandibular joint dysfunction

Pain and other symptoms affecting the head, jaw, and face that are thought to occur when the *temporomandibular joints* and the muscles and ligaments attached to them do not work together correctly.

CAUSES

A common cause of temporomandibular joint dysfunction is spasm of the chewing muscles, often caused by clenching or grinding the teeth as a result of emotional tension. *Malocclusion* (an incorrect bite) may be a contributing

factor because it places additional stress on the muscles. Temporomandibular joint problems may also be caused by jaw, head, or neck injuries. In rare cases, *osteoarthritis* may be the cause.

SYMPOTMS

Common symptoms include headaches, tenderness of the jaw muscles, and an aching facial pain, especially in or around the ear. There may also be difficulty in opening the mouth, locking of the jaws, clicking noises as the mouth is closed or opened, or pain caused by opening the mouth wide or chewing.

TREATMENT

In most cases, treatment involves eliminating muscle spasm and relieving pain with *analgesic drugs*. In some cases, injections of *corticosteroid drugs* into the joint may be given. The bite may need to be adjusted by the use of an *orthodontic appliance*. In severe cases, surgery on one or both temporomandibular joints may be needed.

tenderness

Pain or abnormal sensitivity in a part of the body when it is pressed or touched.

tendinitis

Inflammation of a tendon, usually due to injury or overuse. Symptoms of tendinitis include restricted movement, pain, and tenderness. Treatment is with *non-steroidal anti-inflammatory drugs* (NSAIDs), *ultrasound treatment*, or injection of a *corticosteroid drug* around the tendon.

tendolysis

An operation performed to free a *tendon* from *adhesions* (fibrous bands) that limit its movement. The adhesions are usually caused by *tenosynovitis* (inflammation of the inner lining of a tendon sheath).

tendon

A fibrous cord that joins muscle to bone. Tendons are strong and flexible, but inelastic. They are made up principally of bundles of collagen (a white, fibrous protein) and contain some blood vessels. Those in the hands, wrists, and feet are enclosed in synovial sheaths (fibrous capsules) that secrete a lubricating fluid, which allows movement without excessive friction.

DISORDERS

Tendinitis, inflammation of a tendon, may follow an injury. *Tenosynovitis*, inflammation of the inner lining of a tendon sheath, usually affects tendons in the hands and wrists and results from

some cases, the tendon may heal if immobilized in a plaster *cast*.

tendon transfer

Surgery to reposition a *tendon* in order for it to make a muscle perform a different function. The tendon is cut from its original point of attachment and reattached elsewhere, making the muscle lie in a different position. The procedure may be used to treat *talipes* (club-foot) or permanent muscle injury or paralysis.

tenecteplase

A *thrombolytic drug* used in the treatment of *myocardial infarction* (heart attack). Tenecteplase is administered by intravenous injection.

tenesmus

A feeling of incomplete emptying of the bowel in which an urge to pass *faeces* accompanies ineffective straining. It may be a symptom of inflammation or of a tumour (see *colon, cancer of*).

tennis elbow

Pain and tenderness on the outside of the elbow and in the back of the forearm. Also called lateral epicondylitis, it is caused by inflammation of the *tendon* that attaches the muscles that straighten the fingers and wrist to the *humerus* (upper-arm bone).

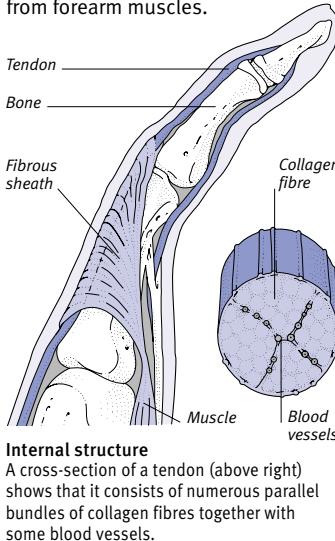

The treatment of tennis elbow consists of resting the arm, applying *ice-packs*, and taking *analgesic drugs* (pain-killers) or *nonsteroidal anti-inflammatory drugs* (NSAIDs). *Ultrasound treatment*, injection of a *corticosteroid drug*, or surgery are sometimes needed.

tenosynovitis

Inflammation of the lining of the sheath that surrounds a *tendon*. The usual cause is excessive friction caused by repetitive

FINGER TENDONS

Tendons on the top and underside of the finger control bending and extension; the tendons originate from forearm muscles.

overuse. Inflammation of the outer wall of a tendon sheath, a condition known as *tenovaginitis*, may restrict movement of the tendon through the sheath.

Injury may cause a *tendon rupture*. The *Achilles tendon* in the heel can rupture during vigorous sprinting and jumping. In many cases, however, because tendons are strong, severe stress results in pulling off a piece of bone where the tendon is attached, rather than tearing of the tendon itself.

tendon release

See *tendolysis*.

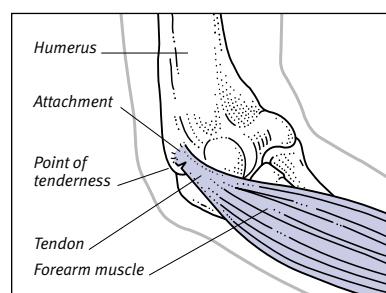

tendon repair

Surgery to join the cut or torn ends of, or to replace, a damaged *tendon*.

tendon rupture

A complete tear in a *tendon*. A tendon may rupture when the muscle to which it is attached contracts suddenly and powerfully, such as during vigorous exercise. Rupture may also be the result of an injury or joint disorder such as *rheumatoid arthritis*.

Symptoms include a snapping sensation, impaired movement, pain, and swelling. Diagnosis is usually obvious from the symptoms alone. Surgery to repair the tendon may be needed. In

Site of tennis elbow

Pulling of the forearm muscles at the point where they attach to the humerus causes tenderness on the outer side of the elbow.

movements; bacterial infection is a rare cause. The hands and wrists are most often affected in tenosynovitis. Symptoms include pain, tenderness, and swelling over the tendon.

Treatment is with *nonsteroidal anti-inflammatory drugs* (NSAIDs) or a local injection of a *corticosteroid drug*. However, if infection is the cause, *antibiotics* are prescribed. A *splint* to immobilize the joint, or surgery, may also be needed.

tenovaginitis

Inflammation or thickening of the fibrous wall of the sheath that surrounds a *tendon*. Tenovaginitis affecting the sheath of one of the tendons that bends a finger results in *trigger finger*.

TENS

Abbreviation for transcutaneous electrical nerve stimulation, a method of pain relief. Minute electrical impulses, which block pain messages to the brain, are relayed from an impulse generator to electrodes attached to the skin in the area of the pain. TENS can help relieve chronic pain not controlled by *analgesic drugs* and may be used in *childbirth*.

tension

A feeling of mental and physical strain associated with *anxiety*. Muscle tension may cause headaches and stiffness. Persistent tension is related to generalized anxiety disorder. (See also *stress*.)

tension headache

See *headache*.

tension pneumothorax

See *pneumothorax*.

teratogen

A physical, chemical, or biological agent, such as radiation, the drug *thalidomide*, or the *rubella* virus, that causes abnormalities in a developing *embryo* or *fetus*.

teratoma

A primary *tumour*, which may be cancerous or noncancerous, consisting of cells totally unlike those normally found in that part of the body. For example, teratomas that develop in the ovary often form cysts that may contain skin, hair, teeth, or bone.

terbinafine

An *antifungal drug* used to treat fungal nail or skin infections. Side effects are rare with topical use but may include

local irritation. Taken as tablets, the drug may cause nausea, abdominal pain, a rash, or, rarely, liver problems.

terbutaline

A *bronchodilator drug* used to treat *asthma* and chronic obstructive *pulmonary disease*, and also to prevent premature labour. Possible adverse effects include nervousness, restlessness, tremor, nausea, and palpitations.

terfenadine

An *antihistamine drug* used to relieve the symptoms of allergies such as *urticaria* (nettle rash) and allergic *rhinitis* (hay fever). The drug is not now commonly prescribed due to the risk of potentially serious *arrhythmias* (irregular heartbeat) associated with high doses.

terminal care

See *dying, care of the*.

termination of pregnancy

See *abortion, induced*.

testicle

See *testis*.

testicular feminization syndrome

A rare inherited condition in which an individual who is genetically male with internal *testes* has the external appearance of a female. The syndrome is a form of *intersex* and is the most common type of male *pseudohermaphroditism*.

CAUSE

The cause is a defective response of the body tissues to the male sex hormone *testosterone*. The causative genes are carried on the X chromosome, and so females can be carriers and pass on the genes to their sons.

SYMPOMTS

Those affected seem to be girls throughout childhood. Most develop normal female secondary *sexual characteristics* at *puberty*; but *menstruation* does not occur because there is no uterus and the vagina is short and blind-ending. People with testicular feminization syndrome tend to be tall, and are of normal health.

DIAGNOSIS AND TREATMENT

Testicular feminizing syndrome may be diagnosed before puberty if a girl is found to have an inguinal *hernia* or a swelling in the labia (skinfolds in front of the vagina) that turns out to be a testis. Otherwise, the diagnosis is usually made during investigations at puberty to

find the cause of *amenorrhoea* (failure to menstruate). This is confirmed by *chromosome analysis*, which shows the presence of male chromosomes, and blood tests, which show male levels of *testosterone*. The treatment of testicular feminization syndrome involves surgical removal of the testes, to prevent cancerous change in later life, and therapy with *oestrogen drugs*. An affected person is not fertile but can live a normal life as a woman.

testicular self-examination

Regular, manual self-examination of the testes in order to detect symptoms that may be an early warning of testicular cancer (see *testis, cancer of*). The man should gently roll each testis between fingers and thumb to feel for unusual lumps and swellings, or changes in skin texture. Anything that feels different to normal should be reported to a doctor.

testis

One of two male sexual organs, also called testicles, that produce *sperm* and the hormone *testosterone*. The testes form within the abdomen early in fetal development. In response to hormones

SELF-EXAMINATION OF THE TESTIS

A lump that can be felt in the testis must be considered potentially malignant until medical tests prove otherwise. Cancers are usually firm to the touch and are often not tender or painful when pressed.

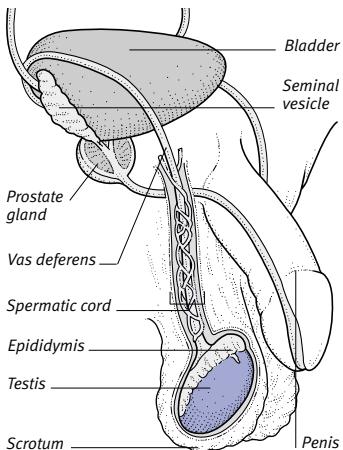

Procedure

Only regular self-examination (at least once a month) of both testes can detect a tumour early enough to provide assurance of a cure. The hands should be warmed, and the entire surface of both testes felt. The skin over the testes moves freely, making palpation easy.

LOCATION OF THE TESTIS

Each testis is suspended in the scrotum by a spermatic cord, which contains the vas deferens, and the arteries, veins and nerves that supply the testis.

produced by both the mother and the fetus, the testes gradually descend. At birth, or within the next few months, they have usually reached the surface of the body and hang suspended in the pouch of skin called the *scrotum*.

STRUCTURE

Within each testis are the seminiferous tubules, delicate coiled tubes that produce sperm. These tubules lead via the vasa efferentia (small ducts) to the *epididymis*, a structure lying behind the testis in which the newly formed sperm mature. Cells between the seminiferous tubules produce testosterone, the male sex hormone, which passes into small blood vessels in the testis and then into the circulation.

Each testis is protected by a tough, fibrous capsule, the tunica albuginea, and is suspended from the body by the *spermatic cord*. This cord is composed of the *vas deferens* (the tube that transports sperm from the epididymis to the urethra), and a number of blood vessels and nerves. (See also *testis, undescended*.)

testis, cancer of

A rare, cancerous tumour of the *testis*. Testicular cancer occurs most commonly in young to middle-aged men, and the risk increases in individuals who have a history of undescended testis (see *testis, undescended*).

TYPES

The most common types of testicular cancer are seminomas, which are made up of only one type of cell, and *teratomas*, which are made up of cells that do not resemble other cells in the testis. Other cancers affecting the testis are extremely rare and develop from testicular tissue or from lymphatic tissue within the testis (see *lymphoma*).

SYMPTOMS

The cancer usually appears as a firm, painless swelling of one testis. In some cases, there may be pain and inflammation.

DIAGNOSIS

Men are recommended to examine their testes regularly to check for unusual changes (see *testicular self-examination*). If a lump is found, the doctor will perform tests, such as *ultrasound scanning*, to exclude other causes of testicular swelling (see *testis, swollen*).

TREATMENT

Biopsy, followed by *orchidectomy* (surgical removal of the testis) is the usual course of action for testicular cancer, and may be combined with *chemotherapy*. The tumours usually respond well to treatment. Provided the other testis is healthy, treatment generally does not destroy its fertility.

testis, ectopic

A *testis* that is absent from the *scrotum* because it has descended into an abnormal position, usually in the groin or at the base of the penis. The condition is most often discovered soon after birth during a routine physical examination. It is treated by *orchidopexy*, an operation to place the testis in the scrotum. (See also *testis, undescended*.)

testis, pain in the

Pain in a *testis* may have a number of causes, including mild injury, a tear in the wall of the testis due to a direct blow, *orchitis* (inflammation of the testis), *epididymo-orchitis* (inflammation of the testis and the epididymis), and torsion of the testis (see *testis, torsion of*).

Sometimes, no cause is found and the pain disappears without treatment. If the wall of the testis is torn, an operation to repair it may be needed.

testis, retractile

A *testis* that is drawn up high into the groin by a pronounced muscle reflex in response to cold or touch. A retractile testis is normal in young children, but it usually disappears by *puberty*.

testis, swollen

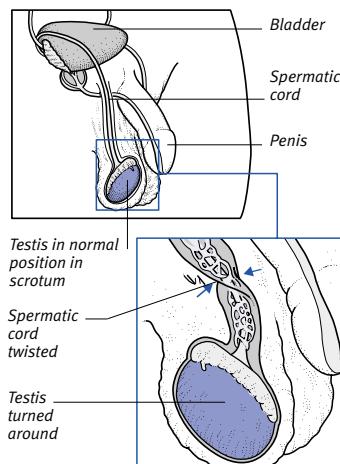

Swelling of the *testis* or surrounding tissues in the *scrotum*. Harmless, painless swellings include *epididymal cysts*, *hydroceles*, *varicoceles*, and *spermatoceles*. Cancer of the testis (see *testis, cancer of*) is a rare cause of swelling; swelling due to a cancerous tumour is usually painless. Painful swelling may be due to a direct blow, torsion of the testis (see *testis, torsion of*), *orchitis* (inflammation of the testis), or *epididymo-orchitis* (inflammation of the testis and epididymis). Any swelling of the testes should be assessed promptly by a doctor. An *ultrasound* scan may be done to aid diagnosis.

testis, torsion of

Twisting of the *spermatic cord* that causes severe pain and swelling of the *testis*. The pain develops rapidly and is sometimes accompanied by abdominal pain and nausea. The testis becomes swollen and very tender, and the skin of the *scrotum* becomes discoloured. Unless the torsion is treated within a few hours, permanent damage to the testis results. The condition is most common around puberty. It is more likely to occur if the testis is unusually mobile within the scrotum.

TORSION OF THE TESTIS

If a testis rotates, veins in the *spermatic cord* become obstructed, causing severe swelling and pain. The condition is most common around puberty but can occur at any age.

**Treatment**

Torsion must be treated by surgery within a few hours, otherwise the testis will have to be removed. In surgery, both testes are secured in the scrotum to prevent recurrence.

Diagnosis is by physical examination. Surgery is performed to untwist the testis and anchor it in the scrotum with small stitches to prevent recurrence. If the damage is irreversible, *orchidectomy* (removal of the testis) is performed. In either case, the other testis is anchored to the scrotum to prevent torsion on that side. With prompt treatment, full recovery is complete.

testis, undescended

A testis that has failed to descend from the abdomen to the *scrotum*. The condition usually affects only one testis. An undescended testis often descends within months of birth but rarely descends after this time. The condition is more common in premature baby boys.

An undescended testis does not develop normally, cannot produce normal sperm, and is at increased risk of testicular cancer (see *testis, cancer of*). If both testes are undescended, *infertility* results.

CAUSES

The final descent of the testis through the inguinal canal in the groin is controlled by hormones produced by the mother and by the testis itself. If these stimuli do not have an effect, the spermatic cord (which carries the *vas deferens* and blood vessels to the testis) fails to lengthen sufficiently to allow full descent. Less commonly, a normal testis is prevented from reaching the scrotum because of fibres blocking its route, and remains in the groin.

DIAGNOSIS AND TREATMENT

A diagnosis is made during a physical examination after birth or later in infancy. Treatment is by *orchidopexy*, an operation to place the testis in the scrotum, which usually reduces the risk of later infertility or testicular cancer. A poorly developed undescended testis may be removed if the other is normal.

test meal

A procedure to measure the output of acid by the *stomach*. A *nasogastric tube* is passed into the stomach after an overnight fast, and a sample of gastric fluid is sucked up through the tube. An injection of *histamine* or, more usually, pentagastrin (a synthetic preparation of the hormone gastrin) is given; further samples of stomach fluid are taken at intervals for up to two hours and analysed for hydrochloric acid content.

The test is used for people thought to be suffering from *Zollinger-Ellison syndrome*, and to confirm the absence of

stomach acid in people with pernicious anaemia (see *anaemia, pernicious*).

testosterone

The main *androgen hormone* (male sex hormone). It stimulates bone and muscle growth and sexual development. It is produced by the *testes* and, in small amounts,

the *ovaries*. Synthetic or animal testosterone is used to stimulate delayed *puberty* or treat some forms of male *infertility*.

tests, medical

Tests may be performed to investigate the cause of symptoms and establish a diagnosis, to monitor the course of

TYPES OF MEDICAL TESTS

The table below lists some commonly performed medical tests, classified according to the body system they are used to study, although all of the tests are often done as part of the investigation for any system. Each test listed in the table has its own entry. Only some of the most important imaging techniques for each body organ have been included; a complete list appears in the appropriate imaging article.

System	Test	
Brain and nervous system	<ul style="list-style-type: none"> ● EEG ● Evoked responses ● Hearing test ● Vision test ● Lumbar puncture ● Intelligence tests 	<ul style="list-style-type: none"> ● Myelography ● Brain imaging ● CT scanning ● MRI ● PET scanning
Skin, bones, and muscles	<ul style="list-style-type: none"> ● EMG ● Biopsy 	<ul style="list-style-type: none"> ● Bone imaging ● X-rays
Endocrine system and metabolism	<ul style="list-style-type: none"> ● Thyroid-function test ● Thyroid scanning 	<ul style="list-style-type: none"> ● Blood tests ● Urinalysis
Blood and immune system	<ul style="list-style-type: none"> ● Blood test ● Lymphangiography 	<ul style="list-style-type: none"> ● Skin tests ● Bone marrow biopsy
Heart and circulation	<ul style="list-style-type: none"> ● Heart imaging ● Chest X-ray ● Angiography ● Echocardiography ● Venography 	<ul style="list-style-type: none"> ● ECG (plus exercise and 24-hour ECG) ● Catheterization, cardiac ● Cardiac stress test ● Thallium scan
Lungs	<ul style="list-style-type: none"> ● Pulmonary function tests ● Blood gases/oxygen saturation ● Peak-flow meter ● Spirometry 	<ul style="list-style-type: none"> ● Chest X-ray ● Bronchoscopy ● Sputum analysis
Biliary system	<ul style="list-style-type: none"> ● Liver-function test ● Liver imaging ● Ultrasound scanning ● Cholangiography 	<ul style="list-style-type: none"> ● Cholecystography ● ERCP ● Liver biopsy
Gastrointestinal tract	<ul style="list-style-type: none"> ● Endoscopy ● Colonoscopy ● Gastroscopy ● Sigmoidoscopy 	<ul style="list-style-type: none"> ● Barium X-ray examinations ● Jejunal biopsy ● Occult blood, faecal ● Microbiology/parasitology
Urinary tract	<ul style="list-style-type: none"> ● Kidney imaging ● Urography (IVU) ● Ultrasound scanning 	<ul style="list-style-type: none"> ● Urinalysis ● Kidney-function tests ● Cystoscopy
Reproductive system	<ul style="list-style-type: none"> ● Pregnancy test ● Hysterosalpingography ● Mammography ● Ultrasound scanning ● Laparoscopy 	<ul style="list-style-type: none"> ● Amniocentesis ● Cervical smear test ● Chorionic villus sampling ● Chromosome analysis ● Seminal fluid analysis

a disease, or to assess response to treatment. A medical testing programme carried out on people who are apparently in good health to find disease at an early stage is known as *screening*.

The accuracy of a test is based on its sensitivity (ability to correctly identify diseased subjects), specificity (ability to correctly identify healthy subjects), and predictive value. The predictive value is determined by a mathematical formula that involves the number of accurate test results and the total number of tests performed. The best tests have both high specificity and high sensitivity, and therefore high predictive value. (See also *Medical tests* box, previous page.)

test-tube baby

The colloquial term for a baby born following *in vitro fertilization*, in which an egg (ovum) is taken from a woman's ovary, fertilized outside the body, and then implanted in the uterus.

tetanus

A serious, sometimes fatal, disease of the *central nervous system* (brain and spinal cord) caused by infection of a wound with spores of the bacterium *CLOSTRIDIUM TETANI*.

CAUSE

The spores live mainly in soil and manure but are also found elsewhere, including in the human intestine. When the spores infect poorly oxygenated tissues they multiply and produce a *toxin* that acts on the nerves responsible for controlling muscle activity.

SYMPOTMS

The most common symptom is *trismus* (stiffness of the jaw, commonly known as lockjaw). Other symptoms include stiffness and aching of the abdominal and back muscles, and contraction of facial muscles, producing a fixed grimace. There may also be a fast pulse, mild fever, and profuse sweating. Painful muscle spasms then develop, and may result in *asphyxia* if they affect the *larynx* or chest wall. The spasms usually subside after 10 to 14 days.

DIAGNOSIS AND TREATMENT

The diagnosis is made from the symptoms and signs, and a course of tetanus *antitoxin* injections is started. Artificial ventilation may be needed. Most people recover completely if treated promptly.

PREVENTION

Prevention of tetanus in the UK relies on the *DPT vaccination* being given rou-

tinely in childhood; and booster injections of tetanus and diphtheria are given at intervals thereafter.

tetany

Spasms and twitching of the muscles, most commonly in the hands and feet, although the muscles of the face, *larynx* (voicebox), or spine may also be affected. The spasms are caused by a biochemical disturbance and are painless at first; if the condition persists, the spasms tend to become increasingly painful.

Muscle damage may result if the cause is not treated. The most common underlying cause is *hypocalcaemia* (a low level of calcium in the blood). Other causes include *hypokalaemia* (a low level of potassium), *hyperventilation* during a panic attack, or, more rarely, *hypoparathyroidism* (underactivity of the parathyroid glands).

tetracosactide

A drug used to test the functioning of the *adrenal glands*. Tetracosactide is a chemical analogue (imitation) of the natural hormone *corticotrophin (ACTH)*. ACTH stimulates the cortices of the adrenal glands to secrete hormones such as *cortisol*. To diagnose a disorder of the adrenal glands, a tetracosactide injection is given and the blood cortisol level measured. Failure of the level to rise indicates an abnormality.

tetracosactrin

The former name for *tetracosactide*.

tetracycline drugs

COMMON DRUGS

- Doxycycline • Minocycline • Oxytetracycline
- Tetracycline

A group of *antibiotic drugs* that are commonly used as a treatment for certain infections including *chlamydial infections*, flare-ups of chronic *bronchitis*, *Lyme disease*, *leptospirosis*, and certain types of *pneumonia*. They are also used to treat some cases of *acne*. It should be noted that if taken with milk or *antacid drugs*, tetracyclines are not absorbed effectively in the intestines.

Possible side effects of tetracycline drugs include nausea, vomiting, diarrhoea, headache, and worsening of kidney disorders and liver function. Tetracyclines may discolour developing teeth and are therefore not usually prescribed for children under the age of 12 or pregnant women.

tetralogy of Fallot

A form of congenital *heart disease* in which the heart has four coexisting anomalies: displacement of the aorta, narrowing of the pulmonary valve, a hole in the ventricular septum, and thickening of the right ventricle wall. Because of these defects, blood pumped from the heart to the body is unsufficiently oxygenated, resulting in *cyanosis* (bluish coloration) and breathlessness.

SYMPTOMS AND SIGNS

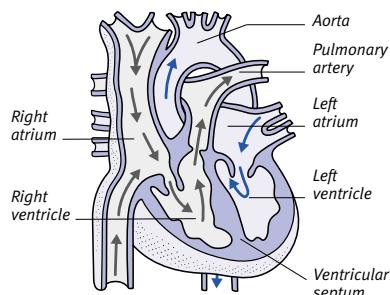

Affected infants appear normal at birth, although disturbed blood flow in the heart may be heard as *murmurs* through a stethoscope. Severely affected infants may become cyanosed and breathless early in life, and may be prone to fainting. Those less severely affected develop these symptoms gradually. Other symptoms include failure to gain weight and poor development.

DIAGNOSIS AND TREATMENT

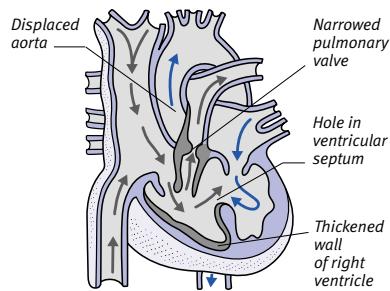

An *ECG*, echocardiogram (see *echocardiography*), and sometimes cardiac *catheterization* are performed to confirm the diagnosis and also to assess the severity of the condition.

Tetralogy of Fallot is corrected by *open heart surgery*. Carrying out the repair

Normal heart

Tetralogy of fallot

Defects of tetralogy of Fallot

The four defects are shown above. Insufficient blood passes to the pulmonary artery and lungs to be oxygenated, and the blood pumped to the body via the aorta is therefore lacking in oxygen.

before the child reaches school age provides the best chance of success and normal future development.

tetraplegia

An alternative term for the condition *quadriplegia*.

thalamus

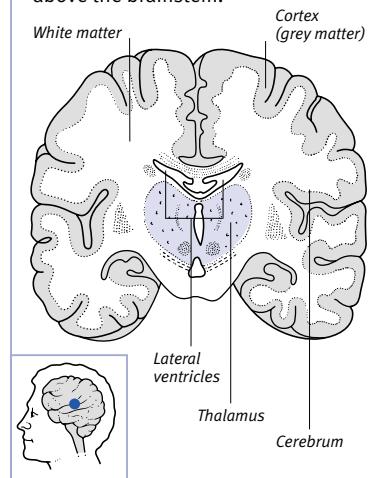

One of a pair of structures in the *brain*, the thalamus is a walnut-sized mass of nerve tissue. The thalamus sit at the top of the *brainstem* and are connected to all parts of the brain.

Each thalamus relays sensory information flowing into the brain. Some basic sensations, such as pain, may reach consciousness within the thalamus. Other types of sensory information are processed and relayed to parts of the cerebral cortex (the outer layer of the brain), where sensations are perceived.

The thalamus acts as a filter by selecting only information that is of particular importance. Certain centres in the thalamus are also thought to play a part in long-term memory.

LOCATION OF THE THALAMUS

The two thalami are situated deep within the brain, at a position just above the brainstem.

thalassaemia

A group of inherited *blood* disorders in which there is a fault in the production of the oxygen-carrying pigment *haemoglobin*. This pigment is normally made in the *bone marrow* for incorporation into *red blood cells*. Many of the red blood cells become fragile and haemolyse (break up), leading to anaemia (see

anaemia, haemolytic). Thalassaemia is prevalent in the Mediterranean, the Middle East, and Southeast Asia, and in families originating from these areas.

CAUSES AND TYPES

Normal adult haemoglobin contains two pairs of globins (protein chains), known as alpha and beta. In thalassaemia, a recessive defective gene results in reduced synthesis of one of the chains. Usually beta-chain production is disturbed (*beta-thalassaemia*). Beta-thalassaemia minor (thalassaemia trait), which is never severe, is caused by a single defective gene. The presence of two defective genes causes beta-thalassaemia major (Cooley's anaemia). The rare disorder alpha-thalassaemia varies in severity, but alpha-thalassaemia major usually results in fetal death.

SYMPOTMS

Symptoms of beta-thalassaemia major appear three to six months after birth and include shortness of breath, *jaundice*, and an enlarged *spleen*. If the condition is untreated, bone marrow cavities expand, leading to characteristic enlargement of the skull and facial bones; normal body growth is arrested and death is likely to occur in early childhood.

DIAGNOSIS AND TREATMENT

Beta-thalassaemia major is diagnosed by microscopic examination of the blood, and from other *blood tests*. Treatment is with *blood transfusions* and, sometimes, *splenectomy* (removal of the spleen). However, successive *blood transfusions* cause a buildup of iron in the body (see *haemosiderosis*). *Chelating agents* are given by mouth or by infusion to help the body excrete the excess iron. A *bone marrow transplant* offers a cure.

PREVENTION

Genetic counselling is advised for parents or other close relatives of a child with thalassaemia, and also for any person with thalassaemia trait.

thalidomide

A drug that was withdrawn in the UK in 1961 after it was found to cause limb deformities in many babies born to women given the drug during pregnancy. Thalidomide is still used to treat certain forms of *Hansen's disease* (leprosy) and *Behcet's syndrome*.

thallium

A rare metallic element that is present as compounds in some zinc and lead ores. Poisoning over a prolonged period causes loss of hair, disorders of the

nerves in the limbs, and disturbance of the stomach and intestines. Thallium-201 (an artificial radioactive isotope) is sometimes used during *radionuclide scanning* of the heart.

THC

The abbreviation for tetrahydrocannabinol, the active ingredient in *marijuana*.

theca

A sheath of tissue covering a body part. An example is the *pericardium*, the membrane that encloses the heart.

thenar

The medical name for the palm of the hand. The term *thenar* is also used to refer specifically to the fleshy part of the palm at the base of the thumb.

theobromine

A substance that is chemically similar to caffeine and occurs naturally in coffee, tea, and cocoa. Theobromine has a weak diuretic effect and also dilates blood vessels. It was formerly used to treat angina but is no longer used medically.

theophylline

A *bronchodilator drug* sometimes used to treat severe *asthma* in cases that have failed to respond to other treatments. Theophylline is given orally, but it is sometimes mixed with another drug in a preparation called *aminophylline* so that it can be given intravenously as emergency treatment.

Possible side effects of theophylline include nausea, vomiting, dizziness, diarrhoea, *palpitations*, and *seizures*. Regular blood tests may be carried out during the course of treatment in order to assess the dosage.

therapeutic

A term meaning related to treatment. The therapeutic dose of a drug is the amount required to have the greatest beneficial effect.

therapeutic community

A method of treating *drug dependence*, *alcohol dependence*, and some *personality disorders* that involves patients living together as a group in a nonhospital environment, usually under supervision. (See also *social skills training*.)

therapy

The treatment of any disease or abnormal physical or mental condition.

therapy, aversion

See *aversion therapy*.

therapy, cognitive

See *cognitive-behavioural therapy*.

therapy, family

See *family therapy*.

therapy, occupational

See *occupational therapy*.

thermography

A technique by which temperature patterns on the surface of the skin are recorded in the form of an image. Thermography provides clues to the presence of diseases and abnormalities that alter the temperature of the skin, such as problems of the circulation, inflammation, and tumours. There are two types of thermography. In one, a camera or scanner picks up infrared radiation naturally emitted from the skin. In the other, sheets of temperature-sensitive liquid crystals are applied to the skin; they change colour in response to changes in temperature.

thermometer

An instrument that is used to measure *temperature*. A traditional clinical thermometer consists of a glass capillary tube (a tube with a very fine bore), which is sealed at one end and has a mercury-filled bulb at the other.

Modern versions of the clinical thermometer include an electronic probe that is connected to a digital display, and an aural thermometer, which measures the temperature of the *ear-drum*. Both of these versions give an almost instant reading. There are also disposable skin thermometers, which employ heat-sensitive chemicals that change colour at specific temperatures. These are not as reliable, however, as standard thermometers.

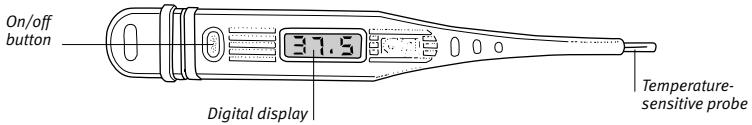

Clinical thermometers may be calibrated in degrees Celsius (sometimes referred to as centigrade), degrees Fahrenheit, or sometimes both.

thermoregulation

The body's internal, automatic temperature-regulating mechanism, which is controlled by the *hypothalamus* in the brain. (See also *temperature*; *heat disorders*; *hyperthermia*; *hypothermia*.)

thiabendazole

See *tiabendazole*.

DIGITAL THERMOMETER**thiamine**

See *vitamin B complex*.

thiazides

A type of *diuretic drug*.

thiazolidinediones

Sometimes referred to as glitazones, a group of oral hypoglycaemic drugs (see *hypoglycaemics, oral*) that are used in the treatment of type 2 *diabetes mellitus*. Thiazolidinediones work by reducing the resistance of the body cells to *insulin* and are often used in combination with other oral hypoglycaemics, such as *metformin* or a sulphonylurea drug. The two main thiazolidinediones are *pioglitazone* and *rosiglitazone*.

thiopental

A *barbiturate drug* that is widely used as a general anaesthetic (see *anaesthesia, general*). Thiopental is given by intravenous injection.

thioridazine

An *antipsychotic drug* that is used to treat *schizophrenia*. It is now used under specialist supervision only because of potentially serious side effects affecting the heart and vision.

thirst

The desire to drink. Thirst is one means by which the amount of water in the body is controlled (the other is the volume of urine excreted).

Thirst is stimulated by an increased concentration of salt, sugar, or certain other substances in the blood. As the blood passes through the *hypothalamus* in the brain, special nerve receptors are stimulated, inducing the sensation of thirst. Thirst is also stimulated if blood volume decreases as a result of sweating, vomiting, diarrhoea, severe bleeding, or extensive burns. Thirst may also be caused by a dry mouth.

thirst, excessive

A strong and persistent need to drink, most commonly due to *dehydration*.

Other possible causes include untreated *diabetes mellitus* and *diabetes insipidus*, kidney failure, treatment with certain drugs such as *phenothiazine drugs*, and severe blood loss. Abnormal thirst may also be due to a psychological condition known as psychogenic polydipsia.

Thomsen's disease

A rare inherited disorder, also called myotonia congenita, in which myotonia (a condition in which muscles contract and then cannot relax again) begins in early childhood and persists throughout life. The myotonia is usually mild. An affected person may experience stiffness and cramps at rest, but symptoms usually subside on exercise. The disorder is inherited in an autosomal dominant manner (see *genetic disorders*).

thoracic outlet syndrome

A condition in which pressure on the *brachial plexus* (the nerve roots that pass into the arms from the neck) causes pain in the arms and shoulders, pins-and-needles sensation in the fingers, and weakness of grip and other hand movements. Severe symptoms are usually caused by a *cervical rib*, which is an extra rib located above the first rib. Thoracic outlet syndrome may also be caused by drooping of the shoulders, an enlarged scalenus muscle in the neck, or a tumour. The condition is made worse by lifting and carrying heavy loads or increases in body weight.

Treatment of thoracic outlet syndrome usually consists of exercises to improve posture, which may sometimes be combined with *nonsteroidal anti-inflammatory drugs* and *muscle-relaxant drugs*. Severe cases may be treated by surgical removal of the first rib.

thoracic surgery

A surgical speciality that is concerned with operations on organs within the chest cavity. Sometimes, thoracic surgery is combined with heart surgery, in which case it is known as cardio-thoracic surgery.

thoracotomy

An operation in which the chest is opened to provide access to organs in the chest (thoracic) cavity.

There are two types of thoracotomy: lateral and anterior. In a lateral thoracotomy the chest is opened between two ribs to provide access to the *lungs*, major blood vessels, and the *oesophagus*. In an anterior thoracotomy, an incision down the length of the sternum (breastbone) provides access to the *heart* and the *coronary arteries*.

thorax

The medical name for the chest. The thorax extends from the base of the neck to the *diaphragm muscle*.

thought

The complex mental activity that enables humans to reason, form judgments, and solve problems. The essential features of thought processes include the substitution of symbols (in the form of words, numbers, or images) for objects, the formation of symbols into ideas, and the arrangement of ideas into a certain order in the mind. (See also *thought disorders*.)

thought disorders

Abnormalities in the structure or content of *thought*, as reflected in a person's speech, writing, or behaviour. *Schizophrenia* causes several types of thought disorder, including the loss of logical connections between associations, the invention of new words (see *neologisms*), thought blocking (sudden interruption in the train of thought), the feeling that thoughts are being inserted into or withdrawn from the mind, and *hallucinations*, usually of an auditory form.

Incoherent thoughts occur in all types of *confusion*, including *dementia* and delirium. Rapidly jumping from one idea to another occurs in *hypomania* and *mania*. In *depression*, thinking becomes slow, and there is a lack of association and a tendency to dwell in great detail on trivial subjects. In *obsessive-compulsive disorder*, recurrent ideas seem to come into a person's mind involuntarily. *Delusions*, which occur in schizophrenia and other psychotic illnesses, may be an expression of distorted thinking.

threadworm infestation

A common infestation with a small worm, *ENTEROBIUS VERMICULARIS* (also called

pinworm), that lives in the intestines. Threadworms mainly affect children.

Female adult threadworms are white and about 1 cm long (large enough to see). They lay eggs in the skin around the anus, and their movements cause itching in the anal region, often at night. Eggs are transferred from the fingers to the mouth to cause reinfection or are carried on toys or blankets to other children. Swallowed eggs hatch in the intestine and the worms reach maturity after a period of two to six weeks. For further information see *Cycle of threadworm infestation* box, overleaf.

DIAGNOSIS AND TREATMENT

Adult worms can sometimes be seen in the faeces or on the buttocks. The worms and their eggs can be collected by applying a piece of sticky tape to the anal area. Treatment is with an *anthelmintic drug*, which usually clears up the problem. Doctors recommend that all members of a family be treated at the same time to prevent reinfection.

threatened miscarriage

Warning signs that a pregnancy may be about to end before full term (see *miscarriage*). There is bleeding from the vagina, although the cervix remains closed and the fetus stays in the uterus. An *ultrasound* scan may help confirm whether the fetus is alive.

thrill

A vibrating sensation felt when the flat of the hand is held against an area of the body. Thrill is caused by turbulent blood flow in an *artery* or the *heart*. The term is also used to describe the feeling produced by fluid within the abdominal cavity in *ascites*.

throat

A popular term for the *pharynx*. The term is also sometimes used to refer to the front of the neck.

throat cancer

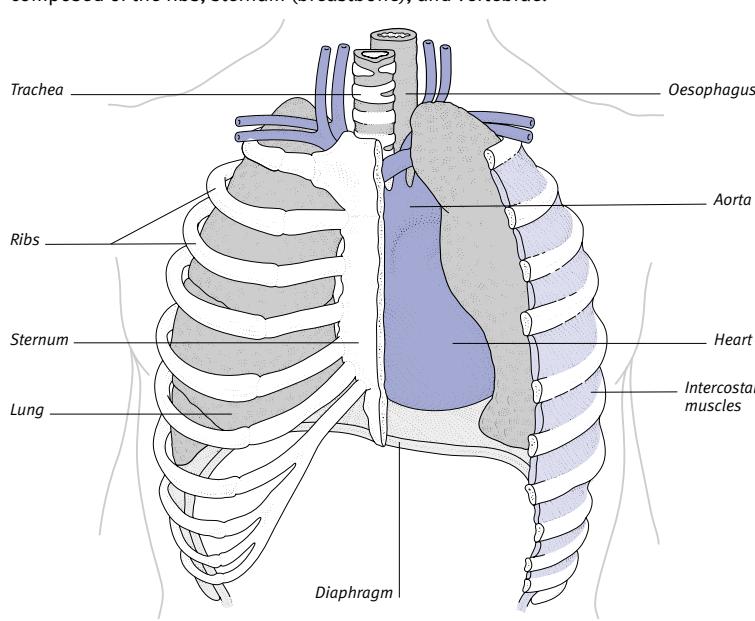

See *pharynx*, *cancer of*; *larynx*, *cancer of*.

thrombectomy

The removal of a *thrombus* (blood clot) that is blocking a blood vessel. It is performed as an emergency procedure if a major artery is blocked, or as a precautionary measure if there is a risk of an *embolus* (fragment) breaking off. Before surgery, the site of the thrombus is established by *angiography* and the patient may be given *anticoagulant drugs*.

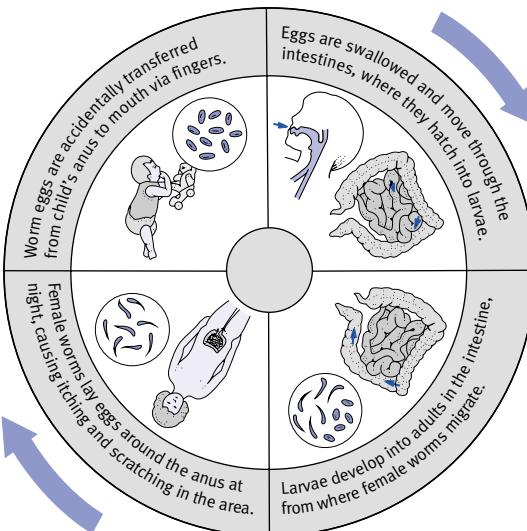

ANATOMY OF THE THORAX

The heart, lungs, and large blood vessels (such as the aorta) occupy almost all of the thoracic cavity; a section of the oesophagus and the trachea are also in the thorax. The thoracic contents are protected and supported by a framework composed of the ribs, sternum (breastbone), and vertebrae.

CYCLE OF THREADWORM INFESTATION

The adult worms live in the large intestine, from where the females migrate to lay eggs around the anal region. Eggs may be transferred to the mouth (via fingers, sheets, or toys), are swallowed, and hatch to start a new infestation. Occasionally, in a girl, worms can affect the vagina, causing discharge.

**thromboangiitis obliterans**

Another name for *Buerger's disease*.

thrombocyte

An alternative name for a *platelet* (the smallest type of blood cell).

thrombocytopenia

A reduction in the number of *platelets* (the smallest type of blood cell) in the blood. Since platelets play a vital role in the blood-clotting process, thrombocytopenia causes a tendency to bleed, especially from smaller vessels. Thrombocytopenic *purpura* (abnormal bleeding into the skin) sometimes develops.

CAUSES

The cause of thrombocytopenia may be a reduced rate of platelet production or a fast rate of platelet destruction. The disorder can be a feature of certain diseases including *leukaemia*, *lymphoma*, systemic *lupus erythematosus*, *megaloblastic anaemia*, and *hypersplenism*. Thrombocytopenia can also be caused by a viral illness, by exposure to *radiation*, or by an adverse reaction to a prescribed drug such as a thiazide *diuretic*. *Idiopathic thrombocytopenic purpura* (ITP) is an *autoimmune disorder*.

DIAGNOSIS AND TREATMENT

Thrombocytopenia is confirmed by a *blood count*. Any underlying disease is treated if possible. Children with ITP may not need treatment, but adults are usually given *corticosteroid drugs*. If

thrombocytopenia persists, *splenectomy* (removal of the spleen) may be performed. When the cause is known, treatment usually results in an increase in platelet numbers.

thromboembolism

The blockage of a blood vessel by a piece of a blood clot (embolus) that has broken off from a *thrombus* elsewhere in the circulation. (See also *thrombosis; embolism*.)

thrombolytic drugs

COMMON DRUGS

- Alteplase • Reteplase • Streptokinase
- Tenecteplase

Sometimes called fibrinolytic drugs, this group of drugs is used to treat acute *myocardial infarction* (heart attack), and *thrombosis* and *embolism* in which a blood vessel is blocked by a blood clot. Thrombolytic drugs act within blood vessels to dissolve clots. They are administered intravenously and must be given promptly after in order for it to be effective. Possible side effects include abnormal bleeding and allergic reaction.

thrombophilia

A tendency for blood to clot too readily, which leads to an increased risk of disorders, such as deep vein thrombosis (see *thrombosis, deep vein*) and *stroke*,

due to blockage of blood vessels by blood clots (called *thrombosis*). This tendency may be due to an inherited deficiency or abnormality in proteins such as *factor V* that are involved in blood clotting. Thrombophilia may also be caused by the immune disorder *anti-phospholipid syndrome*, which is associated with an increased risk of miscarriage as well as of circulatory disorders due to thrombosis.

Thrombophilia may go unrecognized until conditions, such as air travel or injury, that increase the risk of clots cause symptoms or signs. Women with thrombophilia are advised not to take the *oral contraceptive pill* or *hormone replacement therapy*.

thrombophlebitis

Inflammation of a section of vein, usually just under the skin, with clot formation in the affected part. This can occur after minor injury to the vein or as a complication of *varicose veins* or *Buerger's disease*. The affected blood vessel is swollen, red, and tender, and feels hard. Fever and malaise may occur. A blood clot may develop.

Treatment includes support with a bandage, *nonsteroidal anti-inflammatory drugs*, and sometimes *antibiotic drugs*. The condition usually clears up in 10–14 days.

thrombosis

The formation of a *thrombus* (blood clot) in an undamaged blood vessel. Clotting is a normal response when a blood vessel wall is injured, but abnormal when a vessel has not been punctured.

A thrombus that forms within an artery supplying the heart muscle (*coronary thrombosis*) is the usual cause of *myocardial infarction* (heart attack). A thrombus in an artery of the brain (*cerebral thrombosis*) is a common cause of *stroke*.

Thrombi may block arteries supplying blood to the legs, kidneys, retinas, intestines, and other organs, sometimes causing severe damage and symptoms such as pain and loss of function. Another danger is that an embolus (fragment of a thrombus) may break off and be carried by the blood to block an important blood vessel in another area (see *embolism*).

Thrombi can also form in veins, either just beneath the skin or in deeper veins (see *thrombosis, deep vein*).

CAUSES

In the blood there is a fine balance between the mechanisms that encourage and discourage clotting, so there

is neither a tendency to bleed nor to form clots (see *blood clotting*). Thrombosis can occur if this mechanism is disturbed in favour of clotting. (See *thrombophilia*.)

In arteries, thrombus formation is encouraged by *atherosclerosis* (a build-up of fatty deposits on the walls of arteries), smoking, *hypertension* (high blood pressure), and damage to blood vessel walls from inflammation in *arteritis* and *phlebitis*. An increased clotting tendency may occur in *pregnancy*, with the use of *oral contraceptives*, or through prolonged immobility.

SYMPOTMS

An arterial thrombosis may cause no symptoms until the blood flow is impaired. When this occurs, it leads to reduced function in the tissue supplied by the affected artery, and sometimes

severe pain. Venous thrombosis may cause pain and swelling.

DIAGNOSIS AND TREATMENT

Diagnosis of thrombosis is by doppler ultrasound. In some cases, angiography or venography may also be used. Treatment may include *anticoagulant drugs* or *thrombolytic drugs*, *nonsteroidal anti-inflammatory drugs*, and, in some cases, *antibiotic drugs*. In life-threatening cases, *thrombectomy* (surgical removal of the blood clot) may be needed.

thrombosis, deep vein

The formation of a *thrombus* (blood clot) within deep-lying veins in the leg.

CAUSES

The cause is usually a combination of slow blood flow through one part of the body (such as when sitting for long periods or when the tissues are com-

pressed, as occurs in long-haul aircraft flights) and an increase in the clotting tendency of the blood, which occurs in dehydration, after surgery or injury, during pregnancy, in some inherited conditions (see *thrombophilia*), and in women taking *oral contraceptives*.

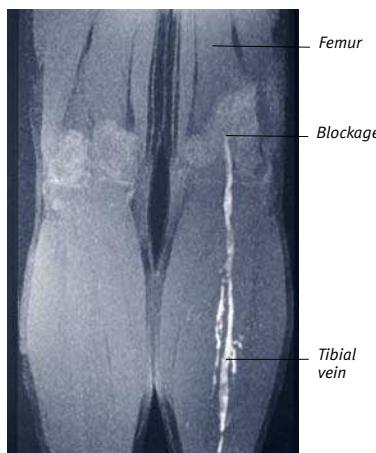

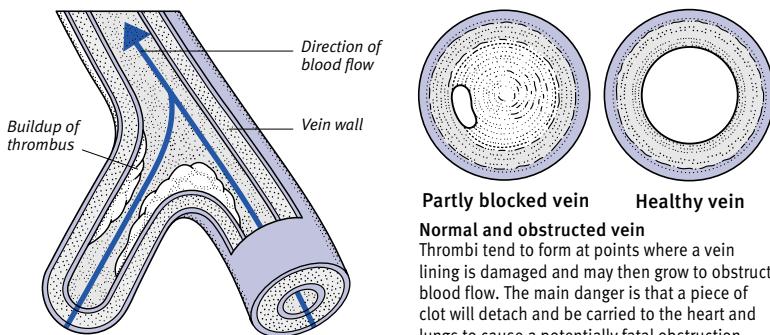

Deep vein thrombosis may also be due to *polycythaemia* (increased numbers of red cells in the blood). Deep vein thrombosis is common in people with *heart failure* and those who have had a *stroke*; it also commonly occurs in people who have been bedridden.

SYMPOTMS

Clots in the leg veins may cause pain, tenderness, swelling, discolouration, and ulceration of the skin, but they can be symptomless. A deep vein thrombosis is not necessarily serious in itself, but part of the clot may break off and travel in

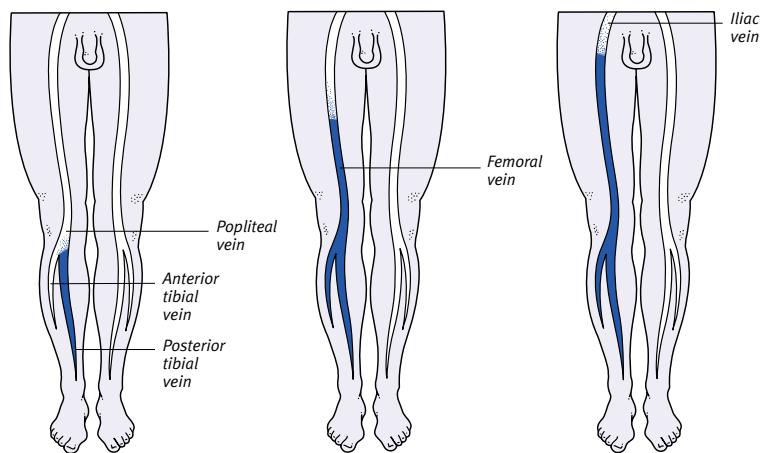

DEEP VEIN THROMBOSIS

Thrombi, or clots, tend to form when blood flow is sluggish or if there is a rise in the level of coagulation factors in the blood. Once a clot has formed, it may provide a site for further clotting, so that a long, snaky clot may grow along the length of a vein. There is a risk that the end of such a clot may break off into the circulation. Thrombi form most commonly in the leg veins and may interfere with the drainage of blood from a leg (below right), causing signs and symptoms of varying severity.

Example of deep vein thrombosis

This MRI of the leg of a patient with deep vein thrombosis shows the vein blocked by a thrombus (blood clot).

Calf vein thrombosis

When clots are localized in the lower-leg veins, there is usually some pain in the calf but there may be little swelling.

Femoral vein thrombosis

If clots are present in the femoral and the lower-leg veins, there is usually pain and swelling up to the region above the knee.

Iliac vein thrombosis

Clots in the iliac vein may affect drainage of blood from the whole leg, causing severe pain and swelling in the leg.

the bloodstream to the lungs. This is known as a *pulmonary embolism*.

DIAGNOSIS AND TREATMENT

A diagnosis is made by doppler *ultrasound scanning*. Treatment depends on the site and extent of the clots. Small clots may not need treatment if they are confined to the calf and the patient is mobile. Otherwise, *anticoagulant drugs* or *thrombolytic drugs* are given. If there is a high risk of pulmonary embolism, *thrombectomy* (surgical removal of the clot) may be performed.

PREVENTION

The risk of deep vein thrombosis during long-haul flights can be reduced by wearing elastic stockings, moving the legs and feet around frequently, and drinking plenty of nonalcoholic fluids.

thrombus

A blood clot that has formed inside an intact blood vessel. A thrombus is life-threatening if it obstructs the blood supply to an organ such as the heart or brain. A thrombus may also lead to *gangrene* (tissue death) in an organ or extremity, or to *embolism*, in which a fragment of the thrombus breaks off and is carried to obstruct the blood circulation elsewhere in the body. (See also *blood clotting; thrombosis*.)

thrush

A common name for the fungal infection *candidiasis*.

thumb-sucking

A common habit in young children, which provides comfort, oral gratification, amusement when bored, and reassurance. Thumb-sucking tends to decrease after age three, and most children grow out of it by age seven. In most cases, it is not harmful. However, *malocclusion* (incorrect alignment) of the permanent teeth may develop if the habit continues past seven years of age. This problem is usually temporary, but if the thumb-sucking persists, an *orthodontic appliance* may be needed.

thymoma

A rare *tumour* of the *thymus gland*. The tumour can arise from any of the cell types in the thymus gland and can be cancerous or noncancerous. Thymoma is associated with the autoimmune disorder *myasthenia gravis*.

thymoxamine

See *moxislyte*.

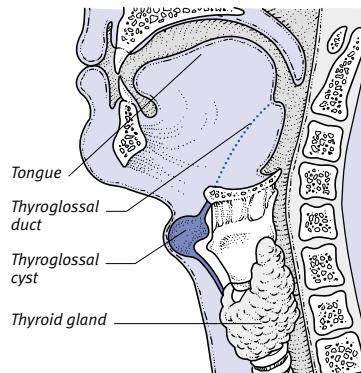

thymus gland

A gland that forms part of the *immune system*. The thymus gland lies behind the *sternum* (breastbone) and consists of two lobes that join in front of the *trachea* (windpipe). Each lobe of the thymus gland is made of lymphoid tissue consisting of *lymphocytes* (white blood cells), *epithelium* (lining cells), and fat.

The thymus conditions lymphocytes to become *T-cells*. It plays a part in the immune response until *puberty*, gradually enlarging during this time. After puberty, it shrinks, but some glandular tissue remains until middle-age.

thyroglossal disorders

A set of congenital defects caused by failure of the thyroglossal duct to close up during embryonic development. In *embryos*, this duct runs from the base of the tongue to the *thyroid gland*. Abnormal development may cause the duct to persist in its entirety or partly as a cyst. A cyst may become infected and swollen, which may lead to formation of a *fistula* (an abnormal passage that develops between the cyst and the surface of the neck). The cyst and any remaining parts of the duct are removed.

Thyroglossal duct and cyst

The thyroglossal duct, lying between the tongue and the thyroid, sometimes persists after fetal life, and a cyst may form at any point along the duct.

thyroid cancer

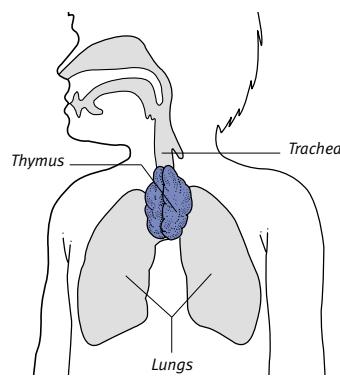

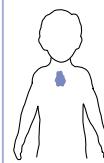

Rare *tumours* of the *thyroid gland*. In most cases the cause is unknown, although exposure to radioactive fallout increases the risk of the condition.

TYPES AND SYMPTOMS

There are several types, depending on the cells involved. In all types, the first sign is a firm nodule in the neck, which may grow slowly or rapidly (however, a nodule does not necessarily indicate cancer: about 10 per cent of thyroid

LOCATION OF THE THYMUS

This is the thymus of a child. At full size, the thymus lies partly in the neck and partly in the chest. It shrinks after puberty.

tumours are found to be cancerous). In many cases, the cancer is painless and symptoms such as difficulty swallowing, and hoarseness or loss of voice, only develop when the tumour presses on other structures.

DIAGNOSIS AND TREATMENT

A diagnosis is made by *thyroid scanning* and *needle aspiration* or a *biopsy*. A *thyroidectomy* (surgical removal of thyroid tissue) is usually followed by treatment with radioactive *iodine* to destroy any residual cancer. Cure rates depend on the cell type and on the size and spread of the tumour when it is diagnosed. Patients need to take the thyroid hormone *thyroxine* for the rest of their lives.

thyroidectomy

Surgical removal of all or part of the *thyroid gland*, which is performed as a treatment for *thyroid cancer*, some cases of *hyperthyroidism* (overactivity of the thyroid) and of *goitre* (enlargement of the thyroid), or a noncancerous tumour of the thyroid gland.

thyroid-function tests

A group of blood tests used to evaluate the function of the *thyroid gland* and to diagnose under- or overactivity of the gland. Tests may include measurement of levels of the thyroid hormones T_3 and T_4 , as well as thyroid-stimulating hormone (TSH), the *pituitary gland* hormone that stimulates the thyroid gland.

thyroid gland

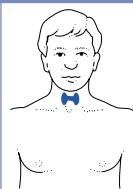

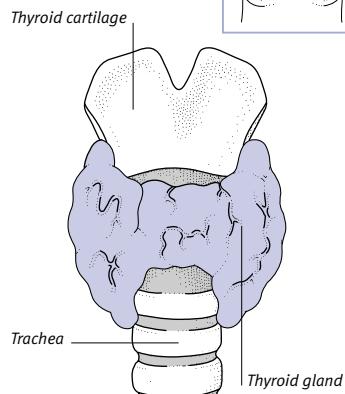

One of the main *endocrine glands*, which helps to regulate the rate of all the body's internal processes. The thyroid is situated in the front of the neck, just below the *larynx* (voicebox). It consists of two lobes, one on each side of the *trachea* (windpipe), joined by a piece of tissue called the *isthmus*.

STRUCTURE AND FUNCTION

Thyroid tissue is composed of follicular cells, which secrete the iodine-containing hormones thyroxine (T_4) and triiodothyronine (T_3), and parafollicular cells (or C cells), which secrete the hormone *calcitonin*. T_4 and T_3 are important in controlling metabolism. Calcitonin helps to regulate calcium balance in the body. (See also *thyroid hormones* and *Disorders of the thyroid gland* box.)

LOCATION OF THE THYROID GLAND

This major gland lies at the base of the neck just in front of the trachea (windpipe).

thyroid hormones

The three hormones produced by the *thyroid gland* are thyroxine (T_4) and triiodothyronine (T_3), which regulate metabolism, and *calcitonin*, which helps to regulate calcium levels in the body. See *Control of thyroid hormone production* box, overleaf.

thyroiditis

Inflammation of the *thyroid gland*; it occurs in several different forms. The most common is *Hashimoto's thyroiditis*, an *autoimmune disorder* that causes *hypothyroidism* (underactivity of the thyroid

DISORDERS OF THE THYROID GLAND

The function of the thyroid gland is controlled by both the *pituitary gland* and the *hypothalamus*, so thyroid disorders may be due not only to defects in the gland itself, but also to disruption of the hypothalamic-pituitary hormonal control system. Disorders of the thyroid gland may cause overproduction of thyroid hormones (*hyperthyroidism*), underproduction of these hormones (*hypothyroidism*), or enlargement or distortion of the gland. *Myxoedema*, *Graves' disease*, and *Hashimoto's thyroiditis* are common disorders. *Goitre* (enlargement of the thyroid gland) may sometimes occur with no accompanying abnormality of thyroid function.

Congenital disorders

In rare cases, the thyroid gland is absent at birth, producing *cretinism*. However, congenital thyroid deficiency more often takes the form of underdevelopment or maldevelopment, in which there is some thyroid tissue but not enough to secrete normal amounts of hormones. A heel-prick blood test is performed on newborns to screen for hypothyroidism. Sometimes the thyroid develops in an abnormal position in the neck, causing, rarely, difficulty swallowing or breathing.

Genetic disorders

Rarely, genetic disorder may impair the thyroid's ability to make hormones. The low blood level of thyroid hormones results in greatly increased secretion by the pituitary gland of thyroid-stimulating hormone (TSH), which, in turn, causes the thyroid to enlarge.

Infection

Thyroid infection is uncommon; it leads to *thyroiditis* (inflammation of the thyroid gland). Viral infection can cause an extremely painful gland and temporary hyperthyroidism.

Tumours

Thyroid tumours may be either cancerous or noncancerous. Thyroid *adenomas* are noncancerous tumours that may secrete thyroid hormone,

sometimes in large enough amounts to cause hyperthyroidism. *Thyroid cancers* are relatively rare. They may be suspected if a single firm or hard lump can be felt in the gland.

Autoimmune disorders

Graves' disease is a form of thyroid overactivity thought to be due to the body's immune system producing antibodies that attack the thyroid gland. In *Hashimoto's thyroiditis*, antibodies damage glandular cells.

Myxoedema

Deficiency of thyroid hormone, which may occur for a variety of reasons, causes a condition known as *myxoedema*, in which the skin becomes dry and thickened and facial features become coarse. Constipation, cold intolerance, and fatigue are other common symptoms.

Hormonal disorders

Hormonal changes during puberty or pregnancy may cause a degree of goitre temporarily. Hyperthyroidism due to excessive production of TSH by the pituitary gland is rare but it may result from a *pituitary tumour*.

Iodine deficiency

Because iodine is necessary for the production of thyroid hormone, its deficiency may lead to goitre, but it is uncommon in developed countries. Severe iodine deficiency in children may cause *myxoedema*.

INVESTIGATION

Blood samples may be taken for *thyroid-function tests*, in which the levels of thyroid or pituitary hormones are measured. The thyroid gland itself may be imaged by various *thyroid scanning* techniques or ultrasound. In some cases, such as a suspected tumour, a *biopsy* may be carried out to obtain a sample of thyroid tissue for microscopic examination.

CONTROL OF THYROID HORMONE PRODUCTION

The blood levels of the hormones T₃ (triiodothyronine) and T₄ (thyroxine) produced by the thyroid must be kept within narrow limits, otherwise hyperthyroidism or hypothyroidism may result. The control systems below exist to achieve this balance but certain disorders may interfere with the system.

Raised blood levels of thyroid hormones

Bloodstream
If blood levels of the thyroid hormones T₃ and T₄ rise, they decrease the sensitivity of the pituitary to thyrotrophin-releasing hormone (TRH), secreted by the hypothalamus.

Hypothalamus
Secretes TRH.

Pituitary gland
The pituitary becomes less sensitive to TRH, so it secretes less thyroid-stimulating hormone (TSH).

Thyroid gland
In response to lowered TSH stimulation, the thyroid reduces its production of the hormones T₃ and T₄.

Bloodstream
The blood levels of T₃ and T₄ thus gradually fall back to normal.

Reduced blood levels of thyroid hormones

Bloodstream
If blood levels of the thyroid hormones T₃ and T₄ fall, the hypothalamus is stimulated to produce more TRH.

Hypothalamus
Increases secretion of TRH.

Pituitary gland
In response to stimulation by TRH, the pituitary increases production of TSH.

Thyroid gland
In response to increased TSH stimulation, the thyroid increases its production of T₃ and T₄.

Bloodstream
The blood levels of T₃ and T₄ thus gradually rise back to normal.

ized as *levothyroxine* and given orally for *hypothyroidism* (an underactive thyroid).

TIA

The abbreviation for *transient ischaemic attack*, a brief interruption of the blood supply to part of the brain.

tiabendazole

A rarely used *anthelmintic drug* used to treat *worm infestations*, including *strongyloidiasis*. It has largely been replaced by newer anthelmintics.

tibia

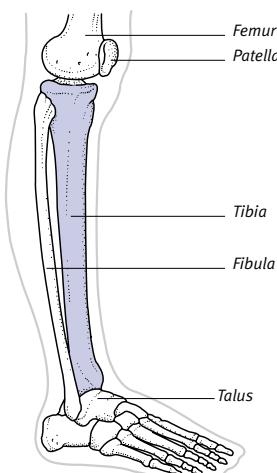

Also called the shin, the inner and thicker of the two long bones in the lower leg. The tibia is the supporting bone of the lower leg. It runs parallel to the *fibula*, the narrower bone to which it is attached by *ligaments*. The upper end articulates with the *femur* (thigh bone) to form the *knee joint*; the lower end articulates with the *talus* to form part of the *ankle joint*. On the inside of the ankle, the tibia is widened and protrudes to form a bony prominence known as the *medial malleolus*.

FRACTURE

One of the most commonly fractured bones, the tibia may break across the shaft or at the upper end from a blow to the outside of the leg below the knee. Prolonged walking or running on hard ground may cause a *stress fracture*.

LOCATION OF THE TIBIA

Also called the shin, the tibia can easily be felt beneath the skin of the lower leg.

gland). Less commonly, it is associated with a viral infection, or it may occur temporarily in women after childbirth.

thyroid scanning

Techniques, such as *radionuclide scanning* and *ultrasound scanning*, that are able to

Thyroid scanning

This is a gamma scan (scintigram) of a healthy thyroid gland. An injected radioactive tracer substance shows areas of activity within the gland.

give information on the location, anatomy, and function of the *thyroid gland* and detect tumours.

thyroid-stimulating hormone

A hormone that is produced in the *pituitary gland*, which is located at the base of the brain. Thyroid-stimulating hormone (TSH) travels in the bloodstream to the *thyroid glands*, which are then stimulated by TSH to release other hormones (known as T₃ and T₄) that are involved in the body's use of energy. (See also *thyroid hormones*.)

thyrotoxicosis

Overactivity of the thyroid gland, also called *hyperthyroidism*.

thyroxine

Represented by the symbol T₄, the most important *thyroid hormone*. It is synthes-

tibolone

A drug used in the short-term treatment of menopausal symptoms. Tibolone is also used to protect against *osteoporosis* (although it is not usually recommended as a first-line treatment). It is given continuously and combines the effects of *oestrogen* and *progestogen drugs*. Possible adverse effects are irregular vaginal bleeding, changes in weight, ankle *oedema* (fluid swelling), dizziness, skin reactions, headache, and facial hair growth.

tic

A repeated, uncontrolled, purposeless contraction of a *muscle* or group of muscles, most commonly in the face, shoulders, or arms. Typical tics include blinking, mouth twitching, and shrugging. Tics usually develop in childhood and are often a sign of a minor psychological disturbance. They usually stop within a year of onset but in some cases persist into adult life. (See also *Gilles de la Tourette's syndrome*.)

tic douloureux

Another name for *trigeminal neuralgia*.

ticks and disease

Ticks are small, eight-legged animals that feed on blood and sometimes transmit diseases to humans via their bites. They are about 3 mm long before feeding and become larger when full of blood. Ticks may be picked up in long grass, scrub, woodland, or caves.

In the UK, the only disease that is known to be transmitted to humans by ticks is *Lyme disease*. Other diseases transmitted in various parts of the world include *relapsing fever*, *Rocky Mountain spotted fever*, *Q fever*, *tularaemia*, tick typhus, and certain types of viral *encephalitis*. The prolonged bite of certain female ticks can cause tick paralysis, in which a toxin in the tick saliva affects the nerves that control movement. In extreme cases, such a reaction to a tick bite can prove fatal.

ticlopidine

A type of *antiplatelet drug* that is prescribed to prevent unwanted blood clotting in people with a history of *stroke* and other circulatory disorders.

Tietze's syndrome

Chest pain localized to an area on the front of the chest wall, usually made worse by movement of the arms or trunk or by pressure on the chest wall.

The syndrome, also called costochondritis, is caused by inflammation of one or several rib cartilages and symptoms may persist for months. Treatment is with *analgesics*, *non-steroidal anti-inflammatory drugs*, or local injections of *corticosteroid drugs* into the cartilage.

Tildiem

A brand name for diltiazem, a *calcium channel blocker* used to treat *hypertension* (high blood pressure) and *angina*.

timolol

A *beta-blocker drug* used to treat *hypertension* (high blood pressure) and *angina pectoris* (chest pain due to inadequate blood supply to the heart). Timolol may be given after a *myocardial infarction* (heart attack). It is used as eye-drops in the treatment of *glaucoma* (raised pressure within the eyeball).

Possible side effects, such as cold hands and feet, are typical of other beta-blockers. The eye-drops may cause irritation, blurred vision, and headache.

tinea

Any of a group of common *fungal infections* of the skin, hair, or nails. Most are caused by fungi called dermatophytes. The infections, often called ringworm, may be acquired from other people, animals, soil, shower floors, or household objects, such as chairs or carpets.

TYPES AND SYMPTOMS

The most common type of tinea infection is *tinea pedis* (*athlete's foot*). *Tinea corporis* (ringworm of the body) causes itchy, usually circular, patches with a prominent edge. *Tinea cruris* (which is commonly called jock itch) produces a reddened, itchy area spreading from the genitals over the inside thighs. This form of tinea is more common in males. *Tinea capitis* (scalp ringworm) causes round, itchy, patches of hair loss on the scalp; it occurs mainly in children. Ringworm of the nails (*tinea unguis*) is often accompanied by scaling of the soles or palms. The nails become thick and turn white or yellow.

DIAGNOSIS AND TREATMENT

Most types of tinea are easily recognizable by appearance, but the diagnosis may be confirmed by culturing the organisms in a laboratory. Treatment is usually with topical *antifungal drugs* in the form of skin creams or ointments. However, for widespread infections or those affecting the hair or nails, oral drug treatment may be necessary.

tinea versicolor

An alternative name for *pityriasis versicolor*, a common skin disorder caused by a fungus.

tingling

See *pins-and-needles*.

tinidazole

An *antibacterial drug* that is particularly useful in treating *anaerobic* infections. Tinidazole is also used with other drugs to eradicate infection with the *HELICOBACTER PYLORI* bacterium. Possible adverse effects of the drug include nausea, vomiting, gastrointestinal disturbances, headache, and dizziness. Alcohol should be avoided during treatment.

tinnitus

A ringing, buzzing, whistling, hissing, or other noise heard one or both ears in the absence of external noise.

CAUSES

In tinnitus, the *acoustic nerve* transmits impulses to the brain, not as the result of vibrations produced by external sound waves, but, for reasons that are not fully understood, as the result of stimuli originating inside the head or within the ear itself. Tinnitus is almost always associated with hearing loss, particularly that due to *presbyacusis* (age-related loss of hearing) and exposure to loud noise. The condition can also occur as a symptom of ear disorders such as *labyrinthitis*, *Ménière's disease*, *otitis media*, *otosclerosis*, *ototoxicity*, and blockage of the ear canal with earwax. It may also be caused by certain drugs, such as *aspirin* or *quinine*, or may follow a *head injury*.

SYMPTOMS

The noise in the ear can sometimes change in nature or intensity. In most cases, however, it is present continuously, although the affected individual may not be aware of its presence all the time. Tolerance of tinnitus varies from one person to another. Many people learn to accept and live with the condition, while other people find it almost intolerable.

TREATMENT

Any underlying disorder is treated if possible. Many sufferers of tinnitus make use of various means, such as a radio, television, cassette player, or headphones, to block out the noise in their ears. A tinnitus masker, a hearing-aid type device that plays white noise (a random mixture of sounds at a wide range of frequencies), may be effective.

tinzaparin

A type of low molecular weight *heparin* (anticoagulant drug) that may be injected once daily in the treatment of deep vein thrombosis (see *thrombosis, deep vein*).

tiotropium

A drug used in the treatment of chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*). Tiotropium, which is taken by inhalation (see *inhaler*), can help to relieve shortness of breath.

tiredness

A common complaint that is usually the result of overwork or poor quality or insufficient sleep. Persistent tiredness may be caused by a number of conditions, including *depression, anxiety, anaemia, and diabetes mellitus*.

tissue

A collection of *cells* specialized to perform a particular function. Examples include muscle tissue, which consists of cells specialized to contract (shorten); epithelial tissue, which forms the *skin* and *mucous membranes* that line the respiratory and other tracts; nerve tissue, comprising cells specialized to conduct electrochemical nerve impulses; and *connective tissue*, which includes *adipose tissue* (fat), and the various fibrous and elastic tissues (such as tendons and cartilage) that hold the body together.

tissue fluid

The watery liquid present in the tiny gaps between body cells, also known as interstitial fluid. Tissue fluid is one component of extracellular fluid (any body fluid outside the cells, including blood and lymph).

To reach cells, oxygen and nutrients must pass from the blood vessels and into the tissue fluid. Similarly, there is a reverse movement of carbon dioxide and other waste products from the cells into the tissue fluid, and then into the bloodstream.

In addition to nutrients and wastes, tissue fluid also contains *ions*. This fluid contains a much higher level of sodium ions, and a much lower level of potassium ions, than intracellular fluid. It is this difference in ion levels that helps to control the movement of water into and out of cells by osmosis; ion levels also play a role in the transmission of electrical impulses through nerves and muscles.

Tissue fluid is formed by the filtration of liquid out through the walls of the first part of blood capillaries (that is, the part nearest an arteriole), where it is forced out by the high blood pressure. In the last part of capillaries (nearest to a venule), blood pressure is much lower, and tissue fluid passes back into the capillaries; some tissue fluid is also drained away into the lymphatic vessels. Thus, there is a continual flow that keeps the amount of tissue fluid constant. Various disorders, for example, congestive *heart failure*, disrupt the balance between formation and drainage of tissue fluid, leading to the accumulation of excess fluid in the tissues, a condition called *oedema*.

tissue-plasminogen activator

Also called TPA, a substance produced by the inner lining of blood vessels that helps dissolve blood clots. TPA can be prepared artificially for use as a *thrombolytic drug*, which is called alteplase. This is used to treat *myocardial infarction* (heart attack) and *pulmonary embolism* (blockage of the artery supplying the lungs). Possible side effects of TPA include nausea and vomiting, bleeding or the formation of a *haematoma* (collection of blood) at the injection site, and an allergic reaction. (See also *fibrinolysis*.)

tissue-typing

The classification of certain characteristics of the *tissues* of prospective organ donors and recipients (see *transplant surgery*). This minimizes the risk of rejection of a donor organ by the recipient's *immune system* after transplantation.

A person's tissue type is classified in terms of his or her *histocompatibility antigens*, the most important of which are human leukocyte antigens (HLAs), on the surface of cells. A person's set of HLAs is inherited and unique (except for identical twins, who have the same set). Nevertheless, close relatives often have closely matching HLA types.

HOW IT IS DONE

A person's tissue-type is established by laboratory tests on cells from a blood sample. In one method, an antiserum containing *antibodies* to a particular HLA is added to the test specimen. If the HLA is present, it is detected by an observable colour or other change.

titanium dental implants

See *implants, dental*.

titubation

Tremor or a nodding movement of the head and/or a stumbling gait, seen in some disorders of the *central nervous system* (brain and spinal cord).

T-lymphocyte

A type of *white blood cell*, also known as a T-cell, that plays a role in the *immune system*. (See also *helper T-cell; killer T-cell; memory T-cell; suppressor T-cell*.)

TMJ dysfunction

See *temporomandibular joint dysfunction*.

toadstool poisoning

See *mushroom poisoning*.

tobacco

The dried leaf of the plant *Nicotiana tabacum*. Tobacco is used for *smoking*, chewing, or as snuff by billions of people. It contains a variable percentage of *nicotine*, and several carcinogenic substances. There is a direct relationship between the amount of tobacco used, the period over which it is used, and the likelihood of *cancer*. All tobacco users have an increased risk of cancers of the oral cavity (see *mouth cancer*), pharynx (see *pharynx, cancer of*), larynx (see *larynx, cancer of*) and oesophagus (see *oesophagus, cancer of*). Smokers are at increased risk of developing *lung cancer, bladder cancer, kidney cancer, and pancreatic cancer* (see *pancreas, cancer of*), as well as several circulatory and lung diseases (see *smoking*).

tobacco-smoking

See *smoking*.

tobramycin

An *antibiotic drug* that is used to treat serious infections such as *septicaemia, meningitis*, and severe infections of the bile ducts, kidneys, prostate gland, and lining of the heart. Tobramycin is sometimes used in the form of eye-drops to treat eye inflammation. High doses of injected preparations of the drug may result in kidney damage, deafness, nausea, vomiting, and headache. Any preparation of tobramycin may cause rash and itching.

tocography

An obstetric procedure that is used to record muscular contractions of the uterus during *childbirth*. It is usually combined with *fetal heart monitoring* (see *cardiotocography*).

tocopherol

A constituent of *vitamin E*. Together, four tocopherols (alpha, beta, gamma, and delta) and several tocopherol derivatives make up the vitamin.

toddler's diarrhoea

A common condition affecting some children for a period after the introduction of an adult diet. It occurs because the child is unable to digest food properly, perhaps because of inadequate chewing. The diarrhoea is no cause for concern, and no treatment is needed.

Todd's paralysis

Weakness in part of the body following some types of epileptic seizure (see *epilepsy*). The weakness may last for minutes, hours, or even days, but there is no lasting effect. The cause is thought to be temporary damage to the motor cortex (the area of the *brain* that controls movement).

toe

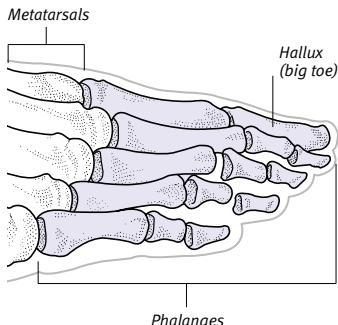

One of the digits of the foot. Each toe has three *phalanges* (bones), except for the *hallux* (big toe), which has two. The phalanges join at hinge joints, which are moved by tendons that flex (bend) or extend (straighten) the toe. An artery, vein, and nerve run down each side of the toe, and the whole structure is enclosed in skin with a nail at the top. The main function of the toes is to maintain balance during walking.

DISORDERS

Congenital disorders include toes missing at birth, *polydactyly* (extra toes), *syn-*

ANATOMY OF THE TOES

Each hallux, or big toe, has two bones called phalanges, which are connected by hinge joints. All the other toes have three phalanges.

dactyly (fused toes), or *webbing* (skin flaps between the toes).

Injuries to the toes, including fractures, are fairly common. Inflammation of the joints, with pain, stiffness, and swelling, may be caused by *osteoarthritis*, *rheumatoid arthritis*, or *gout*.

A common deformity of the big toe is *hallux valgus*, in which the toe turns inwards to the others. This often leads to the development of a *bunion* (a fluid-filled swelling) over the joint at the base of the toe. Abnormality of a tendon in one of the toes may also cause distortion (see *hammer toe*).

toenail, ingrowing

A painful condition of a toe (usually the big toe) in which one or both edges of the *nail* press into the adjacent skin, leading to infection and inflammation. The cause is usually incorrect cutting of the nail or wearing tight-fitting shoes.

Pain relief can be obtained by bathing the foot once or twice daily in a strong, warm, salt solution, then covering the nail with a dry gauze dressing. *Antibiotics* may be prescribed. In some cases, the edge of the nail is removed and the nail bed obliterated to prevent recurrence.

toilet-training

The process of teaching a young child to acquire complete bowel and bladder control. A child is unlikely to be completely toilet-trained before age three and may normally take much longer to remain dry at night (see *enuresis*).

WHEN TO START

Up to about 18 months, emptying of the bladder or bowel is a totally automatic reaction. The child is not yet able to connect the actions of defaecation and urination with their results, and cannot control these actions at will.

At around 18 months, a child can usually indicate that he or she has passed urine or a bowel movement, but is not yet aware when he or she is about to do so. At this stage, the child is not quite ready to use a potty, but can practise sitting on it. By the age of two, a child is aware when he or she is about to pass urine or a bowel movement and says so. At this stage, the child is ready to start using the potty.

METHODS

Toilet-training should be approached in a relaxed, unhurried manner. A child should never be forced to sit on a potty. Boys initially urinate sitting down but soon learn how to manage standing up.

Once a child uses the potty confidently, he or she can gradually progress to using the toilet.

When reasonable control has been achieved, the child can be taken out of nappies during the day. Nappies should be worn at night until the child is usually dry on waking.

Toilet accidents, particularly wetting, are common up to the age of five, because a young child can delay urination for only a few minutes. Some children revert to soiling or wetting when anxious or under stress. (See also *encopresis*; *enuresis*; *soiling*.)

tolbutamide

An oral hypoglycaemic drug (see *hypoglycaemics, oral*) used in the treatment of type 2 *diabetes mellitus*.

tolerance

The need to take increasingly higher doses of a *drug* to obtain the same physical or mental effect. Tolerance develops after taking a drug over a period of time, and usually results either from the liver becoming more efficient at breaking the drug down or from tissues becoming less sensitive to it.

tolnaftate

An *antifungal drug* applied to the skin to treat, and sometimes prevent, recurrent *tinea* infections, including *athlete's foot*. In rare cases, tolnaftate may cause skin irritation or a rash.

tomography

An *imaging technique* that produces a cross-sectional image ("slice") of an organ or part. Most tomography today is performed using *CT scanning* and *MRI*, producing accurate and detailed images.

-tomy

A suffix denoting the operation of cutting or making an incision.

tone, muscle

The natural tension in the *muscle* fibres. At rest, all muscle fibres are kept in a state of partial contraction by nerve impulses from the spinal cord. Abnormally high muscle tone causes increased resistance to movement, *spasticity*, and rigidity. Abnormally low muscle tone causes floppiness (see *hypotonia*).

tongue

A muscular, flexible organ in the floor of the *mouth*.

STRUCTURE AND FUNCTION

The tongue is composed of a mass of muscles covered by a *mucous membrane*. The muscles are attached to the *mandible* (lower jaw) and *hyoid* bone above the *larynx* (voicebox).

Tiny nodules called papillae stick out from the tongue's upper surface, giving it a rough texture. On the papillae at the sides and base of the tongue are the *taste buds*. Taste and other sensory signals are picked up by nerve fibres from one of four *cranial nerves*, and impulses then travel to the brain. The tongue plays an essential part in *mastication* (chewing), *swallowing*, and *speech*.

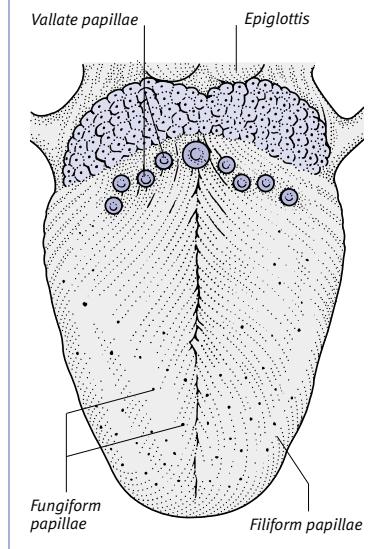

DISORDERS

A large tongue is a feature of *Down's syndrome*, *cretinism*, and *acromegaly*. Temporary enlargement of the tongue as a result of swelling and inflammation may occur in *glossitis*.

Cracks on the surface of the tongue are common and usually cause no problems. However, they are occasionally deep enough to trap food particles, causing discomfort. Unnatural smoothness of the tongue that is accompanied by redness and soreness (*glossitis*) is a feature of certain types of anaemia (see *anaemia*, *iron-deficiency*; *anaemia megloblastic*). Dryness or excessive furring of the tongue may be an indication of

ANATOMY OF THE TONGUE

The tongue consists mainly of muscle; on its surface, it has various types of papillae that contain the taste buds.

dehydration or may be symptoms of *Sjögren's syndrome* or, in infants, *candidiasis*.

In rare cases, for unknown reasons, the papillae on the tongue become elongated and turn black or brown, a condition known as black tongue. This disorder is harmless but unsightly and persistent. The discolouration can be removed by cleaning the tongue twice a day with a soft toothbrush dipped in antiseptic mouthwash.

The tongue can be a site for *mouth ulcers* and *leukoplakia* (thickened white or grey patches), a condition that occasionally becomes cancerous (see *tongue cancer*). Any ulcer developing on the tongue that does not disappear within about three weeks should be reported to a doctor without further delay.

tongue cancer

The most serious type of *mouth cancer* due to its rapid spread. It mainly affects people over 40 and is associated with *smoking*, heavy alcohol consumption, and poor oral hygiene. The edge of the tongue is most commonly affected. The first sign may be a small ulcer with a raised margin, a white patch of thickened tissue called a *leukoplakia*, a fissure, or a raised, hard mass.

Diagnosis of tongue cancer is made by a *biopsy* (tissue sampling). Small tumours, especially those at the tip of the tongue, are removed surgically. Larger tumours or those that have spread often require *radiotherapy*.

**Appearance of tongue cancer**

The cancer often starts at the edge of the tongue. It may appear as a raised mass (as here), as a fissure, or as an ulcer.

tongue depressor

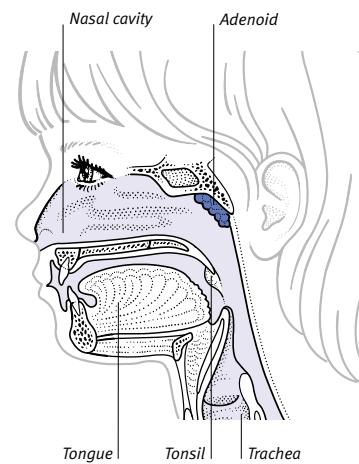

A flat instrument used to hold the tongue on the floor of the mouth to allow examination of the throat.

tongue-tie

A minor *mouth* defect, also known as *ankyloglossia*, in which the frenulum (band of tissue attaching the underside of the tongue to the floor of the mouth)

LOCATION OF THE TONSILS

The tonsils can be easily seen on either side of the back of the throat. They reach their maximum size at about the age of seven years and then shrink.

is too short and extends forwards to the tip of the tongue. There are usually no symptoms apart from limited movement of the tongue. Rarely, the condition causes a speech defect, and minor surgery is required to divide the frenulum.

tonic

One of a group of remedies intended to relieve symptoms such as malaise, lethargy, and appetite loss. Evidence suggests that tonics mainly have a *placebo* effect. The term is also used adjectively to relate to muscle tone (see *tone, muscle*), as in tonic neck reflex, one of the primitive *reflexes* found in newborn infants.

tonic-clonic seizure

Formerly called grand mal, a type of seizure in which consciousness is lost and there is muscle stiffness followed by uncontrolled, jerking movements. The seizure normally lasts only a few minutes; prolonged tonic-clonic seizures can be life-threatening. (See *epilepsy*.)

tonometry

The procedure for measuring the pressure of the fluid within the *eye*, usually performed by an ophthalmologist or optician during an eye examination (see *eye, examination of*). Tonometry is useful in diagnosing *glaucoma* (increased pressure within the eyeball).

tonsil

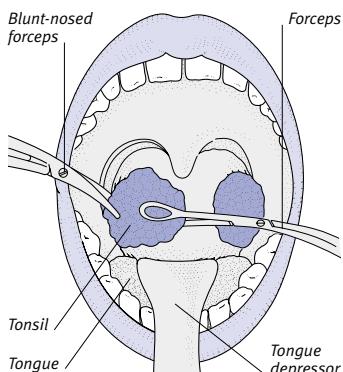

One of a pair of oval tissue masses at the back of the throat on either side. The tonsils are made up of lymphoid tissue and form part of the *lymphatic system*. Along with the *adenoids*, the tonsils protect against upper respiratory tract infections. The tonsils gradually enlarge from birth until age seven, after which time they shrink substantially. *Tonsillitis* is a common childhood infection.

tonsillectomy

Surgical removal of the *tonsils*, which is now performed only if the patient suffers from frequent, recurrent attacks of severe *tonsillitis*. The operation is also carried out as a treatment for *quinsy* (an abscess around the tonsil).

PROCEDURE FOR TONSILLECTOMY

A tonsillectomy may be performed if the tonsils are very enlarged, after an abscess on the tonsil, or if tonsil infections are frequent and severe.

**Standard technique**

With the patient under a general anaesthetic, the tongue is depressed downwards and the tonsils prised from the back of the throat so that they can then be cut away.

tonsillitis

Inflammation of the *tonsils* as a result of infection. Tonsillitis mainly occurs in children under age nine. Sometimes the tonsils become repeatedly infected by the microorganisms they are supposed to protect against.

SYMPTOMS

The main symptoms are a sore throat and difficulty in swallowing. The throat is visibly inflamed. Other common symptoms are fever, headache, earache, enlarged and tender *lymph nodes* in the

neck, and bad breath. Occasionally, there may be additional problems, such as temporary deafness or *quinsy* (an abscess around the tonsil).

TREATMENT

Tonsillitis is treated with plenty of fluids and an *analgesic drug* (painkiller) such as paracetamol; in some cases *antibiotic drugs* may also be prescribed.

tooth

See *teeth*.

tooth abscess

See *abscess, dental*.

toothache

Pain in one or more *teeth* and sometimes the *gums*.

CAUSES

Early dental *caries* (decay) may cause mild toothache when very hot, cold, or sweet food is eaten. More advanced decay or a fractured tooth (see *fracture, dental*), or a deep, unlined filling (see *filling, dental*) may lead to pulpitis (pulp inflammation). This usually causes a sharp, stabbing pain, which is often worse when the person is lying down.

If the inflammation spreads, the supporting tissues round the root of the tooth may be affected (a disorder known as *periapical periodontitis*). This causes localized pain brought on mainly by biting and chewing. A dental abscess (see *abscess, dental*) may also occur. In this case, pain is severe and often continuous, the gum surrounding the affected tooth is tender and swollen, and there may be swelling of the face and neck accompanied by fever.

Sometimes, toothache is caused by *sinusitis* (inflammation of the membrane lining the facial air cavities), when pain is referred to the upper molar and premolar teeth (see *referred pain*).

TREATMENT

Analgesic drugs may provide temporary pain relief. A visit to the dentist should be arranged as early as possible.

tooth avulsion

See *avulsed tooth*.

toothbrushing

Cleaning of the *teeth* with a brush in order to remove *plaque* and food particles from the tooth surfaces and to stimulate the gums. Brushing the teeth should be carried out twice a day using a *dentifrice* (usually toothpaste) that contains fluoride.

tooth decay

See *caries, dental*.

tooth extraction

See *extraction, dental*.

toothpaste

See *dentifrice*.

tophus

A collection of *uric acid* crystals that is deposited in certain tissues, especially those around the joints, but occasionally in other places such as the ear. Tophus is a sign of *hyperuricaemia*, a condition that accompanies *gout*.

topical

A term describing a *drug* that is applied to the surface of the body, not swallowed or injected.

toric lens

A type of *contact lens* specially shaped to correct *astigmatism*.

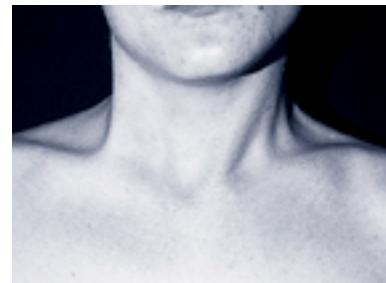

torsion

A term that means twisting, often applied to the intestine or *testis*.

torticollis

Twisting of the neck, causing the head to be tilted and fixed in an abnormal position (wry neck). There is often neck pain and stiffness. The cause is usually a minor neck injury that irritates cervical nerves, leading to *muscle spasm*. Other causes are sleeping in an awkward position, a neck-muscle injury occurring at birth, and a burn or injury that has caused heavy scarring.

Torticollis resulting from muscle spasm may be treated by use of an orthopaedic collar (see *collar, orthopaedic*), *heat treatment*, *ultrasound treatment*, *physiotherapy*, or injections of the toxin

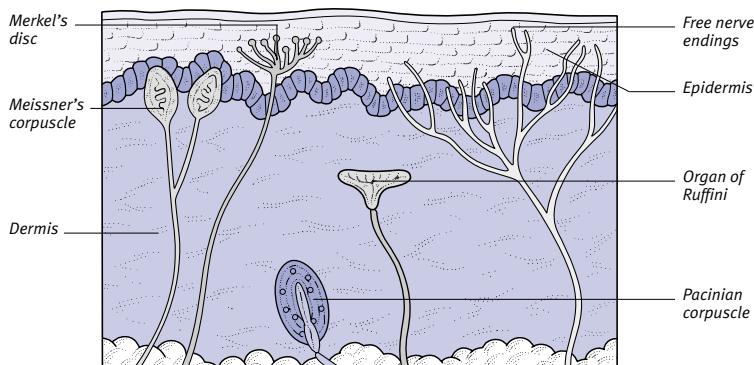

Woman with torticollis

The muscles on the left side of the neck have gone into spasm, causing the head to be pulled over to that side and causing pain.

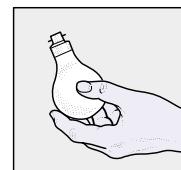

THE SENSE OF TOUCH

The skin contains many thousands of specialized cells that respond to a variety of external stimuli, such as touch, heat, cold, and pressure. These cells (receptors) are divided into two different types. One type of receptor consists only of a thin nerve fibre, which may wrap around an individual hair and respond to its movement. The other type of receptor has

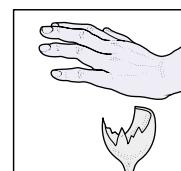

a specialized structure, which is known as an end organ, that surrounds the nerve ending. Some skin receptors consist of several layers of cells that are attached to one nerve fibre. Others contain several nerve fibres that are arranged in a loop or coil. It is probable that several varieties of receptors play a part in each of the different types of touch modality.

**Skin receptors**

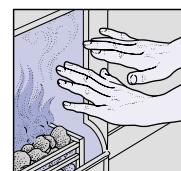

These receptors vary from free nerve endings to corpuscular or bulb-like structures. Individual receptors do not seem to be associated exclusively with any one skin sensation (e.g. cold or pain).

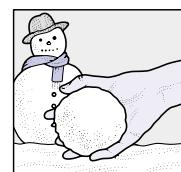

Delicate touch
The ability to detect light contact between an object and the skin. Areas with more receptors are more sensitive.

Pain
Pain warns the brain about possible injury from an external stimulus and can trigger a reflex withdrawal.

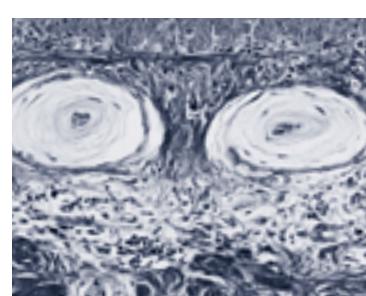

Heat
Some free nerve endings respond to heat. The inner wrist is good for testing temperature. Extreme heat stimulates pain receptors.

Cold
Cold on the skin is detected by specialized end organs. Extreme cold also stimulates pain receptors.

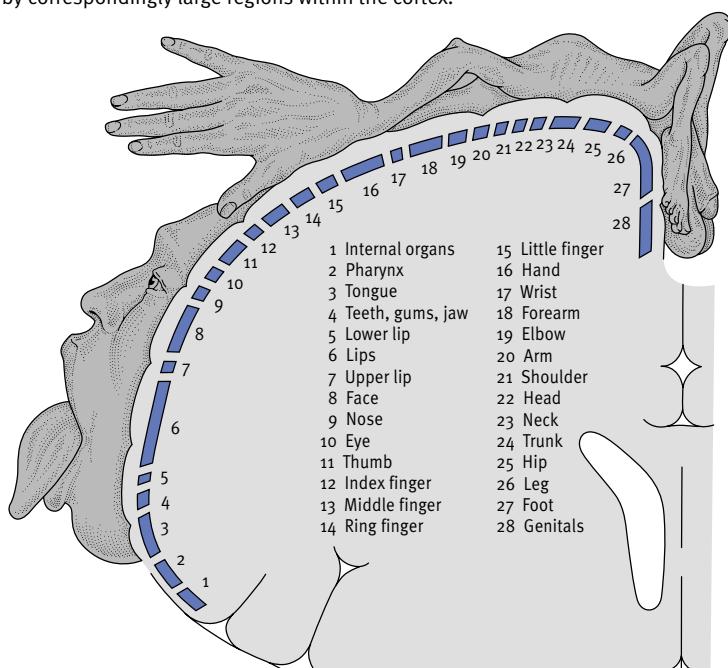

Pressure
A change in pressure on the skin is detected by specialized end organs called pacinian corpuscles.

Pacinian corpuscle
These receptors are 1 mm to 4 mm long and occur in hairless areas of skin, especially the fingers.

TOUCH PERCEPTION

General sensations that emanate from various parts of the body are perceived at specific points within the brain's cerebral cortex. Some of the more highly sensitive body parts, such as the lips and hands, are represented in the brain by correspondingly large regions within the cortex.

that causes *botulism*. When the cause of torticollis is an injury arising from birth, the muscle is gently stretched several times each day; occasionally, an operation is required.

touch

The sense by which certain characteristics of objects, such as their shape, size, temperature, and surface texture, can be ascertained by physical contact.

The skin has many types of touch receptors, including Meissner's corpuscles and Merkel's discs to detect light touch, and Pacinian corpuscles to sense deep pressure and vibration. Signals from these receptors pass via sensory nerves to the spinal cord, then to the *thalamus* in the brain, and on to the *sensory cortex*, where touch sensations are perceived and interpreted.

The various parts of the body differ markedly in their sensitivity to touch discrimination. For example, the fingertips are considerably more sensitive to the sense of touch than the trunk. (See also *sensation*.)

Tourette's syndrome

See *Gilles de la Tourette's syndrome*.

tourniquet

A device that is placed around a limb in order to compress blood vessels. A tourniquet may be used to locate a vein for the purposes of an intravenous injection or the withdrawal of blood. An inflatable tourniquet, called an *Esmarch's bandage*, is used to control blood flow in some limb operations. The use of a tourniquet as a first-aid measure to stop severe bleeding can cause *gangrene* (tissue death); first-aid courses now teach use of pressure to control bleeding in preference to a tourniquet.

toxaemia

Presence in the bloodstream of *toxins*, commonly produced by *bacteria*. (See also *pre-eclampsia*; *toxic shock syndrome*.)

toxaemia of pregnancy

See *pre-eclampsia*.

toxicity

The property of being toxic (poisonous). The term also refers to the severity of adverse effects or illness produced by a *toxin*, a *poison*, or a drug overdose.

toxicology

The study of *poisons*.

toxic shock syndrome

An uncommon, severe illness caused by a *toxin* produced by the bacterium *STAPHYLOCOCCUS AUREUS*.

CAUSES

The condition occurs mostly in women who use highly absorbent vaginal tampons. Other cases have been linked to use of a contraceptive cap, diaphragm, or sponge (see *contraception*), or to skin wounds or staphylococcus infections elsewhere in the body.

SYMPTOMS AND COMPLICATIONS

A high fever, vomiting, diarrhoea, headache, muscle aches and pains, dizziness, and disorientation develop suddenly. A widespread skin rash that resembles sunburn and also affects the palms and soles, develops. Blood pressure may fall dangerously low, and *shock* may develop. Other complications include *kidney failure* and *liver failure*.

TREATMENT

Antibiotics and treatment in an intensive care unit may be needed.

toxin

A poisonous protein produced by pathogenic (disease-causing) bacteria, various animals, or some plants. Bacterial toxins are sometimes subdivided into three categories: *endotoxins*, which are released from dead bacteria; *exotoxins*, which are released from live bacteria; and *enterotoxins*, which inflame the intestine. (See also *poison*; *poisoning*; *toxaemia*.)

toxocariasis

An infestation of humans, usually children, with the larvae of *TOXOCARA CANIS*: a small, threadlike worm that lives in the intestines of dogs.

CAUSE

Children who play with an infested dog or soil contaminated with dog faeces, and who then put their fingers in their mouths, may swallow worm eggs. The eggs hatch in the intestines, and the released larvae then migrate to organs such as the liver, lungs, brain, and eyes.

SYMPOTMS

Usually, infestation causes mild fever and *malaise*, which soon clears up; heavy infestation may lead to *asthma*, *pneumonia*, and *seizures*. Vision may be lost if larvae enter the eye and die there.

DIAGNOSIS AND TREATMENT

A diagnosis of toxocariasis is made from sputum analysis, and by a *liver biopsy*. Severe cases require treatment in hospital with a drug such as *tiabendazole* and an *anticonvulsant drug*.

toxoid

An inactivated bacterial *toxin*. Certain toxoids are used to immunize against specific diseases, such as *tetanus*.

toxoplasmosis

An infection that is caused by the *protozoan* *TOXOPLASMA GONDII* that is often caused by eating undercooked meat from infected animals, or by handling faeces from infected cats.

SYMPTOMS AND COMPLICATIONS

In most cases, there are no symptoms, but there may be a feverish illness that resembles infectious *mononucleosis* (glandular fever). Retinitis (inflammation of the eye's retina) and *choroiditis* (inflammation of the choroid of the eye) may also develop. In people who have an *immuno-deficiency disorder*, toxoplasmosis may cause further problems such as lung and heart damage, *stroke*, seizures, and severe *encephalitis* (brain inflammation).

Toxoplasmosis that is contracted by a pregnant woman is transmitted to the fetus in about a third of cases. The infection may result in *miscarriage* or *stillbirth*, or the infant may have an enlarged liver and spleen, blindness, *hydrocephalus* (fluid around the brain), learning difficulties, seizures, or may die during infancy. Infection in late pregnancy usually has no ill effects.

DIAGNOSIS AND TREATMENT

The diagnosis is made from *blood tests*. Treatment (with *pyrimethamine* and a *sulphonamide drug*) is necessary only in pregnant women, in children with severe symptoms, in people with an immune system deficiency, and in cases of retinitis or choroiditis.

TPA

The abbreviation used for *tissue-plasminogen activator*.

trabecula

A band of fibrous tissue that divides the inner part of an organ, for example the penis, into different sections. The term trabecula (plural *trabeculae*) is also used to describe the bony struts that make up the meshlike structure that is found inside spongy bone.

trabeculectomy

A surgical procedure that is used to control *glaucoma* (raised pressure within the eyeball). Trabeculectomy operates by allowing the fluid that accumulates in the front chamber of the eye to drain out under the conjunctiva.

trace elements

Minerals necessary in minute amounts in the diet to maintain health. Examples are *chromium*, *copper*, *zinc*, and *selenium*. (See also *nutrition*.)

tracer

A radioactive substance that is introduced into the body so that its distribution, processing, and elimination from the body can be monitored.

trachea

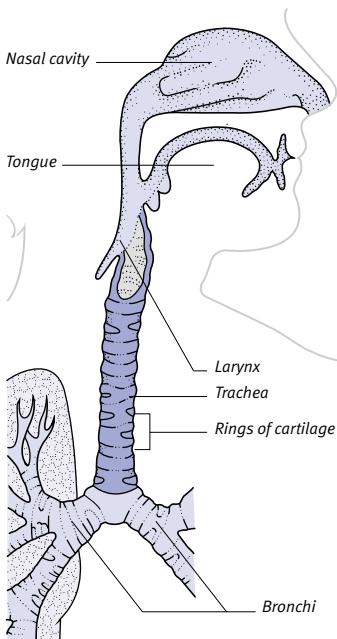

The air passage, also called the windpipe, that runs from just below the *larynx* (voicebox) to behind the upper part of the *sternum* (breastbone), where it divides to form the *bronchi*.

STRUCTURE

The trachea is made up of fibrous and elastic tissue and also smooth muscle. It also contains about 20 rings of *cartilage*, which help to keep it open. The trachea lining has specialized cells (goblet cells) that secrete mucus and cells with *cilia* (hairlike structures), which beat the mucus upwards to help keep the lungs and airways clear.

LOCATION OF THE TRACHEA

The trachea extends down from the larynx for about 10 cm to the point where it divides into the two bronchi.

**DISORDERS**

One of the most common disorders of the trachea is *tracheitis* (inflammation of the trachea lining), which is usually caused by an infection (especially by a virus) and is often associated with *bronchitis* or *laryngitis*. Obstruction of the trachea by an inhaled object is rare because the narrowest part of the upper respiratory tract is the larynx, and any objects that pass through there usually also continue through the trachea. However, the trachea may become obstructed by a tumour or narrowed as a result of scarring from a *tracheostomy* tube inserted to create an artificial airway through the front of the neck.

Rarely, a congenital malformation occurs in which an abnormal channel forms between the trachea and the oesophagus immediately behind it (see *tracheoesophageal fistula*).

tracheitis

Inflammation of the *trachea* (windpipe). Tracheitis is usually caused by a viral infection and is aggravated by inhaled fumes and especially by tobacco smoke; it often occurs with *laryngitis* and *bronchitis* in a condition known as laryngotracheobronchitis.

Symptoms include a painful dry cough and hoarseness. In most cases, no treatment is needed.

tracheoesophageal fistula

A rare *birth defect* in which an abnormal passage connects the *trachea* (windpipe) with the *oesophagus* (gullet). In the most common form of this type of fistula, the lower end of the oesophagus connects with the trachea, and the upper end of the oesophagus is underdeveloped, forming a blind-ended pouch.

SYMPTOMS AND SIGNS

The affected baby cannot swallow saliva and drools constantly. During feeding, food is regurgitated and enters the lungs, causing the baby to choke, cough, and sometimes to turn blue due to lack of oxygen. The abdomen swells because inhaled air passes into the stomach through the fistula. The acidic fluid in the stomach passes up into the lungs through the fistula, leading to *pneumonia* and *atelectasis* (lung collapse).

DIAGNOSIS AND TREATMENT

The condition is often discovered soon after birth, although mild forms may not be detected until childhood or even adult life, usually after recurrent attacks of pneumonia. The diagnosis may be

confirmed by *X-rays*. Treatment of tracheoesophageal fistula consists of an operation that closes the fistula and connects the trachea and oesophagus together correctly.

tracheostomy

An operation in which an opening is made in the *trachea* (windpipe) and a tube is inserted in order to maintain an effective airway. A tracheostomy is used for the emergency treatment of various airway problems involving the *larynx* (voicebox).

A planned tracheostomy is most commonly performed on a person who has lost the ability to breathe naturally and is undergoing long-term *ventilation* or is unable to keep saliva and other secretions out of the trachea. Permanent tracheostomy is needed after *laryngectomy* (removal of the larynx).

**Tracheostomy tube**

The tube readily becomes blocked by secretions; it has a metal inner lining that can be removed for cleaning.

tracheotomy

Cutting of the *trachea* (windpipe). (See also *tracheostomy*.)

trachoma

A persistent infectious disease of the *cornea* and *conjunctiva* of the eye. Trachoma is caused by the bacteria *CHLAMYDIA TRACHOMATIS* and is spread by direct contact and possibly by flies (see *chlamydial infections*). The disease is uncommon in the UK, but, worldwide, trachoma is the most common cause of blindness. Treatment is with *antibiotic drugs*.

tract

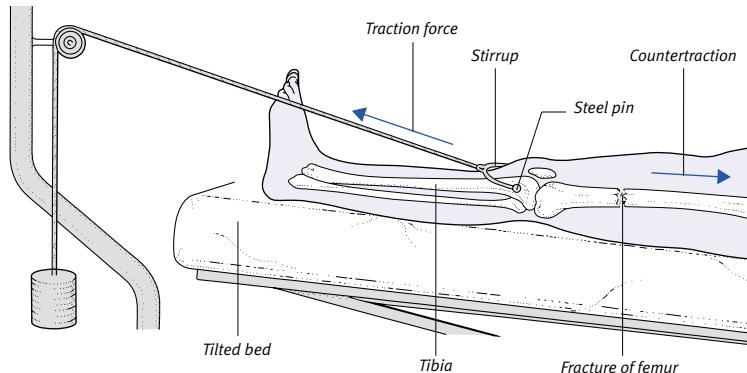

Any one of a group of organs that form a common pathway with the purpose of performing a particular function. The term also refers to a bundle of nerve fibres with a common function.

traction

A procedure in which part of the body is placed under tension to correct the alignment of two adjoining structures.

TRACTION FOR FEMORAL FRACTURE

The thigh muscles have a tendency to go into spasm, because of their immense power, and fractures of the femur (thigh-bone) tend to override this force. Without traction to prevent this, the bone would heal with overlapping ends with the result that the leg would be permanently shortened.

Procedure

Traction is usually performed by means of a narrow steel pin that is pushed through the upper end of the tibia (shin); a steel stirrup is attached to this in order that a cord and weight

can be used to apply the force. The other end of the femur must be immobilized (or counter-traction applied) in order that the fractured bone ends are kept in alignment.

or to hold them in place. Traction is most commonly used to treat a *fracture* in which muscles around the bone ends are pulling the bones out of alignment.

tragus

The small projection of cartilage in front of the opening of the ear canal.

training

A programme of exercises that is undertaken to prepare for a particular sport. Training may be concentrated on improving skills or on improving physical *fitness*. Fitness training should include both *aerobic* and anaerobic exercises, which together build up strength, flexibility, and endurance. Interval training is a type of fitness programme in which a particular exercise is repeated several times with a rest period between. Circuit training consists of performing a set number of different exercises.

trait

Any characteristic or condition that is inherited (which means that is determined by one or more *genes*). Blue or brown eye colour, dark or light skin, and nose shape are examples of genetic traits. The term trait is also sometimes used to describe a mild form of a recessive *genetic disorder*, for example *thalassaemia* trait.

transcutaneous electrical nerve stimulation

See *TENS*.

transdermal patch

A method of administering medication through the skin, using a drug-impregnated, adhesive patch. The drug is released from the patch over a period of time and is absorbed by the skin.

transference

The unconscious displacement of emotions from people who were important during one's childhood, such as parents, to other people during adulthood. For example, during psychotherapy, anger that the analysand feels towards his or her father may be transferred to the therapist. (See also *psychoanalysis*.)

transfusion

See *blood transfusion*.

transfusion, autologous

See *blood transfusion, autologous*.

transient ischaemic attack (TIA)

A brief interruption of the blood supply to part of the brain, which causes temporary impairment of vision, speech, sensation, or movement. The episode typically lasts for several minutes or, at most, for a few hours. TIAs are sometimes described as mini strokes, and can be the prelude to a *stroke*. A stroke occurs within five years in up to one third of patients who have had a TIA.

CAUSES

TIAs may be caused by a blood clot (see *embolism*) that temporarily blocks an artery supplying the brain, or by narrowing of an artery as a result of *atherosclerosis* (buildup of fatty deposits in the artery wall).

INVESTIGATION

After a TIA, tests such as *CT scanning*, *blood tests*, and *angiography* or *Doppler ultrasound scanning* of the carotid artery in the neck may be needed to find a cause. In some cases, the heart is studied as a possible source of blood clots.

TREATMENT

Treatment, which is aimed at preventing a stroke includes *endarterectomy* (an operation to remove the lining of an artery affected by atherosclerosis), *aspirin* (which reduces the "stickiness" of blood), or *anticoagulant drugs*. People who have had a TIA can help prevent a stroke by lifestyle changes such as stopping smoking and adopting a low-fat diet.

transillumination

A procedure that is sometimes carried out during the physical examination of a lump or swelling. Light that comes from a small torch is shone onto one side of the lump; if the light can be seen on the other side, the lump contains clear fluid.

transitional cell carcinoma

A type of cancerous tumour that can develop in the bladder or kidney. In the bladder, transitional cell carcinomas develop within the bladder lining (see *bladder tumours*). In the kidney (see *kidney cancer*), this type of tumour develops in the lining of the renal pelvis (the urine-collecting chamber at the centre of the kidney).

translocation

A rearrangement of the *chromosomes* inside a person's cells; it is a type of *mutation*. Sections of chromosomes may be exchanged or the main parts of two chromosomes may be joined. A translocation may be inherited or acquired as the result of a new mutation.

In many cases a translocation has no obvious effect, and causes no apparent abnormality. However, it sometimes means that some of the affected person's sperm or egg cells carry too much or too little chromosomal material, which may cause a *chromosomal abnormality*, such as *Down's syndrome*, in the individual's children.

transmissible

A term meaning capable of being passed from one person, or one organism, to another.

transplant surgery

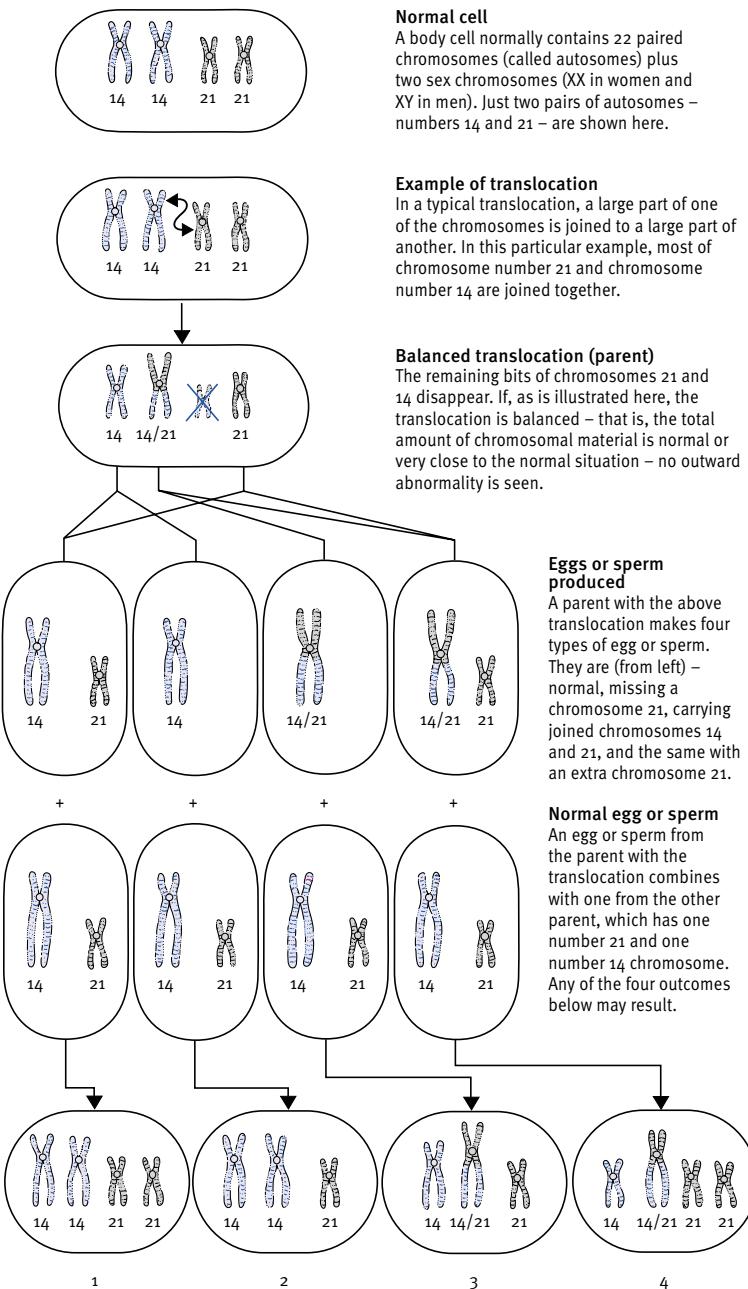

Replacement of a diseased organ or tissue with a healthy, living substitute. The organ is usually taken from a person who has just died. Some kidneys are transplanted from a patient's living relatives (see *organ donation*). The results of surgery have been improved by testing for *histocompatibility antigens* and *tissue-typing*.

Rejection is a major problem. A combination of a *corticosteroid drug* and an *immunosuppressant drug* are given in order to suppress this response.

Every patient who has to undergo an organ transplant operation must be given immunosuppressant drugs for an indefinite period. (See also *heart-lung transplant*; *heart transplant*; *kidney transplant*; *liver transplant*.)

EFFECT OF CHROMOSOMAL TRANSLOCATION

A translocation is a rearrangement of the chromosomes in body cells. A person carrying a translocation may show no abnormality but there is a risk of his or her child having a chromosomal abnormality.

The effect in the child

The child may have any of the following:

- (1) normal chromosomes,
- (2) a missing chromosome 21 (incompatible with life),
- (3) a balanced translocation (like the parent),

and (4) effectively, an extra chromosome 21, leading to *Down's syndrome*. In the last case, the parents of the affected child may benefit from genetic counselling.

transposition of the great vessels

A serious form of congenital *heart disease* in which the two major vessels that carry blood away from the heart (the *aorta* and the pulmonary artery) are transposed. This means that insufficient oxygenated blood is supplied to the body's tissues. *Cyanosis* (blueness of the skin) usually develops and the baby becomes increasingly short of breath and feeds poorly. *Open heart surgery* is needed in order to correct the defect.

transsexualism

A rare condition in which an individual wishes to live as a member of the opposite sex. Transsexuals commonly seek hormonal or surgical treatment in order to bring about a physical *sex change*. A psychiatric evaluation and a physical examination are necessary before such treatment is undertaken.

transverse colon

One of the four major sections of the *colon*, or large intestine. The transverse colon lies across the abdomen.

transverse fracture

A *fracture* in which there is a straight break across the bone.

transverse myelitis

See *myelitis*.

transvestism

A persistent desire by a man to dress in women's clothing, also known as cross-dressing. Transvestism ranges from the occasional wearing of female underclothes to dressing in female clothes in public and involvement in transvestite subculture. Most transvestites are heterosexual and many have a sexual relationship with a female partner who is aware of the cross-dressing and can accept it as a special need.

tranylcypromine

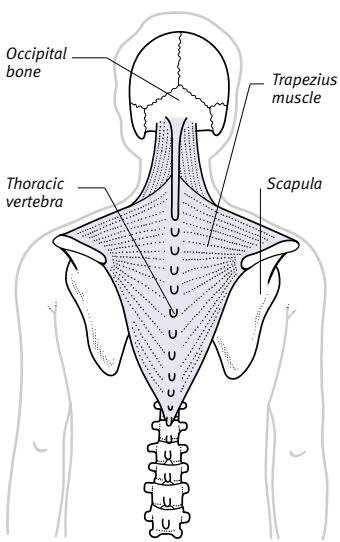

An *antidepressant drug* that belongs to the *monoamine-oxidase inhibitor* (MAOI) group and is used mainly in patients with severe depression.

trapezius muscle

A large, diamond-shaped *muscle* that extends from the back of the skull to the lower part of the spine in the chest and across the width of the shoulders. The trapezius muscle is attached to the top and back of the shoulderblade and

LOCATION OF THE TRAPEZIUS MUSCLE

The trapezius is a large, diamond-shaped muscle in the upper part of the back. The trapezius muscle helps to support the neck and head and is also involved in raising the arms.

to the outermost part of the collarbone. It helps to support the neck and spine and is also involved in moving the arm.

trapped nerve

See *nerve, trapped*.

trastuzamab

A type of drug used in the treatment of *breast cancer*. Trastuzamab is given by intravenous infusion, and only in hospital under specialist supervision. The drug can have potentially serious side effects, which include breathing difficulties and disturbance of heart function.

trauma

Any serious physical injury or severe emotional shock. (See also *post-traumatic stress disorder*.)

trauma surgery

See *traumatology*.

traumatic amputation

See *amputation, traumatic*.

traumatology

Emergency treatment of patients suffering from acute trauma (such as severe and/or multiple injuries).

travel immunization

Anyone planning to travel abroad may need immunizations. Although few are compulsory for international travel, some are recommended for the protection of the traveller and to prevent the spread of diseases. (See *Guidelines for travel immunization* box, overleaf).

Travel agents and tour operators often include information concerning the immunizations that may be needed. However, travellers are recommended to consult a doctor or travel nurse about individual needs. Some vaccines must be given in two or three doses several weeks apart. Therefore, a doctor should be consulted at least two to three months prior to departure. Children under one year of age, pregnant women, and those individuals who have a compromised immune system or a serious illness may not be able to have some vaccinations, such as those for yellow fever and tuberculosis (BCG).

traveller's diarrhoea

A disorder that occurs in individuals who are visiting foreign countries. Episodes of diarrhoea range in severity and are the result of *gastroenteritis*. Attention to hygiene, drinking bottled water, avoiding ice in drinks, and eating peelable fruit can prevent a large proportion of episodes.

travel sickness

See *motion sickness*.

trazodone

An *antidepressant drug* with a strong sedative effect that is used to treat *depression* accompanied by *anxiety* or *insomnia*. Possible side effects of trazodone include drowsiness, constipation, a dry mouth, dizziness, and, rarely, *priapism*.

treadmill test

A test that involves exercise at varying degrees of inclination on a treadmill while the heart function is monitored (see *exercise ECG*).

treatment

A measure taken to prevent or cure a disease or disorder or to relieve symptoms.

trematode

The scientific name for any *fluke* or *schistosome*.

trembling

See *tremor*.

GUIDELINES FOR TRAVEL IMMUNIZATION		
Immunization	Reason for Immunization	Effectiveness
Yellow fever	Compulsory for entry to some countries and advisable for visits to others within yellow fever zones in Africa and South America. May also be needed when travelling from yellow fever zones to some Asian countries.	Almost 100 per cent protection for at least 10 years. Certificate provided.
Cholera	No longer recommended for routine preventive use. No vaccine is available in the UK. Anyone intending to travel and asked to provide a vaccination certificate is given instead a certificate explaining that the vaccine is not recommended.	Poor.
Typhoid fever	Recommended when travelling anywhere outside several countries, including Europe, the US, Canada, Australia, New Zealand, and Japan for anyone who has not received immunization or a booster within the past three years.	Gives moderate protection for about three years, after which a booster is needed.
Tetanus	Advisable for anyone who has not received childhood immunization or a booster within the past 10 years.	Highly effective, with booster needed every 10 years. Usually no more than five doses needed.
Poliomyelitis	Advisable for anyone who has not received childhood immunization or a booster within the last 10 years.	Highly effective, with booster needed every 10 years in some areas.
Hepatitis A	Recommended for protection against viral hepatitis type A when travelling to any country where hygiene and sanitary standards are low.	Highly effective. Booster needed every 10 years.
Diphtheria	Advisable for anyone who has not received childhood immunization.	Highly effective.
Hepatitis B; rabies	Recommended only for people who are special risk because of their occupation or the nature of their visit abroad.	Highly effective.
Meningitis A and C	May be recommended when travelling to most of Africa, Brazil, and Nepal and some other areas. An immunization certificate is needed for travel to Mecca.	Highly effective.
Japanese B encephalitis; tick-borne encephalitis	May sometimes be recommended when travelling to specific risk areas.	Moderately effective.

tremor

An involuntary, rhythmic, oscillating movement in the *muscles* of part of the body; the most commonly affected muscles are those of the hands, feet, jaw, tongue, or head. Tremor is the result of rapidly alternating muscle contraction and relaxation. Occasional tremors are experienced by the majority of people and are due to increased production of the hormone *adrenaline*

(epinephrine). A slight, persistent tremor is common in elderly people.

Essential tremor, a type that runs in families, is a fine-to-moderate tremor (about six to ten movements per second) that may be temporarily relieved by consuming a small amount of alcohol or by taking *beta-blocker drugs*.

Coarse tremor (about four to five movements per second) is present at rest but reduced during movement, and

is often a sign of the movement disorder *Parkinson's disease*. An intention tremor (tremor that is worse on movement of the affected part) may be a sign of *cerebellar ataxia*.

Tremor may also be caused by *multiple sclerosis*, *Wilson's disease*, *mercury poisoning*, *thyrotoxicosis*, or hepatic *encephalopathy*; drugs, such as *amphetamines* and *caffeine*; and withdrawal from drugs, including *alcohol*.

trench fever

An infectious disease that is now rare or unknown in most parts of the world. The disease is caused by *rickettsiae* (micro-organisms that are similar to bacteria) spread by body *lice*. Symptoms include headache, muscle pains, and fever, which may occur in bouts. Treatment is with *antibiotic drugs*.

trench foot

See *immersion foot*.

trench mouth

See *gingivitis, acute ulcerative*.

Trendelenburg's test

A test that is used to assess the function of each hip in turn. It involves standing on one leg and lifting the other leg while keeping the spine straight. Normally, as the leg is raised the pelvis on the same side should lift. Drooping of the pelvis on the side of the raised leg indicates that there may be a problem, such as a hip dislocation or weakness of the buttock muscles.

trephine

A hollow, cylindrical instrument with a saw-toothed edge used for cutting a circular hole, usually in bone.

Treponema pallidum

The species of bacteria responsible for causing *syphilis*.

tretinoin

A *topical* drug that is chemically related to *vitamin A* and that is used to treat *acne* and certain skin disorders such as *ichthyosis*. Tretinoin may aggravate acne at the start of treatment but usually improves the condition within three to four months.

Possible side effects are irritation, peeling, and skin discolouration. Exposing the skin to sunlight while using tretinoin may aggravate irritation and can cause *sunburn*.

triage

A classification system for establishing priority for treatment among a group of patients. Triage is used in hospital accident and emergency departments to sort patients into categories according to the nature of their injuries and their need for emergency treatment. It is intended to give the best chance of survival to the greatest number of people.

trial, clinical

A test on human volunteers of the effectiveness and safety of a drug. A clinical trial can also involve systematic comparison of alternative forms of medical or surgical treatment for a particular disorder. Patients involved in clinical trials have to give their consent, and the trials are approved and supervised by an ethics committee.

triamicinolone

A *corticosteroid drug* that is used to treat inflammation of the mouth, gums, skin, and joints.

triamterene

A *diuretic drug* that is used to treat *hypertension* (high blood pressure) and *oedema* (accumulation of fluid in tissues). Possible adverse effects include nausea, vomiting, weakness, and rash.

tribavirin

see *ribavirin*.

triceps muscle

The *muscle* at the back of the upper arm. At the upper end of the triceps are three "heads"; one is attached to the outer edge of the *scapula* (shoulderblade), and the other two to either side of the *humerus* (upper-arm bone). The lower part of the triceps is attached to the olecranon process of the ulna (the bony prominence on the elbow). Contraction of the muscle straightens the arm. (See also *biceps muscle*.)

trichiasis

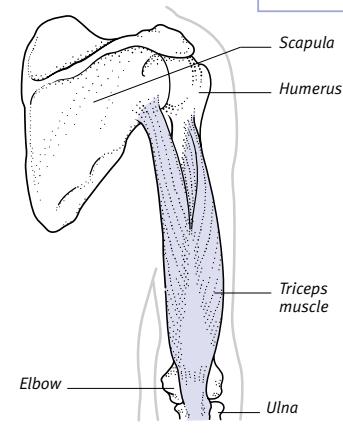

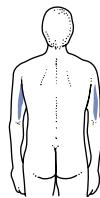

An alteration in the direction of eyelash growth, in which the lashes grow inwards towards the eyeball. They can rub against the eye, causing severe discomfort and sometimes damage to the *cornea*. *Trachoma* is a possible cause.

trichinosis

An infestation with the larvae of the *TRICHINELLA SPIRALIS* worm, which is usually acquired by eating undercooked

LOCATION OF THE TRICEPS MUSCLE

This muscle at the back of the upper arm functions to straighten the elbow joint, thus opposing the action of the biceps at the front of the upper arm.

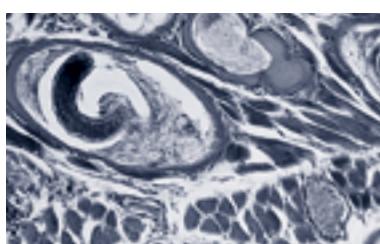

pork. Trichinosis is rare in the UK. The thorough cooking of pork products, and freezing meat to a temperature below -18°C for 24 hours, helps to avoid infection.

SYMPOTMS

Slight infestation usually causes no symptoms. However, heavy infestation may cause diarrhoea and vomiting within a day or two of eating the infected meat; gastrointestinal symptoms are followed by fever; swelling around the eyelids; severe muscle pains, which may last for several weeks; and inflammation of the heart muscle (*myocarditis*).

DIAGNOSIS AND TREATMENT

Trichinosis may be suspected from the symptoms, and the diagnosis is confirmed by *blood tests*, or by a muscle

Biopsy specimen showing trichinosis
This light micrograph of a section of a patient's muscle shows a cyst formed by a *TRICHINELLA SPIRALIS* larva.

biopsy (tissue sample). Treatment of the infestation is with an *anthelmintic drug*.

trichloroethylene

An inhaled drug that produces short-term *anaesthesia*. Trichloroethylene is not now commonly used.

trichology

The study of hair, including its structure, patterns of growth, and diseases.

trichomoniasis

An infection caused by the *protozoan* (single-celled microorganism) *TRICHO-MONAS VAGINALIS*. Trichomoniasis is one of the common causes of *vaginitis* (inflammation of the vagina) in women. The infection is usually sexually transmitted. Trichomoniasis is less common in men, in whom it affects the urethra.

CAUSES

In women, the causative organism may inhabit the vagina for many years without causing symptoms. However, if symptoms do occur, they include painful inflammation of the vagina and *vulva*, and a greenish, frothy, offensive-smelling discharge. Sexual intercourse may be painful. Men usually have no symptoms, but some may have discomfort on passing urine.

DIAGNOSIS AND TREATMENT

The diagnosis is made from examination of a sample of the discharge. However, diagnosis is usually difficult to confirm in men.

Treatment is with *metronidazole*. The sexual partner or partners of an infected person should be treated at the same time to prevent reinfection.

Trichophyton

A genus of fungi that can cause diseases of the hair, skin, and nails in humans (see *fungal infections*). *Athlete's foot* and ringworm of the scalp (see *tinea*) are among common disorders caused by *TRICHOPHYTON* species.

trichotillomania

The habit of constantly pulling out one's own hair. It can be associated with severe *mental handicap* or with a psychotic illness. Trichotillomania may also occur in psychologically disturbed children. The trichotillomania sufferer will typically pull, twist, and break off chunks of hair from his or her scalp, leaving visible bald patches. Occasionally, the pubic hair is pulled out in addition to or instead of hair on the head.

Children sometimes eat the removed hair, which may form a hairball in the stomach, known medically as a trichobezoar (see *bezoar*).

Treatment depends on the cause of the problem, and it may consist of *psychotherapy* or *antipsychotic drugs*.

trichuriasis

A parasitic infestation with the mainly tropical worm *TRICHURIS TRICHRURIA* (whip-worm). Children are most commonly affected. Infestation occurs when eggs are ingested and then develop into adult worms in the intestines. Severe infestation may cause bloody diarrhoea, abdominal pain, and weight loss. Treatment of trichuriasis is with *anthelmintic drugs*.

triclosan

An *antiseptic* used for disinfecting the skin. For example, triclosan may be used by doctors and other hospital staff for cleansing the hands before carrying out surgical procedures.

tricuspid incompetence

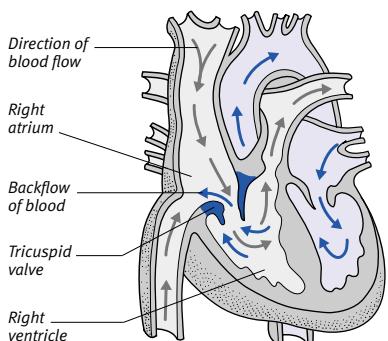

Failure of the heart's *tricuspid valve* to close fully, allowing blood to leak back into the right atrium (upper chamber) when the right ventricle (lower chamber) contracts. Tricuspid incompetence, also known as tricuspid insufficiency, reduces the heart's pumping efficiency.

CAUSES

The usual cause is *pulmonary hypertension* (high pressure in the blood supply to the lungs). More rarely, it follows *rheumatic fever*, or, in intravenous drug users, bacterial infection of the heart.

SYMPOTMS

Tricuspid incompetence results in symptoms of right-sided *heart failure*, notably

Defect in tricuspid incompetence

The tricuspid valve lies between the atrium and ventricle in the right side of the heart. Incompetence means that when the right ventricle contracts, some blood escapes back into the right atrium.

oedema (fluid swelling) of the ankles and abdomen. The liver is swollen and tender, and veins in the neck are distended.

DIAGNOSIS AND TREATMENT

A diagnosis is made from the symptoms, from hearing a heart *murmur* through a stethoscope, and by tests that may include an *ECG*, *chest X-rays*, *echocardiography*, and *cardiac catheterization*. Treatment with *diuretic drugs* and *ACE inhibitors* often relieves the symptoms.

tricuspid stenosis

Narrowing of the opening of the *tricuspid valve* of the heart, usually caused by a previous attack of *rheumatic fever*. Tricuspid stenosis is uncommon and often occurs with another heart-valve disorder. For example, *tricuspid incompetence* may also occur in intravenous drug users who have a bacterial infection of the heart. Tricuspid stenosis causes enlargement of the right atrium (upper heart chamber).

The symptoms and diagnosis of tricuspid stenosis are similar to those of tricuspid incompetence. Treatment is with drugs such as *diuretic drugs* and sometimes a *digitalis drug*. *Heart-valve surgery* is sometimes needed.

tricuspid valve

One of the valves in the *heart* that consists of three flaps that lies between the right atrium (upper chamber) and the right ventricle (lower chamber). Its function is to ensure that that blood

flow from the atrium to the ventricle occurs in one direction only.

tricyclic antidepressants

A type of *antidepressant drug*. Tricyclic antidepressants work by preventing *neurotransmitters* (chemicals released from nerve endings) in the brain from being reabsorbed, thereby increasing their level. Examples include *amitriptyline*, *clomipramine*, and *imipramine*.

trifluoperazine

An *antipsychotic drug* that is used in the treatment of *schizophrenia*.

trigeminal nerve

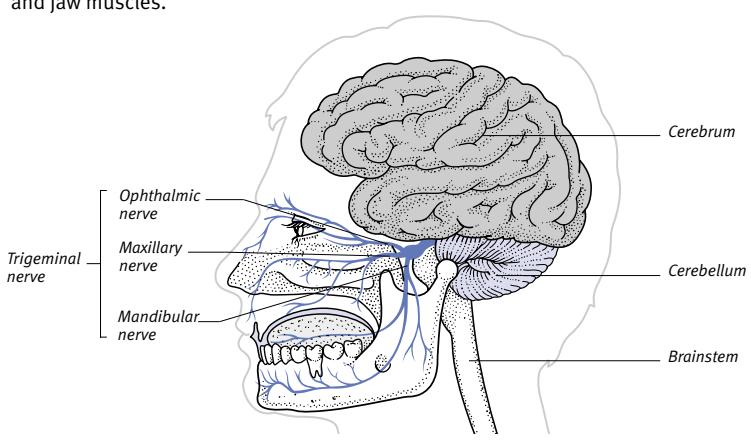

The fifth *cranial nerve*. The trigeminal nerves, one on each side of the face, arise from the *brainstem*. Both nerves divide into three branches that supply sensation to the face, scalp, nose, teeth, lining of the mouth, upper eyelid, *sinuses*, and the front portion of the tongue. They also stimulate contraction of the *jaw muscles* for chewing.

trigeminal neuralgia

A disorder of the *trigeminal nerve* in which brief episodes of severe, stabbing pain affect the cheek, lips, gums, or chin on one side of the face. The disorder usually occurs in people over the age of 50. Pain may come in bouts that last for weeks at a time. The cause is uncertain, and pain is often brought on by touching the face, eating, drinking, or talking.

LOCATION OF THE TRIGEMINAL NERVE

The trigeminal nerve splits into three main branches. The ophthalmic nerve supplies most of the scalp, the upper eyelid, and the cornea; the maxillary nerve supplies the upper jaw; and the mandibular nerve supplies the tongue, lower jaw, and jaw muscles.

Analgesic drugs (painkillers) may be prescribed. However, in many cases, *carbamazepine* is more effective. If this fails, surgery may prove helpful.

trigger finger

Locking of one or several fingers in a bent position due to inflammation of the sheath enclosing the *tendon* of the affected finger. The finger is usually tender at the base and slightly swollen over the tendon. Treatment involves local injection of a *corticosteroid drug* or, if this is unsuccessful, surgery.

Appearance of trigger finger

The disorder is caused by inflammation of the sheath of one of the tendons involved in controlling the finger's movements.

trigger point

A localized area of the body that is painful to the touch or to pressure.

triglyceride

A type of simple fat (see *fats and oils*) made up of a molecule of *glycerol* and three molecules of fatty acids. Triglycerides are the main type of fat found in stores of body fat.

trimeprazine

A former name for *alimemazine*, an *antihistamine drug*.

trimester

A period of three months; it is used particularly with reference to human *pregnancy*, which is conventionally divided into three trimesters.

trimethoprim

An *antibacterial drug* used to treat a range of infections, most commonly those of the urinary tract. Possible side effects include rash, itching, nausea, vomiting, diarrhoea, and a sore tongue.

trimipramine

A tricyclic *antidepressant drug* used to treat *depression* accompanied by *anxiety*.

or *insomnia*. Possible side effects include dry mouth, blurred vision, dizziness, constipation, and nausea.

triplets

Three offspring resulting from one pregnancy (see *pregnancy, multiple*).

triple X syndrome

A group of features that may occur in females due to inheriting three female sex chromosomes (XXX) rather than the usual two (see *chromosomes*). The defect results from errors in the division of one parent's egg or sperm cells.

The features of triple X syndrome can vary greatly. In some cases there are no obvious signs. More severely affected females may show delays in developing speech and motor skills, an IQ that may be lower than that of any siblings, and behavioural problems such as tantrums or shyness. Adult women may be taller than average, but show normal sexual development and are fertile.

triprolidine

An *antihistamine drug* that is used as an ingredient of cough and cold remedies. Possible side effects of triprolidine include dry mouth, dizziness, difficulty in passing urine, and *hyperactivity*.

trismus

Involuntary contraction of the jaw muscles, which causes the mouth to become tightly closed; commonly known as lockjaw. Trismus may develop as a symptom of *tetanus*, *tonsillitis*, *mumps*, or acute ulcerative *gingivitis* (gum disease), or of other dental problems that affect the back teeth. Treatment is for the underlying cause.

trisomy

Any condition in which there is an extra *chromosome* within a person's cells, making three of a particular chromosome instead of the usual two.

CAUSE

A fault during *meiosis* (cell division) to form egg or sperm cells can sometimes leave an egg or sperm with an extra chromosome. When the egg or sperm takes part in fertilization, the resulting embryo inherits an extra chromosome in each of its cells.

TYPES AND SYMPTOMS

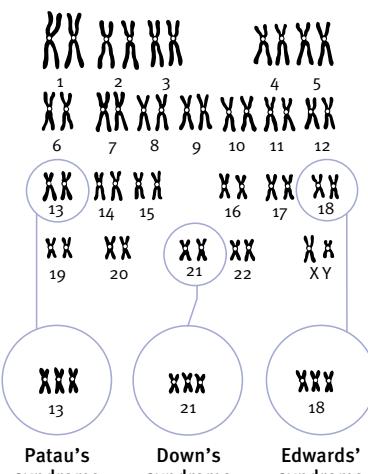

The most common type of trisomy is of chromosome 21 (*Down's syndrome*). Trisomy 18 (Edward's syndrome) and trisomy 13 (Patau's syndrome) are less

common; trisomy 8 and trisomy 22 are very rare. Partial trisomy, with only part of a chromosome reproduced in triplicate, also occurs.

Full trisomies cause abnormalities such as skeletal and heart defects and learning difficulties. Except in Down's syndrome, babies usually die in early infancy. The effects of partial trisomies depend on the amount of extra chromosomal material present.

DIAGNOSIS AND PREVENTION

Diagnosis is made by *chromosome analysis* of cells, which may be obtained from the fetus by *amniocentesis* or after the birth. There is no specific treatment. Parents of an affected child may wish to have *genetic counselling*.

Types of trisomy

In all trisomies a child is born with three chromosomes, instead of the usual complement of two, of a particular number. Down's syndrome is by far the most common trisomy.

trisomy 21 syndrome

Another name for *Down's syndrome*.

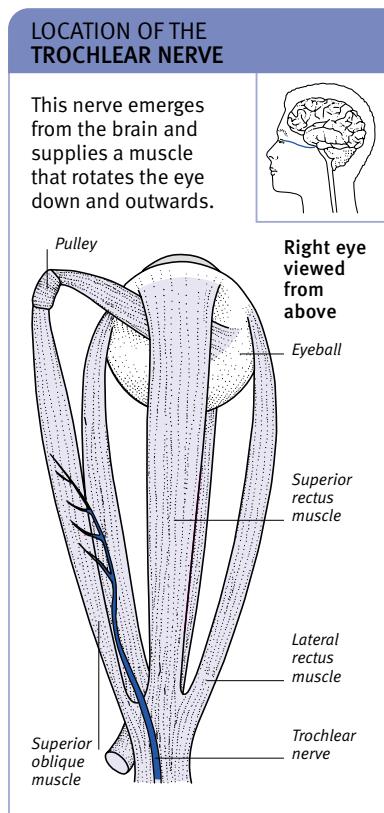

trochanteric bursitis

Inflammation of the bursa (fluid-filled sac) located towards the upper end of the femur (thigh bone). Trochanteric bursitis may be due to repeated strain on the hip joint in activities such as running, or may result from sudden injury (for example, in a fall or during contact sports). It may also occur after surgery on the hip, or develop in a person whose legs are of different lengths. In some cases, there is no apparent cause. The main symptom is pain at the side of the hip; the pain may also spread down the side of the thigh.

Treatment often includes rest, application of ice packs (or heat treatment), and the use of *nonsteroidal anti-inflammatory drugs* (NSAIDs) for pain relief. A *corticosteroid* injection may be given into the bursa, often providing a rapid relief from the symptoms. *Physiotherapy* may also be helpful.

trochlear nerve

The fourth *cranial nerve*. There are two trochlear nerves, which arise in the *brainstem*, one on each side of the mid-brain. They enter the eye sockets through gaps in the skull bones. Each trochlear nerve controls one of the two superior oblique muscles, which are responsible for rotation of the eyes both downwards and outwards.

disease or injury. Trophic ulcers most commonly appear on the feet and can be a complication of disorders such as *diabetes mellitus* and *Hansen's disease*.

trophoblastic tumour

A growth arising from the tissues that develop into the *placenta*. The most common type is a *hydatidiform mole*. (See also *choriocarcinoma*.)

tropical diseases

Many diseases prevalent in the tropics are primarily caused by overcrowded living conditions and inadequate diet. *Malnutrition* is one of the major causes of illness in the tropics. Apart from resulting in nutritional deficiency disorders, a poor diet weakens the body's ability to fight infectious diseases such as *measles*, *diphtheria*, and *tuberculosis*.

Lack of sanitary facilities, which encourages the contamination of water and soil with human excrement, causes a number of diseases, including *typhoid fever*, *shigellosis*, *cholera*, *amoebiasis*, and *nematode* and *tapeworm infestations*.

Diseases that are spread through the tropics by insects include *malaria*, *yellow fever*, *sleeping sickness*, and *leishmaniasis*. Exposure to strong tropical sunlight causes an increased tendency to *skin cancer* among people with fair skin; sunlight may also damage the outer tissues of the eye, leading to such disorders as *pinguecula* and *pterygium*.

tropical sprue

See *sprue*, *tropical*.

tropical ulcer

An area of persistent skin and tissue loss caused by infection with one or more organisms. The condition is most common in malnourished people living in the tropics. Treatment is cleaning and dressing of the ulcer, a course of *antibiotic drugs*, and a high protein diet. The ulcer usually heals but may scar.

tropicamide

A drug used to dilate the *pupil* before an eye examination. Adverse effects of the drug include blurred vision, increased sensitivity to light, stinging, and, rarely, dry mouth, flushing, and *glaucoma*.

trunk

The centre of the body, comprising the chest and abdomen. It also refers to any large blood vessel or nerve, from which smaller vessels or nerves branch off.

truss

An elastic, canvas, or padded appliance that is used to hold an abdominal *hernia* in place. Trusses are used only in situations where corrective surgery cannot be undertaken.

trypanosomiasis

A tropical disease that is caused by *TRYPARASMA* parasites. (See also *Chagas' disease*; *sleeping sickness*.)

trypsin

A type of *enzyme*, secreted by the pancreas, that plays an important role in the process of digestion by breaking down proteins.

tryptophan

An essential *amino acid* (a building block of proteins). Tryptophan, which is necessary for normal growth, is not manufactured within the body but must be obtained from the diet.

tsetse fly bites

The bites of tsetse flies, which are found in Africa, can be very painful. The flies, resembling brown houseflies, spread *sleeping sickness*.

TSH

The abbreviation for *thyroid-stimulating hormone*.

T-tube cholangiography

An *imaging technique* that is performed in order to check that there are no *gallstones* left in the bile duct following a *cholecystectomy* (surgical removal of the gallbladder). A T-shaped rubber tube is inserted into the bile duct during the surgery and is left in place. After about a week, *contrast medium* is inserted into the tube and *X-rays* are taken. If there are no stones, the tube is pulled out. If there are, they may be removed by *ERCP* or by a stone-dissolving solvent administered through the tube.

tubal ligation

See *sterilization, female*.

tubal pregnancy

See *ectopic pregnancy*.

tubercle

A grey, nodular mass that is found in tissues affected by *tuberculosis*. The term also refers to a small rounded protrusion that sometimes occurs on the surface of a bone.

tuberculin tests

Skin tests used to determine whether or not a person has been exposed to the bacterium that causes *tuberculosis*. Tuberculin tests are carried out for diagnosis of tuberculosis, and before *BCG vaccination*. A small amount of tuberculin (purified protein from the bacteria) is injected into the skin. A few days later, the skin reaction, if any, is noted. A reaction indicates previous exposure, by infection or vaccination.

tuberculosis

An infectious disease, commonly called TB, caused in humans by the bacterium *MYCOBACTERIUM TUBERCULOSIS*.

CAUSES AND TYPES

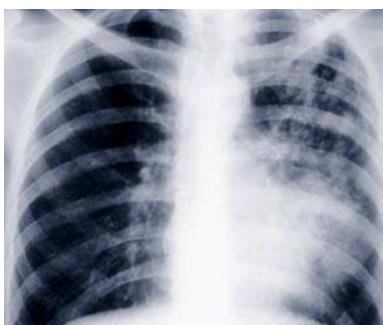

TB is usually transmitted in airborne droplets expelled when an infected person coughs or sneezes. Inhaled droplets enter the lungs and the bacteria multiply.

The immune system usually seals off the infection at this point, but in some cases the infection spreads to the *lymph nodes*. It may also spread to other organs in the bloodstream, which may lead to miliary tuberculosis, a potentially fatal form of the disease, or to *meningitis* (inflammation of the membranes around the brain and spinal cord), bone infection, genitourinary infection, or *pericarditis* (inflammation of the membranes around the heart).

In other cases, bacteria held in a dormant state by the immune system become reactivated months, or even years, later. Reactivation may occur when old age, poor health, or reduced immunity increase susceptibility to the infection. The infection may then progressively damage the lungs.

SYMPOTMS

The primary infection is usually without symptoms. Progressive infection in

Chest X-ray showing tuberculosis

The right lung (left) appears normal, but the left lung shows dense opacities (white areas) adjoining the heart shadow, indicating tuberculosis.

the lungs causes coughing (sometimes bringing up blood), chest pain, shortness of breath, fever and sweating, poor appetite, and weight loss. *Pleural effusion* (collection of fluid between the lung and chest wall) or *pneumonia* may develop. The lung damage may be fatal.

DIAGNOSIS

A diagnosis is made from the symptoms and signs, from a *chest X-ray*, and from tests on the sputum. Alternatively, a *bronchoscopy* may also be carried out to obtain samples for culture.

TREATMENT

Treatment is usually with a course of three or four drugs, taken daily for two months, followed by daily doses of *isoniazid* and *rifampicin* for four months. However, TB bacteria are increasingly resistant to the drugs used in treatment, and others may have to be used and treatment carried out for a longer period. If the full course of drugs is taken, most patients recover.

PREVENTION

Tuberculosis can be prevented by *BCG vaccination*, which may be offered just after birth or routinely at age 10–14. Contacts of an infected person are traced and, if necessary, are treated early to reduce the risk of the infection spreading.

tuberosity

A prominent area on a *bone* to which *tendons* are attached.

tuberous sclerosis

An inherited disorder that affects the skin and *nervous system*. Symptoms may include a condition of the face that is similar to acne, *epilepsy*, and *learning difficulties*. In addition, noncancerous tumours of the brain, kidney, retina, and heart may also develop. There is no cure for tuberous sclerosis, and treatment aims only to relieve symptoms. In serious cases, death occurs before the age of 30. *Genetic counselling* is recommended for affected families.

tuboplasty

Surgery in which a damaged *fallopian tube* is repaired to treat *infertility*. It may be performed by *microsurgery*.

tularaemia

A bacterial infection that affects wild animals that is sometimes transmitted to humans. Tularaemia does not occur in the UK but is seen in North America. It may result from contact with an infected animal or carcass, or a tick, flea, fly,

or louse bite. Diagnosis is by blood tests. Treatment of the infection is with *antibiotic drugs*.

tumbu fly

A tropical fly found in Africa whose larvae infest the skin and cause *myiasis*.

tumour

A term that describes any swelling but which is generally used to refer to an abnormal mass of tissue that forms when cells in a specific area reproduce at an increased rate. Tumours can be *cancerous* or *noncancerous*.

Cancerous tumours invade surrounding tissues and may spread through the bloodstream or lymphatic system to form a secondary growth (a *metastasis*) elsewhere in the body. A cancerous tumour that arises from epithelial tissues (such as the skin) is known as a carcinoma; one that arises from connective tissue (such as muscle, bone, or fibrous tissue) is called a sarcoma.

Noncancerous tumours usually grow slowly and do not metastasize. Such tumours tend to stay confined within a fibrous capsule, making surgical removal relatively straightforward. Noncancerous tumours sometimes grow large enough to press on nearby structures, which can be dangerous in confined spaces such as the skull.

tumour marker

A substance produced by a *tumour* that can be detected in the bloodstream. Tests for the presence of markers can assist in the diagnosis and treatment of tumours. Markers are often substances that occur normally in the body, but are produced in larger amounts when a particular kind of tumour is present. For example, *alpha-fetoprotein*, which is produced in normal pregnancy, is present at elevated levels in a certain type of primary liver cancer.

tuning fork tests

Hearing tests that are carried out in order to differentiate between conductive *deafness* and sensorineural deafness. In the *Weber test*, a vibrating tuning fork is held against the forehead. If there is conductive hearing loss, the sound seems louder in the affected ear. In the *Rinne test*, a vibrating tuning fork is held first near the ear, then against the bone behind it. If it sounds louder when against the bone, there is conductive hearing loss.

tunnel vision

Loss of the peripheral *visual field* to the extent that only objects straight ahead can be seen clearly. Tunnel vision is most often caused by chronic *glaucoma* (raised pressure within the eyeball). *Retinitis pigmentosa* (degeneration of the retina) is another possible cause.

turbinate

One of the three shell-shaped bony projections in the side of the nasal cavity.

Turner's syndrome

A disorder caused by a *chromosomal abnormality* that only affects females.

CAUSES

The abnormality may arise in one of three ways: affected females may possess only one X *chromosome* instead of the normal two; they may possess one normal and one defective X chromosome; or they may possess a mixture of cells (see *mosaicism*), in which some of the cells are missing an X chromosome, some have extra chromosomes, and others have the normal complement of chromosomes.

SYMPOTMS

The characteristics of Turner's syndrome are: short stature; webbing of the skin of the neck; absence or retarded development of sexual characteristics; *amenorrhea* (failure to menstruate), *coarctation of the aorta*, and abnormalities of the eyes and bones.

TREATMENT

Treatment with *growth hormone* from infancy helps girls with Turner's syndrome to achieve near normal height. Coarctation of the aorta is treated surgically. Treatment with *oestrogen drugs* induces menstruation, but it does not make affected girls fertile.

TURP

The abbreviation for transurethral resection of the prostate. TURP is a surgical procedure in which the central part of an enlarged *prostate gland* is removed (see *prostate, enlarged*). A viewing instrument called a *resectoscope* is passed along the *urethra* until it reaches the prostate. A heated wire loop, or sometimes a cutting edge, is inserted through the resectoscope and used to cut away excess prostate tissue.

twins

Two offspring resulting from one pregnancy. Twins may develop from a single ovum (egg) or from two ova.

Monozygotic, or identical, twins develop when a single fertilized egg divides at an early stage of development. Incomplete division of the egg results in conjoined twins (see *twins, conjoined*). Monozygotic twins share the same *placenta*. Although one is often much bigger than the other at birth, they are always of the same sex and look remarkably alike.

Dizygotic, or fraternal, twins develop when two eggs are fertilized at the same time. The ova they develop from may be released by the same or different ovaries;

fertilization occurs simultaneously. They each have a placenta and may be of different sexes and look quite different.

Twins occur in about one in 80 pregnancies. (See also *pregnancy, multiple*.)

twins, conjoined

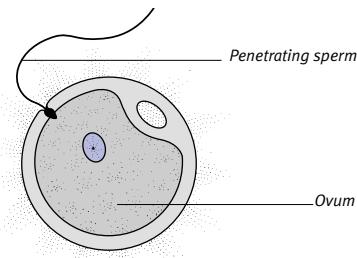

Identical twins physically joined due to a failure to separate during development from a single fertilized egg. Conjoined twins are also called Siamese twins.

twitch

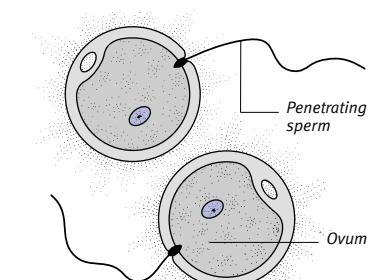

See *fasciculation; tic*.

TWO TYPES OF TWINS

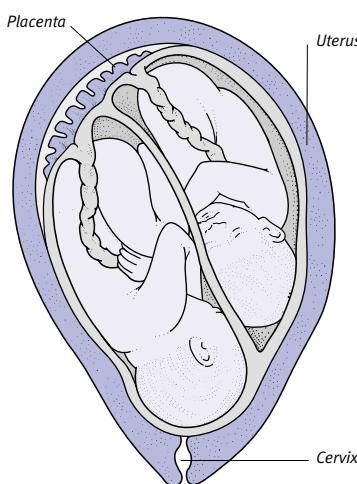

During each menstrual cycle, either one ovum or a small number of ova are released. If one ovum is fertilized and the two cells formed from its first division develop independently, the result is identical twins. If two ova are fertilized and mature normally, nonidentical twins result.

IDENTICAL TWINS**Fertilization of a single ovum**

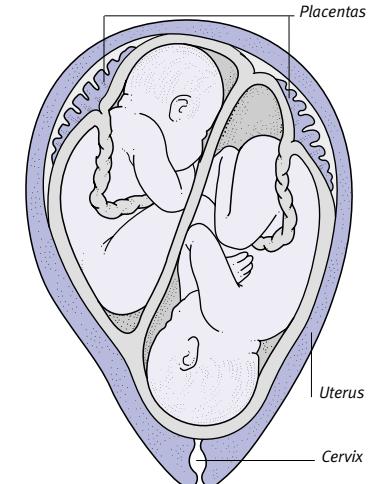

Identical twins come from a single fertilized ovum. When the ovum splits, the two cells formed develop independently.

NONIDENTICAL TWINS**Fertilization of two separate ova**

Nonidentical twins are the result of two separate ova that have been fertilized by two separate sperm.

**Identical twins in the uterus**

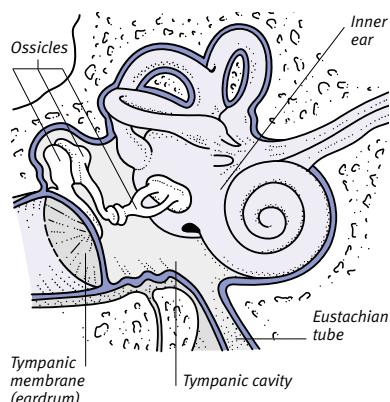

The result is a pair of genetically identical twins sharing the same placenta. They are also known as monozygotic, or monovular, twins.

**Nonidentical twins in the uterus**

The resulting individuals are genetically distinct and have separate placentas. They are also known as dizygotic, or binovular, twins.

tympanic cavity

The medical term for the middle ear.

Anatomy of the tympanic cavity

The tympanic cavity contains three movable bones (the malleus, incus, and stapes), which transmit sound from the tympanic membrane (the eardrum) to the inner ear.

tympanic membrane

The medical term for the eardrum.

tympanometry

A type of *hearing test* that is used to establish the cause of conductive *deafness*. During the test, a probe that contains a tone generator, a microphone, and an air pump is introduced into the outer-ear canal. The air pressure in the ear is varied and tones are played into it. The tone pattern reflected from the *eardrum* and received by the microphone shows if the eardrum is moving normally.

Tympanometry is a particularly useful technique for use in children because it does not rely on a response from the person being tested.

tympanoplasty

An operation on the *ear* to treat conductive *deafness* by repairing a hole in the eardrum (see *myringoplasty*) or by repositioning or reconstructing the diseased *ossicles* (tiny bones in the middle ear that conduct sound).

tympanum

A term referring either to the middle-*ear* cavity (tympanic cavity) or to the *eardrum* (tympanic membrane).

type 1 diabetes

See *diabetes mellitus*.

type 2 diabetes

See *diabetes mellitus*.

typhoid fever

An infectious disease, also known as enteric fever, contracted by eating food or drinking water contaminated with the bacterium *SALMONELLA TYPHI*. An almost identical disease, *paratyphoid fever*, is caused by related bacteria.

CAUSES

The infection is contracted from the faeces of a person who has the disease or who is a symptomless carrier of the bacteria. Typhoid fever is commonly spread by drinking water contaminated with sewage, by flies carrying the bacteria from faeces to food, or by infected people handling food.

The bacteria pass from the intestines into the blood, then to the spleen and liver, where they multiply. The organisms are excreted from the liver, accumulate in the gallbladder, and are released in large numbers into the intestine. Carriers, after recovering from the condition, may continue to harbour typhoid bacteria in the gallbladder and shed them in faeces for many years.

SYMPTOMS

Typhoid has an incubation period of 7 to 21 days. The first symptom is usually a severe headache followed by fever, loss of appetite, *malaise*, abdominal pain, constipation, and often delirium. Diarrhoea soon develops. In the second week of illness, small, raised pink spots develop on the chest and abdomen, and the liver and *spleen* enlarge.

The illness usually clears up within four weeks. However, potentially fatal complications may develop, including intestinal bleeding, perforation of the intestine leading to *peritonitis*, *osteomyelitis*, *pyelonephritis*, and *kidney failure*.

DIAGNOSIS AND TREATMENT

Diagnosis of typhoid is confirmed by a *blood test* or by obtaining a *culture* of typhoid bacteria from blood, faeces, or urine. Treatment with *antibiotic drugs* usually brings the disease under control within a few days.

typhus

Any of a group of infectious diseases with similar symptoms that are caused by *rickettsiae* (microorganisms similar to bacteria) and are spread by insects or similar animals.

TYPES

Of the various types, epidemic typhus, which is spread between humans by body lice, is historically the most important. This disease formerly killed hundreds of thousands of people in

times of war, famine, or other natural disasters. Except in some highland areas of tropical Africa and South America, epidemic typhus is rare today.

Endemic typhus, also called murine typhus, is a disease of *rats* that is occasionally spread to humans by fleas; sporadic cases occur in North and Central America. Scrub typhus is spread by *mites* and occurs in India and Southeast Asia.

SYMPTOMS

The symptoms and complications of all types of typhus are similar. Symptoms include severe headache, back and limb pain, coughing, constipation, high fever, a measles-type rash that may develop into *purpura*, confusion, and exhaustion. If typhus is left untreated, the condition may be fatal, especially in elderly or debilitated people.

DIAGNOSIS AND TREATMENT

Diagnosis is made by *blood tests*, and the infection is treated with *antibiotic drugs* and supportive treatment.

typing

A general term for procedures by which blood or tissues are classified (see *blood groups*; *tissue-typing*).

tyramine

An *amino acid* present in various foods, including cheese, chocolate, red wine, and beer. Tyramine has a stimulating effect on the body. The substance interacts with certain drugs (*monoamine oxidase inhibitors*) used to treat depression; taking both together can cause adverse reactions such as headache and a rise in blood pressure.

tyrosine

A non-essential *amino acid* (a building-block of proteins). Tyrosine plays a role in the healthy functioning of the nervous and endocrine systems.

U

ulcer

An open sore appearing on the skin or on a *mucous membrane* that results from the destruction of surface tissue. Ulcers may be shallow, or deep and crater-shaped, and they are usually inflamed and painful. An indolent ulcer is one that is slow to heal but is not painful.

SKIN ULCERS

Skin ulcers most commonly occur on the leg (see *leg ulcer*), usually as the result of inadequate blood supply to, or drainage from, the limb. In some cases skin cancers, particularly *basal cell carcinomas* or *squamous cell carcinomas*, may be ulcerated. Rarely, a cancer may develop in the skin at the edge of a longstanding ulcer.

DIGESTIVE TRACT ULCERS

Ulcers of the mucous membranes most commonly develop within the digestive tract (the collection of tubular structures that runs from the mouth to the anus). The ulcers include *mouth ulcers* (see also *ulcer, aphthous*), *peptic ulcers* (affecting the stomach or duodenum), and the ulcers that occur in *ulcerative colitis*, an inflammatory disorder of the colon or rectum.

GENITAL ULCERS

Ulcers may also affect the skin or mucous membranes of the genitalia (see *genital ulcer*). Most genital ulcers are caused by sexually transmitted infections. Examples of this type of ulcer are hard chancres (see *chancroid, hard*), which develop during the first stage of *syphilis*, and soft chancres (see *chancroid*).

EYE ULCERS

Ulcers may also develop on the cornea, the transparent covering at the front of the eyeball (see *corneal ulcers*).

SOLITARY RECTAL ULCER

A break in the lining of the lower part of the large intestine that fails to heal. Symptoms may include bleeding or mucus discharge from the anus, tenesmus (a feeling that the rectum has not been completely emptied), and pain. There may also be diarrhoea or constipation; and rectal prolapse (in which

part of the rectum protrudes outside the anus) is often present.

Diagnosis may be made by endoscopy (use of a viewing instrument) of the rectum and biopsy (taking a tissue sample). Treatment may include laxatives and a high-fibre diet. Surgery may be recommended to excise the ulcer.

ulcer, aphthous

A small, painful *ulcer* that occurs, alone or in a group, on the inside of the cheek or lip or underneath the tongue.

Aphthous ulcers are most common in people between the ages of 10 and 40 and affect more women than men. The most severely affected people have continually recurring ulcers; others have just one or two ulcers each year.

CAUSES

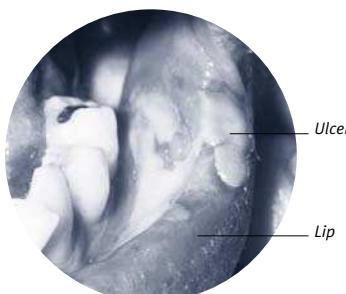

The ulcer, which usually lasts for one to two weeks, may be a hypersensitive reaction to haemolytic streptococcus bacteria. Other factors that are commonly associated with the occurrence of these ulcers are minor injuries (such as at an injection site or from a toothbrush), acute stress, or allergies. In women, aphthous ulcers are most common during the premenstrual period. They may also be more likely to occur if other family members suffer from recurrent ulcerative conditions such as *Crohn's disease*.

SYMPTOMS

Each ulcer is usually small and oval, with a grey centre and a surrounding red, inflamed halo. The ulcers usually last for one to two weeks.

TREATMENT

Analgesic mouth gels or mouthwashes may ease the pain of an aphthous ulcer. Some ointments form a waterproof covering that protects the ulcer while it is healing. Ulcers heal by themselves, but a doctor may prescribe a paste con-

Ulcers in the mouth

Aphthous ulcers are common, painful, and they typically last for one or two weeks. Most aphthous ulcers heal well without leaving scars.

taining a *corticosteroid drug* or a mouth-wash containing an *antibiotic drug* to speed up the healing process.

ulceration

The formation or presence of one or more *ulcers*.

ulcerative colitis

Chronic inflammation and ulceration of the lining of the *colon* and *rectum*, or, especially at the start of the condition, of the rectum alone. The cause of ulcerative colitis is unknown, but the condition is most common in young and middle-aged adults.

SYMPTOMS

The main symptom of ulcerative colitis is bloody diarrhoea; the faeces may also contain mucus. In severe cases, the diarrhoea and bleeding are extensive, and there may be abdominal pain, fever, weight loss, and general malaise. The incidence of attacks varies considerably from person to person. Most commonly, the attacks occur at intervals of a few months. However, in some cases, there may be only a single episode.

COMPLICATIONS

Ulcerative colitis may lead to *anaemia*, due to blood loss. Other complications include a toxic form of *megacolon* (an abnormally enlarged colon), which may become life-threatening; rashes; *mouth ulcers*; *arthritis*; *conjunctivitis* (inflammation of the membrane covering the eyeball); and *uveitis* (inflammation of the iris or choroid of the eye). In addition, people whose entire colon has been affected for more than 10 years are at increased risk of developing cancer of the colon (see *colon, cancer of*).

DIAGNOSIS

Diagnosis is based on examination of the rectum and the lower colon (see *sigmoidoscopy*) or of the entire colon (see *colonoscopy*), or is made by a barium enema (see *barium X-ray examination*). During sigmoidoscopy or colonoscopy, a *biopsy* (removal of a tissue sample) may be performed. Samples of faeces may be taken for analysis in a laboratory to exclude the possibility of infection by bacteria or parasites. *Blood tests* may also be necessary.

People who have suffered from ulcerative colitis for a number of years need periodic colonoscopy and biopsy to check for the development of cancer.

TREATMENT

In most cases, medical treatment effectively controls the disease by relieving

symptoms and preventing complications from occurring. For ulcerative colitis occurring in the last part of the colon or the rectum, the drugs may be administered as suppositories. If the condition occurs higher up in the intestine, the drugs are taken orally.

Aminosalicylate drugs, such as *sulphasalazine* (or the newer drugs *mesalazine* and *olsalazine*, which have fewer side effects), are used to treat acute attacks and maintain long-term freedom from symptoms. *Corticosteroid drugs* are given to reduce inflammation during sudden flare-ups. Once the disease is under control, *immunosuppressant drugs* may be used to prevent relapses.

Colectomy (surgical removal of the colon) may be required for a severe attack that fails to respond to other treatments, for those with complications such as toxic megacolon, or to avoid colonic cancer in those people who are at high risk. This operation usually produces a dramatic improvement in health, although the person is usually left with an *ileostomy* (an opening in the surface of the abdomen through which faeces are passed).

ulcer-healing drugs

COMMON DRUGS

H₂-RECEPTOR ANTAGONISTS

- Cimetidine
- Famotidine • Nizatidine • Ranitidine

PROTON PUMP INHIBITORS

- Omeprazole • Pantoprazole
- Rabeprazole

OTHER DRUGS

- Antacids • Antibiotics
- Bismuth • Carbenoxolone • Misoprostol
- Ranitidine bismuth citrate • Sucralfate

A group of drugs used to treat or to prevent ulcers of the stomach or duodenum (see *peptic ulcers*). The ulcers occur when some of the mucus covering these areas is eroded and irritants attack the tissues, causing a sore to develop. Causes of peptic ulcers include infection with the bacterium *HELICOBACTER PYLORI*; external irritants, such as tobacco smoke, alcohol, or nonsteroidal anti-inflammatory drugs (NSAIDs); or excessive production of stomach acid.

HOW THEY WORK

Ulcer-healing drugs work in several ways. They may either reduce or neutralize stomach acid or protect the ulcerated area, thus allowing the damaged tissue to heal.

Taking *antacid drugs* regularly may be effective in healing duodenal ulcers because the drugs neutralize excess

acid; however, the rate of healing may be slow. *H₂-receptor antagonists* function by blocking the effects of histamine, a chemical that normally stimulates the release of acid into the stomach. Drugs such as *omeprazole* are called proton pump inhibitors. They work by blocking an enzyme system called the proton pump, which stimulates the secretion of acid; as a result, they stop acid production until the body can make new supplies of the enzymes. Other drugs, such as *misoprostol*, also work by reducing acid secretion.

Other ulcer-healing drugs, such as *sucralfate*, are believed to work by forming a protective barrier over the ulcer, allowing healing of the underlying tissues to take place.

CHOICE OF DRUG

The eradication of *HELICOBACTER PYLORI* infection by treatment with *antibiotic drugs*, together with the use of a drug to reduce acid secretion, is the preferred treatment for most cases of peptic ulceration. The choice of ulcer-healing drugs may depend on the length of time for which symptoms have been present and the appearance of the ulcer when viewed by *gastroscopy*. If the ulcer has developed only recently, a course of acid-blocking drugs or antacids often gives rapid relief. Recurrent ulcers usually need antibiotic treatment.

POSSIBLE ADVERSE EFFECTS

Ulcer-healing drugs do not usually have side effects. Those that do occur may include diarrhoea, constipation, skin rashes, or dizziness. *H₂-receptor antagonists* may cause confusion in elderly people. Misoprostol can induce miscarriage or may cause fetal abnormalities, so it should not be taken by any woman who is (or may be) pregnant.

ulcer, trophic

See *trophic ulcer*.

ulna

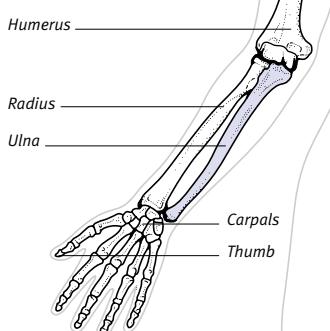

The longer of the two bones of the forearm; the other is the *radius*. The ulna is the bone running down the forearm on the side of the little finger.

The upper end of the ulna articulates with the radius and extends into a rounded projection (which is known as the *olecranon process*) that fits around the lower end of the humerus to form part of the *elbow joint*. The lower end of the ulna articulates with the carpal (wrist bones) and the lower part of the radius.

LOCATION OF THE ULNA

The ulna hinges at the elbow on the inner side of the lower end of the humerus (upper-arm bone). It is less mobile than the radius.

Right arm

ulna, fracture of

A fracture of the *ulna*, one of the two bones of the forearm. Ulnar fractures typically occur across the shaft or at the *olecranon* process (the rounded projection at the tip of the elbow).

A fracture to the shaft usually results from a blow to the forearm or a fall on to the hand. Sometimes the radius (the other bone in the forearm) is fractured at the same time (see *radius, fracture of*). Surgery is usually needed to reposition the broken bone ends and fix them together using either a plate and screws or a long nail down the centre of the bone. The arm is immobilized in a *cast*, with the elbow at a right-angle, until the fracture heals.

A fracture of the *olecranon* process is usually the result of a fall on to the *elbow*. If the bone ends have not been displaced, the arm is immobilized in a cast that holds the elbow at a right-angle. If the bone ends are displaced, however, they are fitted together and fixed with a metal screw.

ulnar nerve

One of the principal *nerves* of the arm. The ulnar nerve, which is a branch of the *brachial plexus*, runs down the full length of the arm and into the hand. The ulnar nerve controls muscles that move the thumb and fingers. It also conveys sensation from the fifth finger, part of the fourth finger, and the area of the palm that is closest to these fingers.

DISORDERS

A blow to the *olecranon* process (the rounded projection at the tip of the elbow), over which the ulnar nerve passes, causes a pins-and-needles sensation and pain in the forearm and fourth and fifth fingers. Repeated leaning on the elbow can have a similar effect.

Persistent numbness and weakness in areas controlled by the ulnar nerve may be caused by an abnormal bony outgrowth from the *humerus* (upper-arm bone), which may be due to *osteoarthritis* or to a fracture of the humerus. Surgery is needed to relieve the pressure on the nerve. If the condition is left untreated, it may cause permanent damage to the ulnar nerve, which can result in *claw-hand*.

ultrasonography, Doppler

See *Doppler ultrasonography*.

ultrasound

Sound with a frequency that is greater than the human ear's upper limit of perception; that is, higher than 20,000 hertz (cycles per second). Ultrasound is used in medicine to produce images of body structures and thus aid diagnosis (see *ultrasound scanning*), or in treatment to aid healing or to destroy abnormalities such as kidney stones (see *ultrasound treatment; lithotripsy*). Ultrasound that is used for these purposes is typically in the range of 1–15 million hertz.

ultrasound scanning

A diagnostic technique in which very high frequency sound waves are passed into the body and the reflected echoes analysed to build a picture of the internal organs or of a fetus in the uterus. Unlike most other imaging techniques, ultrasound scanning can produce moving images. The procedure is painless and is considered safe.

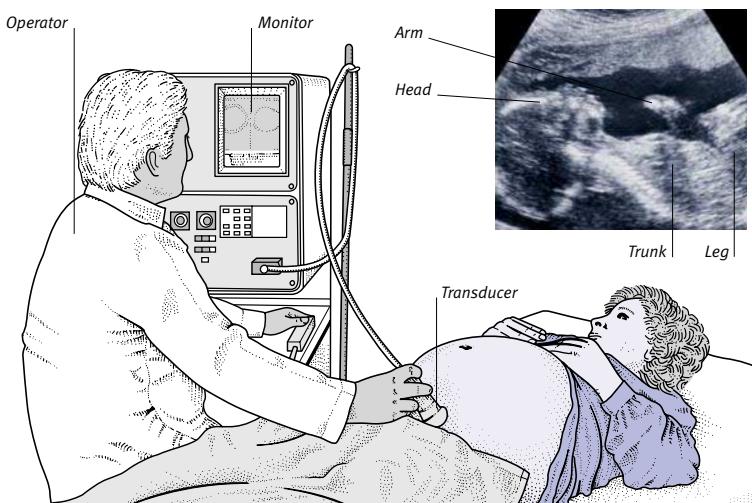

WHY IT IS DONE

The ability of ultrasound scanning to show soft tissues makes the procedure useful for examining fluid-filled or soft structures within the body. Ultrasound waves cannot, however, pass through bone or gas; therefore, they are of limited use for viewing any areas that are surrounded by bone (such as the brain in adults) or those that are filled with gas (such as the lungs or the intestines). **Obstetric and neonatal uses** One of the most common uses of ultrasound is to view the uterus and fetus, at any time during *pregnancy*.

HOW ULTRASOUND SCANNING WORKS

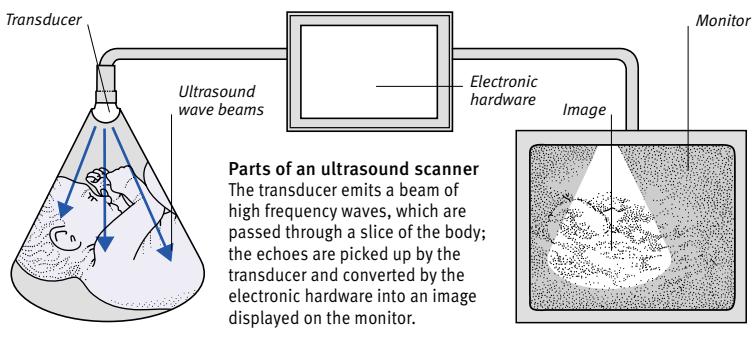

Ultrasound waves are emitted by a transducer, a device placed on the skin over the area to be viewed. Gel is used to ensure good contact between the transducer and the skin. The transducer contains a crystal that converts an electric current into sound waves. The waves have frequencies in the range of 1 to 15 million hertz. At these high frequencies, they can be focused into a fine parallel beam, which passes

through a "slice" of the body if the transducer crystal is oscillated back and forth. Some of the waves are reflected at tissue boundaries, so a series of echoes is returned. The transducer also acts as a receiver, converting these echoes into electrical signals, which are processed and displayed on a screen as two-dimensional images of the scanned body slice. By moving the transducer, different slices can be seen.

**Using ultrasound**

Ultrasound has wide applications in medicine and is especially useful in obstetrics. It offers no known risk to the baby. By movement of the

transducer across the outer wall of the abdomen, views of the growing fetus are obtained from various angles, so it is possible to screen for abnormalities.

**Parts of an ultrasound scanner**

The transducer emits a beam of high frequency waves, which are passed through a slice of the body; the echoes are picked up by the transducer and converted by the electronic hardware into an image displayed on the monitor.

The age, size, and growth rate of the fetus can be determined by means of ultrasound. If the date of conception is known, the scan shows whether the fetus is of the expected size for its age; conversely, the size of the fetus can help to establish the accurate date of conception and therefore help doctors and midwives to predict the expected date of delivery.

Ultrasound scans will show if there is more than one fetus (see *pregnancy, multiple*). They also aid the detection of certain problems in the fetus, such as *neural tube defects* or congenital heart disease, so that an affected infant can receive treatment as soon as possible after birth. In addition, the scans show the position of the placenta (the organ through which the fetus receives oxy-

gen and nutrients). If the placenta is in a position that could obstruct normal delivery (see *placenta praevia*), delivery by *caesarean section* may be necessary.

Scans are often performed at 18–20 weeks. They may be taken early in pregnancy if problems such as an *ectopic pregnancy* (the presence of an embryo outside the uterus) or impending *miscarriage* are suspected. Scanning is also a vital part of procedures such as *amniocentesis* (removal of amniotic fluid for analysis) and *chorionic villus sampling* (removal of tissue from the placenta); it shows the position of the fetus and placenta, and helps in guiding the needle into the uterus. Scans may be performed later in pregnancy if the growth rate of the fetus seems slow, if fetal movements cease or become excessive, or if the mother has vaginal bleeding. For high-risk or overdue pregnancies, a scan may be carried out just before delivery to check on fetal size, development, and position in the uterus, and assess the amount of amniotic fluid, and to re-check the position of the placenta.

Ultrasound scanning can also be used in newborn babies to examine the brain through a gap in the skull, to investigate abnormalities such as *hydrocephalus* (an excessive amount of fluid within the skull).

Non-obstetric uses The liver can be clearly viewed by ultrasound; scans can be used to diagnose liver disorders such as *cirrhosis*, cysts, abscesses, or tumours. Ultrasound shows the presence of *gallstones* in the gallbladder or bile ducts. In a patient with *jaundice*, a scan can help to establish whether the jaundice is due to obstruction of the bile ducts or to liver disease. The pancreas can be scanned for cysts, tumours, or for *pancreatitis*, and the kidneys for congenital defects, cysts, tumours, and *hydronephrosis* (swelling due to obstruction preventing the outflow of urine). Other organs that may be scanned by ultrasound (primarily for the purpose of looking for cysts, solid tumours, or foreign bodies) include the thyroid gland, breasts, bladder, testes, uterus, fallopian tubes, ovaries, spleen, and eyes. Ultrasound can be used to assess the risk of fracture in suspected *osteoporosis*.

Echocardiography is an ultrasound technique that is used to look at the heart. This technique is particularly useful for investigating heart *murmurs*, congenital heart disease, heart failure, and disorders of the heart valves.

Ultrasound scanning is also used during needle *biopsy* (insertion of a very thin hollow needle into an organ to remove cells, tissue, or fluid for examination) to help guide the needle accurately to a specific spot.

Doppler ultrasound scanning This technique is a modified form of ultrasound scanning that uses the *Doppler effect* (the change in pitch that occurs when a sound source is moving relative to the detector) for the purposes of investigating moving objects. Doppler ultrasound scanning can be used to examine the fetal heartbeat and to obtain information about the rate of blood flow in blood vessels, for example through the fetus's umbilical cord.

HOW IT IS DONE

The patient removes all clothing that is covering the area to be viewed. A gel is then smeared over the skin to ensure that there is good contact between the skin and the transducer (the device that emits and receives ultrasonic waves). The transducer is placed on the skin over the part of the body that is to be viewed and is moved back and forth. At the boundaries, or edges, of tissues, echoes are bounced back to the transducer. The device converts the sound echoes into electrical signals and sends these to a computer, which converts the data into an image. For scans in early pregnancy or for gynaecological purposes, a transducer may instead be inserted into the vagina (which is known as transvaginal ultrasound).

For a scan in early pregnancy, the woman is usually asked not to pass urine for a few hours beforehand; a full bladder helps to improve the view of the uterus by displacing nearby loops of intestine. For a liver or gallbladder scan, the patient is usually asked to fast for several hours beforehand.

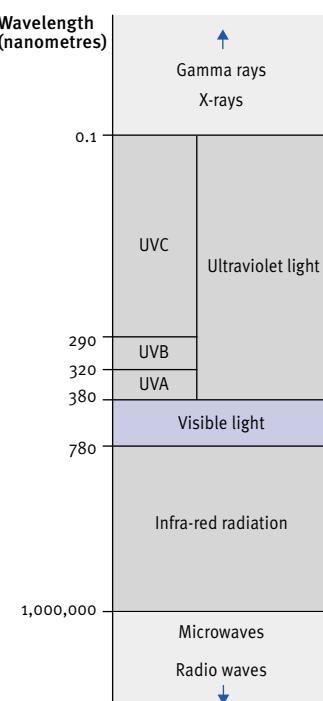

ultrasound treatment

The use of high-frequency sound waves in order to treat soft-tissue injuries (such as injuries to ligaments, muscles, and tendons). Ultrasound treatment reduces inflammation and speeds up the healing process. It is thought to work by improving blood flow in tissues under the skin.

ultraviolet light

Invisible light from the part of the electromagnetic spectrum immediately beyond the violet end of the visible light spectrum (see *colour vision*). Long-

ELECTROMAGNETIC SPECTRUM

Ultraviolet light in the spectrum

Different types of electromagnetic radiation are defined according to their wavelengths. The diagram shows the different types (which together make up the electromagnetic spectrum) and their wavelength limits in nanometres (one nanometre equals one thousand-millionth of a metre). Ultraviolet light is the part of the electromagnetic spectrum between visible light and X-rays.

wavelength ultraviolet light is termed UVA, intermediate UVB, and short-wavelength UVC.

Ultraviolet light occurs in sunlight, but much of it is absorbed by the ozone layer of the atmosphere. The ultraviolet light (mainly UVA) that reaches the Earth's surface causes the tanning effects of sunlight and the production of *vitamin D* in the skin. It can also have harmful effects, such as *skin cancer* (see *sunlight, adverse effects of*).

This form of light is generated by tanning beds to produce a suntan. Tanning beds are designed to emit only UVA rays; in practice they also give off a small amount of UVB (which is more likely to cause burning than UVA). Tanning beds may also cause skin cancer. Ultraviolet light is also produced by certain other types of equipment, such

as welding torches, carbon arcs, and lasers. Special precautions, such as the use of goggles, should always be taken when using such equipment.

MEDICAL USES

Ultraviolet light is sometimes used in *phototherapy* to treat certain skin disorders, such as psoriasis and eczema, and jaundice in newborn babies. A mercury-vapour lamp (Wood's light) can be used to produce ultraviolet light artificially. This device is used to diagnose skin conditions such as *tinea* because it causes the infected area to fluoresce.

umbilical cord

The ropelike structure connecting the *fetus* to the *placenta*. The umbilical cord supplies the fetus with oxygen and nutrients from the mother's circulation. It is usually 40–60 cm long. It consists of a jellylike substance that contains two arteries and a vein.

After delivery, the umbilical cord is clamped and then cut about 2.5 cm from the baby's abdomen. The stump falls off within a couple of weeks, leaving a scar called the umbilicus (navel).

DISORDERS

In rare cases, the umbilical cord protrudes down through the mother's cervix during labour. This situation is dangerous, because the cord can be squeezed between the mother's pelvis and the baby's body, causing the baby's oxygen supply to be cut off. Prompt delivery, by caesarean section or forceps, is necessary. Another problem that may occur during delivery is the cord wrapping around the baby's neck, causing strangulation. This problem can usually be remedied by someone slipping the cord over the baby's head.

Rarely, there is only one artery in the umbilical cord. This condition may be associated with birth defects.

umbilical hernia

A soft swelling at the *umbilicus* (navel) caused by the protrusion of the abdominal contents through a weak area of abdominal wall. Umbilical hernias, which are common in newborn babies, occur twice as often in boys as in girls. The swelling increases in size when the baby cries, and may cause discomfort. Umbilical hernias usually disappear without treatment by the age of two. If a hernia is still present at the age of four, surgery may be needed.

Umbilical hernias sometimes develop in adults, especially in women after

Umbilical hernia

This condition, which is present from birth, is caused by a localized weakness in the abdominal wall. It usually disappears without treatment.

childbirth. Surgery may be needed for a large, persistent, or disfiguring hernia.

umbilicus

The scar on the abdomen that marks the site of attachment of the *umbilical cord* to the *fetus*. It is commonly called the navel or belly button.

DISORDERS

Various umbilical disorders may occur in newborns. Occasionally, problems may occur in adults.

Problems in newborns The baby's umbilical stump sometimes becomes infected and may ooze pus. Called omphalitis, this condition generally begins during the first week of life. Treatment involves gently wiping the umbilicus with sterile cotton wool and water. Treatment with *antibiotic drugs* may also be necessary. Another common problem is the development of an *umbilical hernia*.

Quite commonly, a fleshy protuberance called a granuloma grows on the umbilical stump, sometimes as a result of chronic infection. Umbilical granulomas may be destroyed by topical application of silver nitrate. Another form of growth is an umbilical polyp (also called umbilical adenoma): a shiny, bright red, raspberry-like growth. Such polyps may require surgical removal.

Problems in adults Adults occasionally develop umbilical hernias. Other problems are rare.

One possible problem is a discharge from the umbilicus, which may be due either to an infection or to an abnormal connection between the umbilicus and the urinary, biliary, or intestinal tracts. Such structural abnormalities may result from a birth defect, *cancer*, or *tuberculosis*. It may be possible to correct them surgically. Occasionally, secondary cancerous tumours may develop in the umbilicus as a result of cancers in the breast, colon, ovary, or stomach. In rare cases, women develop *endometri-*

osis in the umbilicus, which causes it to bleed during *menstruation*.

unconscious

A specific part of the mind in which ideas, memories, perceptions, or feelings that a person is not currently aware of are stored and processed. The contents of the unconscious mind are not easily retrieved, in contrast to those of the *subconscious*. (See also *Freudian theory*; *Jungian theory*.)

unconsciousness

An abnormal loss of awareness of self and one's surroundings due to a reduced level of activity in the reticular formation of the *brainstem*. An unconscious person can be roused only with difficulty or not at all. Unconsciousness may be brief and light, as in *fainting* or *concussion*, or deep and prolonged (see *coma*).

underbite

See *prognathism*.

undescended testis

See *testis*, *undescended*.

undulant fever

Another name for *brucellosis*.

unguent

An alternative term for an *ointment*.

unit of alcohol

See *alcohol*, *unit of*.

unsaturated fats

See *fats and oils*.

unstable angina

A form of *angina pectoris* (chest pain due to impaired blood supply to the heart muscle) that develops during sleep or without provocation (the pain is usually provoked by exercise in angina). The term unstable may also refer to angina that is becoming more frequent or more severe. Unstable angina is a medical emergency because there is a high risk of *myocardial infarction* (heart attack). Drugs are given and *angioplasty* may be necessary.

unstable bladder

Another name for *irritable bladder*.

uraemia

The presence of excess *urea* and other chemical waste products in the blood, caused by *kidney failure*.

uranium

A radioactive metallic element that does not occur naturally in its pure form but is widely found in ores such as pitch-blende, carnotite, and uraninite. Radioactive decay of uranium causes *radiation* to be emitted and yields a series of radioactive products, including *radium* and *radon*, which may cause tissue damage or cancer (see *radiation hazards*; *radiation sickness*). Uranium is also chemically poisonous and can cause damage to the urinary system.

urea

A waste product from the breakdown of proteins. Proteins in food are digested to form *amino acids*. In the liver, excess amino acids are converted into urea, which is carried by the bloodstream to the kidneys and excreted in the urine. A high-protein diet increases the amount of urea produced.

The kidneys are usually highly efficient at eliminating urea from the body. Healthy kidneys can cope with increased urea production, but *kidney failure* lessens this ability and leads to *uraemia* (abnormally high blood levels of urea). For this reason, the measurement of urea levels in the blood may be one of the routine *kidney-function tests*.

Urea is also formed in the body from the breakdown of cell proteins. If there is a large increase in urea from this source (due, for example, to severe tissue damage resulting from injury or surgery), the kidneys are sometimes unable to cope and *uraemia* results.

Certain conditions (such as liver damage) may lead to a decrease in the blood level of urea. Blood levels of urea also fall during pregnancy, when the blood is more dilute than usual.

MEDICAL USES

Urea is used in various creams and ointments to moisturize and soften the skin in disorders such as *psoriasis*, *atopic dermatitis*, *ichthyosis*, and other conditions in which the skin is dry and scaly.

ureter

One of the two tubes that carry urine from the *kidneys* to the *bladder*. Urine flows down the ureters, partly by gravity, but mainly by *peristalsis* (rhythmic contractions of the muscular ureter walls).

Each ureter is 25–30 cm long. The walls of the ureters have three layers: a fibrous outer layer; a muscular middle layer; and an inner watertight layer. The ureters are supplied by blood vessels

and nerves. They join the bladder via a tunnel in the bladder wall, which is angled to prevent reflux (backflow) of urine, into the ureters when the bladder muscle contracts.

DISORDERS

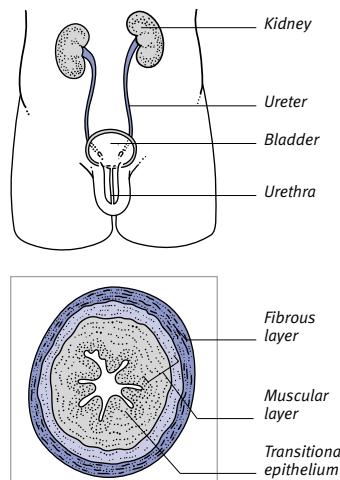

Some people are born with duplex (double) ureters, on one or both sides of the body, usually in association with partial *duplex kidney* on an affected side. Double ureters may be separate along their entire length, or they may join to form a Y shape. In many cases, the condition causes no problems, but if duplicated ureters enter the bladder separately there may be *vesicoureteric reflux* (backflow of urine into the ureter). There may also be problems, such as *incontinence* or infection, if a ureter enters the urethra or the vagina instead of the bladder. Corrective surgery can be performed if necessary.

Spasms of the ureter may occur if a stone (see *calculus*, *urinary tract*) passes down or becomes stuck in a ureter. This extremely painful condition is commonly known as *renal colic*.

Ureteritis is an inflammatory condition that may occur if the ureter is blocked by a stone, or be caused by the spread of infection from the bladder.

ANATOMY OF THE URETER

The ureters are tubes that carry urine from the kidneys to the bladder. They enter the back of the bladder at an angle.

Cross-section
Each ureter has three layers: a fibrous layer, muscular middle layer, and inner transitional epithelial layer, which is the same tissue that lines the bladder.

ureteric colic

See *renal colic*.

ureterolithotomy

The surgical removal of a stone (see *calculus*, *urinary tract*) from a *ureter* (tube that carries urine from a kidney to the bladder). Ureterolithotomy is not often used because *lithotripsy* and *cystoscopy* can deal with stones.

urethra

The tube through which *urine* is excreted from the *bladder*. In females, the urethra is short and opens to the outside of the body in front of the *vagina*. In males, the urethra is much longer; it is surrounded by the *prostate gland* at its upper end, and it forms a channel through the length of the penis, with its outlet in the *glans*. (see *Location of the urethra* box, overleaf).

DISORDERS

Urethral infections, scarring, and congenital abnormalities occur in both sexes, but these are much more common and serious in males than in females.

Inflammation of the urethra, called *urethritis*, may be due to an infection such as chlamydia or gonorrhoea, irritation, or minor surgery. It may lead to *urethral stricture* (narrowing of a section of the urethra) in men. In addition, the male urethra is easily damaged in accidents involving pelvic injury and may require surgical repair.

Male infants sometimes have a urethral valve, which is a flap that grows from the lining of the urethra. The valve impedes the flow of urine and causes back pressure on the kidneys as urine overfills the bladder, ureters, and collecting ducts of the kidneys. Permanent and severe damage to the kidneys can occur if the urethral valve is not removed surgically.

urethral dilatation

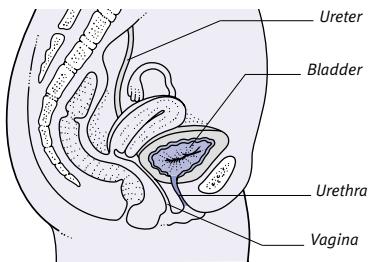

The procedure in which a *urethral stricture* (a narrowed section of the urethra) in a male is widened by the insertion of a slim, round-tipped instrument through the opening of the urethra at the tip of the *penis*.

urethral discharge

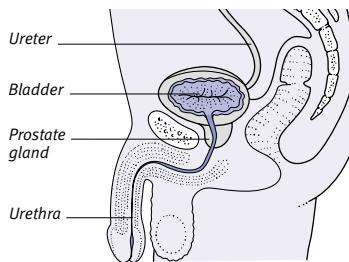

A fluid, distinct from urine, that flows from the *urethra* in some cases of *urethritis* (urethral inflammation) caused by infection. In most types of infection, the discharge is clear; in *gonorrhoea*, it is yellow and contains pus.

LOCATION OF THE URETHRA

The urethra is the tube through which urine is passed from the bladder. There is no voluntary muscle in the urethra. The flow of urine is controlled by muscles in the wall and outlet of the bladder.

**Urethra in a woman**

The female urethra is short (about 4 cm long) and runs down to open to the exterior just in front of the vagina.

**Urethra in a man**

The male urethra is about 18–20 cm long. It passes through the prostate gland and along the full length of the penis.

urethral stricture

A rare condition in which the male *urethra* becomes narrowed and sometimes shortened due to shrinkage of scar tissue in its walls. Scar tissue may form after injury to the urethra or persistent *urethritis* (inflammation of the urethra).

A stricture may make passing urine or ejaculation difficult or painful, and it may cause some deformation of the penis when erect. It may also encourage the development of *urinary tract infection* due to a build-up of stagnant urine. In some cases, trapped urine puts back-pressure on the kidneys and may result in kidney damage.

Treatment is usually by *urethral dilatation* (surgical widening of the urethra). If this operation fails, a surgeon may cut through the scar tissue or, in some cases, the stricture may be completely removed and the urethra is reconstructed by *plastic surgery*.

urethral syndrome, acute

A set of symptoms, usually affecting women, that are very similar to *cystitis* but which occur without the presence of any infection. The symptoms consist of pain and discomfort in the lower abdomen, a frequent urge to pass urine, and, in women, pain around the *vulva*. Middle-aged women are the most commonly affected by this syndrome.

In most cases, kidney function and urinary tract anatomy are normal. The symptoms often occur after sexual intercourse. In women who have gone through the *menopause*, the symptoms may be due to inflammation of the

vulva associated with thinning of tissues (see *vulvitis*). Emotional and psychological factors may contribute.

Treatment may be difficult. Cases due to vulvitis may be relieved by creams containing *oestrogen drugs* or *corticosteroid drugs*. Antiseptic creams and strong soaps should be avoided because they may worsen the symptoms. Good personal hygiene and a high fluid intake are usually recommended. Changing sex positions, for example, with the woman on top, may be helpful, as may passing urine before and after sex.

urethritis

Inflammation of the *urethra*. Urethritis may be caused by various infectious organisms, including chlamydia and the bacterium that causes *gonorrhoea*. *Non-gonococcal urethritis* may be caused by any of a large number of different types of microorganism. Urethritis may also be caused by damage from an accident or from a *catheter* or *cystoscope*. Other possible causes include irritant chemicals, such as some spermicides.

SYMPTOMS AND TREATMENT

Urethritis causes a burning sensation and intense pain when passing urine. The urine may be bloodstained and, particularly if gonorrhoea is the cause, may contain a pus-filled discharge.

The inflammation may lead to *urethral stricture* (narrowing), which can make it difficult for the person to pass urine.

The cause of urethritis is identified by analysis of a urine sample or swabs taken from the urethra. Infections are treated with *antibiotic drugs*.

urethrocele

An anatomical abnormality in females caused by a weakness in the tissues in the front wall of the *vagina*. The urethra bulges backwards and downwards into the vagina. A urethrocele may be congenital, but more commonly develops after *childbirth*. It is usually treated by surgery to tighten the vaginal tissues.

-uria

A suffix relating to *urine*. For example, haematuria means blood in the urine.

uric acid

A waste product of the breakdown of *nucleic acids* in body cells. A small amount is also produced by the digestion of foods rich in nucleic acids, such as liver, kidney, and other offal. Most uric acid produced in the body passes to the kidneys, which excrete it in the *urine*, but some goes into the intestine, where it is broken down into chemicals excreted in the *faeces*.

When uric acid excretion is disrupted, for example by kidney disease, it may result in *hyperuricaemia* (abnormally high levels of uric acid in the blood), which may in turn lead to *gout* or kidney stones (see *calculi, urinary tract*).

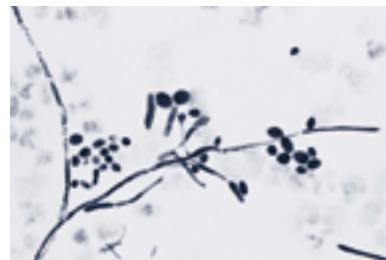

urinal

A container for *urine*, useful for bedridden men (women use a *bedpan*).

urinalysis

Tests that are carried out on *urine*, including measurements of its physical characteristics (such as colour, cloudiness, and concentration); microscopic examination to identify abnormalities such as blood or uric acid crystals; a *urine culture* to detect infectious organisms; and chemical testing such as dipstick urinalysis.

Dipstick urinalysis involves dipping a test stick into a urine sample; chem-

**Candida in urine**

This infection can be diagnosed using urinalysis. In this light micrograph, the hyphae (strands) and blastospores of the fungus are clearly visible.

ically impregnated squares on the stick change colour in the presence of test substances. The intensity of the colour change shows the amount of the substance present in the urine.

Urinalysis can be used to check kidney function and to diagnose urinary tract infections and disorders such as *diabetes mellitus*. Urinalysis is also used in *pregnancy tests*.

urinary diversion

Any surgical procedure (temporary or permanent) that enables urine to flow when the outlet of the *urinary tract*, via the bladder and urethra, is obstructed or cannot be used, or the bladder has been surgically removed.

TEMPORARY DIVERSION

Temporary urinary diversion may be necessary when the passage of urine is blocked by *prostate gland* enlargement or by *urethral stricture* (narrowing of the urethra). A tube is passed into the bladder through an opening in the abdomen (see *catheterization, urinary*). Temporary diversion is also required after some urinary tract operations; a tube is introduced into the kidney and brought to the abdominal surface.

PERMANENT DIVERSION

Permanent urinary diversion is needed when the bladder has been surgically removed; when neurological bladder control is severely disturbed, such as after severe spinal injury; or if there is

an irreparable *fistula* (abnormal opening) between a woman's bladder or urethra and her vagina.

A section of the *ileum* (the lower part of the small intestine) is removed to create a substitute bladder, into one end of which the surgeon implants the ureters. The other end of the substitute bladder is then brought out through an incision in the abdominal wall. The patient wears a bag attached to the skin to collect urine.

urinary incontinence

See *incontinence, urinary*.

urinary retention

Inability to empty the *bladder* or difficulty in doing so. Urinary retention may be complete (in which urine cannot be passed voluntarily at all) or incomplete (in which the bladder fails to empty completely).

CAUSES

In males, causes of urinary retention include *phimosis* (tight foreskin), *urethral stricture* (narrowing of the urethra), *prostatitis* (inflammation of the prostate gland), a stone in the bladder (see *calculus, urinary tract*), and enlargement or tumour of the prostate (see *prostate, enlarged; prostate, cancer of*). In females, causes include pressure on the urethra from *uterine fibroids* or from a growing *fetus* in the uterus. In either sex, the cause may be a bladder tumour.

Urinary retention may also be caused by a defective functioning of the nerve pathways that supply the bladder as a result of general or spinal *anaesthesia*, of drugs affecting the bladder, of surgery, of injury to the nerves, or of disease of the spinal cord.

SYMPOTMS

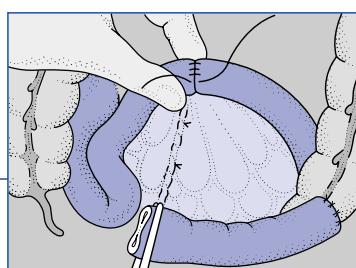

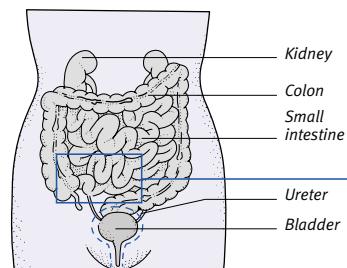

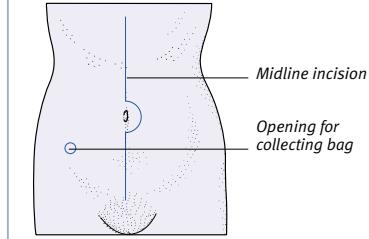

Complete urinary retention causes discomfort and lower abdominal pain (except when the nerve pathways are defective). The full bladder can be felt above the pubic bone. Chronic or partial urinary retention, however, may not cause problems, and the affected individual may be unaware of the condition. Urinary retention can lead to kidney damage and, often, a urinary tract infection.

TREATMENT

The condition is treated by catheterization (see *catheterization, urinary*). The cause is then investigated. Obstruction can usually be treated; if nerve damage is the cause, permanent or intermittent catheterization is sometimes necessary.

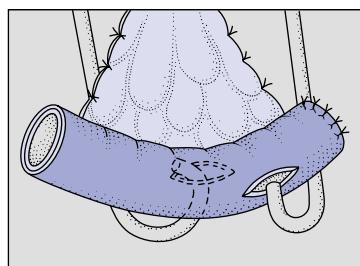

URINARY DIVERSION USING ILEAL CONDUIT

This is one of the standard operations that can be performed when the bladder has to be removed. A midline incision in the abdomen is used; before making the incision, the surgeon creates an opening through the abdominal wall in a good position for later attachment of the collecting bag.

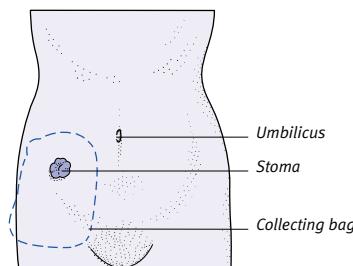

1 A short length is cut out of the ileum (the lower part of the small intestine), retaining the mesentery (supporting folds of tissue) and the essential blood vessels that supply the freed section.

2 The cut ends of the intestine are rejoined. One end of the freed length of intestine is closed, and the other end is temporarily clamped. The bladder is removed.

3 The ureters are now implanted into the isolated length of ileum. The open end of this segment is brought through the abdominal wall and stitched in place.

4 A disposable collecting bag for receiving the patient's urine is attached with adhesive around the new stoma (opening) in the wall of the abdomen.

urinary system

See *urinary tract*.

urinary tract

The part of the body concerned with the formation and excretion of *urine*. The urinary tract consists of the *kidneys* (with their blood and nerve supplies), the renal pelvises (funnel-shaped ducts that channel urine from the kidneys), the *ureters*, the *bladder*, and the *urethra*.

The kidneys make urine by filtering blood. The urine collects in the renal pelvises and is then passed down the ureters into the bladder by the actions of gravity and *peristalsis* (wavelike contractions of the muscular ureter walls). Urine is stored in the bladder until there is a sufficient amount present to stimulate *micturition* (passage of urine). When the bladder contracts, the urine is expelled through the urethra. (See also *urinary tract infection*.)

urinary tract infection

An infection anywhere in the *urinary tract*. These often cause inflammation of the urethra (see *urethritis*), bladder (see *cystitis*), or kidneys (see *pyelonephritis*). The symptoms depend on the area affected.

CAUSES AND INCIDENCE

Urethritis is often due to a *sexually transmitted infection*, such as gonorrhoea, but may have other causes. Cystitis and pyelonephritis are almost always the result of a bacterial infection that has travelled up the urinary tract from the urethra; the causative organisms are often bacteria from the rectum that have entered the urethra. Backflow of urine into the ureters from the bladder (see *vesicoureteric reflux*) causes recurrent urinary infection in children that often results in acute pyelonephritis. Infectious organisms may also be carried to the urinary tract in the bloodstream.

Infections of the urethra are more common in men. Infections further up the urinary tract are more common in women, and are more likely to occur during pregnancy. However, an enlarged prostate gland (see *prostate, enlarged*) is often a predisposing factor to bladder or kidney infection in men.

In both sexes, causes of urinary tract infections include stones (see *calculus, urinary tract*), *bladder tumours*, congenital abnormalities of the urinary tract, or defective bladder emptying as a result of *spina bifida* or a *spinal injury*.

The risk of a urinary tract infection can be reduced by care over personal

hygiene, regularly emptying the bladder, and drinking plenty of fluids.

TYPES AND SYMPTOMS

Urethritis causes a burning sensation when urine is passed. Cystitis causes a frequent urge to pass urine, lower abdominal pain, *haematuria* (blood in the urine), and, often, general malaise with a mild fever. Pyelonephritis causes fever, pain in the back under the ribs, and sometimes also violent shivering, nausea, and vomiting.

COMPLICATIONS

Urethritis can lead to the formation of a *urethral stricture* (narrowing of a section of the urethra). Cystitis does not usually cause complications unless the infection spreads to the *kidneys*. Pyelonephritis, if left untreated, can lead to permanent kidney damage, *septicaemia* (blood poisoning), and *septic shock*.

DIAGNOSIS AND TREATMENT

Urinary tract infection is diagnosed by examination of a urine *culture*. Further investigations using *intravenous urography* or *ultrasound scanning* may be necessary. Most urinary tract infections are treated with *antibiotic drugs*. Increasing fluid intake and taking preparations such as potassium citrate that make the urine less acidic can relieve the symptoms.

urination, excessive

The production by an individual of more *urine* than is usual for them. In an adult, an output of about 3 litres a day would be considered abnormal, a condition known medically as polyuria.

CAUSES

Various diseases may cause abnormal amounts of certain substances to be excreted in the urine; these substances draw water with them, thus increasing the urine volume. The most important disease in this group is *diabetes mellitus*, in which excess glucose passes from the blood into the urine. Certain kidney diseases, called salt-losing states, lead to excessive salt loss in the urine, with an accompanying increase in volume.

Excessive urination may also be due to *diabetes insipidus*. In central diabetes insipidus, the production of *ADH* (anti-diuretic hormone) by the pituitary gland is reduced. ADH normally acts on the kidneys to concentrate the urine, so low levels of this hormone cause a marked increase in urine volume. In nephrogenic diabetes insipidus, which may result from various kidney disorders, normal amounts of ADH are produced but the kidneys fail to respond to it.

Excessive urination is sometimes due to psychiatric problems, which may cause a person to drink compulsively. This leads inevitably to a high urine output.

Alcoholic drinks and drinks containing caffeine have a *diuretic* effect, which temporarily increases urine output.

DIAGNOSIS

Any person who starts to pass larger quantities of urine than is usual for them should consult a doctor.

One simple diagnostic test involves restricting the patient's fluid intake. In a compulsive drinker, urine volume soon drops if water intake is restricted, but if a person has *diabetes insipidus*, urine production will remain excessive. If *diabetes insipidus* is suspected, synthetic *ADH* may be given to establish the type; central diabetes insipidus improves after administration of *ADH*, but the nephrogenic form does not.

Chemical tests on urine (see *urinalysis*) may also aid diagnosis. In patients with *diabetes mellitus*, the glucose level in the blood and urine is high; in salt-losing patients, an excessive amount of sodium is detectable in the urine.

TREATMENT

Treatment of excessive urination varies according to the underlying cause. (See also *urination, frequent*.)

urination, frequent

Also known as urinary "frequency", passing of urine more often than the average of four to six times daily.

Causes of frequent urination include excessive production of urine (see *urination, excessive*), *cystitis* (inflammation of the bladder), *anxiety*, stones in the bladder (see *calculus, urinary tract*), enlargement of the prostate gland (see *prostate, enlarged*) in men, and, rarely, a *bladder tumour*. In addition, some people who are suffering from *kidney failure* pass urine more frequently, especially during the night. A temporary increase in frequency can result from consuming alcoholic or caffeinated drinks.

Treatment of frequent urination is always aimed at the underlying cause.

urination, painful

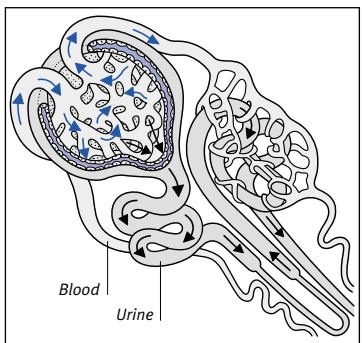

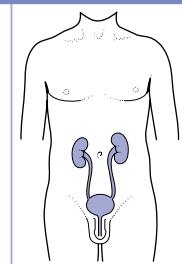

Pain or discomfort that occurs when urine is being passed. Painful urination is known medically as *dysuria*. The pain is often described as burning; sometimes it is preceded by difficulty in starting urine flow. Pain after the flow has ceased, with a strong desire to continue, is called *strangury*.

THE URINARY TRACT

Also known as the urinary system, the urinary tract consists of the kidneys, in which urine is formed to carry away waste materials from the blood; the ureters, which transport the urine from the kidneys; the bladder, where the urine is stored until it can be conveniently disposed of; and the urethra, through which the bladder is emptied to the outside. The kidneys require a large blood supply and are connected close to the body's main artery, the aorta. More than a litre of blood passes through the kidneys every minute.

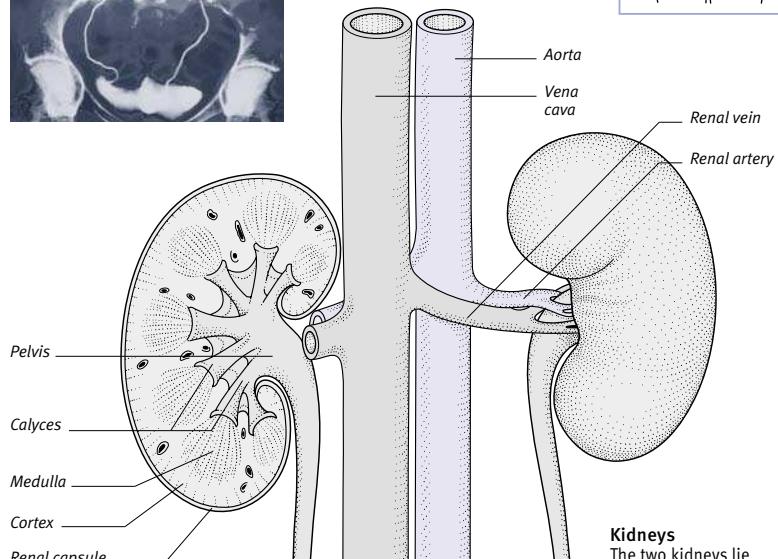

X-ray showing urinary tract
The X-ray on the left, taken using the technique of intravenous urography, shows (as lighter areas) the calyces and pelvis of each kidney, the ureters and bladder, as well as the bones of the lower spine and pelvic girdle.

The filtering units

Each kidney has about one million of these units, which form dilute urine by filtering the blood.

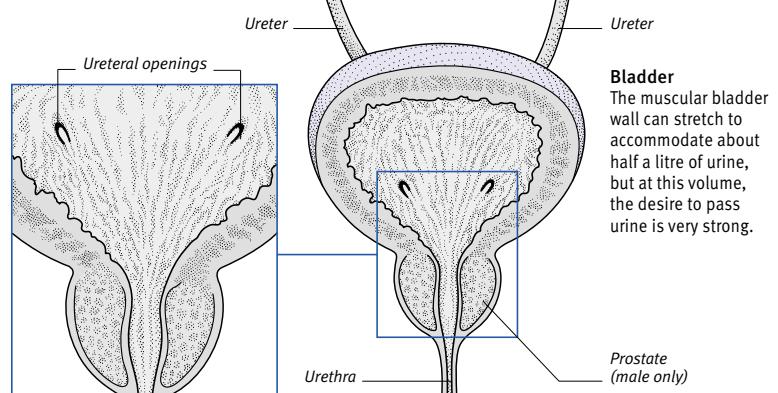

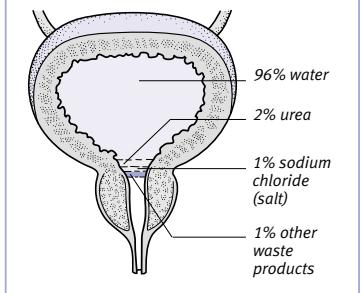

Kidneys

The two kidneys lie within large pads of fat on the inside of the back wall of the abdomen, close to, and on either side of, the spine. Each kidney consists of an outer cortex, an inner medulla, and a urine-collecting system that includes the calyces and the pelvis of the kidney.

COMPOSITION OF URINE

Urine consists almost entirely of water, with only small amounts of urea (the main waste product), other waste products (e.g. creatinine and uric acid), and sodium chloride (salt).

Interior of bladder

The two ureteral openings, shown on the right, and the urethral orifice form a triangle at the base of the bladder. In males, the urethra runs through the body of the prostate gland situated below the bladder.

The most common cause of strangury, especially in women, is *cystitis* (inflammation of the bladder). Other causes include a *bladder tumour*, bladder stone (see *calculus*, *urinary tract*), and *urethritis* (inflammation of the urethra). In men, possible causes include *balanitis* (inflammation of the head of the penis) and *prostatitis* (inflammation of the prostate gland). Vaginal *candidiasis* (thrush) may be a cause in women.

Strangury is usually caused by spasm of an inflamed bladder wall, but it may be due to bladder stones. Mild discomfort when passing urine may be caused by highly concentrated urine.

Dysuria may be investigated by means of a physical examination, *urinalysis*, *intravenous urography*, or *cystoscopy*. Treatment is of the cause. (See also *urethral syndrome, acute*.)

urine

The pale yellow fluid produced by the *kidneys* and excreted from the body via the *ureters*, *bladder*, and *urethra*. Urine is normally sterile when passed and has only a faint odour. Stale urine has an unpleasant smell, however, because of the action of bacteria, which causes the release of ammonia.

URINE PRODUCTION

Urine is produced when blood is filtered through the *kidneys* to remove waste products and excess water or chemical substances.

A healthy adult produces 0.5–2 litres of urine per day. The minimum volume needed to remove all waste products is about 0.5 litres. A high fluid intake increases the amount of urine produced. High fluid loss from sweating, vomiting, or diarrhoea leads to reduced production.

COMPOSITION

After water, the main component of urine is *urea*. The other substances that are normally excreted in urine are shown in the diagram on p.775.

The volume, acidity, and salt concentration of urine are carefully regulated by hormones such as *ADH* (anti-diuretic hormone), *atrial natriuretic peptide*, and *aldosterone*. These hormones act on the kidneys to ensure that the body's levels of water and salt, and the *acid-base balance* (the acidity or alkalinity of the blood and tissue fluids), are kept within narrow limits.

Measurements of the composition of urine are useful in the diagnosis of numerous conditions, from kidney disease and diabetes mellitus to pregnancy.

urine, abnormal

Urine may be produced in abnormal amounts or have an abnormal appearance or composition.

ABNORMAL VOLUME

Certain conditions may cause excess urine to be passed (see *urination, excessive*): in adults, more than about 3 litres of urine per day. In contrast, abnormally low urine production (see *oliguria*), of less than about 0.4 litres per day, may occur in severe *dehydration* or acute *kidney failure*. If severely damaged, the kidneys may fail to produce any urine (see *anuria*). Obstruction of the urinary tract by a stone, for example, may also cause the cessation of urine flow.

ABNORMAL APPEARANCE

Cloudy urine may be due to a *urinary tract infection*, a stone (see *calculus*, *urinary tract*), or the presence of salts. Haematuria (blood in the urine) may be due to bleeding in the urinary tract. Urine may become discoloured due to ingestion of certain foods or drugs. An excess of protein may cause urine to become frothy.

ABNORMAL COMPOSITION

Certain disorders cause abnormal substances to be excreted in the urine. In *diabetes mellitus*, glucose enters the urine. *Glomerulonephritis* (inflammation of the filtering units of the kidneys) or *nephrotic syndrome* cause protein to leak into the urine. Some disorders cause abnormal levels of normal waste products, or other chemical imbalances. *Kidney failure* reduces the total amounts of waste products such as urea. Other kidney disorders, such as *Fanconi's syndrome* and *renal tubular acidosis*, may make the urine too acid or alkaline, or may cause it to contain excess amino acids, phosphates, salts, or water.

urine tests

See *urinalysis*.

urodynamics

A group of tests carried out to investigate problems with *bladder* control, such as *incontinence*. These studies involve the insertion of probes into the bladder and the *rectum* or *vagina* to monitor pressure changes while the bladder is filled and emptied. The patient may also wear an absorbent electronic pad to detect any leakage of urine.

HOW IT IS DONE

In *X-ray* monitoring, the patient stands against an upright table while his or her bladder is filled with a *contrast medium* through a *catheter* and is then emptied

again. The shape of the bladder, and the functioning of the urethra, can then be viewed on an *X-ray* monitor. At the same time, the probes make a continuous recording of pressure changes within the bladder, which is transmitted to a computer and then printed out on a paper trace. As the bladder is being filled, the patient is asked to cough. This action increases the pressure in and around the bladder; if it causes leakage of urine on to the electronic pad, the patient has stress incontinence (see *incontinence, urinary*).

urography

See *intravenous urography*.

urology

A branch of medicine concerned with the structure, functioning, and disorders of the *urinary tract* in males and females, and of the *reproductive system* in males. Investigative techniques that are used in urology include *intravenous urography*, *cystoscopy*, *ultrasound scanning*, *cystometry*, and *urinalysis*.

ursodeoxycholic acid

A drug used to dissolve *gallstones*. Ursodeoxycholic acid is suitable only if the stones are made exclusively of *cholesterol* and only if the gallbladder is functioning normally. Side effects of the drug are rare but can include diarrhoea, indigestion, and a rash. Drug treatment is less commonly used since the introduction of *minimally invasive surgery*.

urticaria

A skin condition, also known as nettle rash or hives, characterized by the development of itchy weals, usually on the limbs and trunk. Large weals may merge to form irregular, raised patches.

SYMPTOMS

Urticaria is generally harmless and lasts only a few hours, but sometimes a persistent or recurrent form develops. The condition is sometimes accompanied by *angioedema* (an allergic condition in which swelling occurs in various parts of the body). *Dermographism* is a less common form of urticaria in which weals form after the skin is stroked.

CAUSES

The cause is often unknown. The most common known cause is an allergic reaction (see *allergy*), often to a food or drug. Urticaria may also follow exposure to heat, cold, or sunlight. Less commonly, it may be associated with

Appearance of urticaria

This skin condition is characterized by itchy weals with a white or yellow centre and an outer area of inflammation.

another disorder, such as *vasculitis*, systemic *lupus erythematosus*, or *cancer*.

TREATMENT

Itching can be relieved by the application of *calamine lotion* or by taking *antihistamine drugs*. Severe cases of urticaria may require *corticosteroid drugs*. Identifying and avoiding trigger factors can help prevent future reactions. A tendency to urticaria often disappears in time without treatment.

urticaria, neonatal

A very common, harmless skin condition, also called *erythema neonatorum* or *toxic erythema*, that affects newborn infants. The cause is unknown. Neonatal urticaria produces a blotchy rash, in which raised white or yellow lumps are surrounded by ill-defined red areas of inflammation. The rash mainly affects the face, chest, arms, and thighs. It usually clears up without treatment.

uterine muscle relaxants

Drugs that are used to delay premature delivery of a *fetus*. Beta₂-adrenoceptor stimulants, such as *salbutamol*, may be used in at-risk pregnancies of 24–33 weeks' gestation; these drugs relax the muscles of the *uterus* and may postpone labour for days or weeks. Delaying of premature labour for up to 48 hours allows time for *corticosteroid drugs* to be given to the mother, to help the fetus's lungs to mature.

uterovaginal prolapse

See *uterus, prolapse of*.

uterus

The hollow, muscular organ of the female reproductive system in which the fertilized *ovum* (egg) normally be-

comes embedded and in which the unborn baby (see *embryo*; *fetus*) develops. The uterus, which is commonly known as the womb, is situated within the pelvic cavity, behind the *bladder* and in front of the intestines.

STRUCTURE

In a nonpregnant woman, the uterus is 7.5–10 cm long and weighs 60–90 g. The lower part of the uterus opens into the *vagina* at the *cervix*; the upper part opens into the *fallopian tubes*.

The inside of the uterus is lined with *endometrium*. During the menstrual cycle, the endometrium thickens to prepare for the possible implantation of a fertilized egg. If conception and fertilization do not occur, hormone levels fall, causing the endometrium to be

expelled from the uterus (see *menstruation*). After the *menopause* (when egg production and menstruation cease), the endometrium atrophies (becomes thinner) and muscle and connective tissue are reduced.

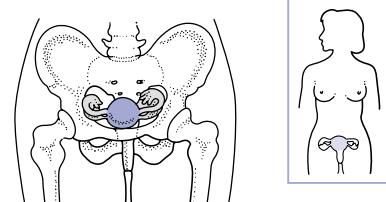

The uterus expands in size during pregnancy to accommodate the growing baby. At full term, the powerful uterine muscles expel the baby via the birth canal (see *childbirth*).

DISORDERS

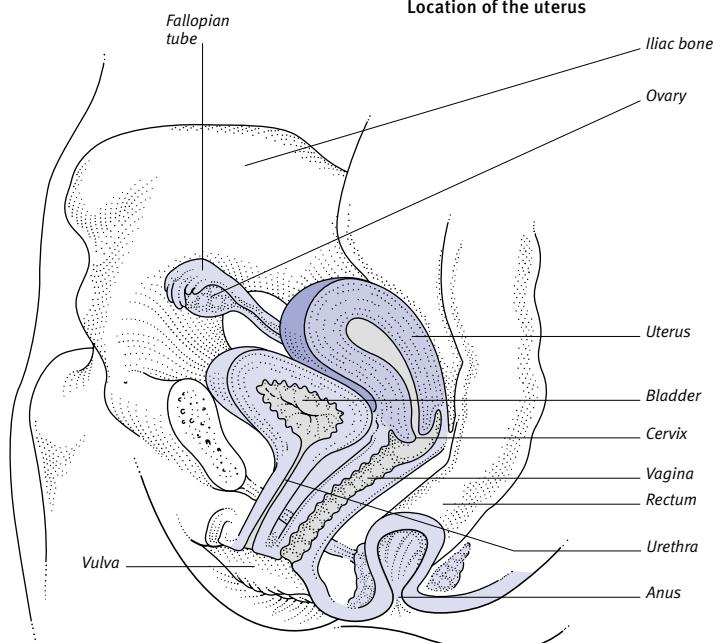

Conditions that affect the uterus include *congenital* disorders such as malformation or absence of the uterus, *duplex uterus*, or *septate uterus*; tumours, including *polyps*, *fibroids*, and cancer of the endometrium (see *uterus, cancer of*); infections, causing inflammation of the

ANATOMY OF THE UTERUS

The nonpregnant uterus lies deep in the pelvis immediately behind and above the urinary bladder and in front of the rectum. It is usually tilted forwards at an angle to the vagina, and is curved downwards slightly. When the bladder is full, the uterus is pushed up and back.

Location of the uterus

The uterus

This thick-walled organ consists mainly of muscle. The fallopian tubes enter on both sides of the uterus just below its uppermost point. The small uterine cavity is lined with a mucous membrane called the *endometrium*,

which undergoes changes during the different phases of the menstrual cycle. The vaginal surface of the cervix is lined with a flatter mucous membrane, which is identical to that of the vagina.

lining of the uterus (see *endometritis*); and hormonal disorders. (See also *uterus, prolapse of; uterus, retroverted*.)

uterus, cancer of

A malignant growth in the tissues of the *uterus*. Cancer of the uterus mainly affects the cervix (see *cervix, cancer of*) and *endometrium* (lining of the uterus). Rarely, the uterine muscle is affected by a type of cancer called a leiomyosarcoma. The term "uterine cancer" usually refers to cancer of the endometrium.

CAUSES

Risk factors for endometrial cancer include anything that may raise levels of the female sex hormone oestrogen in the body, such as *obesity*, a history of failure to ovulate, or taking *oestrogen hormones* long term if these are not balanced with *progestogen drugs*. The drug *tamoxifen*, used to treat breast cancer, increases the risk of uterine cancer. The cancer is more common in women who have had few or no children.

SYMPOTMS

Before the *menopause*, the first symptom of cancer of the uterus may be *menorrhagia* (heavy periods), or bleeding between periods or after sexual intercourse. After the menopause, the first symptom is usually a bloodstained vaginal discharge.

DIAGNOSIS AND TREATMENT

Diagnosis is made by *hysteroscopy* (examination of the inside of the uterus using a viewing instrument), with a *biopsy* (tissue sampling for microscopic analysis). Very early endometrial cancer is usually treated by *hysterectomy* (surgical removal of the uterus) and removal of the fallopian tubes and ovaries. If the cancer has spread beyond the uterus, *radiotherapy* and *anticancer drugs* may also be used.

uterus, prolapse of

A condition in which the *uterus* descends from its normal position into the *vagina*. The degree of prolapse varies from first-degree prolapse, in which there is only slight displacement of the uterus, to third-degree prolapse (*procidentia*), in which the uterus can be seen outside the *vulva*.

The condition may sometimes be associated with defects of the vagina that include *cystocele*, in which the bladder bulges into the front wall of the vagina; *urethrocele*, in which the urethra bulges into the front wall of the vagina; and *rectocele*, in which the rectal wall bulges into the back wall of the vagina.

CAUSES

Stretching of the ligaments that support the uterus is the most common cause of prolapse. Prolapse of the uterus is also aggravated by obesity.

SYMPTOMS AND DIAGNOSIS

There are often no symptoms, but there is sometimes a dragging feeling in the pelvis. In severe cases, part or all of the uterus may be visible. An accompanying cystocele, urethrocele, or rectocele may cause leakage of urine or difficulty in passing urine or faeces. Diagnosis is made by examination.

PREVENTION AND TREATMENT

Pelvic floor exercises strengthen the muscles of the vagina and can therefore

reduce the risk of a prolapse, especially following childbirth. Often, surgery is necessary to repair structures that support the uterus.

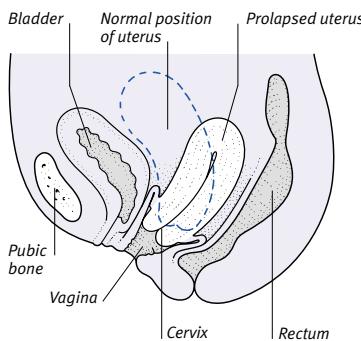

For a severe prolapse, treatment usually involves *hysterectomy* (removal of the uterus) and tightening of the ligaments. Rarely, if surgery is not advised, a plastic, ring-shaped pessary may be inserted into the vagina to hold the uterus in position. (See also *cystocele*; *rectocele*; *urethrocele*.)

uterus, retroverted

A harmless variation in the position of the uterus, which is normally retroverted in infancy, tilting forwards at puberty; a

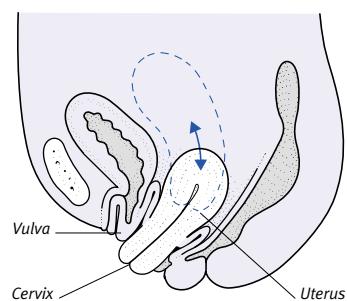

PROLAPSE OF THE UTERUS

This condition is caused by weakening and slackness of the various ligaments, muscles and connective tissues that help to keep the uterus in position in the pelvis. Prolapse of the uterus, which is more common in women who have had children, may occur in conjunction with a rectocele or cystocele. There are three degrees of uterine prolapse, as shown below.

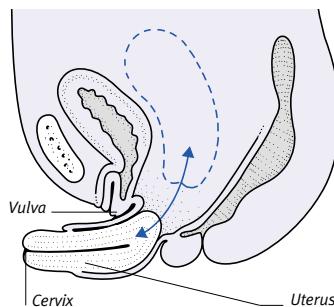

First degree prolapse

In this, the least severe degree of prolapse, strain causes the cervix (neck) of the uterus to move farther down in the vagina; however, it remains well within the vagina.

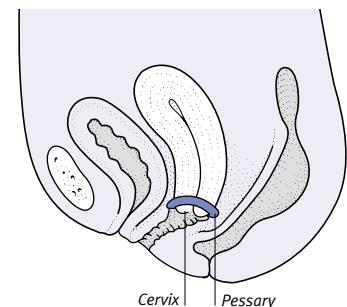

Second degree prolapse

The cervix protrudes beyond the vulva during straining, but retracts on relaxation. The vagina is partly everted (turned inside out).

Third degree prolapse

The whole uterus projects outside the vulva. The surface of the cervix and the everted vaginal wall eventually dry out and are replaced by thick white tissue.

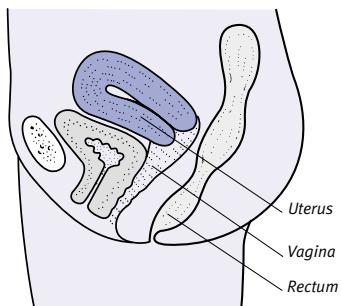

Treatment of prolapse

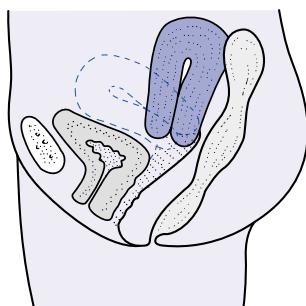

Surgery to repair the prolapse or, if necessary, to perform a *hysterectomy*, is the usual treatment. The uterus may be held in position by a plastic pessary inserted into the vagina.

RETROVERTED UTERUS

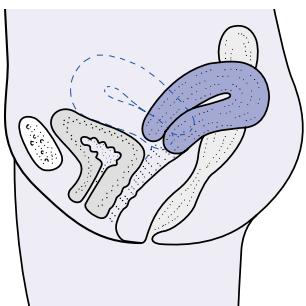

In about 80 per cent of women, the uterus is antverted (tilted forwards). In addition, the body of the organ is anteflexed (bent forwards). In simple retroversion, the organ is tilted back, but not bent back. A retroverted uterus may also be retroflexed (bent back). Retroversion is a normal variant and does not cause symptoms.

Anteflexion (most common position)
The illustration shows the usual position of the uterus, lying bent and tilted forwards, at right angles to the vagina.

Simple retroversion
A retroverted uterus that can easily be antverted by manipulation seldom causes any symptoms.

Retroversion and retroflexion
The retroversion and retroflexion may be the result of disease such as endometriosis. There may be symptoms including painful intercourse.

A retroverted uterus inclines backwards. About 1 in 5 females has a retroverted uterus. In some cases, the uterus has failed to incline forwards during the normal process of maturation. Other cases are due to changes in position after childbirth. Less commonly, retroversion is caused by a disease, such as a tumour; scarring caused by *endometriosis*; or *pelvic inflammatory disease*.

A retroverted uterus rarely causes problems. If it is associated with underlying disease, however, it may cause symptoms such as *dysmenorrhoea* (painful periods), pain during intercourse (see *intercourse, painful*), and *infertility*. Rarely, a retroverted uterus may fail to lift out of the pelvis after about 12 weeks of pregnancy, as is usual, which may lead to urinary retention needing catheterization.

Diagnosis of a retroverted uterus is by means of physical examination (see *pelvic examination*). *Laparoscopy* (examination of the abdominal cavity with a viewing instrument) may be performed if an underlying disease is suspected. Treatment of the condition is not necessary unless the retroversion is causing symptoms, in which case the underlying cause is treated or the uterus may be manipulated back into position or surgically repositioned.

uvea

Part of the *eye*, comprising the *iris* (the pigmented area around the pupil), the *ciliary body* and its muscle, which focuses the *lens*, and the *choroid* (the blood-rich layer just under the *retina*).

The uvea is well supplied with blood vessels. Those in the iris supply the muscles that control dilation (widening) and constriction (narrowing) of the pupil. The vessels in the choroid supply oxygen and nutrients to the retina.

Pigment cells, which are concentrated in the back of the iris and scattered throughout the choroid, give the eye its colour and improve optical efficiency.

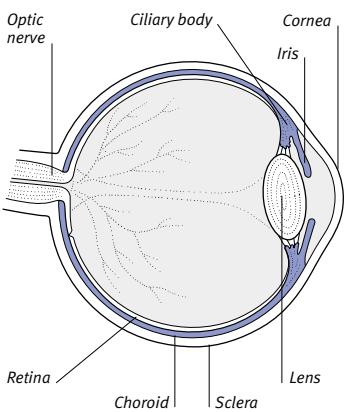

uveitis

Inflammation of the *uvea*. Uveitis may affect any part of the uvea, including the *iris* (when it is called iritis), the *ciliary body* (when it is known as cyclitis), or the *choroid* (when it is called chorioiditis). It may seriously affect vision.

The most common cause is an *autoimmune disorder*, and it is associated with joint problems. Other causes include infections such as *tuberculosis* and *syphilis*.

LOCATION OF THE UVEA

The uvea consists of the *iris*, *ciliary body*, and *choroid*.

Treatment is with *corticosteroid drugs* to relieve inflammation, and eye-drops containing a substance related to *atropine*, which blocks nerve impulses to the muscles of the iris and ciliary body. The inflammation is monitored with a *slit-lamp*. Other drugs may be given for an infection.

uvula

The small, fleshy protuberance that hangs from the middle of the lower edge of the soft *palate*. It is composed of muscle and connective tissue, with a covering of mucous membrane.

V

vaccination

A form of *immunization* in which a *vaccine*, in the form of weakened or killed *microorganisms* or inactivated bacterial *toxins*, is introduced into the body. A vaccine is given, usually in the form of an injection, in order to sensitize the *immune system*. If disease-causing organisms or toxins of the same type enter the body in the future, the sensitized immune system rapidly produces *antibodies* that destroy them.

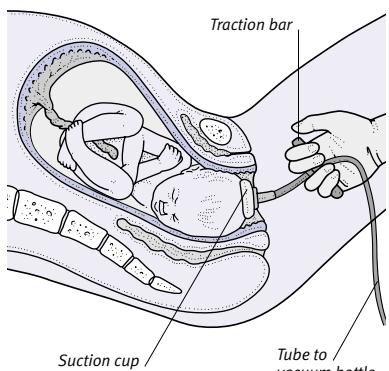

vaccine

A preparation that is given to induce *immunity* against an infectious disease. Most vaccines contain the organisms (or parts of the organisms) against which protection is sought.

Vaccines are usually given by injection into the upper arm, but some (such as the *poliomyelitis* vaccine) may be given orally. Some vaccines require several doses that are spaced some weeks apart; others require only one dose. (See also *immunization*.)

vacuum extraction

An obstetric procedure to facilitate the delivery of a baby. Vacuum extraction may be used if the second stage of

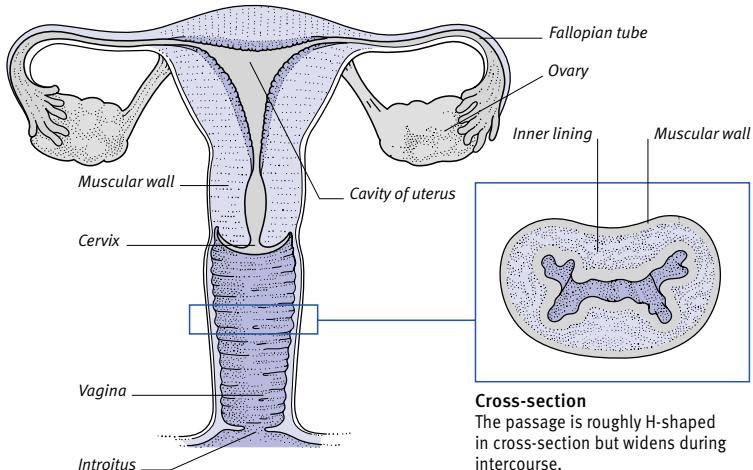

Technique of vacuum extraction

Once the suction cup is attached to the baby's head, the obstetrician pulls on the traction bar during each contraction, and the baby is drawn out through the vagina.

STRUCTURE OF THE VAGINA

The vagina has highly elastic muscular walls to allow intercourse and childbirth; it has a ribbed inner lining that secretes a lubricating fluid during sexual arousal and intercourse. It has no glands itself but is kept moist by cervical and uterine glands.

Cross-section
The passage is roughly H-shaped in cross-section but widens during intercourse.

labour (see *childbirth*) is prolonged, if the mother becomes exhausted, or if the baby shows signs of *fetal distress*.

The vacuum extraction instrument consists of a suction cup connected to a vacuum bottle. The suction cup is placed on the baby's head in the birth canal, and the vacuum machine sucks the baby's scalp into the cup. The obstetrician draws the baby out of the mother's vagina by gently pulling on the cup with each uterine contraction.

The baby is born with a swelling on the scalp, but this disappears after a few days, usually without treatment. Vacuum suction techniques are also used to perform early *abortions*.

vagina

The muscular passage, forming part of the female *reproductive system*, occurring between the *cervix* (the neck of the uterus) and the external genitalia. The vagina has highly elastic muscular walls to enable *sexual intercourse* and *childbirth* to take place and are richly supplied with blood vessels.

vaginal bleeding

Bleeding, via the *vagina*, that may originate in the *uterus*, the *cervix* (neck of the uterus), or in the *vagina* itself.

BLEEDING FROM THE UTERUS

The uterus is the most common source of vaginal bleeding and the most likely

cause is *menstruation*. From puberty to the menopause, menstrual bleeding usually occurs at regular intervals. However, problems may occur with either the character or the timing of the bleeding (see *menstruation, disorders of*).

Nonmenstrual bleeding from the uterus may have a variety of causes. Hormonal drugs, such as *oral contraceptives*, can cause spotting. *Endometritis* (infection of the uterine lining) and endometrial cancer (see *uterus, cancer of*) are other possible causes. Bleeding in early pregnancy may be a sign of threatened *miscarriage*. Later in pregnancy, it may indicate *placenta praevia* (implantation of the placenta in the lower part of the uterus) or *placental abruption* (separation of all or part of the placenta from the uterus wall).

BLEEDING FROM THE CERVIX

Bleeding from the cervix may be due to *cervical erosion*, in which case it may occur after intercourse. *Cervicitis* (infection of the cervix) and *cervical polyps* may also cause bleeding. More seriously, bleeding may be a sign of cervical cancer (see *cervix, cancer of*).

BLEEDING FROM THE VAGINA

A possible cause of bleeding from the vagina is injury during intercourse, especially following the menopause, when the walls of the vagina become thinner and more fragile. Occasionally, severe *vaginitis* (inflammation of the vagina)

leads to bleeding. Rarely, vaginal bleeding is caused by cancer of the vagina.

vaginal discharge

The emission of secretions from the *vagina*. Some mucous secretion from the vaginal walls and the cervix is normal in the reproductive years; its amount and nature vary from woman to woman and at different times in the menstrual cycle (see *menstruation*). *Oral contraceptives* can increase or decrease this discharge. Secretions tend to be greater during pregnancy. Sexual stimulation also produces increased vaginal discharge.

ABNORMAL DISCHARGE

Discharge may be abnormal if it is excessive, offensive-smelling, yellow or green, or if it causes itching. Abnormal discharge may accompany *vaginitis* (inflammation of the vagina), which may be the result of infection, such as *candidiasis* (thrush) or *trichomoniasis*, or may be due to a foreign body, such as a forgotten tampon, in the vagina.

vaginal itching

Irritation in the *vagina*, often associated with *vulval itching*. Itching is, in many cases, a symptom of *vaginitis* (inflammation of the vagina), which may be due to infection or by an allergic reaction to chemicals in hygiene or spermicidal products. Vaginal itching is common after the *menopause*, when it may be caused by low oestrogen levels. Treatment depends on the cause; it may involve *antibiotic drugs* or hormones.

vaginal repair

An operation to correct prolapse (displacement) of the vaginal wall. This may be accompanied by a vaginal *hysterectomy* (surgical removal of the uterus and vagina) if the uterus is also prolapsed (see *uterus, prolapse of*).

vaginismus

Painful, involuntary spasm of the muscles surrounding the entrance to the *vagina*. Vaginismus interferes with *sexual intercourse*. It can sometimes also interfere with medical vaginal examinations. The cause of the condition is usually psychological. (See also *intercourse, painful; psychosexual dysfunction*.)

vaginitis

Inflammation of the *vagina* that may be caused by infection, commonly with the fungus *CANDIDA ALBICANS* (see *candidiasis*), the parasite *TRICHOMONAS VAGINALIS* (see *trichomoniasis*), or bacteria.

After the *menopause* the vaginal lining becomes fragile and prone to inflammation. This is called atrophic vaginitis and is due to a reduction in the production of *oestrogen hormones*.

Infections are treated with *antibiotic drugs* or *antifungal drugs*. In cases of allergy, irritants should be avoided. Any foreign bodies, including tampons that may have been left in, are removed. Atrophic vaginitis is treated with *oestrogen drugs*. (See also *vulvitis; vulvovaginitis*.)

vagotomy

An operation in which the *vagus nerve*, which controls production of digestive acid by the stomach wall, is cut. Once widely used to treat some cases of *peptic ulcer*, it has now largely been replaced by drug treatment.

vagus nerve

The tenth *cranial nerve* and the principal component of the parasympathetic divi-

sion of the *autonomic nervous system*. The *vagus nerve* passes from the medulla oblongata (in the *brainstem*) through the neck and chest to the abdomen and has branches to most of the major organs, including the larynx (voicebox), pharynx (throat), trachea (windpipe), lungs, heart, and digestive system.

valgus

The medical term for outward displacement of a part of the body.

Valium

A former brand name for diazepam, a *benzodiazepine* antianxiety drug, *muscle relaxant*, and *anticonvulsant drug*.

valproate

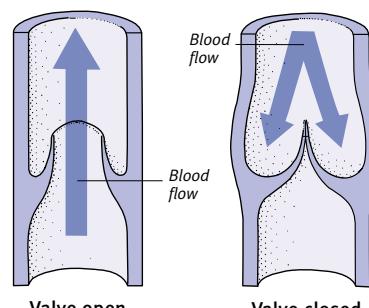

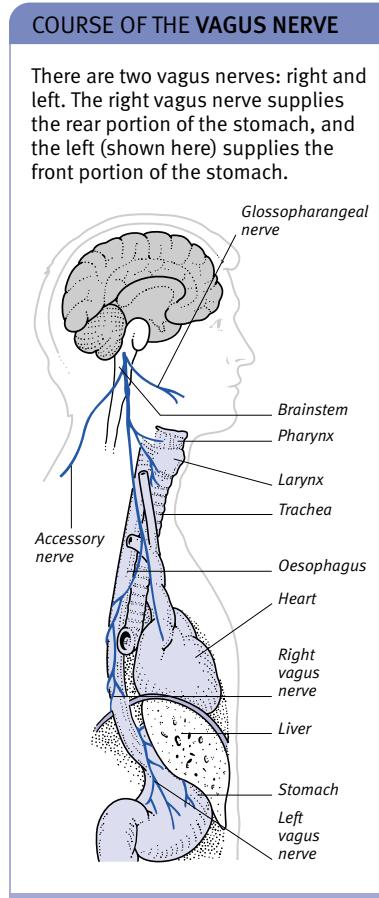

See *sodium valproate*.

Valsalva's manoeuvre

A forcible attempt to breathe out when the airway is closed. The manoeuvre occurs naturally when an attempt is made to breathe out while holding the *vocal cords* tightly together. This happens, for example, at the beginning of a sneeze. When performed deliberately by pinching the nose and holding the mouth closed, the manoeuvre can prevent pressure damage to the eardrums (see *barotrauma*).

valve

A structure that allows fluid or semi-fluid material to flow through a tube or passageway in one direction but which closes to prevent reflux (backflow) in the opposite direction. The valves at the exits from the *heart* chambers and in the *veins* are essential components of the *circulatory system*. There are also small valves in the vessels that make up the *lymphatic system*.

Valves in the circulatory system

The valves are flaps that open to allow blood to flow in one direction but close to prevent blood flow in the opposite direction.

valve replacement

A surgical operation to replace a defective or diseased heart valve. (See also *heart-valve surgery*.)

valvotomy

An operation that is performed to correct a narrowed *heart valve*. Cuts are made, or pressure is applied, to separate the flaps of the valve where they have joined, reducing the degree of narrowing. Valvotomy is performed either by opening the heart up (see *heart-valve surgery*) or by balloon *valvuloplasty*.

valvular heart disease

A defect that occurs in one or more of the *heart valves*.

valvuloplasty

Reconstructive or repair surgery on a defective heart valve (see *heart-valve surgery*). Valvuloplasty may be performed as *open heart surgery*. However, the technique of balloon valvuloplasty makes it possible to treat a narrowed valve without opening the chest. A *balloon catheter* is passed through the skin into a blood vessel and from there to the heart. Inflation of the balloon via the catheter then separates the flaps of a narrowed valve.

vaporizer

A device for converting a drug or water into a fine spray so that medication can be taken by inhalation or so that inhaled air can be moistened.

variant angina

A form of *angina pectoris* (chest pain as a result of insufficient blood supply to the heart muscle), also known as Prinzmetal's angina, in which chest pain occurs when at rest, often during sleep. The pain may be accompanied by breathlessness and *palpitations*. Variant angina is thought to be due to narrowing of the *coronary arteries* by muscular spasm in their walls. Treatment with *calcium channel blockers* or *nitrate drugs* is usually effective.

variant CJD

One form of *Creutzfeldt-Jakob disease*.

varicella

Another name for *chickenpox*.

varicella-zoster

The virus that is responsible for *chickenpox* and *shingles*.

varices

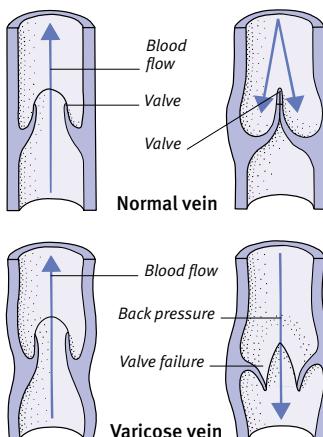

Enlarged, tortuous, or twisted sections of vessels, usually veins. Varices is the plural of varix. A vein affected by varices is called a *varicose vein*.

varicocele

Varicose veins surrounding a *testis*. Varicocele is a common condition. It almost exclusively affects the left testis and is usually harmless, although there may be aching in the *scrotum* or an abnormally low sperm count (see *infertility*). Aching

VARICOSE VEINS

When a vein's valves work correctly, the weight of the blood column is well distributed. When they fail, the back pressure is from a much larger column of blood; some veins become engorged with blood and swell.

**How varicosities are caused**

In a normal vein, valves stop blood from draining down due to gravity. If valves fail, blood is able to pool downwards.

**Appearance of varicose veins**

This varicosity of the saphenous vein on the front of the lower legs shows the typical tortuous, swollen appearance.

may be relieved by supportive underwear. Surgery to divide and tie off the swollen veins may be performed if the sperm count is low.

varicose veins

Enlarged, tortuous veins just beneath the surface of the skin. Varicose veins most commonly occur in the legs but can also occur in the anus (see *haemorrhoids*), oesophagus (see *oesophageal varices*), and scrotum (see *varicocele*).

CAUSES

A defect of the *valves* in the leg's perforating veins (which lie between the superficial veins (those near the skin's surface) and the deep-lying veins) causes blood to pool in the superficial veins. The buildup of pressure in these veins causes them to become varicose. Factors that contribute to varicose veins include *obesity*, hormonal changes and pressure on the pelvic veins during *pregnancy*, hormonal changes occurring at the *menopause*, and standing for long periods of time. Varicose veins are common, tend to run in families, and affect more women than men.

SYMPOTMS

Varicose veins may not cause any problems, but they may ache severely and the feet and ankles may be swollen; persistent itching can also occur. These symptoms may worsen during the day and may be relieved by sitting with the legs raised. In women, symptoms are often worse just before menstruation. In severe cases, *leg ulcers* may develop. *Thrombophlebitis* (inflammation and clotting of blood in the veins) may be associated with varicose veins.

TREATMENT

Usually, support stockings, regular walking, and sitting with the feet up as much as possible are the only measures required. In more severe cases, *sclerotherapy* may be carried out. Varicose veins may require surgical removal (by an operation known as stripping) if they become painful or ulcerated, however, they may later develop elsewhere.

variola

Another name for *smallpox*.

varus

The medical term for an inward displacement of part of the body.

vascular

Relating to the blood vessels (see *circulatory system*).

vasculitis

Inflammation of blood vessels. Vasculitis usually leads to damage to the lining of vessels, with narrowing or blockage, that restricts or stops blood flow. As a result, the body tissues supplied by the affected vessels are damaged, or they are destroyed by *ischaemia*.

Vasculitis is thought to be caused in most cases by the presence of minute bodies, called immune complexes, in the circulating blood. Immune complexes (consisting of *antigens* bound to *antibodies*) are normally destroyed by white blood cells, but sometimes adhere to the walls of blood vessels, where they cause inflammation. In some cases, the antigens are *viruses*.

Vasculitis is the basic disease process that occurs in a number of disorders. These include *polyarteritis nodosa*, *erythema nodosum*, *Henoch-Schönlein purpura*, *serum sickness*, *temporal arteritis*, and *Buerger's disease*.

vas deferens

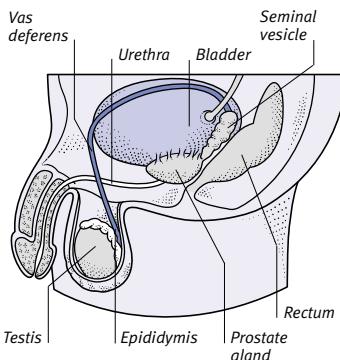

Either of a pair of tubes that convey *sperm* from each *testis* to the *urethra* (the tube that carries sperm and urine through the penis to be expelled). The plural form is *vasa deferentia*.

vasectomy

The operation of male sterilization. Vasectomy is a minor surgical procedure, performed under a local anaesthetic (see *anaesthesia, local*), that consists of

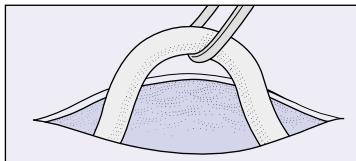

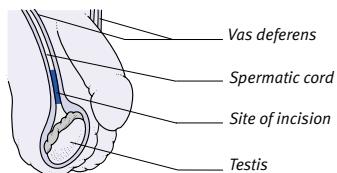

LOCATION OF THE VAS DEFERENS

The vas deferens passes from the epididymis, up and around the bladder, before entering the prostate, where it connects to a tube from the seminal vesicle to form the ejaculatory duct.

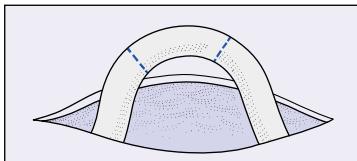

HOW VASECTOMY IS PERFORMED

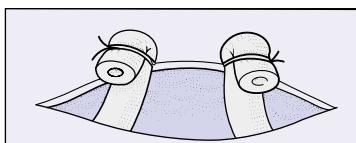

This operation blocks the passage of sperm from the testes but does not prevent the prostate and other glands from secreting the fluids that form most of the semen. Hence it has little effect on the volume of the ejaculate and no effect on orgasm.

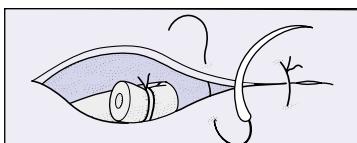

1 Under a local anaesthetic, incisions are made on both sides of the scrotum; the vas deferens is then cut free from the spermatic cord.

2 A loop of the vas deferens is freed and brought out through the incision. There are now several possibilities; usually, a length of the vas deferens is cut out.

3 In order to prevent the cut ends from rejoining, they are often bent back and tightly closed with ligatures. They are then pushed back into the spermatic cord.

4 The skin incision is now closed with three or four dissolvable or tape sutures. When the local anaesthetic wears off, there is usually a mild, dull, aching pain for a few days.

cutting out a short length of each *vas deferens* (a duct that carries sperm from a testis to the urethra). For more detail on how the procedure is performed, see *How vasectomy is performed* box, above. After vasectomy, the man continues to achieve orgasm and ejaculate as normal, but the *semen* no longer contains *sperm*, which are reabsorbed in the testes.

Male sterilization is a safe and effective method of *contraception*. Rarely, the severed ends of a vas deferens reunite, and sperm appear in the ejaculate. If this occurs, the man can safely undergo another vasectomy. Some operations to restore fertility after vasectomy are successful, but the process should be regarded as irreversible.

vasoconstriction

Narrowing of blood vessels, causing reduced blood flow to a part of the body. Vasoconstriction under the skin occurs in response to the cold and reduces heat loss from the body.

vasodilation

Widening of blood vessels that causes increased blood flow to a part of the

body. Vasodilation under the skin occurs as a response to hot weather, resulting in increased heat loss from the body.

vasodilator drugs

A group of drugs that widen the blood vessels. Vasodilator drugs include *ACE inhibitor drugs*, *alpha-blocker drugs*, *calcium channel blockers*, and *nitrate drugs*. Some vasodilators are used to treat disorders in which abnormal narrowing of blood vessels reduces blood flow through the tissues, thereby impairing the supply of oxygen. Such disorders include *angina pectoris* and *peripheral vascular disease*. Vasodilators are also used to treat *hypertension* (high blood pressure) and *heart failure* (reduced pumping efficiency). Vasodilator drugs may cause flushing, headaches, dizziness, fainting, and swollen ankles.

vasopressin

Another name for *ADH*.

vasovagal attack

Temporary loss of consciousness as a result of sudden slowing of the heartbeat, usually brought on by severe

pain, stress, shock, or fear. A vasovagal attack, a common cause of *fainting* in healthy people, results from overstimulation of the *vagus nerve*.

VD

The abbreviation for venereal disease, an outdated term for *sexually transmitted infections*.

VDRL test

A blood test that is used to screen for *syphilis*. The initials "VDRL" stand for Venereal Disease Research Laboratory. Occasionally, the VDRL test may give a positive result in other conditions, such as glandular fever (see *mononucleosis, infectious*); the test is therefore often carried out alongside a test for specific *antibodies* to syphilis to enable doctors to confirm the diagnosis.

vector

An animal that transmits a particular *infectious disease*. A vector picks up disease-causing organisms from a source of infection (such as the blood or faeces of an infected person or animal), carries them in or on its body, and then deposits them, where they go on to infect a new host. Part of the disease-causing organism's lifecycle must usually take place in the body of a vector.

Mosquitoes, fleas, lice, ticks, and flies are the most important vectors of disease to humans. Many organisms have developed a close relationship with a specific vector, as *TRYpanosoma* parasites have with *tsetse flies*.

veganism

The adoption of a diet that excludes all meat and fish and all animal products, including milk and eggs. A vegan diet is likely to result in the deficiency of *vitamin B₁₂*. Supplements of this vitamin are essential during pregnancy.

vegetarianism

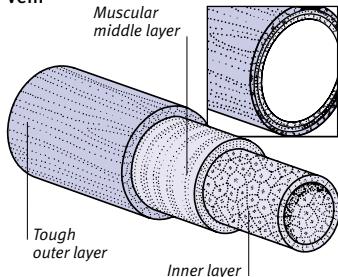

Eating a diet that excludes meat and fish, and sometimes all other animal products. Humans do not need to eat meat or animal products to maintain health as long as the nutrients supplied by plant foods provide a balanced diet (see *nutrition*). However, those people who exclude all animal products (vegans) need to plan their diet carefully or take supplements to avoid being deficient in *vitamin B₁₂* or *calcium*.

Vegetarian diets are relatively rich in *fibre*, which may help to protect against

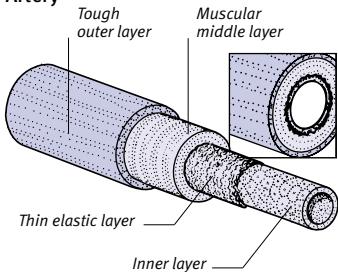

STRUCTURE OF VEIN AND ARTERY

Like arteries, the walls of veins have a smooth inner layer, a muscular middle layer, and a fibrous outer layer. However, the walls are thinner and less muscular than those of arteries.

Vein

Artery

diverticular disease and cancer of the intestine (see *colon, cancer of, rectum, cancer of*). Vegetarian diets are lower in *fats*, especially saturated fats (which may contribute to *coronary artery disease* and possibly some forms of cancer). These diets are also likely to contain much less *sodium* and more *potassium*, and vegetarians tend to have lower blood pressure than people who eat meat.

vegetative state, persistent

See *persistent vegetative state*.

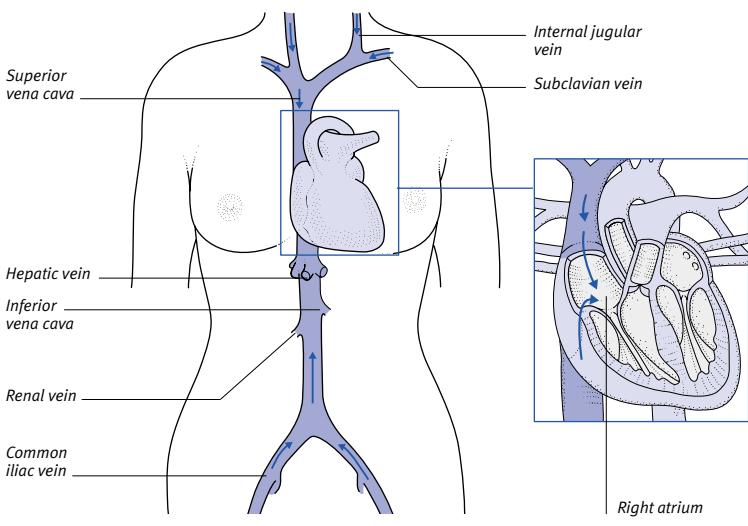

vein

A blood vessel that returns blood towards the *heart* from the various organs and tissues of the body. The walls of veins, like those of arteries, consist of a smooth inner lining, a muscular middle layer, and a fibrous outer covering. However, blood pressure in the veins is lower than that in the arteries. In addition, the walls of veins are thinner, less elastic, less muscular, and weaker than those of arteries.

The linings of many veins contain folds, which act as valves, ensuring that the blood flows only towards the heart. Blood is helped on its way through the veins by pressure on the vessel walls from the contraction of surrounding muscles. (See also *circulatory system*.)

LOCATION OF THE VENAE CAVAE

All the circulating blood, after being pumped to the body, returns to the heart via the *venae cavae*. The *superior vena cava* collects blood from the whole of the upper trunk, head, neck, and arms. The *inferior vena cava* drains blood from all parts of the body below the chest.

veins, disorders of

Common disorders that affect the veins include *varicose veins*, in which the affected vein becomes enlarged, tortuous, or twisted; deep vein thrombosis (see *thrombosis, deep vein*), in which a blood clot forms in a deep-lying vein of the leg; and *thrombophlebitis*, which involves inflammation of and blood clotting in a vein.

vena cava

Either of two large veins into which all circulating deoxygenated blood drains. The venae cavae (superior and inferior) deliver blood to the right atrium (the upper chamber) of the heart for pumping to the lungs.

SUPERIOR VENA CAVA

The superior vena cava starts at the top of the chest, near the sternum (breastbone), and passes down through the pericardium (outer lining of the heart) before connecting to the right atrium. It collects blood from the upper trunk, head, neck, and arms.

INFERIOR VENA CAVA

The inferior vena cava starts in the lower abdomen and travels upwards in front of the spine, behind the liver, and through the diaphragm before joining the right atrium. It collects blood from the legs, pelvic organs, liver, and kidneys.

venepuncture

A common procedure in which a vein, usually in the forearm, is pierced with a needle to inject fluid or withdraw blood. A *tourniquet* is used to swell the veins, and a sterile needle is inserted. A syringe is attached to the needle if blood is to be taken or medication injected. For *intravenous infusion*, a cannula (tube) is inserted via the needle. After fluid has been injected or withdrawn, the needle or cannula is removed. The area is then covered and pressure applied to stop any bleeding. The procedure is not usually painful but may cause discomfort.

venereal diseases

See *sexually transmitted infections*.

venereology

The former name for the medical discipline concerned with the study and treatment of *sexually transmitted infections*. It is now called *genito-urinary medicine*.

venesection

The process of withdrawing blood from a vein for *blood donation* or therapeutic bloodletting. Regular bloodletting is per-

formed in the treatment of *polycythaemia* (a disorder in which the blood is too thick) and *haemochromatosis* (a disorder of body iron chemistry).

venlafaxine

A serotonin and noradrenaline reuptake inhibitor (SNRI) drug that is used in the treatment of *depression*. Venlafaxine combines the effects of *selective serotonin reuptake inhibitors* and *tricyclic antidepressants*. The drug produces fewer side effects than other tricyclic antidepressants. Side effects may include nausea, dry mouth, and constipation.

venography

A diagnostic procedure that enables veins to be seen on an X-ray film after they have been injected with a substance opaque to X-rays. It is used to detect abnormalities or diseases of the veins, such as narrowing or blockage from *thrombosis* (formation of blood clots).

venomous bites and stings

The injection of venom by certain animals via their mouthparts (bites) or other injecting apparatus (stings). Venoms are often carried to discourage predators, and are sometimes used to kill or immobilize prey. It is rare for a venomous animal to attack a person unless it has been provoked or disturbed. Specific *antivenoms* are available to treat many, though not all, types of

animal venom. (See also *insect stings; jellyfish stings; scorpion stings; snake bites; spider bites*.)

ventilation

The use of a machine called a *ventilator* to take over or assist *breathing*. Arrested or severely impaired breathing may be due to *head injury*, brain disease, an overdose of *opioid drugs*, chest injury, respiratory disease, a nerve or muscle disorder, or major chest or abdominal surgery.

Ventilation may be needed if a muscle relaxant has been given, as part of general *anaesthesia*, during an operation. Premature babies with *respiratory distress syndrome* may also need ventilation for a period until their lungs develop sufficiently. Positive pressure ventilation (continuous pumping of air under high pressure) may be used in the home in the treatment of *sleep apnoea* (temporary cessation of breathing during sleep).

ventilator

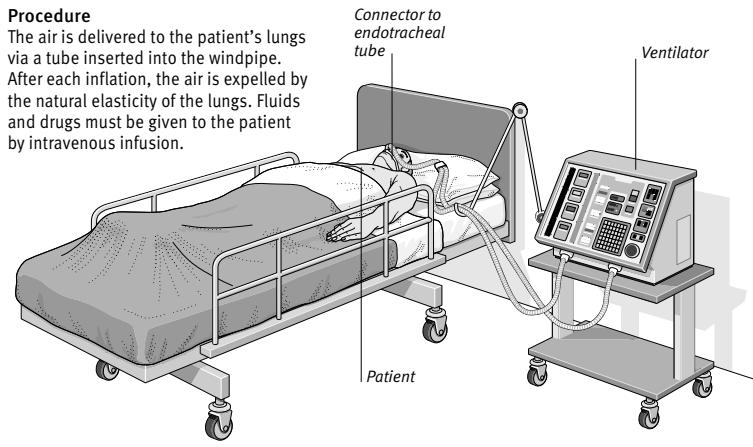

A device used for the artificial *ventilation* of a person who is unable to breathe naturally. A ventilator is an electrical pump connected to an air supply that works like bellows. Air is directed through a tube passed down the windpipe to inflate the lungs. The air is then expelled by the natural elasticity of the lungs and ribcage. A valve on the ventilator prevents the expelled air from re-entering the lungs.

TECHNIQUE OF ARTIFICIAL VENTILATION

Machine-assisted breathing may be needed when a person has lost the ability to breathe naturally (often following a severe head injury, narcotic drug overdose, or in various other medical emergencies). It may also be needed when a muscle relaxant has been given during an operation as part of a general anaesthetic.

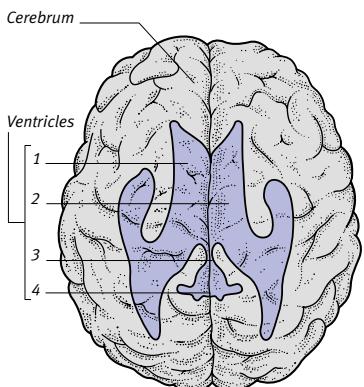

Procedure

The air is delivered to the patient's lungs via a tube inserted into the windpipe. After each inflation, the air is expelled by the natural elasticity of the lungs. Fluids and drugs must be given to the patient by intravenous infusion.

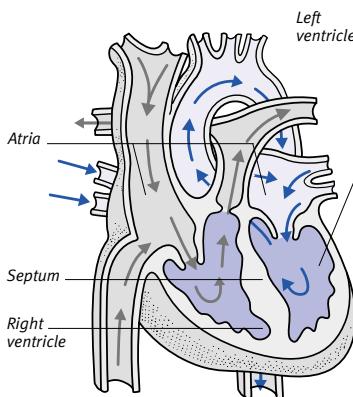

LOCATION OF THE VENTRICLES

The location of the ventricles in the brain (seen from above) and in the heart are shown below. Of the heart ventricles, the right ventricle pumps blood to the lungs, the left pumps blood to the rest of the body.

**Ventricles in the brain**

Together, these four irregularly shaped cavities contain approximately 25 ml of cerebrospinal fluid.

**Ventricles in the heart**

The ventricles of the heart are the large lower chambers that are separated by a muscular wall, the septum.

ventilatory failure

See [respiratory failure](#).

ventouse

See [vacuum extraction](#).

ventral

Relating to the front of the body, or describing the lowermost part of a body structure when a person is lying face-down. The opposite is *dorsal*.

ventricle

A cavity or chamber. Both the *heart* and *brain* have anatomical parts that are known as ventricles.

The brain has four ventricles: one in each of the two cerebral hemispheres; a third at the centre of the brain, above the brainstem; and a fourth between the brainstem and cerebellum. These cavities are filled with *cerebrospinal fluid*.

The ventricles of the heart are its two lower chambers. The ventricles receive blood from each *atrium* (upper chamber) and pump it to the lungs and to the rest of the body.

ventricular aneurysm

A balloonlike bulge in the wall of the left ventricle of the *heart* (the chamber that pumps oxygen-rich blood around the body). Commonly developing as a result of a *myocardial infarction* (heart attack), ventricular aneurysm may, in

It is a common complication of *myocardial infarction* (heart attack) and may also be caused by electrocution or drowning.

The diagnosis is confirmed by *ECG*. Emergency treatment is with *defibrillation* (administration of an electric shock to the heart) and *antiarrhythmic drugs*.

ventricular septal defect

The medical term meaning a hole between the lower two chambers of the heart. The abnormality is present from birth and in many cases is small and closes without treatment. Surgery may be performed for larger defects, usually with good results.

ventricular tachycardia

A serious cardiac *arrhythmia* in which each heartbeat is initiated from electrical activity in the *ventricles* (lower heart chambers) rather than from the *sinoatrial node* in the right atrium (upper heart chamber).

It is an abnormally fast heart rate due to serious heart disease, such as *myocardial infarction* (heart attack) or *cardiomyopathy* (disease of the heart muscle). It may last for a few seconds or for several days.

Diagnosis is confirmed by *ECG*. Emergency treatment is with *defibrillation* (administration of an electric shock to the heart) and an *antiarrhythmic drug*.

verapamil

A drug that acts as a *calcium channel blocker* to treat *hypertension* (high blood pressure), *angina pectoris* (chest pain due to inadequate blood supply to the heart), and certain *arrhythmias* (abnormalities of the heartbeat). Possible side effects include headache, flushing, dizziness, and ankle swelling.

vernix

The white, cheeselike substance covering a newborn baby. Vernix comprises fatty secretions and dead cells. It protects the skin, insulates against heat loss before birth, and lubricates the baby's passage down the birth canal.

verruca

The Latin name for a *wart*, commonly applied to warts on the soles.

version

A change in the direction in which a *fetus* lies so that a *malpresentation*, most commonly a *breech* (bottom-down) presentation, replaces the normal head-down presentation.

vertebra

Any of the 33 roughly cylindrical bones that form the *spine*. There are seven vertebrae in the cervical spine; 12 in the thoracic; five in the lumbar; five (fused) in the *sacrum*; and four (fused) in the *coccyx*. The top 24 vertebrae are separated by discs of cartilage (see *disc, intervertebral*). Each vertebra has a hole in the centre through which the *spinal cord* runs, and processes to which muscles are attached. (See also *Location and structure of the vertebrae* box, overleaf.)

vertebrobasilar insufficiency

Intermittent episodes of dizziness, weakness, double vision, and difficulty in speaking caused by reduced blood flow to parts of the *brain*. The condition is usually a result of *atherosclerosis* (narrowing due to accumulation of fatty deposits) of the basilar and vertebral arteries and other arteries in the base of the brain. Vertebralbasilar insufficiency sometimes precedes a *stroke*.

vertigo

An illusion that an individual or his or her surroundings are spinning. Vertigo is usually the result of a disturbance of

the *semicircular canals* in the inner ear or the nerve tracts leading from them. The condition may also be caused by certain *brain* disorders affecting the brainstem, the cerebellum, or the cerebral cortex. Sudden-onset vertigo is treated with rest and *antihistamine drugs*, which, in some cases, are also given to prevent recurrent attacks.

vesicle

A small *blister*, usually filled with clear fluid, that forms at a site of skin damage. The term is also used to refer to any small saclike structure in the body.

vesicoureteric reflux

Backflow of urine from the bladder into the ureters (the tubes that carry urine from the kidneys to the bladder). Vesicoureteric reflux causes recurrent urinary infection in children that often results in acute *pyelonephritis* and scarring of the kidneys. The condition, which is caused by a faulty valve mechanism, is diagnosed using micturating cystourethrography (see *cystourethrography, micturating*). *Antibiotic drugs* are given to prevent infection, but corrective surgery may also be needed.

vestibule

A chamber. The vestibule in the inner ear is a hollow chamber that connects the three *semicircular canals*.

vestibulitis

Inflammation of the nasal vestibule (the part of the nasal cavity just inside the nostril) or of the area between the labia minora in the vulva, usually as a result of bacterial infection.

vestibulocochlear nerve

The eighth *cranial nerve*. The vestibulocochlear nerve consists of two branches: the vestibular nerve (which is concerned with balance) and the cochlear nerve (which is concerned with hearing). Each vestibulocochlear nerve (one on each side) carries sensory impulses from the inner *ear* to the *brain*, which it enters between the pons and medulla oblongata (in the *brainstem*).

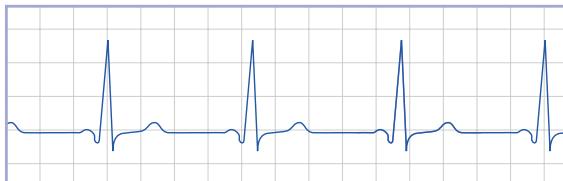

DISORDERS

A tumour of the cells that surround the vestibulocochlear nerve (see *acoustic neuroma*) may result in loss of balance, *tinnitus* (ringing in the ear), and *deafness*. Deafness may also be the result of damage to the nerve, which may be

TYPES OF VENTRICULAR ARRHYTHMIA

The ventricles (lower chambers) of the heart usually beat regularly in response to excitatory waves that spread from the upper chambers. Any disturbances to that rhythm

(arrhythmia) may be associated with heart disease. The different types of ventricular arrhythmia can be seen on these electrocardiograph (ECG) recordings.

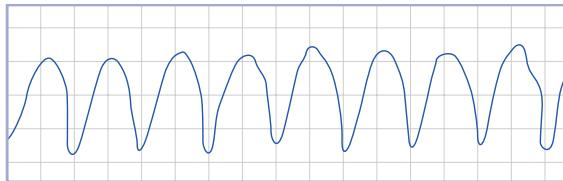

Normal heartbeat

This is the normal ECG appearance of the heartbeat. The regular spikes coincide with beats of the ventricles (lower heart chambers). The small rises before each spike coincide with contractions of the atria (upper chambers).

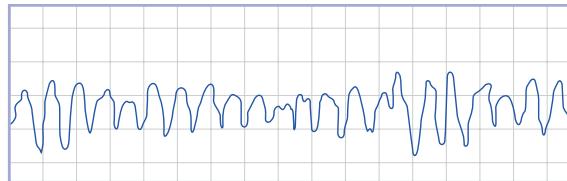

Ventricular ectopic beat

Here there is an abnormal beat, which has a broad, bizarre-looking waveform on the ECG; it occurs just before the expected normal beat. To the patient, the heart may seem to stop at time A and restart with a thump at time B.

Ventricular tachycardia

Here, there is a rapid succession of abnormal beats, caused by an abnormal focus of electrical activity in a ventricle. It usually indicates serious underlying heart disease. The rate of beating may be very high – up to 220 beats per minute.

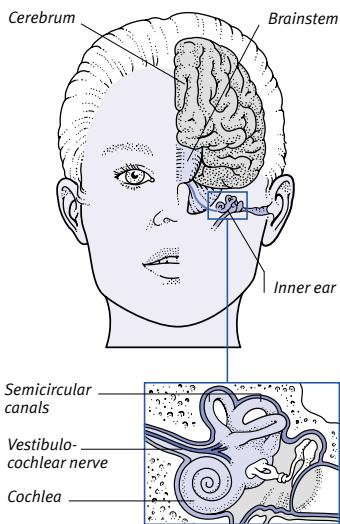

Ventricular fibrillation

This pattern is seen only when the heart is in a state of virtual arrest, usually after a heart attack, with the ventricles twitching in a rapid and totally irregular manner. Unless a normal rhythm can be restored, the condition is rapidly fatal.

LOCATION OF THE VESTIBULOCOCHLEAR NERVE

This nerve originates in the brainstem. It conducts sensory impulses concerned with hearing and balance from different parts of the inner ear to the brain.

caused by an infection, such as *meningitis* or *encephalitis*, or to a reaction to a drug such as *streptomycin*.

viability

The capability of independent survival and development.

Viagra

The brand name for *sildenafil*, a drug used in the treatment of *impotence*.

villus

A minute fingerlike projection from a membranous surface. Millions of villi are present on the mucous lining of

Microvilli in the intestine

This scanning electron micrograph shows numerous microvilli projecting from a single cell in the lining of the small intestine.

the small *intestine*. Each intestinal villus contains a small *lymph* vessel and a network of *capillaries* (tiny blood vessels). Its surface is covered with hundreds of hairlike structures (microvilli). The villi and microvilli provide a large surface area for the absorption of food molecules from the intestine into the blood and the lymphatic system.

vinca alkaloids

A group of substances derived from the periwinkle plant (*VINCA ROSEA*) that are used to treat *leukaemias* (cancers of the blood), *lymphomas* (cancers of lymphoid tissue), and some solid tumours, such as *breast cancer* and *lung cancer*.

All vinca alkaloids can cause neurological toxicity, which appears as *neuropathy* (nerve damage). Other side effects may include abdominal pain, constipation, and reversible *alopecia* (hair loss). Common vinca alkaloids include *vinblastine*, *vindesine*, and *vincristine*.

Vincent's disease

A severe form of *gingivitis* (gum disease) in which bacterial infection causes painful ulceration of the gums. (See also *gingivitis*, *acute ulcerative*.)

vincristine

A *vinca alkaloid* used to treat certain cancers. One particular side effect of vincristine is peripheral or autonomic *neuropathy* (nerve damage); but, unlike the other vinca alkaloids, it causes very little reduction in blood-cell production by the bone marrow. Other side effects may include abdominal pain, constipation, and reversible *alopecia* (hair loss).

viraemia

The presence of *virus* particles in the blood. Viraemia can occur at certain stages in various viral infections. Some viruses, such as those responsible for *viral hepatitis*, *yellow fever*, and *poliomyelitis*, are transported in the bloodstream to their target tissue or organ, for example the liver, where they multiply. Others, such as the *rubella* virus and *HIV*, multiply in, and spread via, certain white blood cells. If viraemia is a feature of a viral infection, there may be a risk that the infection will be transmitted to other people in blood or blood products, or by insects that feed on blood.

viral haemorrhagic fever

Diseases that are prevalent in Africa and cause severe bleeding. There are several

types, including Ebola fever, Lassa fever, Hantavirus, and Marburg fever. The diseases are fatal in a large percentage of cases, but Lassa fever may respond to *antiviral drugs* if given in the first week.

virginity

The physical state of not having experienced sexual intercourse.

virilism

The presence in a woman of masculine characteristics, caused by excessive levels of *androgen hormones*. Androgens are male sex hormones which, in women, are normally secreted in small amounts by the adrenal glands and ovaries.

Raised levels induce various changes in women, including *hirsutism* (excessive hairiness); male-pattern baldness (see *alopecia*); disruption or cessation of *menstruation*; enlargement of the *clitoris*; loss of normal fat deposits around the hips; development of the arm and shoulder muscles; and deepening of the voice (see *virilization*).

virility

A term used to describe the quality of maleness, especially in sexual characteristics and performance.

virilization

The development in a woman of male characteristics as a result of overproduction of *androgen hormones* by the adrenal glands and/or ovaries. This may be due to various conditions such as certain *adrenal tumours*, *polycystic ovary* (see *ovary, polycystic*) and some other *ovarian cysts*, or congenital *adrenal hyperplasia* (a rare genetic disorder).

virion

A single, complete, *virus* particle.

virology

The study of *viruses* and the *epidemiology* and treatment of diseases caused by viruses. In a more restricted sense, virology also refers to the isolation and identification of viruses to diagnose specific viral infections. Depending on the type of virus, this may involve growing viruses in cultures of human or animal cells, *staining* or microscopic examination of specimens containing viruses, or *immunoassay* techniques.

virulence

The ability of a microorganism to cause disease. This can be assessed by measur-

ing what proportion of the population exposed to the microorganism develops symptoms of disease, how rapidly the infection spreads through the body, or the mortality from the infection.

viruses

One of the smallest known types of infectious agent. It is debatable whether viruses are truly living organisms or

just collections of molecules capable of self-replication under specific conditions. Their sole activity is to invade the cells of other organisms, which they then take over to make copies of themselves. Outside living cells, viruses are inert.

STRUCTURE

A single virus particle (virion) consists of an inner core of *nucleic acid*, which may be either *DNA* or *RNA*, surrounded

by one or two protective protein shells (capsids). Surrounding the outer capsid may be another layer, the viral envelope, which consists mainly of protein. The nucleic acid consists of a string of *genes* that contain coded instructions for making copies of the virus (see *Viruses and disease* box, overleaf).

VIRAL DISEASES

Common viral conditions include the common cold (see *cold, common*), *influenza*, *chickenpox*, *cold sores*, and *warts*. *AIDS* is caused by the human immunodeficiency virus (see *HIV*).

viscera

A collective term used to describe the internal organs.

viscosity

The resistance to flow of a fluid; its "stickiness". The viscosity of blood affects its ability to flow through small vessels. An increased blood viscosity increases the risk of *thrombosis* (abnormal blood clotting).

vision

The faculty of sight. When light-rays reach the *eye*, most of the focusing is done by the *cornea*, but the eye also has *accommodation*, an automatic fine-focusing facility that operates by altering the curvature of the *lens*. Together, these systems form an image on the *retina*. The light-sensitive rod and cone cells in the retina convert the elements of this image into nerve impulses that pass into the visual cortex of the *brain* via the *optic nerves*. The rods, which are more concentrated at the periphery of the retina, are highly sensitive to light but not to colour. The colour-sensitive cones are concentrated more at the centre of the retina (see *colour vision*).

The brain coordinates the motor nerve impulses to the six tiny muscles that move each eye to achieve alignment of the eyes. Accurate alignment allows the brain to fuse the images from each eye, but because each eye has a slightly different view of a given object, the brain obtains information that is interpreted as solidity or depth. This stereoscopic vision is important in judging distance. (See also *Types of vision test* box, overleaf; *The sense of vision* box, p.792.)

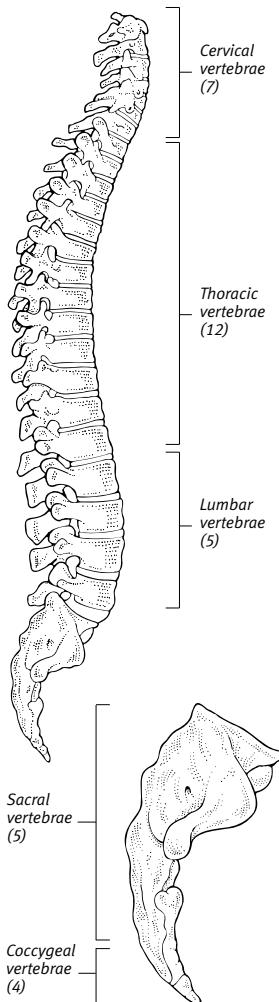

vision, disorders of

The most common visual disorders are refractive errors, such as *astigmatism* (the abnormal curvature of the front of

LOCATION AND STRUCTURE OF THE VERTEBRAE

The 33 vertebrae are arranged as shown. Apart from the top two, all have a similar structure. The top cervical vertebra (atlas) has no body. The second (the axis) forms a pivot on which the atlas can rotate, allowing the head to be turned in all directions.

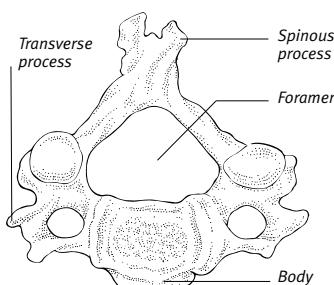

THE SPINE

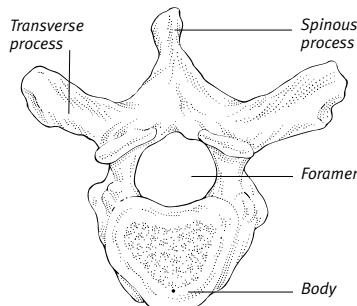

Arrangement

The vertebrae fall into five groups – cervical, thoracic, lumbar, sacral, and coccygeal. The top 24 are separated by discs of cartilage.

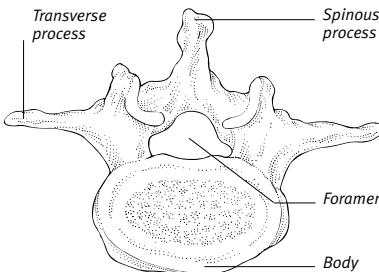

CERVICAL VERTEBRAE

THORACIC VERTEBRAE

LUMBAR VERTEBRAE

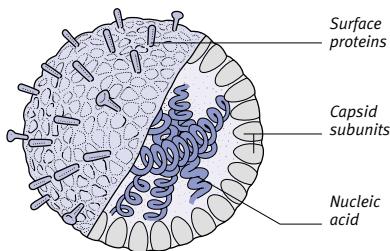

Structure

Three typical vertebrae are shown above. The foramen in each is the channel through which the spinal cord runs. The processes serve as muscle attachments.

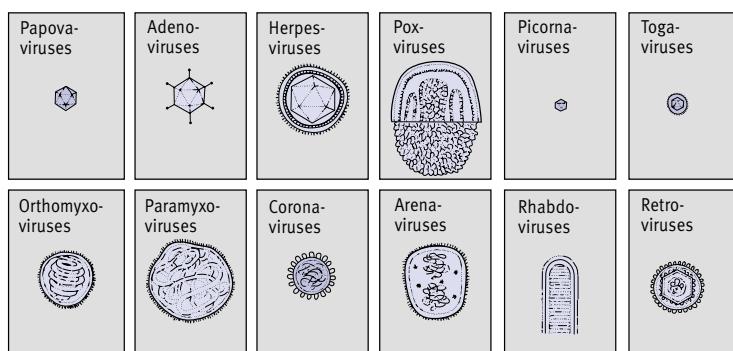

VIRUSES AND DISEASE

All viruses have the same basic structure (right), but they come in various shapes and sizes. Examples from the main families are shown below (some in cross-section). All are tiny – from about 15 to 300 nanometres in diameter (one nanometre equals one thousand-millionth of a metre); most are so small that they can be seen only with an electron microscope. All types of viruses can multiply only within cells of their host (far right).

Structure of a typical virus particle
Nucleic acid in the centre is surrounded by one or more capsids made of protein subunits.

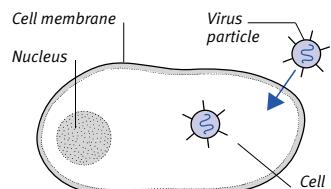

TYPES OF VIRUS

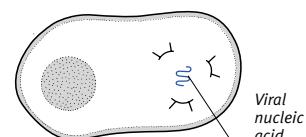

Family	Examples of conditions or diseases
Papovaviruses	Warts, cervical cancers, anal cancers
Adenoviruses	Respiratory and eye infections
Herpesviruses	Cold sores, genital herpes, chickenpox, herpes zoster (shingles), glandular fever, cytomegalovirus (CMV)
Poxviruses	Cowpox, smallpox (eradicated), molluscum contagiosum
Picornaviruses	Poliomyelitis, viral hepatitis type A, respiratory infections, myocarditis
Togaviruses	Rubella, yellow fever, dengue, encephalitis
Orthomyxoviruses	Influenza
Paramyxo-viruses	Mumps, measles, respiratory syncytial virus (RSV)
Coronaviruses	Common cold
Arenaviruses	Lassa fever
Rhabdoviruses	Rabies
Retroviruses	AIDS, some leukaemias

VIRAL REPLICATION

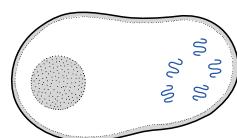

The sequence below shows how a virus multiplies. The signs and symptoms of viral infection are caused by the virus interfering with or destroying the host's cells.

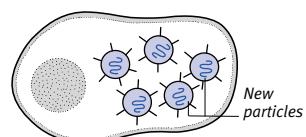

1 The virus particle first attaches itself to it and then injects itself into the host cell.

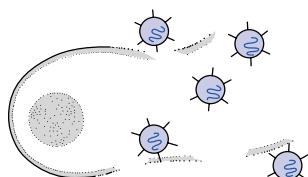

2 The viral capsid breaks down and the viral nucleic acid (DNA or RNA) contained inside is released.

3 The viral nucleic acid replicates itself; the new copies are made from raw materials in the host cell.

4 Each of the new copies of the viral nucleic acid now directs the manufacture of a capsid for itself.

5 The newly formed virus particles are released in large numbers, and the host cell may be destroyed.

the eye), *myopia* (shortsightedness), and *hypermetropia* (longsightedness), which can almost always be corrected by *glasses* or *contact lenses*. Other disorders of vision include *amblyopia* (lazy eye); *double vision*; and disorders of the *eye* or *optic nerve*, of the nerve pathways connecting the optic nerves to the *brain*, and of the brain itself.

CAUSES IN THE EYE

The eye may lose its transparency through corneal opacities, *cataract*, or *vitreous haemorrhage* (bleeding into the gel of the eye behind the lens). Defects near the centre of the retina cause loss of the corresponding parts of the *visual field* (see *macular degeneration*). *Floaters*, which are usually insignificant, may indicate a *retinal tear* or haemorrhage, or they may herald a *retinal detachment*. *Optic neuritis* (inflammation of the optic nerve) can cause a blind spot in the centre of the visual field.

CAUSES IN THE BRAIN

Damage to the brain (for example, from a *stroke*) may cause visual impairment such as *hemianopia* (loss of half the visual field), *agnosia* (failure to recognize objects), visual perseveration (in which a scene continues to be perceived after the direction of gaze has shifted), and visual hallucinations.

vision, loss of

The inability to see. Loss of vision may develop slowly or suddenly, and it may be temporary or permanent, depending on the cause. Loss of vision may affect one eye or both of the eyes. It can cause complete *blindness* or may affect only peripheral or central vision.

SLOW VISION LOSS

Progressive loss of visual clarity is common with age and may be due to a number of disorders (see *vision, disorders of*).

SUDDEN VISION LOSS

Sudden loss of vision may be caused by disorders such as *hyphaema* (bleeding into the aqueous humour), severe *uveitis* (inflammation of the iris or the choroid), *vitreous haemorrhage* (bleeding into the gel within the eye), or *retinal haemorrhage*. *Optic neuritis* (inflammation of the optic nerve) can reduce vision in one eye.

Damage to the nerve connections between the eyes and brain, or to the visual area of the brain, can cause loss of peripheral vision. This nerve damage may be caused by a number of disorders such as an *embolism*, *ischaemia*, tumour, inflammation, or injury.

vision tests

The part of an *eye examination* that determines reduction in the ability to see.

VISUAL ACUITY TESTS

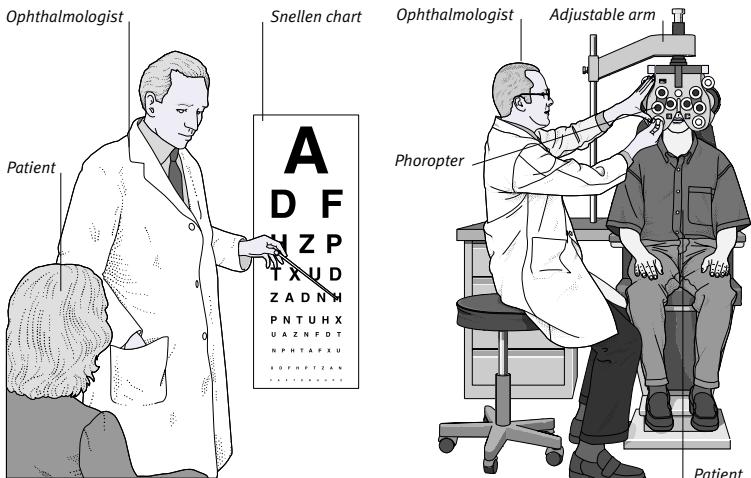

Tests of *visual acuity* (sharpness of central vision) include a *Snellen chart*, which is used to test a patient's distance vision, and close-reading test cards, which may be used to assess his or her near vision.

REFRACTION TESTS

Refraction tests assess the ability of the eye to focus light clearly on the retina via the cornea and lens. They can be used to detect *hypermetropia* (longsightedness), *myopia* (shortsightedness), and *astigmatism* (abnormal curvature of the front of the eye). By observing the effect of different lenses on movement

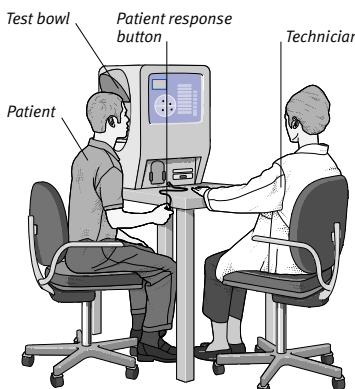

TYPES OF VISION TESTS

These tests are performed to measure a number of variables: the acuity of a patient's distance vision and the power of the lenses he or she may need (visual acuity and refraction test), the extent of peripheral vision (visual field test), and the ability to focus on near objects (accommodation tests).

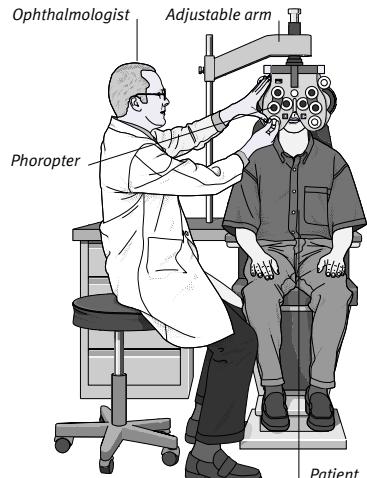

Visual acuity test

These tests use the familiar Snellen chart. Visual acuity is measured according to how far down the chart the patient can read accurately.

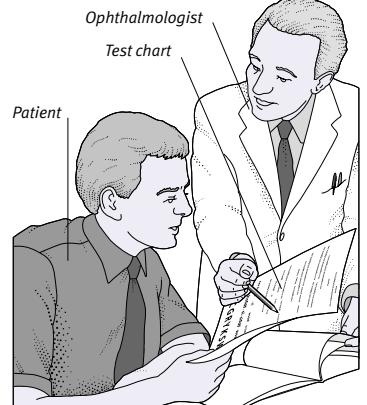

Visual field test

One eye is covered and the other is fixed on a central target inside the test bowl. A response button is pressed when the patient sees lights flashing in different parts of the visual field.

Refraction test

Lenses in the phoropter are changed until the letters near the bottom of the Snellen chart can be read. This allows the optician to make a prescription for appropriate lenses.

Accommodation test

After any distance-focusing ability has been corrected with glasses, the ability to read small print close-up is measured to test accommodation.

THE SENSE OF VISION

Vision starts in the retina, the membrane at the back of the eye that contains the light-sensitive rod and cone cells. Much of the rest of the eye is concerned with focusing light, in the

right quantities, on to the retina. Huge amounts of data are sent from the retina, through the optic nerves, to the brain for analysis.

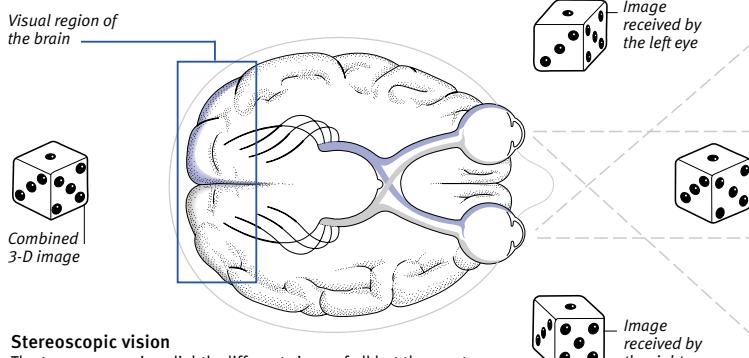

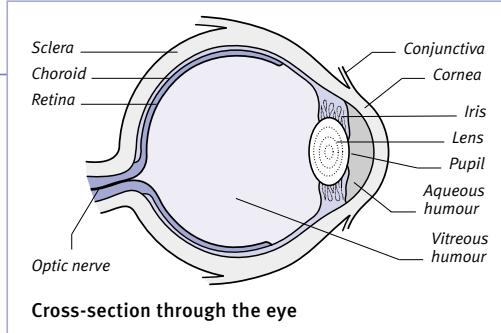

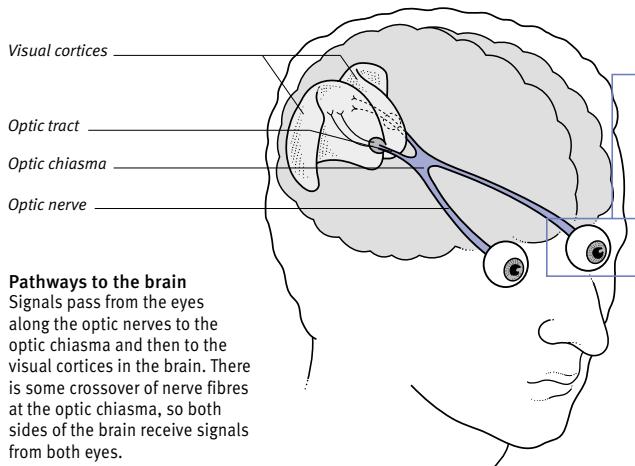

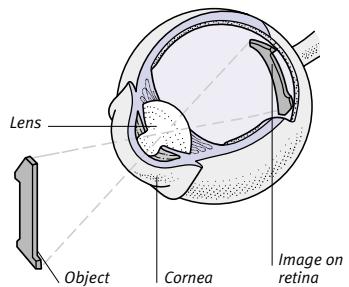

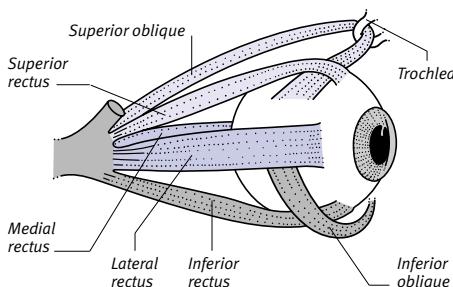

IMAGE RECEPTION

The light-rays from an object stimulate a group of receptors in the retina within an area that has the same shape as the object but is upside down. The brain automatically interprets the image the right way up.

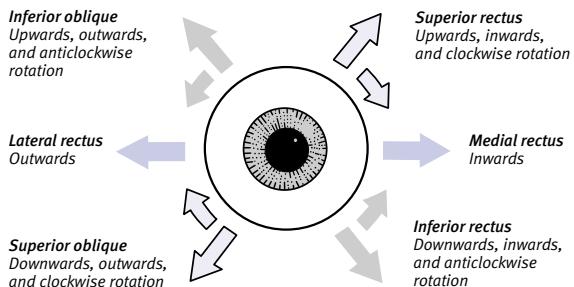

EYEBALL MOVEMENTS

In order to maintain the image of any moving object on the centre of the retina, precise eyeball movements, which are achieved by the six muscles shown below, are necessary.

The muscles act to swivel the eyeball (here, the right) in the directions indicated. The muscles always act in groups to achieve movement.

of light reflected from the eye, the strength and type of *glasses* or *contact lenses* needed to correct the visual defect can be assessed objectively. Visual acuity tests are then used to check that the patient can see clearly using the new lenses. Further minor adjustments to the lenses may be required.

VISUAL FIELD TESTS

Tests of the *visual field* may be performed to assess disorders of the eye, such as *glaucoma* (increased pressure of fluid within the eyeball), or disorders of the nervous system, such as a *stroke*.

visual acuity

Sharpness of central *vision*. Refractive errors, such as *myopia* (shortsightedness), *hypermetropia* (longsightedness), and *astigmatism* (abnormal curvature of the front of the eye), are the most common causes of poor visual acuity. Poor visual acuity for near objects occurs in the condition *presbyopia* (age-related deterioration in focusing power).

visual field

The total area in which visual perception is possible while a person is looking straight ahead. The visual fields normally extend outwards over an angle of about 90 degrees on either side of the midline of the face, but are more restricted above and below, especially if the eyes are deep-set or the eyebrows are prominent. The visual fields of the two eyes overlap to a large extent, giving binocular vision (see the illustrated box). Partial loss of the visual field may occur in *glaucoma* (raised pressure within the eyeball) or *stroke*.

vital sign

An indication that a person is still alive. Vital signs include chest movements that are caused by breathing, the presence of a pulse, and the constriction of the *pupil* of the eye when it is exposed to a bright light.

vitamin

Any of a group of complex organic substances essential, in small amounts, for the normal functioning of the body. There are 13 vitamins: A, C, D, E, K, B₁₂, and seven grouped under the *vitamin B complex*. Apart from vitamin D, which the body can synthesize itself, vitamins must be obtained from the diet. A varied diet is likely to contain adequate amounts of all the vitamins, but *vitamin supplements* may be helpful for: young chil-

dren, pregnant or breast-feeding women, or those taking drugs that interfere with vitamin function.

TYPES

Vitamins can be categorized as fat-soluble or water-soluble.

Fat-soluble vitamins (A, D, E, and K) are absorbed with fats from the intestine into the bloodstream and are then stored in fatty tissue (mainly in the liver). Because body reserves of some of these vitamins last for several years, a daily intake is not usually necessary. Deficiency of a fat-soluble vitamin is usually due to a disorder in which intestinal absorption of fats is impaired (see *malabsorption*) or to a prolonged poor diet.

Vitamins C, B₁₂, and those of the B complex are water-soluble. Vitamin C

and B complex vitamins can be stored in the body in only limited amounts and are excreted in the urine if taken in greater amounts than needed. A regular intake is therefore essential to prevent deficiency. However, vitamin B₁₂ is stored in the liver; these stores may last for years.

FUNCTION IN THE BODY

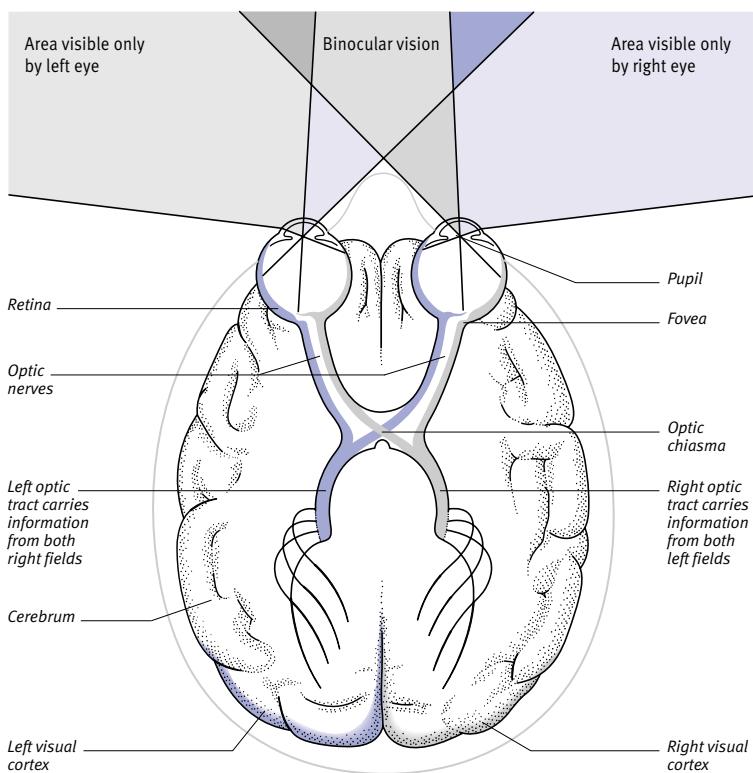

The role of all the vitamins in the body is not fully understood. Most have several important actions on one or more body systems, and many are involved in the activities of *enzymes*. (See also individual vitamin entries; *Reference Nutrient Intake* table, overleaf.)

vitamin A

A fat-soluble *vitamin* vital for growth, for bone and teeth formation, for cell struc-

THE VISUAL FIELDS

The field of vision of each eye (with the head and eyes immobile) extends through an angle of 130 degrees and is divided into an area that overlaps with the visual field of the other eye (binocular vision) and an area that can be seen only by one eye.

Route of visual signals

Note that all light from the fields left of the centre of both eyes (grey) falls on the right sides of the two retinas; and information about these fields goes to the right visual cortex. Information

about the right fields of vision (blue) goes to the left cortex. Data about the area of binocular vision (visible to both eyes) go to both left and right visual cortices.

VITAMIN B

ture, for night vision, and for protecting the linings of the respiratory, digestive, and urinary tracts against infection.

Vitamin A is absorbed by the body in the form of retinol. This is found in liver, fish-liver oils, egg yolk, dairy produce, and is added to margarines. *Carotene*, which the body converts into retinol, is found in various vegetables and fruits.

DEFICIENCY

Vitamin A deficiency is rare in developed countries. In most cases, it is due to *malabsorption*. Vitamin A deficiency may also result from long-term treatment with certain *lipid-lowering drugs*. Deficiency is common in some developing countries due to poor diet.

The first symptom of deficiency is night blindness, followed by dryness and eye inflammation (see *xerophthalmia*), *kera-tomelacia* (damage to the cornea), and eventually blindness. Deficiency also causes reduced resistance to infection, dry skin, and, in children, stunted growth.

EXCESS

Prolonged excessive intake of vitamin A can cause headache, nausea, loss of appetite, skin peeling, hair loss, and irregular menstruation. In severe cases, the liver and spleen become enlarged. Excess vitamin A, especially in the form of retinol, has been linked with an increased risk of bone fractures. Excessive intake during pregnancy may cause

birth defects. In infants, excessive intake may cause skull deformities, which disappear if the diet is corrected.

MEDICAL USES

The drug *tretinoin* (a derivative of vitamin A) is used to treat severe *acne*.

vitamin B

See *vitamin B₁₂*; *vitamin B complex*.

vitamin B₁₂

A water-soluble *vitamin* that plays a vital role in the activities of several *enzymes* in the body. Vitamin B₁₂ is important in the production of the genetic material of cells (and thus in growth and development), in the production of red

REFERENCE NUTRIENT INTAKE (RNI) FOR SELECTED VITAMINS

The table (below) gives the reference nutrient intake (RNI) of vitamins for which amounts have been established; the RNI for males and females, when they are different, are denoted by the letters M and F.

Vitamin	Birth–6 months	6 months –1 year	1–3 years	4–6 years	7–10 years	11–14 years	15–18 years	19–50 years	51+ years	Extra needed: Pregnancy	Breast-feeding
Folic acid (mcg/day)	50	50	70	100	150	200	200	200	200	+100	+60
Niacin (mg/day)	3	5	8	11	12	M 15 F 12	M 18 F 14	M 17 F 13	M 16 F 12	0	+2
Vitamin B ₆ (mg/day)	0.2	0.4	0.7	0.9	1.0	M 1.2 F 1.0	M 1.5 F 1.2	M 1.4 F 1.2	M 1.4 F 1.2	0	0
Riboflavin (mg/day)	0.4	0.4	0.6	0.8	1.0	M 1.2 F 1.1	M 1.3 F 1.1	M 1.3 F 1.1	M 1.3 F 1.1	+0.3	+0.5
Thiamine (mg/day)	0.2	0.2	0.5	0.7	0.7	M 0.9 F 0.7	M 1.1 F 0.8	M 1.0 F 0.8	M 0.9 F 0.8	+0.3	+0.2

Vitamin B ₁₂ (mcg/day)	0.3	0.4	0.5	0.8	1.0	1.2	1.5	1.5	1.5	0	+0.5
Vitamin C (mg/day)	25	25	30	30	30	35	40	40	40	+10*	+30
Vitamin D ** (mcg/day)	8.5	7	7	0	0	0	0	0	10†	+10	+10

Vitamin E

There is no recommended intake for vitamin E. The amount that is needed depends on the amount of polyunsaturated fatty acids in the diet. There is some evidence that high levels of vitamin E protect against cancer and heart disease, although intake of high levels are not yet recommended. The safe daily intake is up to 4 mg for males and up to 3 mg for females.

Units

mg = milligrams (thousandths of a gram)
mcg = micrograms (millionths of a gram)

* For last trimester only

** Vitamin D is derived from sunlight. Certain individuals or at-risk groups may require dietary vitamin D

† For people aged 65 years or more only

blood cells in bone marrow, in the utilization of folic acid in the diet, and in the functioning of the nervous system. Foods that are rich in vitamin B_{12} include liver, kidney, chicken, beef, pork, fish, eggs, and dairy products.

DEFICIENCY

Deficiency is almost always due to inability of the intestine to absorb vitamin B_{12} , usually because of pernicious anaemia (see *anaemia, megaloblastic*). Less commonly, deficiency may result from *gastrectomy* (removal of all or part of the stomach), *malabsorption*, or *veganism*.

The effects of deficiency are megaloblastic anaemia, sore mouth and tongue, and symptoms resulting from damage to the *spinal cord*, such as numbness and tingling in the limbs. There may also be depression and loss of memory.

EXCESS

A high intake of vitamin B_{12} has no known harmful effects.

vitamin B complex

A group of water-soluble *vitamins* that comprise thiamine (vitamin B_1), riboflavin (vitamin B_2), niacin, pantothenic acid, pyridoxine (vitamin B_6), biotin (vitamin H), and folic acid. *Vitamin B₁₂* is discussed above.

THIAMINE

Thiamine plays a role in the activities of various *enzymes* that are involved in the utilization of *carbohydrates* and thus in the functioning of nerves, muscles, and the heart. Sources include whole-grain cereals, wholemeal breads, brown rice, pasta, liver, kidney, pork, fish, beans, nuts, and eggs.

Those who are susceptible to deficiency include elderly people on a poor diet, and people with *hyperthyroidism* (overactivity of the thyroid gland), *malabsorption*, or severe *alcohol dependence*. Deficiency may also occur as a result of severe illness, surgery, or injury.

Mild deficiency of the vitamins may cause tiredness, irritability, and loss of appetite. Severe deficiency may cause abdominal pain, constipation, depression, memory impairment, and *beriberi*; in alcoholics, it may cause *Wernicke-Korsakoff syndrome*. Excessive intake is not known to cause harmful effects.

RIBOFLAVIN

Riboflavin is necessary for the activities of various enzymes that are involved in the breakdown and utilization of carbohydrates, fats, and proteins; production energy in cells; utilization of other B vitamins; and hormone production by

the adrenal glands. Liver, whole grains, milk, eggs, and brewer's yeast are good sources of these vitamins.

People who are susceptible to riboflavin deficiency include those taking phenothiazine *antipsychotic drugs*, tricyclic *antidepressant drugs*, or oestrogen-containing *oral contraceptives*, and those with malabsorption or severe alcohol dependence. Deficiency may also occur through serious illness, surgery, or injury.

Prolonged deficiency may cause soreness of the tongue and the corners of the mouth, and eye disorders such as *amblyopia* and *photophobia*. Excessive intake is not known to have any harmful effects.

NIACIN

Niacin plays an essential role in the activities of various enzymes involved in the metabolism of carbohydrates and fats, the functioning of the nervous and digestive systems, the manufacture of sex hormones, and the maintenance of healthy skin. The main dietary sources are liver, lean meat, fish, nuts, and dried beans. Niacin can be made in the body from tryptophan (an *amino acid*).

Most cases of deficiency are due to malabsorption disorders or to severe alcohol dependence. Prolonged niacin deficiency causes *pellagra*, the main symptoms of which are soreness and cracking of the skin, inflammation of the mouth and tongue, and mental disturbances. Excessive intake of niacin is not known to cause harmful effects.

PANTOTHENIC ACID

Pantothenic acid is essential for the activities of various enzymes that are involved in carbohydrate and fat metabolism, manufacture of *corticosteroids* and *sex hormones*, utilization of other vitamins, the functioning of the nervous system and *adrenal glands*, and growth and development. It is present in almost all vegetables, cereals, and animal foods.

Deficiency of pantothenic acid usually occurs as a result of malabsorption or alcoholism, but may also occur after severe illness, surgery, or injury. The effects include fatigue, headache, nausea, abdominal pain, numbness and tingling, muscle cramps, and susceptibility to respiratory infections. Excessive intake has no known harmful effects.

PYRIDOXINE

Pyridoxine aids the activities of various enzymes and hormones involved in the utilization of carbohydrates, fats, and proteins, the manufacture of red blood cells and antibodies, the functioning of the digestive and nervous systems, and

the maintenance of healthy skin. Dietary sources are liver, chicken, pork, fish, whole grains, wheat-germ, bananas, potatoes, and dried beans. Pyridoxine is also manufactured by intestinal bacteria.

People who are susceptible to a deficiency of pyridoxine include elderly people who have a poor diet, those with malabsorption or severe alcohol dependence, or those who are taking certain drugs (including *penicillamine* and *isoniazid*). Deficiency may cause weakness, irritability, depression, skin disorders, inflammation of the mouth and tongue, *anaemia*, and, in infants, *seizures*. In very large amounts, pyridoxine may cause *neuritis* (nerve inflammation).

BIOTIN

Biotin is essential for the activities of various enzymes involved in the breakdown of fatty acids and carbohydrates and for the excretion of the waste products of protein breakdown. It is present in many foods, especially liver, peanuts, dried beans, egg yolk, mushrooms, bananas, grapefruit, and watermelon. Biotin is also manufactured by bacteria in the intestines.

Deficiency of biotin may occur during prolonged treatment with *antibiotics* or *sulphonamide drugs*. Symptoms are weakness, tiredness, poor appetite, hair loss, depression, inflammation of the tongue, and eczema. Excessive intake has no known harmful effects.

FOLIC ACID

Folic acid is vital for various enzymes involved in the manufacture of *nucleic acids* and consequently for growth and reproduction, the production of red blood cells, and the functioning of the nervous system. Sources of folic acid include green vegetables, mushrooms, liver, nuts, dried beans, peas, egg yolk, and wholemeal bread.

Mild folic acid deficiency is common, but it can usually be corrected by increasing dietary intake. More severe deficiency may occur during pregnancy or breast-feeding, in premature or low-birthweight infants, in people on *dialysis*, in people with certain blood disorders, the skin disorder *psoriasis*, malabsorption, or alcohol dependence, and in people taking certain drugs.

The main effects include anaemia, sores around the mouth, and, in children, poor growth. Supplements of folic acid taken just before conception, and for the first 12 weeks of pregnancy, have been shown to reduce the risk of a *neural tube defect* in the baby.

vitamin C

A water-soluble *vitamin* that plays an essential role in the activities of various *enzymes*. Vitamin C is important for the growth and maintenance of healthy bones, teeth, gums, blood vessels, and ligaments; in the production of certain *neurotransmitters* (chemicals that transmit nerve impulses) and adrenal gland hormones; in the response of the *immune system* to infection; in wound healing; and in the absorption of *iron*.

The main dietary sources are fruits and vegetables. Considerable amounts of vitamin C are lost when foods are processed, cooked, or kept warm.

DEFICIENCY

Mild deficiency of vitamin C may result from a serious injury or severe burn. It may also occur from use of *oral contraceptives* or continual inhalation of carbon monoxide (from traffic fumes or tobacco smoke), or after major surgery or a fever. It may cause weakness, general aches, swollen gums, and *nosebleeds*. More serious deficiency is usually due to a very restricted diet. Severe deficiency leads to *scurvy* and *anaemia*.

EXCESS

If the daily dose of vitamin C exceeds about 1g, it may cause nausea, stomach cramps, diarrhoea, or kidney stones (see *calculus, urinary tract*).

VITAMINS AND MAIN FOOD SOURCES

A varied diet usually provides all the body's vitamin needs. For vegans (who eat no fish or animal products, including dairy products), vitamin B₁₂ and vitamin D may be lacking; these vitamins can be obtained from supplements or, in the case of vitamin D, through adequate exposure to sunlight.

Fat-soluble	Good sources
Vitamin A	Liver, fish-liver oils; egg yolk, milk and dairy products; margarine, various fruits and vegetables (such as oranges and carrots)
Vitamin D	Cod-liver oil, oily fish (such as sardines, herring, salmon, and tuna); liver; egg yolk; margarine
Vitamin E	Vegetable oils (such as corn, soya bean, olive and sunflower oils); nuts; meat; green, leafy vegetables; cereals; wheat-germ; egg yolk
Vitamin K	Green, leafy vegetables (especially cabbage, broccoli, and turnip greens); vegetable oils; egg yolk; cheese; pork liver
Water-soluble	Good sources
Thiamine (vitamin B ₁)	Wheat-germ; bran; whole-grain or enriched cereals; wholemeal bread; brown rice; pasta; liver; kidney; pork; fish; beans; nuts; eggs
Riboflavin (vitamin B ₂)	Brewer's yeast; liver; kidney; milk; cheese; eggs; whole grains; enriched cereals; wheat-germ
Niacin	Liver; lean meat; poultry; fish; nuts; dried beans; enriched cereals; bread; wheat-germ; potatoes
Pantothenic acid	Liver; heart; kidney; fish; egg yolk; wheat-germ; most vegetables; most cereals
Pyridoxine (vitamin B ₆)	Liver; chicken; pork; fish; whole grains; wheat-germ; bananas; potatoes; dried beans
Biotin (vitamin H)	Liver; peanuts; dried beans; egg yolk; mushrooms; bananas; grapefruit; watermelons
Folic acid	Green, leafy vegetables; mushrooms; liver; nuts; dried beans; peas; egg yolk; wholemeal bread
Vitamin B ₁₂ (cyanocobalamin)	Liver; kidney; chicken; beef; pork; fish; eggs; milk; cheese; enriched cereals
Vitamin C	Citrus fruits; tomatoes; green leafy vegetables; potatoes; green peppers; strawberries; blackcurrants

vitamin D

The collective term for a group of substances that help to regulate the balance of *phosphate* and *calcium* in the body, aid calcium absorption in the intestine, and promote strong bones and teeth.

Good sources of vitamin D include oily fish, liver, and egg yolk; the vitamin is also added to margarines. In the body, vitamin D is synthesized by the action of ultraviolet light on a particular chemical in the skin.

DEFICIENCY

Deficiency of vitamin D may occur in individuals with a poor diet, in premature infants, and in those who are deprived of sunlight. It can also result from *malabsorption*. Other causes include liver or kidney disorders and some genetic defects. Prolonged use of certain drugs, such as the anticonvulsant *phenytoin*, may also lead to deficiency. Deficiency in young children causes the bone disorder *rickets*; long-term deficiency in adults leads to *osteomalacia*.

EXCESS

Excessive intake of vitamin D may lead to *hypercalcaemia* (an abnormally high level of calcium in the blood) and abnormal calcium deposits in the soft tissues, kidneys, and blood vessel walls. In children, it may cause growth retardation.

vitamin E

The collective term for a group of substances that are essential for normal cell structure, for maintenance of the activities of certain *enzymes*, and for the formation of red blood cells. Vitamin E also protects the lungs and other tissues from damage by pollutants and is believed to slow ageing of cells. Sources include vegetable oils, nuts, meat, green vegetables, cereals, and egg yolk.

DEFICIENCY

Dietary deficiency of vitamin E is rare; deficiency is most common in people

with *malabsorption*, certain liver disorders, and in premature infants. It leads to the destruction of red blood cells, which eventually leads to *anaemia*. In infants, it causes irritability and *oedema* (accumulation of fluid in tissues).

EXCESS

Prolonged excessive intake of vitamin E may cause abdominal pain, nausea, and diarrhoea. It may also reduce intestinal absorption of vitamins A, D, and K.

vitamin K

A fat-soluble *vitamin* that is essential for the formation in the liver of substances that promote blood clotting. Green vegetables, vegetable oils, egg yolk, cheese, pork, and liver are good sources of vitamin K, which is also manufactured by bacteria in the intestine.

DEFICIENCY

Dietary deficiency of vitamin K rarely occurs. Deficiency may develop in people with *malabsorption*, certain liver disorders, or chronic diarrhoea. It may also result from prolonged treatment with *antibiotic drugs*. Newborn babies lack the intestinal bacteria that produce vitamin K and are routinely given supplements to prevent deficiency. Vitamin K deficiency may cause nosebleeds and bleeding from the gums, intestine, and urinary tract. In rare, severe cases, brain haemorrhage may result.

EXCESS

Excessive intake of vitamin K is not known to cause harmful effects.

vitamin supplements

A group of dietary preparations containing one or more *vitamins*. Some multivitamin preparations also contain *minerals*, such as iron and calcium. A healthy person with a balanced diet should not need to take supplements (see *nutrition*). Excessive doses of certain vitamins (especially vitamins A, B₆, and D) may actually be harmful.

Vitamin supplements may be given in order to prevent vitamin deficiency in susceptible people, including those individuals with increased requirements (such as women who are pregnant or breast-feeding); those people who follow a restricted diet (such as *veganism*); those who have severe *alcohol dependence*; and those people suffering from disorders that may cause vitamin deficiencies, such as *malabsorption* and some liver and kidney disorders.

Vitamin supplements are also used in the treatment of certain disorders,

including diagnosed vitamin deficiency. For example, vitamin D is used to treat the bone condition *osteomalacia* and vitamin A derivatives are given in the treatment of severe *acne*. Supplementary vitamins may be given orally or may be injected (as is the case with vitamin B₁₂ and vitamin K).

vitiligo

A common disorder of *skin* pigmentation in which patches of skin, most commonly on the face, hands, armpits, and groin, lose their colour. Vitiligo is thought to be an *autoimmune disorder* (in which the body's immune system attacks its own tissues). The condition may occur at any age, but it usually develops in early adulthood.

Spontaneous repigmentation occurs in some cases. A course of *phototherapy* using *PUVA* can also induce repigmentation of the skin, and creams containing *corticosteroid drugs* may help.

Vitiligo affecting the hands

Loss of pigment is the only skin change that occurs. The usual remedy for the condition is to mask the white patches with cosmetics.

vitreous haemorrhage

Bleeding into the *vitreous humour*, the gel-like substance that fills the main cavity of the eye. A common cause of a vitreous haemorrhage is diabetic *retinopathy*, in which new, fragile blood capillaries form on the retina. Vitreous haemorrhage often affects vision; a major haemorrhage causes poor vision until the blood is reabsorbed, which may not be for several months, if at all.

vitreous humour

The transparent, gel-like body that fills the rear compartment of the *eye* between the crystalline lens and the retina. The vitreous humour is composed almost entirely of water.

vivisection

The performance of a surgical operation on a live animal, particularly for the purposes of research. (See also *animal experimentation*.)

vocal cords

Two fibrous sheets of tissue in the *larynx* (voicebox) that are responsible for voice production. The vocal cords are attached at the front to the thyroid cartilage and at the rear to the arytenoid cartilages (see *Location of the vocal cords* box, overleaf).

In order to produce sound, the vocal cords (which normally form a V-shaped opening) close and vibrate as air that is expelled from the lungs passes between them. Alterations in cord tension produce sounds of different pitch, which are modified by the tongue, mouth, and lips to form speech

voicebox

See *larynx*.

voice, loss of

Inability to speak normally. Temporary partial loss of voice commonly results from straining of the muscles of the *larynx* (voicebox) through overuse of the voice or from inflammation of the *vocal cords* in *laryngitis*.

Persistent or recurrent loss of voice may be the result of *polyps* on the vocal cords, thickening of the vocal cords in *hypothyroidism* (underactivity of the thyroid gland), or interference with the nerve supply to the larynx muscles as a result of cancer of the larynx, *thyroid gland*, or *oesophagus*. Total loss of voice is rare and is usually of psychological origin. (See also *hoarseness*; *larynx, disorders of*).

Volkmann's contracture

A disorder of the wrist and fingers in which they become permanently fixed in a bent position.

CAUSE

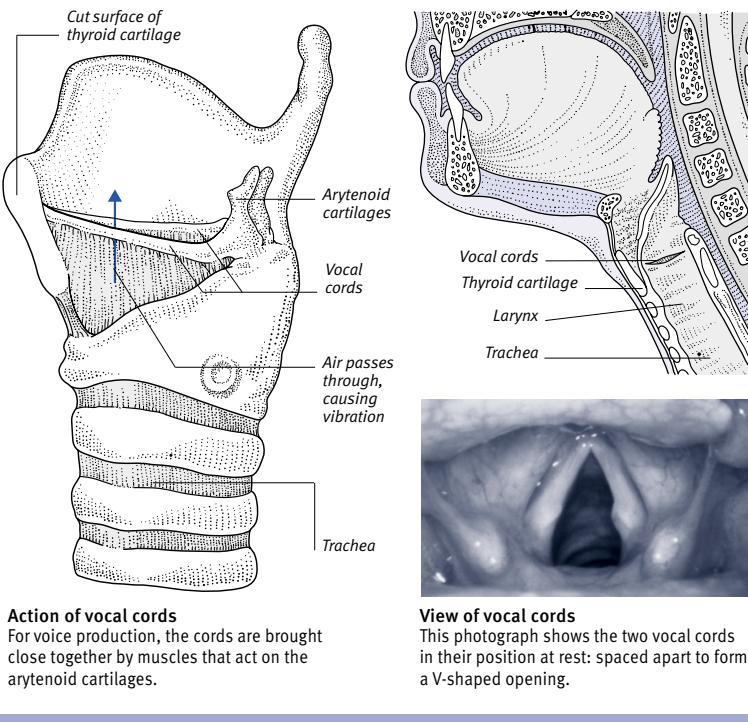

Volkmann's contracture occurs because of an inadequate blood supply to the forearm muscles that control the wrist and fingers. This is most likely to be the result of an injury.

SYMPTOMS

Initially, the fingers become cold, numb, and white or blue. Finger movements are weak and painful, and there is no pulse at the wrist. Unless treatment is started within a few hours, wrist and finger deformity develops.

LOCATION OF THE VOCAL CORDS

The vocal cords are located at the top of the larynx (voicebox). Their top edges stretch between the thyroid cartilage at the front and the arytenoid cartilages at the back. If they are brought close together, the vocal cords vibrate and emit sounds as air passes between them.

TREATMENT

Treatment of the condition is by manipulation back into position of displaced bones, followed, if necessary, by surgical restoration of blood flow in the forearm. If there is permanent deformity, *physiotherapy* may help to restore function of the affected parts.

volvulus

Twisting of a loop of *intestine* or, in rare cases, of the *stomach*. Volvulus is a serious condition that causes obstruction of the passage of intestinal contents (see *intestine, obstruction of*) and a risk of *strangulation*. If strangulation occurs, blockage of blood flow to the affected area leads to potentially fatal *gangrene* (death of tissues in the area).

The symptoms of volvulus are severe episodes of abdominal pain followed by vomiting. Volvulus may be present from birth or may be a result of *adhesions* (areas of scar tissue binding loops of intestine). It requires emergency treatment, usually by surgery.

It is also common in gastrointestinal disorders such as *peptic ulcer*, acute *appendicitis*, *gastroenteritis*, and *food poisoning*. Less commonly, it is due to obstruction, due for example to *pyloric stenosis* or *intussusception*, or a tumour of the digestive tract. It may also be due to inflammation of associated organs (see *hepatitis*; *pancreatitis*; *cholecystitis*).

Other possible causes of vomiting are pressure within the skull (see *encephalitis*; *hydrocephalus*; a *brain tumour*; a *head injury*), *migraine*, conditions that affect the ear's balancing mechanism (see *Ménière's disease*; *labyrinthitis*; *motion sickness*), and hormonal disorders such as *Addison's disease*.

Vomiting may be a symptom of ketoacidosis in poorly controlled *diabetes mellitus*. It may also be a symptom of an emotional problem or be part of the disorders *anorexia nervosa* or *bulimia*.

TREATMENT

Persistent vomiting requires medical investigation. Treatment depends on the cause. *Antiemetics* may be given. (See also *vomiting blood*; *vomiting in pregnancy*.)

vomiting blood

A symptom of bleeding from within the digestive tract. The vomiting of blood may be the result of a tear in the lower oesophagus (see *Mallory-Weiss syndrome*), bleeding from *oesophageal varices* (enlarged veins in the oesophagus), erosive *gastritis* (inflammation of the stomach lining), a *peptic ulcer*, or, rarely, *stomach cancer*. A person can also vomit blood if the blood is swallowed during a nosebleed.

Vomited blood may be dark red, brown, black, or it may resemble coffee grounds. Vomiting of blood is often accompanied by the passing of black, tarry faeces.

The cause of vomiting blood is investigated by *endoscopy* of the oesophagus and stomach, or by *barium X-ray examinations*. If blood loss is severe, *blood transfusion*, and possibly surgery to stop the bleeding, may be required.

vomiting in pregnancy

Nausea and vomiting in early *pregnancy* are common and are most likely to be caused by changes in hormone levels. Vomiting occurs most frequently in the morning, but it may occur at any time. It is sometimes precipitated by stress, travelling, or food.

In rare cases, the vomiting becomes severe and prolonged. This can cause

dehydration, nutritional deficiency, alterations in blood acidity, and weight loss. Immediate hospital admission is then required to replace lost fluids and chemicals by *intravenous infusion*, to rule out any serious underlying disorder, and to control the vomiting.

von Recklinghausen's disease

Another name for *neurofibromatosis*.

von Willebrand's disease

An inherited lifelong *bleeding disorder* that is similar to *haemophilia*. People with the condition have a reduced concentration in their blood of a substance called von Willebrand factor, which helps *platelets* in the blood to plug injured blood vessel walls and forms part of *factor VIII* (a substance that is vital to blood coagulation).

SYMPOTMS

Symptoms of deficiency of this factor include excessive bleeding from the gums and from cuts and nosebleeds. Women may have heavy menstrual bleeding. In severe cases, bleeding into joints and muscles may occur.

DIAGNOSIS AND TREATMENT

The disease is diagnosed by means of *blood-clotting tests* and measurement of blood levels of von Willebrand factor. Bleeding episodes can be prevented or controlled by desmopressin (a substance resembling *ADH*). Factor VIII or concentrated von Willebrand factor may also be used to treat bleeding.

voyeurism

The observation, on a regular basis, of unsuspecting individuals who may be naked, getting undressed, or who are engaged in sexual activity, in order to achieve sexual arousal.

VSD

The abbreviation for *ventricular septal defect*.

vulva

The external part of the female genitalia, comprising the *clitoris* and two pairs of skin folds called *labia*.

Conditions that affect the vulva include *vulval itching*; inflammation (see *vulvitis* and *vulvovaginitis*); skin conditions, such as *dermatitis* and *lichen sclerosus et atrophicus*; genital warts (see *warts, genital*); genital herpes (see *herpes, genital*); *leukoplakia* (raised white patches due to tissue thickening); and cancer (see *vulva, cancer of*).

vulva, cancer of

A malignant tumour of the vulva (the external part of the female genitalia), a rare disorder that most commonly affects postmenopausal women. Cancer of the vulva may be preceded by a phase of vulval cell changes that cause itching, but, in many cases, the first symptom of the condition is a lump or painful ulcer on the vulva.

Diagnosis is confirmed using *biopsy* (removal of a small sample of tissue for microscopic analysis). Treatment is by surgical removal of the affected tissue. The outlook depends on how early treatment is commenced.

vulval itching

Irritation of the vulva (the external part of the female genitalia), known medically as *pruritus vulvae*. Vulval itching may be caused by localized conditions, including infections (such as *candidiasis*), infestations (such as with *pubic lice*), or abnormal changes in the vulval skin (due, for example, to *leukoplakia* or *cancer*). It may also be caused by any condition leading to generalized itching or by skin conditions, such as *dermatitis* and *psoriasis*. Itching may also result from an *allergy* to chemicals in spermicidal or hygiene products.

Treatment of vulval itching depends on the cause, but may involve *antibiotic drugs* or hormones.

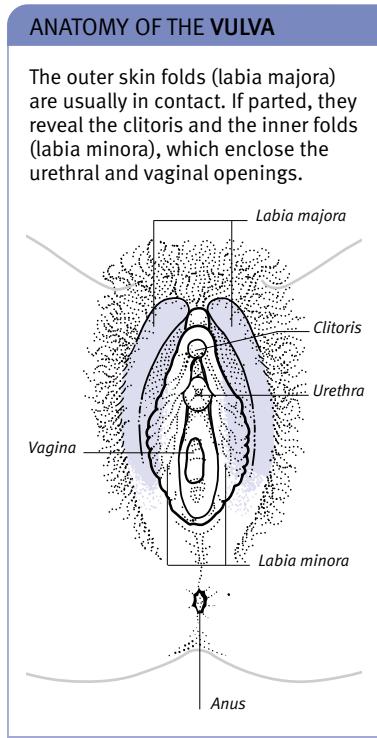

vulvitis

Inflammation of the vulva (the external part of the female genitalia). Infections that may lead to vulvitis include *candidiasis* (thrush) and *genital herpes* (see *herpes, genital*). Infestations with *pubic lice* or *scabies* are other possible causes. Vulvitis may also occur as a result of changes in the vulval skin, which tend to affect women after the *menopause*. Such changes may take the form of red or white patches and/or thickened or thinned areas that may be inflamed (see *lichen sclerosus et atrophicus*; *leukoplakia*). Other possible causes of vulvitis include allergic reactions to hygiene products, excessive vaginal discharge, or urinary incontinence (see *incontinence, urinary*).

Treatment depends on the cause, but may involve the topical application of a combination of drugs; good hygiene is usually recommended. If there are skin changes, a *biopsy* (tissue sample) may be taken to exclude the possibility of vulval cancer. (See also *vaginitis*; *vulvovaginitis*.)

vulvovaginitis

Inflammation of the vulva (see *vulvitis*) and vagina (see *vaginitis*). Vulvovaginitis is often caused by infections such as *candidiasis* (thrush) or *trichomoniasis*.

W

walking

Movement of the body by lifting the feet alternately, bringing one foot into contact with the ground before the other starts to leave it. A person's gait (style of walking) is determined by body shape, size, and posture. The age at which children first walk varies enormously.

Walking is controlled by nerve signals to the muscles. The signals travel to the muscles, via the spinal cord, from the motor cortex of the brain (see *cerebrum*), *basal ganglia*, and *cerebellum*.

DISORDERS

Abnormal gait may be caused by joint stiffness, muscle weakness (sometimes due to conditions such as *poliomyelitis* or *muscular dystrophy*), skeletal abnormalities (see, for example, *arthritis*; *bone tumour*; *hip, congenital dislocation of*; *scoliosis*; *talipes*). A painful limp may be due

to a fracture or disease of the leg bones (the *tibia*, the *fibula*, or the *femur*). Children may develop *knock-knee* or *bowleg*; *synovitis* of the hip and *Perthes' disease* are also common. Adolescents may develop a painful limp due to a slipped epiphysis (see *femoral epiphysis, slipped*).

Abnormal gait may also be caused by neurological disorders such as *stroke* (commonly causing *hemiplegia*), *multiple sclerosis*, *parkinsonism*, peripheral *neuritis*, various forms of *myelitis*, and *chorea*. *Ménière's disease* may cause severe loss of balance and instability.

walking aids

Equipment for increasing the mobility of people who have a disorder affecting their ability to *walk*. Such aids include sticks, crutches, and frames.

walking, delayed

Most children start to walk by around 15 months of age. Delayed walking may be suspected if the child is unable to walk unassisted by the age of 18 months (see *developmental delay*).

warfarin

An *anticoagulant drug* used in the prevention and treatment of abnormal *blood clotting*. Warfarin is used to treat deep

vein thrombosis (formation of a blood clot within the deep-lying veins of the leg; see *thrombosis, deep vein*), *pulmonary embolism* (a fragment of a blood clot travelling in the bloodstream becoming lodged in the lungs), and people with *atrial fibrillation* (an abnormality of the heartbeat) who are at risk of an *embolism*. It is also prescribed to prevent emboli from developing on replacement valves (see *heart-valve surgery*).

A faster-acting anticoagulant, such as *heparin*, may also be prescribed for the first few days following a deep vein thrombosis or pulmonary embolism.

Warfarin may cause abnormal bleeding in different parts of the body, so regular tests are carried out to allow careful regulation of dosage. Warfarin may also cause nausea, diarrhoea, and a rash.

wart

A common, contagious, and harmless growth that occurs on the skin or mucous membranes. Only the topmost layer of skin is affected. An overgrowth of cells in this layer causes a visible lump to develop.

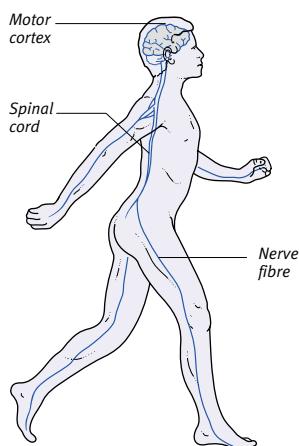

CAUSES AND TYPES

Warts are caused by the human papillomavirus, of which at least 70 different types are known. These cause different

THE MECHANICS OF WALKING

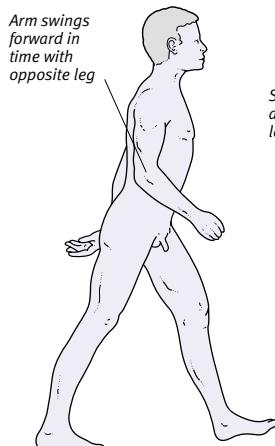

Many different muscles take part in the walking process. They contract in a complex, rhythmic sequence in response to programmes of signals sent from the motor cortex in the

brain. Feedback of information from the muscles and joints to the brain helps to ensure that the gait is smooth, steady, and coordinated.

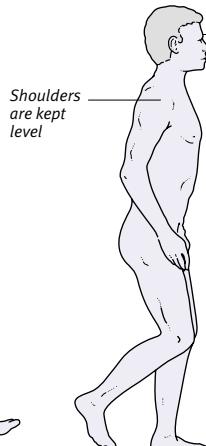

Route of the signals

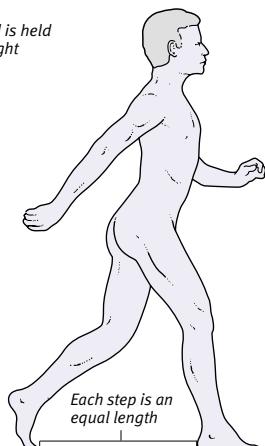

The signals for walking originate in the motor cortex and are carried via the spinal cord and nerve fibres to muscles.

1 As the left foot touches the ground, the right arm swings forward and the right foot shifts on to tiptoe.

2 Once the left foot is fully planted on the ground and supporting the body, the right foot is raised.

3 A sequence of muscle contractions advances the right leg, and the left arm swings forward.

Common warts on finger

Warts often grow in crops. In time they disappear spontaneously, but they can be removed by freezing.

types of warts at various sites, such as on the hands, feet (see *wart, plantar*), or genitals (see *warts, genital*). Flat warts are flesh-coloured; they are sometimes itchy lumps with flat tops that occur mainly on the wrists, backs of the hands, and the face.

TREATMENT

Many warts disappear in 6 to 12 months without treatment. Genital warts should be treated promptly, however. Common, flat, and plantar warts can sometimes be destroyed using a wart-removing liquid or special plaster. Several treatments may be necessary, however, and sometimes the wart returns. Warts are commonly treated by *cryosurgery*.

wart, plantar

A hard, horny, and rough-surfaced area on the sole of the foot caused by a virus called a papillomavirus. Plantar warts, also known as verrucas, may occur singly or in clusters. The wart is flattened and forced into the skin and may cause discomfort or pain when walking. Infection is usually acquired from contaminated floors in swimming pools and communal showers.

Many plantar warts disappear without treatment, but some persist for years or disappear for a short time before recurring. They can be removed by *cryosurgery* or by applying plasters or gel containing *salicylic acid*.

Typical plantar wart

This type of wart may need treatment; a doctor may treat it by paring it down with a scalpel and applying a corrosive paint.

warts, genital

Fleshy, painless, usually soft lumps that grow in and around the vagina, around the anus, and on the penis. Genital warts are transmitted by sexual contact, and they are caused by some forms of *human papillomavirus* (HPV). The warts appear from a few weeks to 18 months after infection. They may be removed by *cryosurgery* or the drug *podophyllin*, but they tend to recur.

Genital warts are not associated with the development of cervical cancer (see *cervix, cancer of*); the two conditions are caused by different forms of HPV.

wasp stings

See *insect stings*.

water

A simple compound that is essential for all life. Its molecular structure is H₂O (two atoms of hydrogen bonded to one of oxygen). Water is the most common substance in the body, accounting for about 99 per cent of all molecules, but a smaller percentage of total body weight. Approximately two-thirds of the body's water content is contained within cells, and the remaining third is extracellular (found, for example, in blood *plasma*, *lymph*, *cerebrospinal fluid*, and *tissue fluid*).

ROLE IN THE BODY

Water provides the medium in which all metabolic reactions take place (see *metabolism*), and transports substances around the body. The blood plasma carries water to all body tissues, and excess water from tissues for elimination via the *liver*, *kidneys*, *lungs*, and *skin*. The passage of water in the tissue fluid into and out of cells takes place by *osmosis*.

WATER BALANCE

Water is taken into the body in food and drink and is lost in *urine* and *faeces*, as exhaled water vapour, and by sweating (see *dehydration*). The amount of water excreted in urine is regulated by the kidneys. Extra water is needed to excrete excess amounts of substances, such as sugar or salt, in the blood.

In some disorders, such as *kidney failure* or *heart failure*, insufficient water is excreted in the urine, resulting in *oedema* (accumulation of water in body tissues).

water-borne infection

A disease caused by infective or parasitic organisms transmitted via water. Infections can be contracted if infected water is drunk, if it contaminates food, or if individuals swim or wade in it. World-

WATER BALANCE IN THE BODY

Intake (litres)

Sweat	0.5	2.4
Breath	0.3	0.5
Faeces	0.1	0.1

Key Cold climate Hot climate

wide, contamination of drinking water is an important mode of transmission for various diseases, including *hepatitis A*, many viral and bacterial causes of *diarrhoea*, *typhoid fever*, *cholera*, *amoebiasis*, and some types of *worm infestation*.

Swimming in polluted water should be avoided because, if swallowed, there is a risk of contracting disease. A form of *leptospirosis* is caused by contact with water contaminated by rat's urine. In tropical countries, there is also a risk of contracting *schistosomiasis* (bilharzia) – a serious disease caused by a fluke that can burrow through the swimmer's skin.

waterbrash

The sudden filling of the mouth with tasteless saliva. It is not to be confused with *acid reflux* (the regurgitation of gastric juices), which has a sour taste. Waterbrash normally has other symptoms, such as abdominal pain before a meal, and usually indicates a disorder of the upper gastrointestinal tract.

Waterhouse–Friderichsen syndrome

A serious condition caused by infection of the bloodstream by bacteria of the meningococcus group. The main features are bleeding into the skin, low blood pressure, and *shock*. Without medical treatment, coma and death follow within

SAFETY OF WATER AND OTHER DRINKS FOR CONSUMPTION

Water from any source that falls into the suspect or very suspect categories should be sterilized. Techniques include boiling, filtering, and chemical treatment.

Category	Developed countries	Developing countries
Usually safe	Tap water from public supply; rainwater; canned or bottled drinks; spring water	Canned or bottled drinks of well-known brands; rainwater
Suspect	Water direct from rivers, streams, lakes, ponds, canals, and wells	Tap water (cities); spring water
Very suspect	Obviously polluted water (i.e. cloudy in appearance or with an unpleasant smell)	Tap water (rural areas); water direct from rivers, streams, lakes, ponds, and canals

hours. The syndrome is often associated with *meningitis*, which affects the membranes covering the brain and spinal cord.

watering eye

An increase in volume of the tear film, usually producing epiphora (overflow of tears). It may be caused by excess tear production due to emotion, conjunctival or corneal irritation, or an obstruction to the channel that drains tears. (See also *lacrimal apparatus*.)

water intoxication

A condition that is caused by excessive water retention in the brain. The principal symptoms are headaches, dizziness, nausea, confusion, and, in severe cases, seizures and unconsciousness.

Various disorders can disrupt the water balance in the body, leading to accumulation of water in the tissues. Examples include *kidney failure*, liver *cirrhosis*, severe *heart failure*, diseases of the *adrenal glands*, and certain lung or ovarian tumours producing a substance similar to *ADH* (antidiuretic hormone). Water intoxication is also seen in association with the use of *Ecstasy* (MDMA), during which excessive amounts of water are drunk. There is also a risk of water intoxication after surgery, caused by increased ADH production.

water on the brain

A nonmedical term for *hydrocephalus*.

water on the knee

A popular term for accumulation of fluid in or around the knee joint. A common cause is *bursitis* (inflammation of a bursa, one of the fluid-filled sacs that cushion pressure points in the body). (See also *effusion, joint*.)

webbing

A flap of skin, such as that which might occur between adjacent fingers or toes. Webbing is a common congenital (present from birth) abnormality that often runs in families and which may affect two or more digits. Mild webbing is completely harmless, but surgical correction may be performed for cosmetic reasons. In severe cases, adjacent digits may be completely fused (see *syndactyly*). Webbing of the neck is a feature of the condition *Turner's syndrome*.

**Webbing of the fingers**

This curious feature is often an inherited trait, appearing in each of several generations of a family. Most cases are completely harmless and do not require treatment.

Wegener's granulomatosis

A rare disorder in which *granulomas* (nodular collections of abnormal cells), associated with areas of chronic tissue inflammation due to *vasculitis* (*inflammation of the blood vessels*) develop in the nasal passages, lungs, and kidneys. It is thought that the condition is an *auto-immune disorder* (in which the body's natural defences attack its own tissues).

SYMPTOMS

Principal symptoms include a bloody nasal discharge, coughing (which sometimes produces bloodstained sputum), breathing difficulty, chest pain, and blood in the urine. There may also be loss of appetite, weight loss, weakness, fatigue, and joint pains.

TREATMENT

Treatment of the condition is with *immunosuppressant drugs*, such as *cyclophosphamide* or *azathioprine*, combined with *corticosteroids* to alleviate symptoms and attempt to bring about a remission.

OUTLOOK

With prompt treatment, most people recover completely from Wegener's granulomatosis within about a year, but *kidney failure* occasionally develops. Without treatment, complications may occur, including perforation of the nasal septum, causing deformity of the nose; inflammation of the eyes; rash, nodules,

or ulcers on the skin; and damage to the heart muscle, which may be fatal.

weight

The heaviness of a person or object. In children, weight is routinely used as an index of growth. In healthy adults, weight remains more or less stable if dietary energy intake matches energy expenditure (see *metabolism*). Weight loss or weight gain occurs if the net balance is disturbed.

WEIGHT ASSESSMENT

One method of assessment is to use the *body mass index* (BMI, or Quetelet's index), obtained by dividing weight in kilograms by the square of height in metres. 20–25 kg/m² is considered to be a healthy weight; a score of greater than 25, however, may indicate that a person is overweight (see the accompanying table).

However, BMI has its limitations when assessing whether a person is medically overweight or underweight: a person with a good muscle bulk may have a high BMI but a healthy body composition; a small-framed person with a lot of body fat may have a normal BMI. For this reason, assessment of the percentage of a person's body fat gives a more accurate idea of healthy versus unhealthy weight. Distribution of body fat is also important: people with central obesity (measured by a high waist:height ratio) are considered to be less healthy than those with a more even distribution of fat.

In children, weight can be compared with standardized predictions for age, which differ according to the gender and race of a child. Such weight charts are used to assess how well a child is thriving. At all ages, divergence from standard figures (either using BMI or body fat percentages) may have medical implications. If an individual is found to be "underweight", their nutrition may be inadequate as a result of a poor diet or disease; if an individual is significantly "overweight", he or she may be suffering from *obesity*.

weight loss

Any time that there is a decrease in energy intake compared with energy expenditure, weight loss is likely to occur. The decrease may be the result of deliberate *weight reduction* or a change in diet or activity level. Weight loss may also result from fluid loss (for example, because of sweating in a hot climate) or

it may be a symptom of a disorder. Unexplained weight loss should always be investigated by a doctor.

LOSS OF APPETITE

Many diseases can disrupt the appetite to the extent that an individual loses the desire to eat, which in turn leads to weight loss. Loss of appetite may also be a sign of generalized ill health. Depression reduces a person's motivation to eat; peptic ulcer causes pain and, in some cases, food avoidance; and some kidney disorders cause loss of appetite due to the effects of *uraemia* (raised levels of the waste product urea in the blood). In the conditions *anorexia nervosa* and *bulimia*, complex psychological factors affect an individual's eating pattern, sometimes with dramatic results.

DIGESTIVE CAUSES

Digestive disorders, such as *gastroenteritis*, lead to weight loss as a result of vomiting or diarrhoea. Weight is also affected by cancer of the oesophagus (see *oesophagus, cancer of*) and *stomach cancer*. *Malabsorption* of nutrients in certain disorders of the intestine or the pancreas also affect weight.

METABOLIC CAUSES

Some disorders cause weight loss by increasing the rate of metabolic activity in cells. Examples are any type of *cancer*, chronic infection such as *tuberculosis*, and *hyperthyroidism* (overactivity of the

thyroid gland). Untreated *diabetes mellitus* may also cause weight loss.

weight reduction

The process of losing excess body fat. A person who is severely overweight (see *obesity*) is at an increased risk of developing various illnesses, such as *diabetes mellitus*, *hypertension* (high blood pressure), and heart disease, so a weight loss programme is a good idea to reduce the risk of developing such conditions.

HOW IT IS DONE

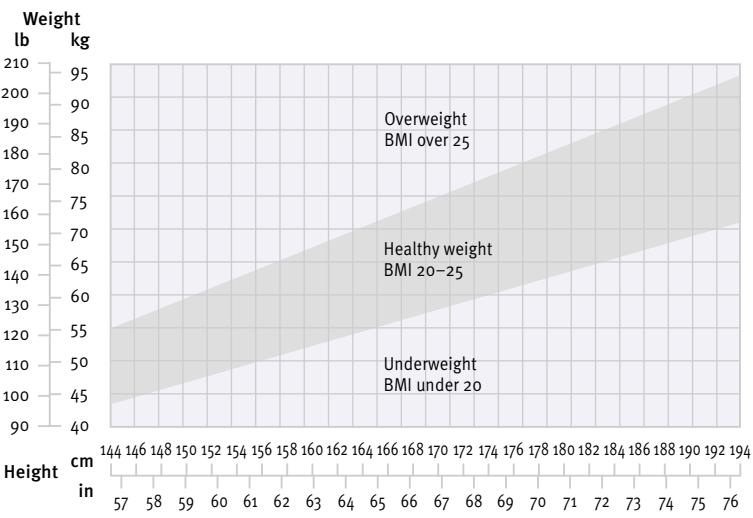

The most efficient way to lose weight is to eat a healthy balanced diet (see *nutrition*). This may involve a reduction in the intake of excess calories (those that are over the recommended daily limit), combined with regular exercise, both *aerobic* (fat-burning) and toning (muscle-building). Motivation, emotional support, and exploration of the psychological factors affecting eating are also important factors for success.

DRUG TREATMENTS

In most circumstances, drugs play little part in a weight-loss programme. However, *orlistat* (an antiobesity drug) may be a useful adjunct to a reduced diet, and they may, in some cases, be appropriate for those individuals who have a high *body mass index*. *Appetite suppressants* that are related to *amphetamines* are not recommended.

WEIGHT/HEIGHT GRAPH FOR MEN AND WOMEN

To find out whether or not you are underweight, normal weight, or overweight, first find your height, then run your finger up to your present weight. People with a BMI of 20–25 kg/m² are considered to be a healthy weight; those whose BMI is greater than 25, however, may be considered to be overweight.

RECOMMENDATIONS FOR WEIGHT REDUCTION

- Cut down drastically on all visible fats, including butter, margarine, cream, and cooking oils, as well as the invisible fats that are present in pastries, biscuits, and cakes. Choose low-fat milk, cheeses, and yogurts.
- Choose lean cuts of meat and avoid processed meat such as salami. Grill or roast meat without adding fat instead of frying.
- Eat more boiled legumes (e.g. lentils and beans), which provide protein but contain very little fat.
- Avoid refined carbohydrates such as sugar (sucrose) as well as refined grain products such as white flour and white rice.
- Increase your consumption of unrefined carbohydrates. Eat wholemeal bread, whole-grain rice and cereals, fresh fruit, and plenty of vegetables.
- Reduce your intake of alcoholic drinks, which are high in calories.

Weil's disease

Another name for *leptospirosis*.

welder's eye

Also known as arc eye, acute *conjunctivitis* and *keratopathy* (corneal damage) that is caused by the intense *ultraviolet light* emitted by an electric welding arc. Welder's eye is a consequence of the failure to wear adequate eye protection while performing welding tasks.

wen

A name for a *sebaceous cyst*.

Werdnig–Hoffmann disease

A very rare inherited disorder of the *nervous system* that affects infants. Also known as infantile spinal muscular atrophy, Werdnig–Hoffmann disease is a type of *motor neuron disease*, affecting the nerve cells in the spinal cord that control muscle movement.

Marked floppiness and paralysis occur during the first few months, and affected children rarely survive beyond the age of three.

There is no cure for the disease. Treatment aims to keep the affected infant as comfortable as possible.

Wernicke–Korsakoff syndrome

An uncommon brain disorder, almost always related to malnutrition, that occurs in chronic alcohol dependence. It may also occasionally occur in cancer.

CAUSES

Wernicke–Korsakoff syndrome results from a deficiency of thiamine (see *vitamin B complex*), which affects the brain and nervous system.

consciousness falls progressively and may lead to coma and death unless treated.

Korsakoff's psychosis may follow Wernicke's encephalopathy if treatment is not prompt. Symptoms consist of *amnesia*, apathy, and disorientation.

TREATMENT AND OUTLOOK

Wernicke's encephalopathy is an emergency. High doses of intravenous thiamine can reverse most symptoms, sometimes within hours. However, once the disease progresses to Korsakoff's psychosis, it is usually irreversible.

Wernicke's area

An area of the cerebral cortex in the brain that is involved in the interpretation of spoken and written language. Damage to Wernicke's area may result in *aphasia* (a complete loss of previously acquired language skills).

Wernicke's encephalopathy

See *Wernicke–Korsakoff syndrome*.

West Nile virus

A virus that is transmitted from infected animals or birds to humans by a mosquito bite. In most cases, there are either no symptoms or there is a flulike illness. Rarely, a serious and potentially fatal illness, in which the virus infects the brain, can develop. The virus is

SYMPTOMS

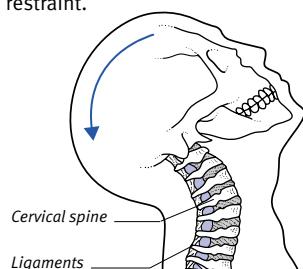

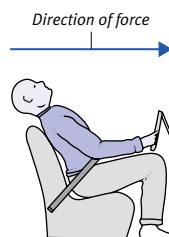

The disease consists of two stages: Wernicke's encephalopathy and Korsakoff's psychosis. Wernicke's encephalopathy usually develops suddenly and produces nystagmus (abnormal, jerky eye movements), ataxia (difficulty coordinating body movements), slowness, and confusion. Sufferers usually have signs of neuropathy (nerve damage), such as sensation loss, pins-and-needles, or impaired reflexes. The level of con-

CAUSE OF WHIPLASH INJURY

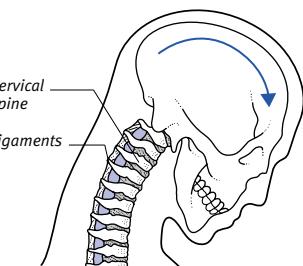

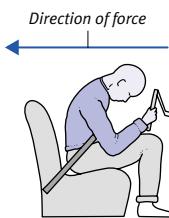

This injury to the neck section of the spine may occur when a car is subjected to a sudden violent force and the occupant's body is restrained in the seat but his or her head is not restrained by an appropriate head restraint.

Sudden acceleration

Here, there is a sudden force from behind (usually due to another vehicle's striking the rear of the car). As the body accelerates forwards, the head jerks violently backwards relative to the body, stretching and bending the neck; the head then rebounds forwards.

**Sudden deceleration**

Here, there is a sudden violent force from the front towards the back of the vehicle, due, for example, to a collision with a tree. The seat belt restrains the body, but the head continues to move forwards, stretching the neck; the head then rebounds backwards.

found in Africa, Eastern Europe, West Asia, the Middle East, and, since 1999, the east coast of the USA.

wet dream

Ejaculation of semen from the penis that occurs during sleep. (See also *nocturnal emission*.)

wet gangrene

A type of *gangrene*.

wheelchair

A chair mounted on wheels used to provide mobility for a person unable to walk. Manual wheelchairs are designed so that the hand-rims can be easily gripped by a disabled person. They can also be pushed by a helper. Powered wheelchairs use batteries and are controlled electronically by finger or chin pressure, or by breath control.

wheeze

A high-pitched, whistling sound produced in the chest, usually on breathing out, that is caused by narrowing of the airways. It is a feature of the lung disorders *asthma*, *bronchitis*, *bronchiolitis*, and *pulmonary oedema* (the accumulation of fluid in the lungs). Inhalation of a foreign body may also be a cause. (See also *breathing difficulty*.)

whiplash injury

An injury to the soft tissues, *ligaments*, and spinal joints of the neck caused by a forcible and violent bending of the neck backwards (hyperextension) and then forwards (flexion), or vice versa. Such injury most commonly results from sudden acceleration or deceleration, as occurs in a car collision (see the illustrated box, left).

Damage to the spine usually involves minor *sprain* of a neck ligament or *subluxation* (partial dislocation) of a cervical joint. Occasionally, a ligament may rupture or a cervical vertebra may fracture (see *spinal injury*). Characteristically, pain and stiffness in the neck are much worse 24 hours after the injury.

Treatment of whiplash injury may involve immobilization of the neck in an orthopaedic collar, *analgesic drugs* (painkillers), *muscle-relaxant drugs*, and *physiotherapy*. It may take a few weeks for pain-free movement to occur.

Whipple's disease

A rare disorder, also called intestinal lipodystrophy, that can affect many

organs. Symptoms include *steatorrhoea* (the presence of fat in the faeces) as a result of *malabsorption*, abdominal pain, joint pains, swollen lymph nodes, progressive weight loss, anaemia, and fever. The heart, lungs, and brain can also be affected. The condition is most common in middle-aged men.

The cause is thought to be bacterial; affected tissues are found to contain macrophages (a type of scavenging cell) containing rod-shaped bacteria.

Treatment is with *antibiotic drugs* for at least a year. Dietary supplements are used to correct nutritional deficiencies occurring as a result of malabsorption.

Whipple's operation

A type of *pancreatectomy* in which the head of the pancreas and the loop of the duodenum (first section of the small intestine) are surgically removed.

whipworm infestation

Small, cylindrical whiplike worms that are 2.5–5 cm long and live in the human large intestine. Infestation occurs worldwide but is most common in the tropics. Light infestation causes no symptoms, but heavy infestation can cause abdominal pain, diarrhoea, and, sometimes, *anaemia*, since a small amount of the host's blood is consumed every day.

Diagnosis is through the identification of eggs in the faeces. Treatment is

with *anthelmintic drugs*, such as *mebendazole*. A heavy infestation may require more than one course of treatment.

white blood cell

Also known as an leucocyte, a *blood cell* that contains a nucleus. Granulocytes, lymphocytes, and monocytes are three types of white blood cell that are involved in the production of antibodies and protection of the body against foreign substances as part of the *immune system*. (See also *red blood cell*.)

whitehead

A very common type of skin blemish (see *milia*).

white matter

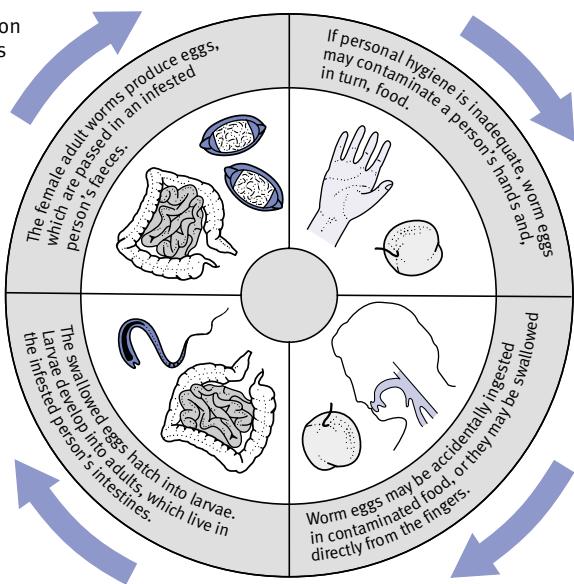

Tissue in the nervous system composed of nerve fibres (*axons*). White matter makes up the bulk of the cerebrum (the two large hemispheres of the *brain*) and continues down into the *spinal cord*; its main role is to transmit nerve impulses. (See also *grey matter*.)

whitlow

An abscess on the fingertip or toe that causes the affected digit to swell and become extremely painful and sensitive to pressure and touch. A whitlow may be due to the virus that causes *herpes simplex* or to a bacterial infection. In some cases, pus needs to be drained from the abscess.

LIFE-CYCLE OF WHIPWORM

Whipworm infestation (known medically as *trichuriasis*) occurs worldwide and is particularly common in the tropics. In the UK, whipworm infestation mainly affects immigrants and residents of psychiatric hospitals. Adult whipworms are 2.5 to 5 cm long. They may live in a person's intestine for up to 20 years. Most infestations do not cause symptoms.

**Herpetic whitlow**

This extremely painful finger infection, caused by the herpes simplex virus, may be helped by applying an antiviral ointment.

WHO

The commonly used abbreviation for the *World Health Organization*.

whooping cough

See *pertussis*.

will, living

See *living will*.

Wilms' tumour

A type of *kidney cancer*, also called nephroblastoma, that occurs mainly in children.

Wilson's disease

A rare, inherited disorder in which copper accumulates in the liver, resulting in conditions such as *hepatitis* and *cirrhosis*. Copper is slowly released into other body parts, damaging the brain, causing mild intellectual impairment, and leading to debilitating rigidity, tremor, and dementia. Symptoms of Wilson's disease usually appear in adolescence, but they can occur much earlier or later.

Lifelong treatment with *penicillamine* is necessary and, if begun soon enough, it can produce an improvement. If the disease is discovered before symptoms begin, the drug may prevent them.

wind

A common name for gas in the gastrointestinal tract, which may be expelled through the mouth (see *belching*) or passed through the anus (see *flatus*).

Babies often swallow air during feeding which, unless the baby is "winded", can accumulate in the stomach and cause discomfort.

windpipe

Another name for the *trachea*.

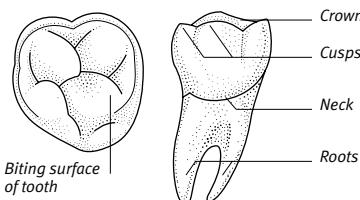

wiring of the jaws

Immobilization of the jaws by means of metal wires to allow a jaw fracture to

heal or as part of treatment for *obesity*. When a fracture is being treated, the jaws are kept wired in a fixed position for about six weeks. For promoting weight loss, the jaws are wired for as long as a year. In both cases, the person is unable to chew and can take only a liquid or semi-liquid diet. This form of diet treatment often fails because the person resumes previous eating habits following removal of the wires.

wisdom tooth

One of the four rearmost *teeth*, also known as third molars. The wisdom teeth normally erupt between the ages of 17 and 21 but often erupt later; in some people, one or more fails to develop or erupt. In many cases, wisdom teeth are unable to emerge fully from the gum as a result of overcrowding (see *impaction, dental*).

**Structure of wisdom tooth**

Like other molars, each wisdom tooth has strong roots and a bulky crown with many cusps and an extensive grinding surface.

Wiskott-Aldrich syndrome

An inherited condition in which the function of the immune system is impaired and there is a low number of platelets (blood cells that are needed for clotting). The defect is inherited in an X-linked recessive manner (see *genetic disorders*). It causes disease in males; females may have no symptoms, but may pass the gene to their children.

Features may include recurrent infections (caused by impaired immunity), an increased tendency to bleed (due to the reduced number of platelets), and *eczema*. Symptoms first develop soon after birth or during the first year of life. Affected individuals also have an increased risk of developing cancers, such as *lymphoma* and *leukaemia*, usually in adolescence or early adulthood.

Treatment is aimed at relieving the symptoms of the condition.

witches' milk

A thin, white discharge from the nipple of a newborn infant, caused by maternal hormones that entered the fetus's

circulation through the placenta. Witches' milk occurs quite commonly. It is usually accompanied by enlargement of one or both of the baby's breasts. The condition is harmless and usually disappears within a few weeks.

withdrawal

The process of retreating from society and from relationships with others; usually indicated by aloofness, lack of interest in social activities, preoccupation with one's own concerns, and difficulty in communicating.

The term is also applied to the psychological and physical symptoms that develop on discontinuing use of a substance on which a person is dependent (see *withdrawal syndrome*).

withdrawal bleeding

Vaginal blood loss that occurs when the level of *oestrogen* or *progesterone hormones* or *progestogen* drugs in the body drops suddenly.

The withdrawal bleeding that occurs at the end of each month's supply of combined *oral contraceptive pills* mimics menstruation but is usually shorter and lighter. Discontinuation of an oestrogen-only or progestogen-only preparation also produces bleeding, which may differ from normal menstruation in its amount and duration.

withdrawal method

See *coitus interruptus*.

withdrawal syndrome

Unpleasant mental and physical symptoms experienced when an individual stops using a drug on which he or she is dependent (see *drug dependence*). Withdrawal syndrome most commonly occurs in those with *alcohol dependence* or dependence on opioid *analgesic drugs*, in smokers, and in people addicted to *tranquillizers*, *amphetamines*, *cocaine*, *marijuana*, and *caffeine*.

ALCOHOL WITHDRAWAL

In an alcohol-dependent person, alcohol withdrawal symptoms start six to eight hours after cessation of intake and may last up to seven days. They include trembling of the hands, nausea, vomiting, sweating, cramps, anxiety, and, sometimes, seizures and visual *hallucinations*.

OPIOID WITHDRAWAL

Withdrawal symptoms from opioids start after eight to 12 hours, and may last for seven to ten days. Symptoms include restlessness, sweating, runny

eyes and nose, yawning, dilated pupils, diarrhoea, vomiting, abdominal cramps, loss of appetite, irritability, weakness, tremor, and depression.

TRANQUILLIZER WITHDRAWAL

Withdrawal symptoms from *barbiturate drugs* and *meprobamate* begin, after 12 to 24 hours, with tremors, anxiety, restlessness, and weakness, sometimes followed by *delirium*, hallucinations, and, occasionally, seizures. A period of prolonged sleep occurs three to eight days after onset. Withdrawal from *benzodiazepine drugs* may begin much more slowly and can be serious, often resulting in depression, confusion, *agoraphobia* (fear of open spaces and public places), and/or *psychosis*.

STOPPING SMOKING

Withdrawal symptoms from *nicotine* develop over 24 to 48 hours and include irritability, concentration problems, frustration, headaches, and anxiety.

WITHDRAWAL FROM OTHER DRUGS

Discontinuation of cocaine or amphetamines results in dizziness, lethargy, and extreme tiredness. Cocaine withdrawal may also lead to tremor, sweating, and severe depression. Withdrawal symptoms from marijuana include tremor, nausea, vomiting, diarrhoea, sweating, irritability, and sleep problems. Withdrawal from caffeine may lead to tiredness, headaches, and irritability.

TREATMENT

Severe withdrawal syndromes require medical treatment. Symptoms may be suppressed by giving the patient small quantities of the drug he or she had been taking. More commonly, a substitute drug is given, such as *methadone* for opioid drugs or a benzodiazepine drug for alcohol. The dose of the drug is then gradually reduced.

wobble board

A balancing board used during *physiotherapy* to improve muscle strength and coordination in the feet, ankles, and legs. A wobble board is sometimes used after an ankle sprain.

womb

See *uterus*.

word blindness

See *alexia; dyslexia*.

World Health Organization (WHO)

An international organization established in 1948 as an agency of the United Nations with responsibilities for

international health matters and public health. The WHO headquarters are in Geneva, Switzerland.

The WHO has campaigned effectively against some infectious diseases, most notably smallpox, tuberculosis, and malaria. Other functions include sponsoring medical research programmes, organizing national laboratories, and providing expert health advice and specific targets to its 192 member states.

worm infestation

Several worms, or their larvae, existing as parasites of humans. They may live in the intestines, blood, lymphatic system, bile ducts, or in organs such as the liver. In many cases, they cause few or no symptoms, but some cause chronic illness. The two main classes are: *roundworms* and *platyhelminths*, with subdivisions, cestodes (tapeworms) and trematodes (flukes).

Worm diseases occurring in developed countries include *threadworm infestation*, *ascariasis*, *whipworm infestation*, *toxocariasis*, liver-fluke infestation, and various *tapeworm infestations*. Those occurring in tropical regions include, in addition, *hookworm infestation*, *filarisis*, *guinea worm disease*, and *schistosomiasis*.

Worms may be acquired by eating undercooked, infected meat, contact with soil or water containing worm larvae, or accidental ingestion of worm eggs from

soil contaminated by infected faeces. Most infestations can be easily eradicated with *anthelmintic drugs*.

wound

Any damage to the skin and/or underlying tissues caused by an accident, act of violence, or surgery. Wounds in which the skin or mucous membrane is broken are called "open"; those in which they remain intact, for example bruises, are termed "closed".

Wounds can be divided into the following categories: an incised wound; an abrasion (or graze); a *laceration*; a penetrating wound; and a *contusion* (see *Types of wounds* box, overleaf).

wound infection

Any type of *wound* is susceptible to the entry of bacteria; the resultant infection may delay healing, result in disability, and even cause death. Infection of a wound is indicated by redness, swelling, warmth, pain, and, sometimes, by the presence of pus or the formation of an *abscess*. Infection may spread locally, to adjacent organs or tissue, or to more distant parts of the body via the blood.

The type of infection depends upon how the wound occurred. For example, a wound in contact with soil can cause *tetanus*. Staphylococcal bacteria, including *MRSA*, commonly infect wounds.

DRUGS TO TREAT WORM INFESTATIONS

Drugs such as those listed below are the main treatment for worm infestations. Usually just one or two doses are required but sometimes longer treatment is needed. Laxatives may also be given to aid expulsion of worms living in the intestines.

Infestation	Drug
Threadworm	Mebendazole, piperazine
Common roundworm (ascariasis)	Mebendazole, piperazine
Whipworm	Mebendazole
Hookworm	Mebendazole
Strongyloidiasis	Tiabendazole, albendazole, ivermectin
Toxocariasis	Diethylcarbamazine, tiabendazole
Tapeworm	Niclosamide, praziquantel
Filarisis	Diethylcarbamazine, ivermectin
Schistosomiasis	Praziquantel

TYPES OF WOUNDS

Wounds can be divided into the following categories: incised wounds, in which the skin is cleanly cut (e.g. surgical incision); abrasion (or grazes), in which surface tissue is scraped away; lacerations, in which the skin is torn (e.g. animal bites); contusions, in which the underlying tissues are damaged by a blunt instrument; and penetrating wounds (e.g. stab or gunshot wounds).

**Abrasions**

Abrasions usually result from sliding falls and may contain dirt. They should be carefully cleaned and dressed.

**Contusion**

Although the skin remains intact in this type of wound (caused, here, by a seat belt), there may be damage to the underlying tissues.

**Penetration wound**

A penetrating wound (here, a stab wound) may appear small, but the knife may have punctured organs deep in the body.

**Laceration**

Such wounds are usually cleaned and then left open to heal. Antibiotic and antitetanus treatment may be given.

Once infection is discovered, a sample of pus or blood may be taken and the patient is given an *antibiotic drug*. An abscess should be drained surgically.

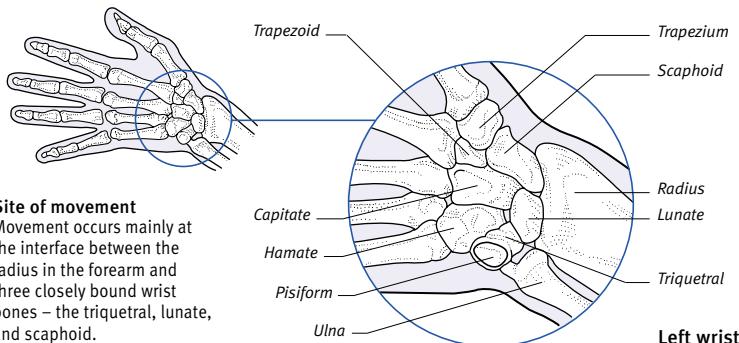

wrinkle

A furrow in the *skin*. Wrinkles are a natural feature of ageing. Wrinkling is the result of loss of skin elasticity. Premature wrinkling is usually caused by overexposure to sunlight, and to smoking.

No treatment of wrinkles can restore the skin's elasticity permanently. However, some *vitamin A* derivatives are believed to reduce wrinkling. A *face-lift* smoothes out wrinkles by stretching the skin, but the effects last for only about five years.

STRUCTURE OF THE WRIST

The wrist is a complex joint that allows the hand to be bent forward and backward relative to the arm (through an angle of almost 180 degrees) and also moved side to side (through about 70 degrees).

**Site of movement**

Movement occurs mainly at the interface between the radius in the forearm and three closely bound wrist bones – the triquetral, lunate, and scaphoid.

wrist

The joint between the *hand* and the arm that allows the hand to be bent forward and backward relative to the arm and also to be moved side to side.

The wrist contains eight bones (known collectively as the *carpus*), arranged in two rows, one articulating with the forearm bones, and the other connecting to the bones of the palm. Tendons connect the forearm muscles to the fingers and thumb, and arteries and nerves supply the muscles, bones, and skin of the hand and fingers.

DISORDERS

Wrist injuries may lead to disability by limiting hand movement. A common injury in adults is *Colles' fracture*, in which the lower end of the radius is fractured and the hand is displaced backwards. In young children, similar displacement results from a fracture through the epiphysis (growing end) of the radius. A *sprain* can affect ligaments at the wrist joint, but most are not severe. (See also *carpal tunnel syndrome*; *osteoarthritis*; *tenosynovitis*; *wrist-drop*.)

wrist-drop

Inability to straighten the *wrist*, so that the back of the hand cannot be brought into line with the back of the forearm, causing weakness of grip.

Wrist-drop is caused by damage to the *radial nerve*, either by prolonged pressure in the armpit (see *crutch palsy*) or by fracture of the humerus (upper-arm bone; see *humerus, fracture of*).

Treatment involves holding the wrist straight. This may be achieved with a splint, but if damage to the radial nerve is permanent, the treatment is *arthrodesis* (surgical fusion) of the wrist bones.

writer's cramp

See *cramp, writer's*.

wry neck

Abnormal tilting and twisting of the head. It may be partly due to neck muscle injury or spasm (see *torticollis*).

Xalacom

A brand-name drug containing latanoprost, a *prostaglandin drug*, and timolol, a *beta-blocker drug*. Xalacom is used as eye-drops to treat *glaucoma* (increased pressure of fluid in the eyeball).

Xalatan

A brand name for latanoprost, a *prostaglandin drug* that is used in the form of eye-drops to treat *glaucoma* (increased pressure of fluid in the eyeball).

xanthelasma

A yellowish deposit of fatty material in the skin around the eyes. Xanthelasmas are common in elderly people and are usually not significant. In younger people, however, they may be associated with *hyperlipidaemias* (excess fat in the blood). Xanthelasmas may be removed, if necessary, by a simple surgical procedure under a local anaesthetic. Any associated hyperlipidaemia must also be treated. (See also *xanthomatosis*.)

Appearance of xanthelasma

These fatty deposits around the eyes are common in elderly people but are usually of no more than cosmetic importance.

xanthine drugs

A group of *bronchodilator drugs* usually used for the long-term prevention of attacks of breathing difficulty, such as in *asthma* and chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*). Xanthine drugs may be given orally, or by intravenous infu-

sion if the condition is severely exacerbated. *Aminophylline* and *theophylline* are common examples of xanthine drugs. Possible side effects of the drugs include headaches, nausea, and palpitations.

xanthoma

A yellowish deposit of fatty material in the skin, often on the elbow or buttock. Xanthomas may be associated with *hyperlipidaemias*, a group of disorders in which there are raised levels of fats in the blood (see *xanthomatosis*).

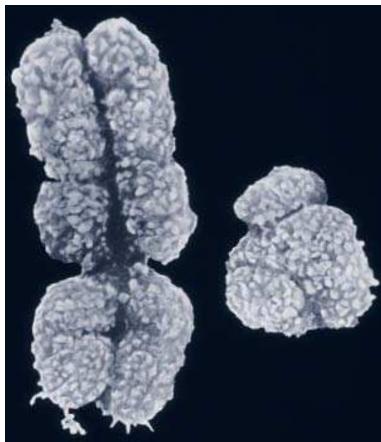

xanthomatosis

A condition in which deposits of yellowish, fatty material develop in various parts of the body, particularly in the skin, internal organs, corneas of the eyes, brain, and tendons. The deposits may occur only in the eyelids (see *xanthelasma*). A key feature of xanthomatosis is the tendency for fatty material to be deposited in the linings of blood vessels, leading to generalized *atherosclerosis*. Xanthomatosis is often associated with *hyperlipidaemias* (a group of disorders in which there are raised levels of fats in the blood).

Treatment aims to lower the levels of fats in the blood by means of a diet that is low in cholesterol and high in polyunsaturated fat, and by drug treatment.

X chromosome

A *sex chromosome*, of which every normal female body cell has a pair. Male body cells have one X and one Y *chromosome*; each sperm carries either an X or

X chromosome

This is a coloured scanning electron microscope (SEM) view of the X chromosome (left), and the Y, which are also known as the sex chromosomes.

a Y chromosome. Abnormal genes that are located on X chromosomes result in *X-linked disorders*.

Xenical

A brand name for *orlistat*, a drug used in the treatment of severe *obesity*.

xenotransplantation

The transplantation of an organ (a heart or lung, for example) from one species into another species, such as the transplantation of pig organs into humans. Research into the *genetic engineering* of pig embryos is currently underway in order to produce animals with organs that will not be rejected by a human body following *transplant surgery*.

xeroderma pigmentosum

A rare, inherited skin disease. The skin is normal at birth, but *photosensitivity* (extreme sensitivity to sunlight) causes it to become dry, wrinkled, freckled, and prematurely aged by about the age of five. Noncancerous skin tumours and *skin cancers* also develop. Xeroderma pigmentosum is often accompanied by related eye problems, such as *photophobia* and *conjunctivitis*.

Treatment of the condition consists of protecting the skin from sunlight. Skin cancers are usually treated surgically or with *radiotherapy*.

xerophthalmia

An *eye* disorder in which deficiency of *vitamin A* causes the conjunctiva and cornea to become abnormally dry. Without treatment, xerophthalmia may progress to *keratomalacia*, a condition in which severe damage is caused to the cornea.

xerostomia

Abnormal dryness of the mouth, which can cause bad breath and may predispose the sufferer towards tooth decay (see *caries, dental*). Xerostomia is sometimes a symptom of *Sjögren's syndrome*. (See also *mouth, dry*.)

xipamide

A thiazide *diuretic* drug that is used to treat *oedema* (accumulation of fluid in the body tissues) and *hypertension* (high blood pressure). Side effects of xipamide may include dizziness and mild gastrointestinal disturbances.

xiphisternum

An alternative name for the *xiphoid process*, the small, leaf-shaped projection

USING X-RAYS TO LOOK AT THE BODY

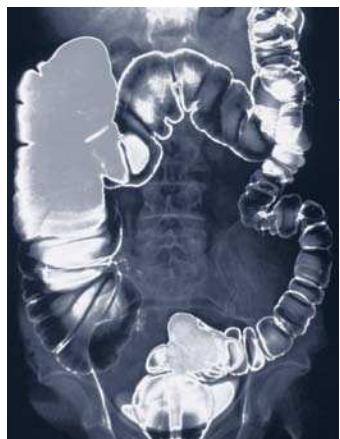

X-rays are perhaps the most widely used method of imaging the body. When passed through body tissues onto photographic film, X-rays cast images of internal structures, allowing alterations in silhouette to be seen. Soft tissues do

not show up as well as bone on X-rays, but, by using a contrast medium, they too can be visualized. New computer techniques produce even clearer, more detailed images, making X-ray an increasingly efficient diagnostic tool.

3-D CT scan

A computer can transform X-ray images of body slices into a three-dimensional image of part of the body.

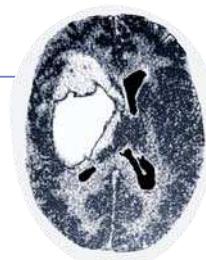

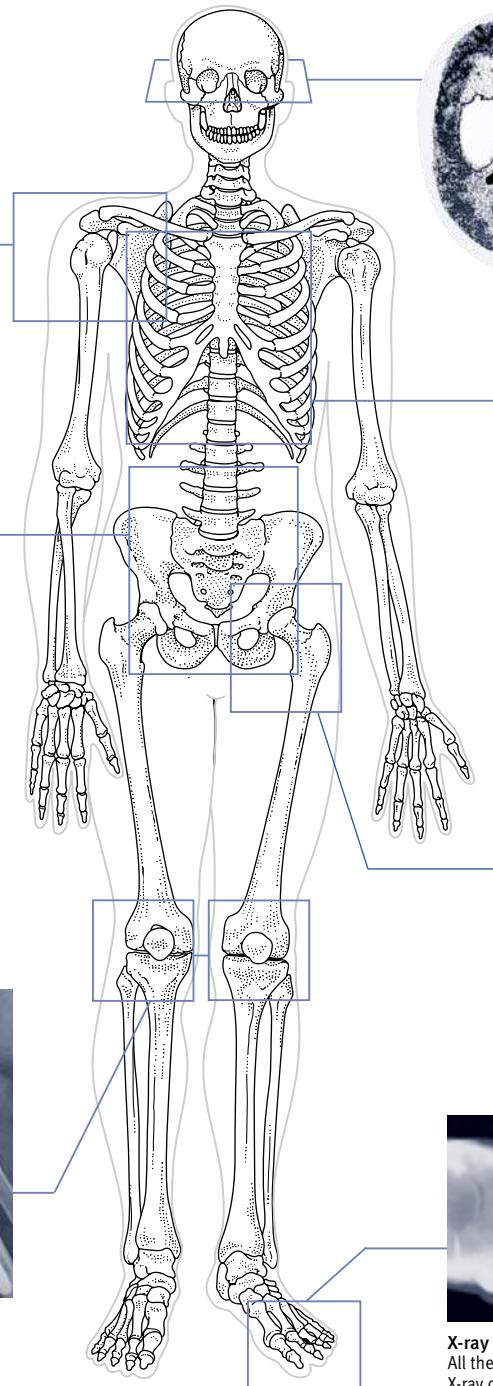

Barium X-ray

Introducing barium, which is opaque to X-rays, into the large intestine allows it to be visualized.

X-rays of knee joint

The X-ray on the left shows erosion of bone and cartilage. The parts of an artificial knee are seen in the X-ray on the right.

CT scan
Combined use of a computer and X-rays produces cross-sectional images. In this brain scan, the white area is a mass of blood (haematoma) caused by a stroke.

Chest X-ray
X-rays allow bones and internal organs to be imaged.

X-ray of hip joint
This X-ray of an osteoarthritic hip shows almost complete degeneration of the cartilage.

X-ray of foot
All the bones can be clearly seen in this X-ray of a healthy foot.

that forms the lowest of the three parts of the *sternum* (breastbone).

xiphoid process

The lowermost section of the *sternum* (breastbone). The xiphoid process is initially composed of *cartilage* (connective tissue formed of collagen), which gradually ossifies throughout a person's life until it is completely replaced by bone. This section of the sternum does not articulate with any of the *ribs*.

X-linked disorders

Sex-linked *genetic disorders* in which the abnormal gene or genes (the causative factors) are located on the X chromosome. Almost all affected people are males. *Haemophilia*, *fragile X syndrome* and *colour vision deficiency* are examples of X-linked disorders.

X-rays

A form of electromagnetic radiation of short wavelength and high energy. X-rays are widely used in medicine for diagnosis because they can be used to image bones, organs, and internal tissues. They are also used in medicine for treatment, particularly of cancer.

HOW THEY WORK

X-rays are produced artificially by bombarding a heavy metal tungsten (or other such metal) target with electrons, in a device known as an X-ray tube. Low doses of the X-rays that are emitted are passed through body tissue and form images on film or a fluorescent screen. The X-ray image, also called a radiograph or roentgenogram, shows the internal

structure of the area being examined. Dense structures, such as bone, absorb X-rays well and appear white on an X-ray image. Soft tissues, such as muscle, absorb less well and appear grey.

SPECIAL X-RAY TECHNIQUES

Hollow or fluid-filled parts of the body often do not show up well on X-ray film unless they first have a contrast medium (a substance that is opaque to X-rays) introduced into them. Contrast-medium X-ray techniques are used to image the gallbladder (see *cholecystography*), bile ducts (see *cholangiography*), the urinary tract (see *urography*), the gastrointestinal tract (see *barium X-ray examinations*), blood vessels (see *angiography; venography*), and the spinal cord (see *myelography*).

X-rays can be used to obtain images of "slices" through an organ or part of the body by using a technique known as *tomography*. More detailed images of a body slice are produced by combining tomography with the capabilities of a computer (see *CT scanning*).

X-RAY SAFETY

Large doses of X-rays can be extremely hazardous, and even small doses carry some risk (see *radiation hazards*). Modern X-ray film, equipment, and techniques produce high-quality images with the lowest possible radiation exposure to the patient. The risk of genetic damage can be minimized by using a lead shield to protect the patient's reproductive organs from X-rays. Radiographers and radiologists wear a *film badge* to monitor their exposure to radiation.

RADIOTHERAPY

Because X-rays can damage living cells, especially those that are dividing rapidly, high doses of radiation are used in the treatment of cancer (see *radiotherapy*). (See also *imaging techniques; radiography; radiology*.)

X-rays, dental

See *dental X-ray*.

xylitol

A naturally occurring *carbohydrate* that is only partially absorbed by the body. Xylitol is sometimes used as a noncariogenic (does not cause dental caries) sweetener in confectionery and drinks. It is also used as a sweetener, in place of sugar, by people with diabetes. Xylitol chewing gum has been shown to reduce recurrent ear infections in some children. Excess xylitol may lead to abdominal discomfort and flatulence.

Skull X-ray

An X-ray of a healthy skull seen from the side. The very white area in the centre shows where the bones of the cranium are fused together.

Xylocaine

A brand name for lidocaine, a local anaesthetic (see *anaesthesia, local*) used to numb tissues before minor surgical procedures and as a *nerve block*.

xylometazoline

A *decongestant* drug that is used in the form of a spray or drops to relieve nasal congestion caused by a common *cold*, *sinusitis*, or hay fever (see *rhinitis, allergic*). Xylometazoline is also used as an ingredient of eye-drops in the treatment of allergic *conjunctivitis*.

Excessive use of xylometazoline may cause headache, palpitations, or drowsiness. Continuous use of the drug may cause nasal congestion to worsen when treatment is stopped.

Y

YAG laser

The abbreviation for yttrium-aluminum-garnet laser, a versatile laser that may be used in a range of treatments, including hair and tattoo removal, dentistry, *lithotripsy* (the breaking up of kidney stones), and the cutting of tissue, for example during *iridotomy*.

Yasmin

The brand name for a combined contraceptive pill (see *oral contraceptives*) that contains drospirenone (a progestogen drug) and ethinylestradiol (an oestrogen drug).

yawning

An involuntary act, or *reflex* action, that is usually associated with drowsiness or boredom. The mouth is opened wide and a slow, deep breath is taken. Yawning is accompanied by a momentary increase in the heart rate and, in many cases, watering of the eyes.

The purpose of yawning is unknown, but one theory suggests that it is triggered by raised levels of carbon dioxide in the blood; its purpose, therefore, could be to reduce the level of carbon dioxide and increase the level of oxygen in the blood.

yaws

An infectious disease that is found in poorer subtropical and tropical areas of the world. Yaws is caused by a form of *spirochaete* (a spiral-shaped bacterium) called *TREPONEMA PERTENUE*, which is similar to the bacterium that causes syphilis. Yaws is not, however, a sexually transmitted infection; it spreads principally in conditions in which there is poor hygiene. The infection is almost always acquired in childhood, and it mainly affects the skin and bones.

SYMPOTMS

The bacteria enter the body through abrasions in the skin. Three or four weeks after infection, a raspberry-like, itchy growth appears at the site of infection, sometimes preceded by fever and

Yaws ulcer on leg

Yaws is an infection that mainly affects the skin and bones. Ulceration and tissue destruction may occur in advanced cases.

pains. The lesion (abnormal area of tissue) is highly infectious; scratching the area spreads the infection and causes more growths to develop elsewhere.

Without treatment, the growths heal slowly over the course of about six months, but recurrence is common. In some untreated cases, widespread tissue loss eventually occurs. This may eventually lead to gross destruction of the skin, bones, and joints of the legs, nose, palate, and upper jaw.

TREATMENT

Yaws can be cured by a single large dose of a *penicillin* drug, which is given by injection into muscle.

Y chromosome

A *sex chromosome* that is present in every normal male body cell. It is paired with an *X chromosome*. Males inherit the Y chromosome from their fathers. Every egg (from the mother) carries an X chromosome, but each sperm (from the father) may carry either a single X or a single Y chromosome. When *fertilization* (the union of an egg and a sperm cell) occurs, the combination of two X chromosomes creates a female offspring, while the combination of an X and a Y produces a male offspring.

Unlike the X chromosome, the Y chromosome carries little genetic material. Its principal function is to stimulate development of the *testes* in the male *embryo*. No significant diseases are related to Y chromosome abnormalities, but hairy ears is a trait thought to be determined by a Y-linked gene.

yeasts

Types of *fungi* in which the body of the fungus comprises individual cells that occur either singly, in pairs, or in longer chains. Certain yeasts can cause infections of the skin or mucous membranes. The most important of these disease-

causing yeasts is *CANDIDA ALBICANS*, which causes *candidiasis* (thrush). Yeasts may also cause *dandruff*, *seborrhoeic dermatitis*, and the nail condition *paronychia*, in which there is swelling of the nail folds.

yellow card system

A method of reporting adverse drug reactions (see *side effect*) in the UK. Doctors or pharmacists complete a yellow card if they suspect that an unwanted or unexpected symptom has occurred as a reaction to a prescribed drug (including vaccines), self medication, or herbal remedy. This information is collected and analysed centrally. The yellow card system is very important for recognizing problems that were not identified during the testing phase of newly introduced drugs.

yellow fever

An infectious disease of short duration and variable severity that is caused by a virus transmitted by mosquitoes. In severe cases, the skin of the sufferer turns yellow due to *jaundice*, from which the name "yellow fever" is derived.

CAUSES

The infection may be spread from monkeys to humans in forest areas through various species of mosquito. In urban areas it can be transmitted from human to human by *AEDES AEGYPTI* mosquitoes.

INCIDENCE

Today, yellow fever is endemic in Central America, parts of South America, and a large area of Africa. The eradication of the infection-bearing mosquito from populated areas has greatly reduced the incidence of the condition.

SYMPTOMS

Yellow fever is characterized by a sudden onset of fever and headache, often with nausea and nosebleeds, which occurs three to six days after infection. Despite the high fever, the heart rate is very slow. In many cases, the affected person recovers quickly.

In serious cases, the fever is higher and there is severe headache and pain in the neck, back, and legs. Damage may occur rapidly in the liver and kidneys, causing jaundice and *kidney failure*. This may be followed by severe agitation and delirium, leading to coma and death.

PREVENTION

Vaccination confers long-lasting immunity and should always be obtained before travel to affected areas. A single injection of the vaccine gives protection for at least 10 years. Reactions to the

vaccine are rare and are usually mild, although children under the age of one year should not be vaccinated.

DIAGNOSIS

During yellow fever epidemics, a diagnosis can be made by the symptoms. It can be confirmed by carrying out blood tests to isolate the causative virus or to find *antibodies* (proteins manufactured by the immune system) to the virus.

TREATMENT

No drug is effective against the yellow fever virus; and treatment is directed at maintaining the blood volume. Transfusion of fluids is often necessary.

Many patients recover in about three days and, in mild to moderate cases, complications are few. Relapses do not occur and one attack confers lifelong immunity. However, the disease is severe in 20–50 per cent of cases and may, in some circumstances, be fatal.

yellow nail syndrome

A condition in which the nails become thickened and yellow, or sometimes green, in colour; this is accompanied by swelling of the legs and *pleural effusion* (the accumulation of fluid around the lungs). Yellow nail syndrome is caused by a defect of lymphatic drainage (see *lymphatic system*).

Yersinia

A group of bacteria containing the organism responsible for the *plague* (*YERSINIA PESTIS*). This organism is carried by fleas on rats, ground squirrels, and other rodents. It is transmitted from rodents to humans by bites from infected fleas. The organism can affect the *lymph nodes* resulting in large swellings, such as occurs in the bubonic form of plague. If the lungs are affected, the result is pneumonic plague; this can be transmitted from person to person if an infected individual spreads droplets in a cough.

Another form, *YERSINIA ENTEROCOLITICA*, can cause the development of *gastroenteritis*, particularly in young children, and *arthritis* and *septicaemia* (blood poisoning) in adults.

yield

The amount or quantity of a particular substance, such as an *enzyme* or *hormone*, that has been produced. For example, higher yields of *insulin* may be prepared for medical purposes using *genetic engineering* than through the natural production of the hormone in the pancreas of an animal.

yin and yang

The two opposing and interdependent principles that are fundamental to traditional *Chinese medicine* and philosophy. Yin is associated with the female, darkness, coldness, and quiescence; yang embodies maleness, brightness, heat, and activity. In a healthy body, yin and yang are in balance. Disorders are said to arise if one or other quality predominates; an excess of yin is said to cause conditions such as osteoarthritis, while an excess of yang causes inflammatory disorders. The concepts of yin and yang are also central to the dietary system known as *macrobiotics*.

yoga

A system of Hindu philosophy and physical discipline that is popular throughout the world. The main form of yoga practised in the West is *hatha yoga*. The follower adopts a series of poses called *asanas*, to stimulate nerves and organs and to strengthen muscles, and performs a system of breathing control techniques called *pranayama* to relax the body and calm the mind. Popular forms of *hatha yoga* include *Iyengar* and *ashtanga* ("power yoga").

The practice of yoga maintains flexibility, teaches physical and mental control, and is a *relaxation technique*.

Yoga should be practised only under the guidance of a qualified teacher. If yoga is attempted by people in poor health, or if it is practised incorrectly, it may pose certain health hazards, such as back disorders, *hypertension* (high blood pressure), and *glaucoma* (an increase in pressure in the eye).

Yoga position

This woman is sitting in a loose lotus position, with her legs crossed and palms open. The position is used for relaxation and meditation.

yohimbine

A naturally occurring *alkaloid* that dilates the pupil of the eye and increases blood flow to the peripheries of the body. Yohimbine has been used in the treatment of *impotence*, due to its aphrodisiac properties, but newer, more effective treatments are generally recommended.

yolk sac

The membranous sac, also called the vitelline sac, that is attached to the front of the *embryo* during the early stages of its existence. The yolk sac is believed to help transfer nutrients from the mother's bloodstream to the early embryo. The size of the sac decreases proportionately to the body, reducing finally to a narrow duct that passes through the *umbilicus*.

Yolk sac

This photograph is of an embryo, approximately 6 weeks old, surrounded by its amniotic sac. The remains of the yolk sac can be seen above its head.

Young's syndrome

A form of *azoospermia* (absence of sperm in the semen) in which sperm production is normal, but the sperm ducts are obstructed. In Young's syndrome, azoospermia may sometimes be associated with *bronchiectasis* (in which the bronchi, the main airways to the lungs, are abnormally widened, distorted, and have damaged linings) and *sinusitis* (inflammation of the lining of the facial sinuses).

yttrium

A very rare metal that, in its radioactive form, is sometimes used in cancer therapy and to treat joints that are affected by arthritis.

Z

zafirlukast

A leukotriene receptor antagonist that is used in the prevention of *asthma*.

Zantac

A brand name for *ranitidine*, an H₂-receptor antagonist (see *ulcer-healing drugs*) that is used in the treatment of *peptic ulcer* and *oesophagitis*.

zidovudine

An antiretroviral drug, (formerly known as azidothymidine, or AZT) used in combination with other antiretroviral drugs to slow the progression of *AIDS*. Zidovudine was the first drug to be introduced to combat *HIV* infection. Antiretrovirals do not constitute a cure; their principal aim is to keep viral replication to as low a level as possible for as long as possible.

Possible side effects include *anaemia*, which may be severe enough to require a blood transfusion; nausea; loss of appetite; headache; and a reduced number of *white blood cells* in the blood.

ZIFT

See *zygote intrafallopian transfer*.

zinc

A trace element that is essential for normal growth, development of the reproductive organs, normal functioning of the prostate gland, manufacture of *proteins* and *nucleic acids*, and healing of wounds, in the body. Zinc also controls the activities of more than 100 enzymes and is involved in the functioning of the hormone *insulin*. Rich sources of zinc include lean meat, seafood, dried beans, wholemeal breads, and wholegrain cereals.

DEFICIENCY

Zinc deficiency is rare. Most cases occur in people who are generally malnourished. Deficiency of zinc may also be due to any disorder that causes *malabsorption*; *acrodermatitis enteropathica* (a disorder of zinc absorption); or increased zinc requirements caused by cell damage (for example, as a result of a burn or in *sickle cell anaemia*).

Symptoms of deficiency include taste impairment and appetite loss; there may also be hair loss and inflammation of the skin, mouth, tongue, and eyelids. In children, zinc deficiency impairs growth and delays sexual development.

EXCESS

Prolonged excessive intake of zinc may interfere with the intestinal absorption of *iron* and *copper*, leading to a deficiency of these minerals.

MEDICAL USES

Zinc compounds, such as *zinc oxide*, are included in many preparations for treating skin and scalp disorders.

zinc oxide

An ingredient of many skin preparations that has a mild *astringent* action and a soothing effect. Zinc oxide is used for painful, itchy, or moist skin conditions and to ease pain due to haemorrhoids and insect bites or stings. It also blocks the sun's ultraviolet rays (see *sunscreens*).

Zollinger–Ellison syndrome

A rare condition characterized by severe and recurrent *peptic ulcers* in the stomach and the duodenum and jejunum (first and middle sections of the small

intestine). Zollinger–Ellison syndrome is caused by one or more gastrin-secreting tumours, which usually arise in the *pancreas* but occasionally develop in the stomach or duodenum. Gastrin stimulates production of large quantities of acid by the stomach, leading to ulceration. The high levels of acid in the digestive tract often also cause diarrhoea.

The tumours are often cancerous but are slow-growing. If possible, they are removed surgically. *Proton pump inhibitor* drugs are given to treat the ulcers.

zolmitriptan

A serotonin agonist that is used in the treatment of acute attacks of *migraine*.

zolpidem

A drug used in the short-term treatment of *insomnia*. Zolpidem causes little hangover effect. Possible side effects include diarrhoea, nausea, and dizziness.

zona pellucida

The thick, transparent, noncellular layer that surrounds a developing egg cell in the ovarian follicle. At the time of *fertilization*, the zona pellucida is penetrated by at least one sperm.

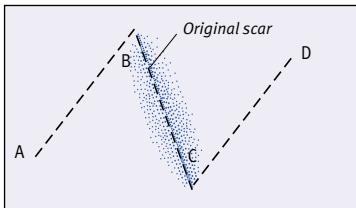

SELECTED ZOONOSES (DISEASES CAUGHT FROM ANIMALS)

With the exception of fungal infections and mites caught from pets, all the diseases listed below are rare or unknown in the UK. Several may be caught from animals used as food (pigs and cows, for example), but such diseases occur mainly where food hygiene regulations and/or practices are lax. Rabies can be caught from various animals in addition to those listed (foxes, skunks, and mongooses, for example).

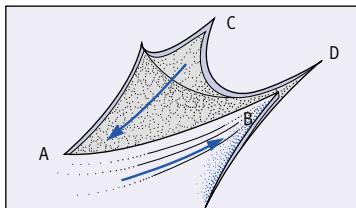

Animal	Disease	Animal	Disease
Bat	<ul style="list-style-type: none"> ● Histoplasmosis ● Rabies 	Horse	<ul style="list-style-type: none"> ● Glanders
Cat	<ul style="list-style-type: none"> ● Toxoplasmosis ● Cat-scratch fever ● Fungal infections 	Pig	<ul style="list-style-type: none"> ● Trichinosis ● Pork tapeworm ● Brucellosis
Chicken	<ul style="list-style-type: none"> ● Salmonella infection ● Psittacosis 	Rabbit	<ul style="list-style-type: none"> ● Tularaemia
Cow	<ul style="list-style-type: none"> ● Brucellosis ● Beef tapeworm ● Q fever ● Cowpox 	Rat	<ul style="list-style-type: none"> ● Leptospirosis
Dog	<ul style="list-style-type: none"> ● Rabies ● Toxocariasis ● Mite infestations ● Fungal infections 	Sheep	<ul style="list-style-type: none"> ● Liver fluke ● Anthrax

TECHNIQUE OF Z-PLASTY

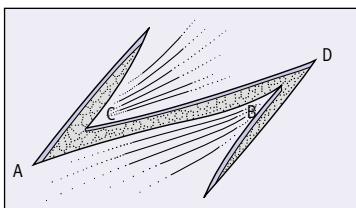

This relatively simple plastic surgery technique is carried out to revise unsightly scars or to relieve skin tension caused by scar contracture. It can be particularly useful for dealing with facial scars or scars that cross natural skin creases.

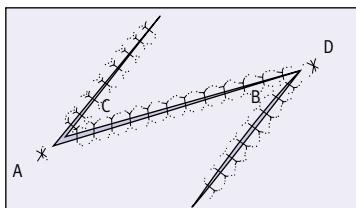

1 Three incisions are made, forming a Z. The central incision is made lengthwise through the scar.

2 Two triangular flaps are developed by cutting skin away from underlying tissue, and the flaps are then transposed.

3 This manoeuvre creates a new Z, of which the central arm is at right angles to the original direction of the scar.

4 The flaps are sutured in place. With careful planning, the suture lines can be hidden in natural skin creases.

ZOONOSIS

Any infectious or parasitic disease affecting animals that can be transmitted to humans. Unlike many disease organisms, zoonotic organisms are flexible, and they can adapt themselves to a large number of different species.

Zoonoses are usually caught from animals that are closely associated with humans, either as pets, as food sources, or as scavenging parasites, such as rats. Examples of such zoonoses include *toxocariasis*, *cat-scratch fever*, some *fungal infections*, *psittacosis*, *brucellosis*, *trichinosis*, and *leptospirosis*. Rabies can infect virtually any mammal, but dog bites are a common cause of zoonosis infection in humans worldwide.

Other zoonoses are transmitted from animals less obviously associated with humans, usually by insect *vectors*. For example, *yellow fever* is transmitted by mosquito bites. (See also *cats*, *diseases from; dogs*, *diseases from; insects and disease*; *rats*, *diseases from*.)

zopiclone

A drug that is used in the short-term treatment of *insomnia*. Zopiclone has a brief duration of action and causes little

hangover effect. Because of the risk of dependence, zopiclone is intended for occasional use only. Possible side effects of the drug include a bitter metallic taste, nausea, and a dry mouth.

Zovirax

A brand name for *aciclovir*, an *antiviral drug* used to treat viral infections such as *herpes simplex*, *herpes zoster*, and some cases of *chickenpox*.

Z-plasty

A technique that is used in *plastic surgery* to change the direction of a pre-existing scar in order for it to be hidden within the natural creases of the skin. Z-plasty is also used to relieve skin tension occurring as a result of *contracture* of a scar. The technique is especially useful for revising unsightly scars on the face and for releasing scarring across joints, such as on the fingers or in the armpits, that may restrict normal movement or cause deformity.

Zyban

A brand name for *amfebutamone*, a drug that is used, along with self-help measures, as an aid to stopping smoking.

zygomatic arch

The arch of bone, commonly known as the cheek bone, on either side of the skull just below the eye socket. The zygomatic arch is formed of the zygomatic and temporal bones.

zygote

The cell that is produced when a *sperm* fertilizes an *ovum* (egg). A zygote, measuring about 0.1 mm in diameter in humans, contains all the genetic material for a new individual. The zygote is surrounded by a protein-rich layer known as the *zona pellucida*.

The zygote travels down one of the woman's *fallopian tubes*, dividing as it does so. After about a week, the mass of cells (now called a *blastocyst*) implants into the lining of the uterus, and the next stage of embryological growth begins. (See also *embryo*; *fertilization*.)

Appearance of a zygote

The photograph shows a human egg shortly after it has been fertilized by a sperm. The two circular areas at the centre of the image are the nuclei of the sperm and egg merging.

zygote intrafallopian transfer

A type of *in vitro fertilization*, also referred to as ZIFT, in which *ova* (eggs) are fertilized outside the body and returned to a *fallopian tube* rather than to the *uterus*.
